A number of authors [1-9,11] have studied the analysis of failure mechanism of the bonded patch repair in laminated composite materials. Wisnom M.R. [10] has reviewed the size effects in the testing of fibre-composite materials. Predictive fracture model for composite bonded joints has been proposed by Goyal V.K. and et al. [12]. Principles and practices of adhesive bonded structural joints and repairs have studied by Davis M. [13]. Little research has been carried out to analyse the ultimate failure load of repaired structures with various repair parameters [15].

In aircraft applications, less weight is the important criteria for the maintenance of the parts. For such repair applications in laminated composite materials, external bonded patch repair technique has been more preferable than using mechanical fastened repair. Because, using mechanical fasteners increase the weight and the stress concentration factor of the repaired structures. Also, in external patch bonding repair, the optimum quantity of repair materials must be used in order to protect weight increment of the repaired structure. These main repair materials are adhesives and composite patches. The adhesives and patches should have been used in minimum quantity in repairs without decrease the load carrying capacity of the structures. Also, in adhesively bonded repairs, the stresses that occur in bonded joints are more uniform than that of pinned joints. These stress representations for various connections are illustrated in Fig. 1.

In this study, various experimental specimens have produced with different repair parameters. Then, by performing unidirectional tensile testing to these prepared specimens, the ultimate failure loads of them were indicated. By analysing these failure loads of the specimens, the effects of repair parameters have been specified.

Fig. 1. Presentation of stress concentration effects for various joint techniques [15].

II. EXPERIMENTAL

The current work investigated the performance of the external bonded patch repairs under tensile loading by indicating the ultimate failure loads of repaired laminated composite structures. For this study, eight plies laminated woven glass and carbon fibers reinforced parent plates were used. By using these parent plates, experimental specimens were prepared. 10 mm holes were drilled in the center of the parent plates to simulate the damages in the structures. Then, these damaged specimens were repaired by using adhesive and composite patches with different parameters in necessary curing temperatures and laboratory conditions. The repaired experimental specimens were shown in Fig. 2 and their geometrical parameters were shown Fig. 3. The materials that used for parent plate specimens, adhesives and patches in repair were listed in Table 1. During the tests, specimens were subjected to longitudinal tensile loads on tensile testing machine in order to indicate the failure loads of repaired structures.

Fig. 2. Presentation of repaired experimental specimens [15].

Table 1. Materials that were used in repair of laminated composite materials

Bonding type	Parent Materials	Adhesive	Patch Material
Wet layout	Woven carbon fibres	Hysol EA9396	0020989
	Woven glass fibres	Hysol EA9396	0021438-09
Prepreg	Woven carbon fibres	C992275 ADH FILM	C992268-14
	Woven glass fibres	C991957-37 ADH FILM	C992270

Fig 3. Geometric presentation of repaired experimental specimens [15]

III. RESULT AND DISCUSSION

[14] Effect of Patch Thickness

The effect of the patch thickness to the ultimate failure loads of repaired structure was indicated in Fig. 4. The ultimate failure loads of the structures repaired with prepreg bonding technique were increased by increasing the patch thickness (increase the ply number). But, for the structure that repaired with W.L. bonding technique, the failure loads have increased gradually to the patch thickness of the 3 plies values and after that, the peeling effect has occurred in repaired structure than, the failure load decrease dramatically. Increase the bonded patch thickness after a certain value (3 plies) in repair of the laminate composite materials does not improve the ultimate failure load. Increase the patch thickness further in repair of air craft structures may cause the weight stability effect. This is the main drawback in repairs of such applications.

Fig. 4. Effect of patch thickness to the failure load of repaired structures with glass prepreg and wet layout patches [15].

B. Effect of Bonding Length

In external bonded patch repairs, if the patch overlap length or bond length too short, the entire adhesive layer is under high shear stress. In the case of longer bond length, most of the load is carried at the ends of the bonded overlap which is the reason for why too large patches fails to enhance the expected ultimate strength [14]. Effect of bonding length of

the patch to failure loads in repaired structures has presented in Fig. 5. The failure loads of structures repaired with glass prepreg patch bonding were increased gradually by increasing the bonding length in repair. In that repair with glass W.L. patch bonding; the failure loads were increased to the bonding length of 40 mm gradually, than decrease dramatically to the 5850 N value due to peeling effect that presented in W.L. applications. In bonded patch repair, for both W.L. and prepreg techniques, 40 mm value of bonding length, was seen as the optimum value.

Fig. 5. Presentation of the effect of bonding length to the failure load of W/D=2 glass repaired structures with glass prepreg and wet layout patches [15].

C. Effect of Patch Shape

In order to specify the effect of patch shapes to the external patch repair, square and circular shape of patches were used. These repairs were performed both with W.L. and prepreg techniques. By performing uniaxial tensile test, the failure loads of specimens were indicated. These failure loads were shown in Figure 6.

As seen in Figure 6, in repair of woven glass fiber reinforced laminated composite materials patch shape had no significant effect in the failure loads of the specimens. But, in repair of woven carbon fiber reinforced laminated composite materials, the shape of patch had significant effect to the ultimate failure loads. In repair of these materials, for prepreg technique, using the circular patch shape had increased the ultimate failure loads of specimens. But, for W.L. techniques, using the square patch shape had increased the ultimate failure loads

Fig. 6. Presentation of the patch shape effect to the failure load of W/D=5 glass repaired structures with glass prepreg patch and wet layout patch [15].

IV. CONCLUSIONS

In the present study, experimental study is carried out to investigate patches parameters effects on the ultimate failure load of adhesively bonded repaired structures, and the following conclusions can be drawn from this study.

1. The ultimate failure loads of the structures repaired with prepreg bonding technique were increased by increasing the patch thickness. But, for the structure that repaired with W.L. bonding technique, the failure loads have increased gradually to the patch thickness of the 3 plies values and after that, the peeling effect has occurred easily and this decrease the failure loads of repaired structures.
2. In bonded patch repair, for both W.L. and prepreg techniques, 40 mm value of bonding length, was obtained as the optimum value.
3. In repair of woven glass fiber reinforced laminated composite materials, patch shape had no significant effect in the failure loads. But, in repair of woven carbon fiber reinforced materials, using the circular patch shape had increased the failure loads for prepreg technique. But, for W.L. technique, using the square patch shape had increased the ultimate failure loads.
4. Ultimate failure loads of repaired structures can be increased by choosing the optimum repair parameters, such as patch thickness and bonding length.

Abstract—Dams, one of the country's most natural and cheapest way to product energy, are built for energy production, agricultural activities and flood protection. Dams with high construction costs are subject to deformation due to some physical factors. Therefore, dams should be kept safe to prevent possible dam accidents, loss of life and property. Engineering structures (such as dams) should be monitored periodically by geodetic and non-geodetic techniques. Deriner dam is Turkey's highest double-curved concrete arch dam. In this study, we monitored deformation with GPS measurements. For this purpose, two period static GPS measurements were performed on the reference and object networks in the study. Afterwards, GPS measurements are adjusted separately with respect to free adjustment method and then deformation analysis were carried out by using the adjusted coordinates and their cofactor vectors. Iterative Weighted Similarity Transformation (IWST) and Least Absolute Sum (LAS) methods were used as deformation methods to detect the displacement of the reference and object points.

Keywords—concrete; arc dam; deformation; analysis; IWST; LAS; GPS

I. INTRODUCTION

The dams are one of the most important engineering structures used for water supply, flood protection and agricultural activities. Besides, it is the most natural and cheapest way of energy production for a country. Dams constructed with high cost expenditures are subjected to deformation due to various loading factors such as water level, air, water temperature and rock deformability. Controlling these dams has become compulsory in order to prevent disasters. In the literature, many deformation monitoring based studies have been reported [1]-[8]. Reference [1] investigated the surface movements of Alibey dam by means of geodetic and geotechnical methods. Geodetic displacement measurements were analysed using the Karlsruhe method. Also, Finite Element Method (FEM) was used to determine the behaviour of the dam. The results of geodetic measurements were compared with those of the FEM analyses. Reference [2] examined the long-term settlement behaviour of the Mornos dam in Greece. The result of geodetic monitoring analysis and that of the the Finite

Element Back analysis were compared. The findings showed a very good agreement between the measured and computed displacements. Reference [3] utilized the Global Positioning System (GPS) technique for monitoring horizontal movements in the Altinkaya dam. A deformation network consisting of 6 reference points and 11 object points along the dam crest were observed for 4 periods. Geodetic displacement measurements were analysed using the IWST and LAS methods to determine the points stability. Reference [4] investigated the magnitude and the direction of radial deformations of the Atatürk dam by means of conventional and GPS techniques. No significant correlation was detected between the radial movements on embankment and reservoir water level. Reference [5] investigated the relationship between displacement and reservoir water levels of the Koyna dam in India. The correlation between the movements and reservoir water level was investigated. Reference [6] evaluated the horizontal movements of the Ermenek dam based on periodic conventional geodetic measurement campaigns during the first filling of the reservoir. The coordinates of the GPS measurements are WGS-84 coordinate system. The points of the coordinates need to be converted from Cartesian to the local topocentric coordinate system in order to see the real directions of the the displacements. Geodetic measurements were compared with those of the FEM. [3]. The aim of this work is to evaluate the horizontal movements of the Deriner dam with GPS measurements. Deformation analyses were performed with the Iterative Weighted Similarity Transformation (IWST) and the Least Absolute Sum (LAS) methods. Finally, the results of these two methods have been compared.

II. ROBUST METHODS

Robust methods are used when there is no previous information about the movement of the points within the network [9]. In this study, the IWST and LAS methods are used to estimate the movements of a monitoring network. The IWST, proposed by [10], is a robust method. According to [11], the Danish, LAS and Huber methods are some of the frequently used robust methods. The IWST and LAS methods are based on

S-transformation [10]-[12]. Both methods are applied as follows;

Adjusted coordinates of the points x_1, x_2 and their cofactor matrix Q_{x1}, Q_{x2} are calculated with two separate free adjustments. The displacement values (d) and cofactor matrix of d Q_d are calculates as;

$$d = x_2 - x_1 \quad (1)$$

$$Q_d = Q_{x1} + Q_{x2} \quad (2)$$

Then displacement values (d) are calculated as (3);

$$\begin{aligned} d^{(k+1)} &= [I - H(H^T W^{(k)} H)^{-1} H^T W^{(k)}] d^{(k)} \\ &= S^{(k)} d^{(k)} \end{aligned} \quad (3)$$

d = displacement vector

k = number of iterations

I = identity matrix

W = weight matrix

S = S-transformations matrix

H matrix for the 3D networks is written as;

$$H = \begin{bmatrix} e & 0 & 0 & 0 & -z_0 & -y_0 & x_0 \\ 0 & e & 0 & -z_0 & 0 & x_0 & y_0 \\ 0 & 0 & e & y_0 & -x_0 & 0 & z_0 \end{bmatrix}_{3m \times 7} \quad (4)$$

where, $e^T = (1, \dots, \dots, 1)$ x_0, y_0 and z_0 are the coordinates of points P_i , which are reduced to the centre of the network (5).

$$\begin{aligned} X_0^i &= X_i - \frac{1}{m} \sum_{i=1}^m x_{i0}, \\ Y_0^i &= Y_i - \frac{1}{m} \sum_{i=1}^m y_{i0}, \\ Z_0^i &= Z_i - \frac{1}{m} \sum_{i=1}^m z_{i0} \end{aligned} \quad (5)$$

Above, z_0^i, y_0^i and x_0^i the i^{th} elements of z^0, y^0 and x^0 respectively, and z_i, y_i and x_i are approximate coordinates of point P_i and m is the number of the points in the network [13]-[15]. The main difference between the IWST and LAS method is in forming the weight matrix. In the first transformation ($k = 1$) the weight matrix is taken as identity ($W^{(k)} = I$) for

all common points, then in the ($k+1$) transformation the weight matrix is defined as;

For the IWST method,

$$W^{(k)} = \text{diag}\{1/|d^{(k)}|\} \quad (6)$$

For the LAS method,

$$W^{(k)} = \text{diag}\left\{\frac{1}{\sqrt{(dx_i^{(k)})^2 + (dy_i^{(k)})^2}}\right\} \quad (7)$$

In equation (6), d is the displacement vector. However, in equation (7), dx_i and dy_i refer to the displacement components in x and y axis respectively. The iterative procedure continues until the differences between displacements of all common points ($d^{(k+1)} - d^{(k)}$) are smaller than a tolerance value ϵ (i.e. 0.0001 m.). In the final iteration cofactor matrix is calculated as;

$$Q_d^{(k+1)} = S^{(k)} Q_d (S^{(k)})^T \quad (8)$$

The IWST method minimizes the total sum of absolute values of the displacement components,

$$\left(\sum |d_i| \Rightarrow \text{minumum}\right) \quad (9)$$

while the LAS method minimizes the sum of the lengths of the displacement,

$$\left(\sum \sqrt{(dx_i^{(k)})^2 + (dy_i^{(k)})^2} \Rightarrow \text{minumum}\right) \quad (10)$$

Equation (11) can be used in order to determine unstable reference and object points in the deformation network with a single point test as shown below [14];

$$T_i = \frac{(d_i^{(k+1)})^T (Q_{di}^{(k+1)})^{-1} d_i^{(k+1)}}{u_d \hat{\sigma}_0^2} \sim F(\alpha, u_d, df) \quad (11)$$

d_i = displacement vector of point i

Q_{di} = cofactor matrix of point i

u_d = dimension of the confidence region (1, 2 or 3)

$\hat{\sigma}_0^2 = \frac{df_i \hat{\sigma}_i^2 + df_j \hat{\sigma}_j^2}{df_i + df_j}$ = pooled variance factor

$\hat{\sigma}_i^2, \hat{\sigma}_j^2$ = a posteriori variance factors of epoch i and j

df_i, df_j = degrees of freedom of epoch i and j

α = significance level

If the test is passed, the point is assumed to be stable, otherwise, it is considered unstable.

III. APPLICATION

The Deriner dam, a double-curvature concrete arch dam, is located on the Çoruh River at Artvin province in the north-eastern part of Turkey. It is the highest dam with a body height of 249 meters in Turkey. The underground powerhouse near the dam includes four units, with an overall capacity of 670 MW. Also, the powerhouse annually generates 2.118 GWh of electricity. The picture of the dam and technical specifications are given in Figure 1 and in Table 1, respectively.

TABLE I. TECHNICAL CHARACTERISTICS OF THE DERINER DAM

Type	Double-curvature concrete arch
Dam crest elevation	397.00 m
Length of dam crest	720.00 m
Height of crest	249.00 m
Total reservoir area	26.40 km ²
Total reservoir volume	1969 hm ³
Electric production capacity	2.117,75 Gwh per year

In order to determine the possible horizontal movements on the crest, 14 reference and 7 objects points were used (Figure 2).

Fig. 1. Deriner Dam

Fig 2. Distrubition of Reference and Object Points in Deriner Dam

The deformation measurements of Deriner dam involved two measurement campaigns. The first campaign was carried out in May 2016 and the second one in September 2016. During the GPS measurements, Topcon Hiper Pro and Topcon GR-5 dual-frequencies receivers were used. The observation period was selected as 2 hours and 1.5 hours for reference and object points, respectively. The sampling rate was chosen as 10 seconds and the satellite elevation mask was selected at 15°. The baselines were processed with the Topcon Tools v.8.2.3 software. MATLAB script was used for network adjustment and deformation analysis. The significance level for deformation detection was specified as 0.05. The adjusted coordinates (WGS-84) and cofactor matrix were obtained from a free network adjustment. Deformation analysis was made with respect to the first period measurement. The two dimensional deformation analysis was made. All WGS-84 coordinates (X, Y, Z) and cofactor matrices were transformed to the local coordinate system (E, N, U). The displacement values (d) were computed by the IWST and LAS methods are shown in Tables 2 and 3. These tables also depicts whether or not the points are stable. Water levels were 389.33 m in the first period and 377.22 m in the second period. The reduction of water level in between the two periods is 12.11 m.

IV. CONCLUSION

Since we have no prior information about the movement of the points within the network, the IWST and LAS methods were used in this study. The IWST and LAS were used to perform 2D deformation analyses. It can be concluded from the results of the analysis that the displacements are dependent on the water level on the reservoir. The maximum horizontal displacement was experienced in the middle of the dam's crest. These results will also be examined with new measurements to be conducted in further periods. Also, precise differential levelling of levelling line along the dam crest will be performed.

Abstract-Grey theory is one of the methods used to study uncertainty. The uncertain systems characterized by small sample and poor information are the study object of grey system theory. Multivariable grey prediction models are part of grey forecasting system. They are presented if there are mutual relations among the factors in the system. They believe that all the influencing factors are not independent of each other and should be regarded as a whole. In multivariable grey forecasting models, the future value of a variable is tried to be forecasted considering the other influential factors in the system. In this study, deformation consisting on the crest of a Dam is aimed to determine by using multivariable grey prediction models.

Keywords—Deformation, Grey method, Deformation predict

I. Introduction

The evaluation of measurements and geodetic deformation measurements covers a significant portion of the engineering measurements. The monitoring of the movements of big engineering structures begins during the construction of the building and continues throughout life. The evaluation of the data and the interpretation phase of the results is the last and most important part of the deformation study. There are damages that can't be compensated by a wrong decision. As a result, it is necessary to be very careful and the results must be absolutely reliable. A large number of measures are needed to be able to give decisions about the behavior of constructions and to interpret the results. But, being able to make more accurate decisions with less data is very important in every circumstance.

The main strength of grey prediction is that it only requires short-term, current and limited data. Grey systems theory was first proposed by Deng [1]. Grey theory is one of the methods used to study uncertainty. The uncertain system characterized by small sample and poor information are the study object of grey system theories. The grey system puts each stochastic variable as a grey quantity that changes within

a given range. It does differ from statistical analysis method to deal with the grey quantity. It deals directly with the original data and searches the intrinsic regularity of the data [2].

II. Multy variable Grey Forecast model

Multivariable grey prediction models are part of grey forecasting system. They are presented if there are mutual relations among the factors in the system. They believe that all the influencing factors are not independent of each other and should be regarded as a whole. In multivariable grey forecasting models, the future value of a variable is tried to be forecasted considering the other influential factors in the system. Because of high accuracy and easy application procedures, multivariable grey models have been applied to many areas in the literature [3-9].

MGM(1,N) model is set up by using Accumulating Generation Operator (AGO). The primitive data are subjected to the AGO to smooth the randomness of the data and to weaken the tendency of variation [10]. Assume that $X^{(0)} = \{x^{(0)}(1), x^{(0)}(2), \dots, x^{(0)}(m)\}$ is an original, non-negative data series taken in consecutive order and at equal time intervals, then $X^{(1)} = \{x^{(1)}(1), x^{(1)}(2), \dots, x^{(1)}(m)\}$ is called 1-AGO where

$$x^{(1)}(k) = \sum_{j=1}^k x^{(0)}(j), \quad k = 1, 2, \dots, m. \text{ Suppose that the}$$

number of variable is represented by n and the number of observation period by m , MGM(1,N) procedure is described in the following parts [10]. The first-order ordinary differential equation for the MGM(1, N) can be written as follows:

$$\begin{aligned}\frac{dx_1^{(1)}}{dt} &= a_{11}x_1^{(1)} + a_{12}x_2^{(1)} + \dots + a_{1m}x_m^{(1)} + b_1 \\ \frac{dx_2^{(1)}}{dt} &= a_{21}x_1^{(1)} + a_{22}x_2^{(1)} + \dots + a_{2m}x_m^{(1)} + b_2 \\ &\dots\dots\dots \\ \frac{dx_n^{(1)}}{dt} &= a_{n1}x_1^{(1)} + a_{n2}x_2^{(1)} + \dots + a_{nm}x_m^{(1)} + b_n\end{aligned}\quad (1)$$

marked as:

$$\frac{dX^{(1)}}{dt} = AX^{(1)} + B \quad (2)$$

The estimate value is obtained by using the least square method:

$$H = (L^T L)^{-1} L^T Y \quad (3)$$

where

$$L = \begin{bmatrix} \bar{x}_1^{(1)}(2) & \bar{x}_2^{(1)}(2) & \dots & \bar{x}_n^{(1)}(2) & 1 \\ \bar{x}_1^{(1)}(3) & \bar{x}_2^{(1)}(3) & \dots & \bar{x}_n^{(1)}(3) & 1 \\ \dots\dots\dots \\ \bar{x}_1^{(1)}(m) & \bar{x}_2^{(1)}(m) & \dots & \bar{x}_n^{(1)}(m) & 1 \end{bmatrix}$$

$$Y = \begin{bmatrix} x_1^{(0)}(2) & x_2^{(0)}(2) & \dots & x_n^{(0)}(2) \\ x_1^{(0)}(3) & x_2^{(0)}(3) & \dots & x_n^{(0)}(3) \\ \dots\dots\dots \\ x_1^{(0)}(m) & x_2^{(0)}(m) & \dots & x_n^{(0)}(m) \end{bmatrix}$$

and $\bar{x}_i^{(1)}(k) = \frac{1}{2}(x_i^{(1)}(k) + x_i^{(1)}(k-1))$. The estimated value \hat{A} and \hat{B} can be obtained from H:

$$\hat{A} = \begin{bmatrix} \hat{a}_{11} & \hat{a}_{21} & \dots & \hat{a}_{n1} \\ \hat{a}_{12} & \hat{a}_{22} & \dots & \hat{a}_{n2} \\ \dots\dots\dots \\ \hat{a}_{1m} & \hat{a}_{2m} & \dots & \hat{a}_{nm} \end{bmatrix}, \quad \hat{B} = \begin{bmatrix} \hat{b}_1 \\ \hat{b}_2 \\ \dots \\ \hat{b}_n \end{bmatrix} \quad (4)$$

Then accumulated predicted values can be calculated by using Equation (4).

$$\hat{X}^{(1)}(k) = e^{\hat{A}(k-1)}(\hat{X}^{(1)}(1) + \hat{A}^{(-1)}\hat{B}) - \hat{A}^{(-1)}\hat{B} \quad (5)$$

where

$$e^{\hat{A}(k-1)} = I + \sum_{i=1}^{\infty} \frac{\hat{A}^i}{i!} (k-1)^i \quad (6)$$

After the inverse first-order accumulated generation operation (1-AGO), we obtain the sequence as $\hat{X}^{(0)}(k) = \hat{X}^{(1)}(k) - \hat{X}^{(1)}(k-1)$. The average fitting precision of the model is

$$\sigma^2 = \frac{\sum_{i=1}^n V_i^T V_i}{nm} \quad (7)$$

where

$$v_i k = x_i^{(0)}(k) - \hat{x}_i^{(0)}(k), V_i = (v_i(1), v_i(2), \dots, v_i(m))^T \quad (8)$$

III. Application

Multivariable Grey Prediction Model which is very efficient methodology in the situation of the limited number of the data has been used to predict deformation in a dam. In this study 11 periods' real measurement values has been used to predict deformations depending on the water level for object points 11, 12 and 13 which are located in the middle of the rockfill dam crest. The first 6 periods' measurements have been used to establish multivariable grey prediction model, and the last six periods' measurement are used to test the accuracy of the proposed method. The original and predicted values are shown in Table 1. The outcomes also presented in Figure 1-3.

The 7th column in the Table 1 shows predicted values for object point 11 depending on the water level. 8th and 9th columns show the predicted values when we apply grey prediction procedure for two object points at the same time. The last three columns show the results if we apply prediction procedure for all object points in this study.

IV. Results

The Grey System Theory provides a solution to the problem even in the case of very limited number of data. The Multi Variable Grey Prediction Model can be used to predict deformation not only for one point but also for many points at the same time. In this study deformation level of the three different object points in a dam crest has been tried to be forecasted depending on the water level by multi variable grey model. Results show that there are great consistency between grey prediction values and real values. Based on the outcomes it is possible to conclude that grey prediction model is a very reliable prediction model in limited data circumstances.

Abstract— Advancing technology enables the extraction of accurate spatial information relating to the features on the ground. Owing to low-altitude flights, stereo aerial photos taken from digital cameras mounted on unmanned aerial vehicles (UAV) make it possible to generate point clouds as dense as LiDAR (Light Detection and Ranging) point clouds. Contrary to stereo aerial photogrammetry, LiDAR technology is capable of providing multiple returns. This is because laser beams are able to penetrate through the vegetation and reach the ground surface to record the spatial information of the ground point to which the laser beam has reached. This, of course, makes it easier to classify the points belong to the bare earth surface and to the above-ground objects, which is the main reason that most of the ground filtering algorithms focus on filtering LiDAR point clouds. However, LiDAR technology is still costly, especially for large-scaled areas. Apart from enabling the generation of dense point clouds, UAV photogrammetry is also cost-efficient with easy-deployable UAVs. Hence, it may be reasonable to use UAV-based point clouds for ground filtering in the absence of LiDAR data. However, ground filtering algorithms developed for LiDAR point clouds are more likely to be unsuccessful in filtering UAV-based point clouds, which encourages the analysts to seek for alternative approaches to filter UAV-based point clouds. This study uses a simple methodology to filter UAV-based point clouds. This methodology filters a UAV-based point cloud with an image classification-based approach. Thematic image produced with the Support Vector Machine (SVM) classifier is overlaid with the point cloud to determine the points corresponding to the above-ground objects. Determined points are then discarded to retrieve ground points. It can be concluded from the evaluation results that the used methodology filtered the UAV-based point cloud with a type I error of 2%, a type II error of 20% and a total error of 10%.

I. INTRODUCTION

Ground filtering, which is the removal of the points belong to above-ground objects to retrieve only the ground points, is essential for most photogrammetric projects. Retrieved ground points are interpolated to generate the Digital Terrain Model (DTM). Ground filtering is a challenging process [1]. Land

topography, and complexities and heights of the above-ground objects are just some of the factors making the ground filtering process challenging. Various ground filtering algorithms have been reported in the literature. These algorithms can be categorized as slope-based [2], segmentation-based [3], morphology-based [4-7] and interpolation-based [8,9] algorithms.

The ground filtering algorithm proposed in [4] separates the ground and non-ground points by comparing the slopes between each point and its neighbors. If the maximum slope is found to be greater than a predefined threshold, then the candidate point is said to be a non-ground point and removed. The slope-based filtering approach was enhanced in [5] by means of a two-step procedure. The first step approximated a rough DTM by using local minima. In the second step, the ground and non-ground points are classified based on a threshold. Reference [10] proposed a TIN (Triangulated Irregular Network)-based approach to remove the non-ground points. This approach uses some seed points to be used for the formation of a sparse TIN. This TIN is then densified iteratively until there is no unclassified points. Reference [11] introduced a multi-directional ground filtering approach that uses the pattern variability along different directions. Reference [12] utilized progressive densification and segmentation techniques to filter LiDAR data. References [13] and [14] conducted a morphology-based procedure that benefits from a variable-size structure element. Reference [15] used an object-based filtering approach that forms the objects with a segmentation algorithm implemented based on a grid index. Repetitive interpolation was utilized in [16] to filter a laser scanner data of a forested area. References [17] and [18] used a 3D active contour to separate the ground and non-ground points. Reference [19] introduced a filtering approach that performs a one-dimensional labelling in two opposite directions. An image classification-based filtering methodology was introduced in [20]. This methodology overlaps a point cloud with a thematic map to detect the points corresponding to the non-ground class. Detected non-ground points are then removed to retrieve ground points.

This study uses the ground filtering methodology proposed in [20] to remove the non-ground points. Further information about this methodology is given in Section II.

II. MATERIAL AND METHODS

A. Study Area

The study area was chosen in Karadeniz Technical University campus, in the city of Trabzon. The city is situated on the north-east of Turkey. A wide variety of different structured above-ground objects exist in the campus, which enables a comprehensive investigation of the success of the used methodology. Elevation ranges from 31 m to 71 m in the study area. The study area is shown in Figure 1.

Fig. 1. Study area.

B. Methodology

As a first step, 12 ground control points (GCP) were established in the entire campus. Plenty of attention was paid to distribute the points evenly over the campus. 3D positions of the GCPs were then measured with the RTK GPS technique. Afterwards, 256 aerial photos (3648 x 2736 resolution) of the entire campus were captured with the RICOH GR DIGITAL IV digital camera mounted on the Gatewing X100 UAV. The aerial photos were taken along nine paths from an altitude of 185 m. After the flight, captured aerial photos were processed in the Agisoft Photoscan Professional software and the point

cloud and orthophoto of the study area were generated. The density of the produced point cloud was 0.1 point/m², whereas the spatial resolution of the orthophoto was 15 cm. Since the density of the point cloud was not enough to separate the ground and non-ground points, the point cloud was densified and a point cloud with a density of 17.1 point/m² was generated. The point cloud and orthophoto were then cropped with respect to the boundary of the study area in order to test the performance of the used methodology. The orthophoto image was classified with Support Vector Machines (SVM) classification algorithm. The reason for using this classifier was that it has been proven to be very successful in classifying the images [20]. The thematic image included six classes as building, soil, shadow, grass, road and tree. Building and tree classes were merged to form non-ground class, whereas the other ones were merged to form the ground class. Densified point cloud was then overlaid with the thematic image and the points corresponding to the non-ground class were identified and removed. As a final step, the DTM of the study area was interpolated from the ground points by means of the Bi-linear interpolation technique.

III. RESULTS AND DISCUSSION

The produced DSM (Digital Surface Model) and DTM are shown in Figures 2 and 3, respectively. Visual investigations showed that the used methodology was, in general, successful in separating the ground and non-ground points. In addition to visual evaluation, quantitative measurements would also be of help to test the performance of the used ground filtering methodology.

Fig. 2. Produced DSM.

Fig. 3. Produced DTM.

Two types of errors arise out of ground filtering process, namely the omission and commission errors [21]. The Type I error (omission error) is the classification of ground points as non-ground, whereas the Type II error (commission error) is the classification of non-ground points as ground [1,21,22]. Evaluation of all points in a point cloud is not practical. Hence, these error metrics are computed by using randomly selected test points [20]. The Type I, Type II and Total error metrics are calculated as [22];

$$\text{Type I error} = o / G \quad (1)$$

$$\text{Type II error} = c / NG \quad (2)$$

$$\text{Total error} = o + c / G + NG \quad (3)$$

where, o , c , G and NG stand for the omission error, commission error, total number of ground points and total number of non-ground points, respectively.

In the study, the number of required test points were calculated with the multinomial distribution approach used in [23]. In cases where there is no information about the area of each class, which is the case in this study, this approach estimates the number of required test points as;

$$n = B / 4b^2 \quad (4)$$

where, $B = \alpha / k$, α is the confidence interval, k is the total number of classes and b is the desired accuracy [20,24]. In the study, the confidence interval was chosen as 95%. Since there are two classes (ground and non-ground) in thematic image, B was computed as 0.025 ($\alpha / k = 0.05 / 2$). It can be seen from the χ^2 table that the corresponding value for 0.025 is 5.02 at one degree freedom. Hence, n was computed as 502 ($5.02 / 4 (0.05^2)$). As can be seen, a minimum of 502 test points were needed to investigate the ground filtering result accurately.

Hence, 665 test points were randomly selected from the point cloud to use for calculation of the metrics. These test points were then overlaid with the orthophoto to evaluate each of them with the aid of the very high-resolution orthophoto. Visual observation of the test points revealed that 288 of the test points were selected for above-ground objects, while the others for the ground. Table 1 shows the calculated metric results.

TABLE 1. CALCULATED METRIC RESULTS

Omission E.	Commission E.	Type I E.	Type II E.	Total E.
9	58	0.02	0.20	0.10

As seen in Table 1, 9 ground points were classified as non-ground; whereas 58 non-ground points were classified as ground. The Type I, Type II and Total errors were calculated as 2%, 20% and 10%, respectively.

IV. CONCLUSIONS

Metric results indicated that the methodology used in this study is capable of keeping ground points successfully. However, in some parts of the study area, it misclassified the non-ground points. In general, 90% of all test points were classified successfully. The advantage of this methodology is that it does not use any morphological operations and require any thresholds. The success of this methodology depends heavily on the performance of the used classification algorithm. Hence, advance classification algorithms such as the SVM, Artificial Neural Network (ANN), Random Forest, Rotation Forest etc. tend to increase the performance of this methodology. In addition, precise selection of training pixels is necessary to perform an accurate classification, which makes high-resolution images more advantageous when using this methodology.

ACKNOWLEDGMENT

The aerial photos used in this study were acquired by the UAV owned by the Geomatics Department of Karadeniz Technical University.

Abstract— *The maps can also be made with inexpensive Unmanned Aerial Vehicle (UAV). The UAVs carry lightweight cameras that can capture good quality images. These cameras on the UAVs can be set to take pictures at regular intervals. Also, thanks to the lightweight GPS units mounted on the UAVs 3-D positions of the UAVs can be recorded when taking each picture. There are plenty of drones with varying prices. In this study, Orthophoto map of Firat University Campus area is produced with the pictures captured with the digital camera mounted on the DJI Phantom3 professional Unmanned Aerial Vehicles. To increase the geometric accuracy of the produced orthophoto map, 7 control points are established and their positions are measured with the RTK GPS method.*

Keywords—Unmanned Aerial Vehicle; Drones; Image Processing; GPS

I. INTRODUCTION

Unmanned aerial vehicles (UAV) are among the common and frequently used tools in mapping activities in recent years. The hints that these tools, which have developed at a high rate of use and technology, will cause a great change especially in the cartography sector and its activities are already seen in studies. Unmanned aerial vehicles can be described as vehicles that operate without a pilot, with the ability to automatically or semi-automatically fly continuously without regard to aerodynamic flight principles [1]. The advantages of these unmanned vehicles can be listed as;

- Affordable prices,
- Quick collection of topographical data,
- Offers orthophoto maps if desired,
- Offers very high-resolution images,
- Makes repetitive measurements possible,
- Autonomous flights with improved navigation software,
- Does not require very talented and very knowledgeable users to use UAVs and process images taken,
- Offers horizontal accuracies generally around 3 - 10 cm.

II. UNMANNED AERIAL VEHICLE (UAV)

Generally known as "Drone" which means male bee in English. The technical meaning is unmanned aerial vehicle or remotely controlled aircraft technology, or shortly called UAV or UAV (Unmanned Aerial Vehicle). The term used to describe UAV in Turkish is taken directly from English equivalent unmanned aerial vehicle remotely controlled from the ground [3-5]. Though they are inexpensive, small and portable, UAVs can carry lightweight digital cameras that can take very good quality images. These cameras can be set to shoot pictures at regular intervals. Their storage areas can be increased via cheap memory cards. UAVs are also equipped with lightweight and portable GPS units.

III. THE PRODUCTION STEPS OF TOPOGRAPHIC MAPS WITH UAVs

The steps in the production of Topographical Maps with UAV is given below. For more detailed information, should be viewed to 6, 7 and 8 resources.

A. Flight Planning

Either for autonomous or manual flight, flight plans should be made carefully before each flight. In any case, project area needs to be analyzed thoroughly before the flight. There can be energy transmission lines, large trees, sensitive/banned zones or other possible dangers in the flight zone. As a result, it would be useful to examine the existing satellite images before flight.

B. Flight Route Planning

Determination of the flight path is an important part of the unmanned aerial mapping process. In this process, proprietary software of drone manufacturers is used. Software with open source code such as Mission Planner, Map Pilot and PIX4D are the most commonly used software. The contents of these software are very similar.

C. Image Overlays

Before flight, forward and side overlap ratios should be determined. The image processing programs should be

designed so that the images overlap sufficiently from the front and side. There is no a universal rule for image overlay and it varies according to topography and flight altitude. While some researchers suggest 80% forward and 70% side overlaps, others suggest 80% forward and 80% side overlapping images. Pix4D software suggests at least 75% forward and 60% side overlapping photos on its web page.

D. Image Quality-Oriented Flight Planning

To get the best image quality, the flight height, the size and the number of pixels of the sensor, the type of the sensor (CCD or CMOS), the focal length of the lens in the camera, the shutter speed, the light condition, the ISO sensitivity and other camera settings are very important.

E. Height

Height is another important criterion to be considered before flight since it directly affects flight security and legal constrains. Although high altitude images have lower spatial resolution, they cover wider areas with fewer images.

F. Viewing Angles

The most used viewing angles are vertical (nadir) and oblique (off nadir). Nadir-viewing photographs are taken at the top of the field where the camera will exactly look down. This perspective is used in the traditional mapping as common. If the angle is oblique, information about the topography of the earth is collected from the photographs taken with an off-nadir angle.

G. GPS and Coordinate Transformation

Coordinate transformation is a necessary process if the maps obtained by unmanned aerial vehicles will have an Earth-based coordinate system. To perform coordinate transformation between image and Earth-based coordinate system, a few points with known coordinates on both systems must be used. These points are called ground control points. Some unmanned aerial vehicles use RTK (Real Time Kinematic) GPS, which eliminates ground control point need in the field.

H. Ground Control Points

The software needs approximately 5 ground control points to perform georeferencing process. More control points will lead to a more accurate results. Ground control points must be evenly distributed over the ground for more accurate results.

J. 3-D Modeling

To produce 3-D map of the project area requires hundreds of overlapping images. UAV photogrammetry software

creates 3D maps by analyzing these overlapping images with the following steps:

1. Image matching and aligning process by finding common points on overlapping images
2. Improving the calibration parameters by finding the camera's position for each image
3. Sparse point cloud creation. This sparse cloud may be sufficient to create a coarse 3-D model that does not require precise coordinates.
4. Creating a dense point cloud cluster.
5. Obtaining a 3-D "mesh" polygon model representing the surface of the object area.
6. Placing texture taken from the original picture on the model and depth and volume rendering.

IV. APPLICATION

Campus area of Firat University, Faculty of Engineering has been selected for the project area (Figure 1). The selected area covers approximately 0.481 km² =481 Acres. Study area has a uniform slope in a North-South direction. There are no obstacles to threaten and obstruct flight safety within the study area. The terrain is covered with buildings, trees and vegetation.

Fig 1. Working area

The DJI Phantom3 Professional Quadcopter, which is purchased with the financial support of FUBAP was used to create the maps. The technical specifications of this Quadcopter are given in the Table 1.

Table 1. Technical specifications of Quadcopter

	
Weight including battery and propeller	1280 gr.
Maximum rise rate	5m/sn
Maximum Descending velocity	3m/sn
Maximum velocity	16m/sn
Operating temperature	0- 40°
GPS mode	GPS/GLONASS
Maximum flight time	23 minute
Sensor	1/2.3" CMOS Effective pixel: 12.4 M (total pixel: 12.76 M)
Maximum image size	4000*3000 (12 Mp)
Lens	FOV 94° 20 mm (35 mm format equivalent) f/2.8, fokus at ∞
Image saving format	JPG, DNG

In order to georeference the Orthophoto map, 7 control points were evenly distributed over the campus area and their positions were measured using RTK GPS method. The distribution of the control points used for georeferencing is shown in Fig 2.

Fig 2. The distribution of the control points

For flight planning, Map Pilot software, developed by Drones Map Easy software for DJI, was used. Flight planning for the study area is given below (Fig 3.).

Fig 3. Flight planning for the study area

According to this plan, the flight will take place over an area of 0.481 km². The maximum flight height is 120 m. and at this altitude 321 pictures will be taken using 2 batteries. Quadcopter will make an autonomous flight according to the pre-determined flight plan.

V. PROCESSING IMAGE DATA OBTAINED FROM UNMANNED AIR VEHICLES

321 images were evaluated with Agisoft Photoscan data processing software. Figure 4 demonstrates how images are overlapped during flight, and the Figure 4 indicates very good forward and side overlaps. This implies that no problems will be encountered in 3-D models obtained from these overlaps. As a result of the evaluation of the images with software, Digital Surface Model (DSM), Orthophoto images and the desired frequency of point cloud data of the study area were obtained.

Fig 4. Images overlap

Once the photos have been aligned, the program creates a sparse point cloud containing the parameters of the camera. Point cloud created in the study is shown in Figure 5.

If ground control points are used, the positions of these points in the ground coordinate system must be entered in the software. In this phase: Camera positions, orientation of the pictures and the production of the 3-dimensional point cloud is performed. 3D point cloud and ground control points produced by software are seen in Figure 5.

Fig 5. 3D point cloud and ground control points produced by software

The software obtains a 3-dimensional "mesh" polygon model representing the object surface from the dense cloud cluster (Fig 6).

Fig 6. 3-dimensional "mesh" polygon model

The last step is to place the texture from the original images onto this model (Figure 7-9). This process gives depth and volume to model.

Fig 7. Texture 1

Fig 8. Texture 2

The digital elevation model is a model that gives the height information of a geographical region. The digital elevation model (DEM) of the study area is given Fig 10. The resolution of this model is 9.76 cm / pixel and the point density is 105 points / m²

Fig 10. The digital elevation model

VI. RESULTS

This study showed that it is possible to produce 3 dimensional map with high position accuracy with the help of the photographs obtained from UAV 's which are not produced for photogrammetric purpose. In this study, the technical specifications of the purchased UAV were used in its original form untouched. The DJI Phantom3 model uses fish-eye lens. Although we do not recommend a fish-eye lens for photogrammetric purposes, the results we obtained are quite reasonable. The studies done with UAV in the literature have obtained values very close to the point position accuracy obtained in this study. As a result of the analysis, the image resolution for the work area of 0.481 km² is 4.88 cm / pixel. This obtained resolution is equivalent to the work done in the literature. Quadcopter was flown in the project area with autonomous flight mode. Although it does not require much pilot experience for such flights, there are many drawbacks. Used UAV does not recognize any obstacles (for example, electrical wires, etc.) automatically and this may lead to danger of falling. So, the land structure for autonomous flight should be analyzed very well before flight. The duration of flights should also be planned by considering the number of sparse batteries you have. In the used system, it is impossible to start from the same place for another flight. When determining the flight height, the optimum height should be determined by considering the legal height limit. With this study, it is seen that the results obtained by using the photogrammetric techniques can serve to needs of different disciplines.

Abstract— Digital Terrain Model (DTM) generation is one of the leading applications in photogrammetry. A DTM is generated by the interpolation of ground points retrieved by ground filtering, which is the removal of the points belong to above-ground objects from point cloud. In the literature, a wide variety of ground filtering approaches have been reported for ground filtering. Complexity of topography makes ground filtering process more challenging, which forces the researchers to developed filtering approaches that require a number of parameters. This, of course, leads the users to try different parameters until they find the optimum filtering result, which is very time consuming in most cases. This study uses the Cloth Simulation Filtering (CSF) algorithm, a recently introduced ground filtering algorithm developed to filter LiDAR (Light Detection and Ranging) data, to filter a point cloud extracted from the aerial photos taken from an unmanned aerial vehicle (UAV). The biggest advantage of the CSF algorithm is that, compared to previously developed ground filtering algorithms, it utilizes less parameters. The results showed that the CSF algorithm committed a type I error of 12.7%, a type II error of 16.7% and a total error of 14.8%.

Keywords— *point cloud; cloth simulation filtering; ground filtering; unmanned aerial vehicle; aerial photogrammetry*

I. INTRODUCTION

DTMs are used in many applications such as mapping, mining engineering, remote sensing, land planning, geology and geomorphology [1,2]. Since a DTM is generated by the interpolation of the points belong to the bare earth surface, there is a need to separate the ground points and points belong to above-ground objects, which is called 'ground filtering'. Ground filtering can be a hard challenge in areas with complex surface variability [3]. A wide variety of ground filtering algorithms have been proposed so far. The users who are willing to perform ground filtering generally try a large number of filtering algorithms until they find the optimum filtering result.

Reference [3] categorized the ground filtering algorithms as morphological filters, segmentation- and cluster-based filters, TIN (Triangulated Irregular Network)-based filters, contour-

based filters, interpolation-based filters and directional scanning filters.

Reference [4] introduced a slope-based filtering approach in which ground filtering is implemented by comparing slopes between a point and its neighbors. Reference [5] used a dual rank filter to remove non-ground points. Reference [6] removed non-ground LiDAR measurements with a progressive morphological filter. This approach filters a point cloud by means of a gradually increasing window and elevation difference thresholds. In this algorithm, slope of the processing area is assumed to be constant, which may lead to poor ground extraction results [7]. To cope with this problem, [8] defined some adjustable parameters to better describe the topography. Reference [9] proposed a morphological filtering algorithm based on multi-gradient analysis. This algorithm first organizes the point clouds by an index mesh. Afterwards, a morphological method is used to compute the multi-gradient of each point. Finally, to remove the above-ground objects, the algorithm iteratively performs an enhanced opening operation constrained by multi-gradient. Reference [10] introduced a TIN (Triangulated Irregular Network)-based filtering algorithm in which seed points are used to generate a sparse TIN, which is then densified until all points are classified as ground and non-ground. This algorithm uses two important parameters; one is the distance between a candidate point and TIN facet, and the other one is the angle between the TIN facet and the line connecting the closest vertex of the facet and candidate point [7]. Reference [11] proposed another surface-based filtering algorithm based on a weighted linear least-squares interpolation. Reference [12] introduced a filtering algorithm in which a hierarchical approach is used together with a weighing function to detect the raster elements containing data relating to above-ground objects. In [13], ground and non-ground points were separated by performing one-dimensional labelling in two opposite directions, both along the scan line profile. Reference [14] used a two-step procedure to remove the non-ground points. The first step includes the initialization of the region growing from ground seeds. In the second step, neighbor points are gradually added based on three mathematical measurements [3].

This study uses the CSF algorithm, a recently introduced ground filtering algorithm, to filter a UAV-based point cloud. Further information about the CSF algorithm can be found in Section II.

II. MATERIAL AND METHODS

A. Study Area

The study area, which is shown in Figure 1, is a small part of the Karadeniz Technical University (KTU) campus in the city of Trabzon, located on the northeastern part of Turkey. As seen in the figure, various above-ground objects (building, tree, mosque etc.) exist in the study area. Elevation ranges from 69 m to 111 m in the study area, whose size is 146 m x 203 m.

Fig. 1. Study area.

B. Methodology

Before the flight, 12 ground control points (GCP) were established in the KTU campus. 3D positions of the GCPs were then measured by means of the RTK GPS technique. Next, the flight was planned, and the flight altitude and total number of flight lines were decided. Afterwards, the flight was conducted with the Gatewing X100 UAV and 256 aerial photos were taken during the flight. The aerial photos were taken by the RICOH GR DIGITAL IV digital camera mounted on the UAV. The flight was conducted from an altitude of 185 m along nine flight lines. After the flight, captured aerial photos were processed by using the Agisoft Photoscan Professional software. A point cloud with a density of 15.2 point/m² was extracted with the software. A 10-cm orthophoto and a 15-cm Digital Surface Model (DSM) were also generated with the same software. The point cloud was then cropped with respect to the boundary of the study area in order to test the performance of the CSF algorithm.

The CSF algorithm, introduced in [7], simulates a simple physical process. Imagine a piece of cloth is placed above a terrain. In this case, the cloth drops because of gravity. If the cloth is soft enough, DSM would be the final shape of the cloth. However, if the terrain is turned upside down and the cloth is specified with rigidity, DTM would be the final shape of the cloth. The CSF algorithm simulates this process [7].

The fundamental implementation steps of the CSF algorithm are as follows [7];

- The outliers are removed with a third-party software.
- The point cloud is inverted.
- The number of particles are determined with respect to the user defined grid resolution.
- All points and grid particles are projected to a horizontal plane. In this plane, a nearest point (CP – corresponding point) is found for each cloth particle.
- The height value of the CP is specified by an intersection height value (IHV), which shows the lowest possible position of each particle.
- The current height value (CHV) of a particle is compared with the IHV in each iteration. A particle is moved back to the position of the IHV and made ‘unmovable’ if the CHV is equal or lower than the IHV.
- Simulation continues until the maximum height variation of all particles is small enough or the maximum iteration number defined by the user is exceeded.
- The cloud-to-cloud distance between the point cloud and grid particles is calculated.
- A point is classified as ground if its distance to the simulated particles is smaller than a threshold, otherwise it is classified as non-ground.

The CSF algorithm uses four user-defined parameters as grid resolution, which is the horizontal distance between two neighboring particles; class threshold, which is a threshold to classify the points as ground and non-ground based on the distances between the original point cloud and the simulated terrain; iterations, which is the maximum iteration times; and time step, which controls the displacement of particles from gravity.

In this study, the CSF algorithm was implemented in MATLAB environment. First, default parameter values given in [7] were tried for three terrain types (flat terrain, steep terrain, and high and steep slopes). Visual observations revealed that the default parameter values did not give satisfactory filtering results. After only a few trials, optimum parameters were found as 0.6, 500, 1 and 0.65 for grid resolution, iterations, class threshold and time step, respectively. Terrain type was also selected as gentle slope. The CSF algorithm removed 235,756 of 449,627 points. The ground points were then interpolated by the bi-linear

interpolation technique to generate the 15-cm DTM of the study area.

III. RESULTS AND DISCUSSION

The produced DSM and DTM are shown in Figures 2 and 3, respectively. It can be seen from Figure 3 that the CSF algorithm performed well in most parts of the study area. However, there can be seen some filtering errors at the boundaries of objects.

Fig. 2. Produced 15-cm DSM.

Fig. 3. Produced 15-cm DTM.

Since visual evaluation depends on the perspective of the analyst, quantitative evaluations may better reveal the performance of the filtering algorithm. Reference [15] stated that there may be two types of errors in ground filtering process; omission error, which is related to the misclassification of ground points; and commission error,

which is the misclassification of non-ground points [15-17]. The Type I, Type II and Total error metrics are calculated as [16];

$$\text{Type I error} = o / G \quad (1)$$

$$\text{Type II error} = c / NG \quad (2)$$

$$\text{Total error} = (o + c) / (G + NG) \quad (3)$$

where, c , o , NG and G are the commission error, omission error, total number of non-ground points and total number of ground points, respectively.

In the study, the Type I, Type II and Total errors were calculated by using 600 test points, which were randomly selected from the point cloud. Actual classes of these test points were specified by overlapping them with the 10-cm orthophoto. Investigation of the test points showed that 283 of them were belong to the ground class and 317 of them belong to the non-ground class. The CSF algorithm misclassified 36 of the 283 ground points, which resulted in a Type I error of 12.7%. These misclassified points generally situate in the vicinity of the above-ground objects. The algorithm did not manage to remove 53 of 317 non-ground points, which shows that the algorithm committed a Type II error of 16.7%. In the study area, there are different interlocking trees with different heights. Commission errors generally occurred in these regions. The Total error was found to be 14.8%, which can be considered quite good for a ground filtering algorithm.

IV. CONCLUSIONS

This study aimed at investigating the UAV-based point cloud filtering capability of the CSF algorithm, which was originally developed to filter raw LiDAR data. It can be inferred from the results that the CSF algorithm is quite successful in filtering point clouds. Since the algorithm does not use complex parameters, it does not take too much time to search for suitable parameters for this algorithm. In addition, the CSF algorithm performs in a short span of time, which is very advantageous compared to other algorithms in the literature. Future studies will focus on comparing the performance of this algorithm with those of other successful filtering algorithms in terrains with higher surface variability.

ACKNOWLEDGMENT

The aerial photos used in this study were acquired by the UAV owned by the Geomatics Department of Karadeniz Technical University.

Abstract— In tunneling, one of the effective parameters on cost is the type of support systems to be used during tunnel excavation. The most important factor in determining the support type depends on the geological and geotechnical characteristics of the rock mass to be excavated. Until today, many empirical rock mass classifications were proposed to determine the type of support such as Rock Mass Rating (RMR), Rock Mass Quality (Q) and Rock Mass Index (RMI). In these classifications, the engineering properties of discontinuities and the rock material are used as input parameters, and the support elements should be used is determined. Today, the most common support elements used are shotcrete and rock bolts. These two support elements are used either alone or together according to the rock mass class. However, the support systems of empirical rock mass classification are inadequate in some cases or may lead to excessive use of support. Another important issue is the technical properties of the support elements such as the strength of shotcrete, the diameter and strength of rock bolt. These technical properties are not defined in the empirical rock mass classification systems and engineers use supports with different technical characteristics in practice. In addition, the effect of the overburden is another important issue that is not explained in empirical rock mass classification. Although revision of the support elements is inevitable in case of the increase in tension due to overburden, actually, support systems with the same technical properties are preferred for different excavation depths in practice.

The aim of this study is to determine the change in the strength of the shotcrete with the increase in depth of the excavation for the same rock mass class. For this aim, numerical modeling was developed by using Finite Element Method (FEM), in order to determine the relationship between the strength of the shotcrete and excavation depth. For the modeling, a tunnel of 10 m wide, 7 m height, single tube, modified horseshoe shaped, was modeled with the Phase² software, using weak, fair and good rock classes obtained from RMR₈₉ system. Very poor and very good rock masses of RMR₈₉ system were not included in this study, due to the main support element type is I-Beam for the very poor rock and spot bolting for the very good rock. In the first stage, shotcrete strength was assumed as 30 MPa and analyses were started to carry out from 10 m depth. The support elements of the poor rock mass provide stability up to 190 m, and the shotcrete elements were yielded after 190 m. Fair rock mass's shotcrete elements were started to yield from 280 m and the yielding depth of the shotcrete for the good rock mass was 530 m. These obtained data showed, the increase in the strength of the shotcrete is necessary for the poor, fair and good rock masses. In the second stage, shotcrete strength was increased to 40 MPa and the numerical analyses developed again. The results of the analysis showed that the shotcrete elements started to yield at 270 m in the weak rock mass, 430 m in the fair rock mass, and 630 m in the good rock mass. In this study, for the support system of the RMR₈₉ to be applicable, the shotcrete strength should be increased with the increase in the overburden was revealed.

Abstract— Forces of friction between structure and soil are taken into account in the design of geotechnical engineering constructions such as piles, retaining walls, sheet piles and diaphragm walls. Although many studies were carried out about the soil-structure interaction in recent years. However, in pile design, frictional forces are still calculated by using the empirical formulas proposed in the first half of the 20th century. Throughout history, wood was often used as friction piles. Steel piles are used extensively in practice. Nowadays, in harsh environmental conditions fiber-reinforced polymer (FRP) piles come into use in numerous cases. As is known, the effect of pile point tip resistance on the bearing capacity is ignored particularly in loose sands and the bearing capacity is fully taken equal to the skin friction. Hence, it is understood that correct determination of skin friction angle is very important in engineering calculations. In this study, various ratios of low plasticity clays (CL) were added to the sandy soil and compacted to standard Proctor density. Thus, soils with various internal friction angles were obtained. By performing interface shear tests (IST), skin friction angles of these soils with steel (st37) and FRP were determined. Based on the data obtained from the test results, a chart was proposed, which engineers can use in pile design. By means of this chart, the skin friction angles of the soils, of which only the internal friction angles are known, with steel and FRP materials can be determined easily.

Keywords— skin friction; design chart; pile materials; direct shear test

I. INTRODUCTION

Skin friction angle between soil and pile materials emerges as an important component in the designs made by geotechnical engineers. Frictional forces between structure and soil are taken into consideration in the design of civil engineering constructions such as retaining walls, sheet piles, diaphragm walls and piles. As is known, the effect of pile point tip resistance on the bearing capacity is ignored particularly in loose sand soils and the bearing capacity is fully taken equal to the skin friction. Hence, it is understood that correct determination of skin friction angle is very important in geotechnical design.

Many geotechnical engineers consider the skin friction angle (δ) as equal to $2/3$ of the internal friction angle (ϕ) of soil

in their designs [1]. However, it is known that δ can change in the event of frictions between the same soil and different materials. Even today, skin friction angles (δ) between soil and pile materials are not exactly known and design engineers use approximate values. δ values used in designs are of essential in the determination of pile number, diameter and length. A low δ value leads making non-economic designs and increases project costs substantially. On the other hand, a high δ value causes to safety problems.

Wood was used as a driven pile material up to the first half of the 20th century. However, the use of wood declined almost non-existing in today due to increasing costs. Nowadays, steel is commonly used as the driven pile material. Plastic composite materials have also been started to be used in recent years as alternative to steel. Today, FRP (fiber-reinforced polymer) material is ever-increasingly used due to the reasons such as being economic, having high tensile and compressive strengths and its resistance to harsh environmental conditions.

Potyondy (1961) conducted interface shear tests (IST) on the soils prepared in four sand/clay ratios and determined the skin friction angles of wood, steel and concrete materials. When examine the IST results, it is seen that the critical value for the cohesion is the situation where sand/clay ratio is 1. The cohesion rises quickly in all values over this ratio [2]. Uesugi and Kishida (1986) determined the friction between mild steel and dry sand by using IST. They found that the type and mean grain diameter of sand (D_{50}) had significant effects on friction angle [3]. There are many studies where the frictions between geosynthetics and sands were analyzed thorough IST [4, 5, 6, 7]. When articles in the literature are examined, it is generally seen that the frictions of clean sands (without fine-grained soils) and pile material surfaces were determined [6, 8, 9, 10]. However, clean sands are hardly seen in nature. Therefore, mixing various ratios of sand and clay soils will allow more realistic results to be obtained in the in laboratory of the soils encountered in the field [11].

Clayey sand soils containing various ratios (0%, 20%, 30%, 40% and 45%) of clay were used in laboratory tests. The produced soils have different internal friction angles, skin friction angles between the soils and pile materials (steel and FRP) were obtained. As a result of the laboratory studies, a

chart was proposed, which shows the relationship between the internal and skin friction angles. By means of this chart, the skin friction angles between soil and pile materials can be obtained based only on the internal friction angles of soils.

II. MATERIAL AND METHOD

The index properties of the sand and low plasticity clay (CL) soil used in the tests were determined and given in Table 1. Black basalt originated river sand (specific gravity 2.77) used in the tests. The sieve analyses, Atterberg limits tests and specific gravity tests were conducted according to standards [12, 13, 14]. Sieve analysis of sand and clay soils can be seen in Figure 1.

Fig. 1. Grain size distribution of soils

CL at the ratios of 0%, 20%, 30%, 40% and 45% in weight were mixed in the sand and optimum water contents (w_{opt}) were determined by performing standard Proctor tests on these mixtures [15]. w_{opt} values and soil classifications according to Unified Soil Classification System (USCS) are shown for each mixture in Table 2. The mechanical properties of the steel and FRP materials used in the tests are shown in Table 3.

TABLE I. INDEX PROPERTIES OF SOILS

	Sand	CL
D_{30} (mm)	0.33	0.0045
D_{50} (mm)	0.57	0.016
Liquid Limit, W_L (%)	-	30
Plastic Limit, W_P (%)	-	15
Specific Gravity, γ_s	2.77	2.68

TABLE II. MIXING RATIOS AND OPTIMUM MOISTURE CONTENT

Mixture	Clay (%)	Sand (%)	Soil Group (USCS)	w_{opt} (%)
m_0	0	100	SP	6.0
m_{20}	20	80	SC	9.0
m_{30}	30	70	SC	10.0
m_{40}	40	60	SC	11.5
m_{45}	45	55	SC	13.0

TABLE III. PROPERTIES OF PILE MATERIALS

	Steel (st37)	FRP (50% glass)
Compression strength (Mpa)	240	200
Tensile strength (Mpa)	360	240
Tensile Elasticity Modulus (Gpa)	210	23
Density (gr/cm ³)	7.85	1.8

The direct shear test (DST) was performed to obtain the internal friction angles (ϕ) of the soil mixtures [16]. Interface shear tests (IST) were conducted in order to determine the skin friction angles (δ) between the produced soil samples and steel, FRP [17]. Test setups can be seen in Figure. 2. and Figure 3. DST and IST tests were performed at a rate of 0.5 mm/min horizontal displacement. Samples prepared at the standard Proctor density and optimum water content were used in DST and IST tests and the results obtained from the tests can be seen in Table 4.

Fig. 2. Sketch of interface shear test setup

Fig. 3. Interface shear test setup; a) IST (steel soil) b) IST (FRP-soil)

TABLE IV. DIRECT SHEAR TEST (DST) AND INTERFACE SHEAR TEST (IST) RESULTS

Mixture	Internal friction angle of soil, ϕ (°)	Skin friction angle, δ (°)	
		Steel	FRP
m_0	43.0	26.5	34.5
m_{20}	39.5	31.5	37.0
m_{30}	41.5	29.2	36.0
m_{40}	35.0	27.0	32.0
m_{45}	28.0	18.0	22.7

Even today, in most projects, skin friction angle is calculated by using $\delta=2\phi/3$ equation. But every material have different skin friction angle with soils [11]. Especially for FRP this equation gives significantly lower δ values than test results. For example, for $\phi=35^\circ$ it is calculated that $\delta=23.3^\circ$. This δ value obtained from IST tests for FRP as 32.0° .

Therefore, as skin friction angle assumed lower values causes increase in number, diameter and depth of piles. Consequently non-economical designs can be made by using this equation.

III. SKIN FRICTION CHART

The results determined from the tests and then analyzed. A skin friction chart was proposed to be used in pile design (Figure 4.). Thanks to this chart, geotechnical engineers will be able to obtain the skin friction angles between the soil and pile materials based on the internal friction angle of soil in the field.

Fig. 4. Skin friction chart for steel and FRP

IV. LITERATURE REVIEW WITH CASES

The results determined through the chart and the studies conducted in the past are shown in Table 5. When the table is examined, it is seen that the δ values obtained through the proposed chart and the values determined in the study performed by Potyondy (1961) show nearly 100% similarity for steel [2]. When results of the chart and the study of Pando et al. (2002) are compared, it is seen that the δ values obtained for FRP material show approximately 90% of similarity [18]. When the results of the chart are compared with the study of Sakr et al. (2005), the δ values show 91% similarity for steel and 94% for FRP material [8]. And when the results of the chart and the studies of Tiwari et al. (2010) and Tiwari and Al-Adhahd (2014) are compared, it is seen that δ values show approximately 90% similarity for steel [10, 19].

Consequently, when δ values obtained from the chart and the studies conducted in the past are compared, these values show similarity more than 90%. The small differences around 10% are considered to arise from types of pile materials (steel hardness and FRP types) used in the tests and the use of dry sand in most studies.

TABLE V. COMPARISON BETWEEN CHART AND OTHER STUDIES

Soil (ϕ) (°)	Potyondy (1961), δ (°)	Pando et al. (2002), δ (°)	Sakr et al. (2005), δ (°)	Tiwari et al. (2010), δ (°)	Tiwari and Al- Adhahd (2014), δ (°)	Similarities between Literature and Skin Friction Chart (%)	
						Steel	FRP

44.5	24.2	-	-	-	-	24.3	100

V. CONCLUSIONS

The use of different pile materials, significantly changes the angle of skin friction (δ). Diameter, length and number of piles are considerably affected from these changes.

- IST were performed on the interfaces between soils and pile materials (steel and FRP). The skin friction angles between these materials and various soils were determined.
- In laboratory studies, soils with internal friction angles ranging between 28° and 43° were used.
- When the results determined from the tests and then analyzed, a chart is proposed which allows acquiring the angle of skin friction to take place between soil, the internal friction angle of which is known, and various pile materials.
- Many articles are found in the literature and then these studies were compared with the chart proposed and it was observed conformity over 90% in the δ values determined.

Nowadays, design engineers use equations that accept δ values equal for all pile materials ($\delta=2\phi/3$). This approach prevents make more realistic designs. True skin friction angles (δ) can be determined by means of the proposed chart. Thus, more economic designs can be made by selecting reasonable pile diameter, length and number.

When the internal friction angles (ϕ) of sand-clay mixture soils are examined, it can be seen that ϕ value decreases as the clay percentage increases. However, a slight increase occurred in ϕ in any cases where the clay content is around 30%. These slight increases in the internal friction angles of sand-clay mixtures with the increase of the clay content were observed by Dafalla (2013) and Bayoğlu (1995) as well [20, 21].

Abstract

In this study, it is aimed to examine the usability of Nakayasu Synthetic Unit Hydrograph (NSUH) method for small scale basins in Turkey. For this purpose, observed average unit hydrograph (OAUH) data of seven small scale basins located in Turkey were used. It has been understood that there are large differences between the unit hydrograph parameters calculated with the help of the NSUH method and the parameters of the observed average unit hydrographs (OAUH) and that the equations given by the NSUH method cannot be used in Turkey's basins. The equations given by NSUH method has been modified to make it suitable for Turkey's basins with the help of regression analysis using OAUH parameters. The difference between the parameters calculated by the help of the modified new equations and the parameters of OAUHs was found to be quite small. For testing the performance of MNSUH equations, the unit hydrograph parameters are calculated by using Mockus method. When the calculated values are examined, it is thought that the equations given by NSUH method can be used by modifying on Turkey's small scale basins.

Keywords: Nakayasu; Synthetic Unit Hydrograph; Watershed; Turkey's Basins

I. INTRODUCTION

When calculating and designing water structures, it is necessary to determine the flood discharge of the regions where they are located. It is known that there are many methods for calculation of flood discharge, but unit hydrograph methods give more realistic results [1]. The unit hydrograph (UH) method can only apply to the watershed where rainfall and stream flow data measured [2]. But always measured data may not be available. In this situation the flood discharge can be calculated using synthetic unit hydrograph methods. There are already several synthetic unit hydrograph (SUH) methods. Among these methods Snyder, Mockus and DSI methods are the most widely used SUH methods in Turkey [3, 4]. One of these SUH methods is NSUH method. NSUH method is developed by Dr. Nakayasu in 1940's for estimating flood discharge of small urban watersheds of Japan [5]. Although this method is widely used in Far Eastern countries it is not used in Turkey and European countries [6].

The aim of this study is to examine usability of NSUH method in Turkey's small-scale basins. For this purpose, seven small-scale basin OAUH data were used.

Firstly, calculations were made by using the equations given by NSUH method. When the calculated UH parameters and OAUH parameters are compared, it has been concluded that the equations given by the NSUH method are not suitable for using in Turkey's small-scale basins.

For this reason, it would be appropriate to use the equations given by NSUH method by modifying, using OAUH data.

The Snyder's SUH method should be applied on the basins which are bigger than 1000 km², DSI SUH method can be applied on drainage area up to 1000 km², since the unit hydrograph used in this method is obtained according to the 2-hour heavy rainfall, the rising time in the unit hydrograph (T_p) should not be less than 2 hours. Otherwise DSI SUH Method does not give healthy results. The Mockus SUH method is used in precipitation areas with a collection time (T_c) of less than 30 hours [15]. Therefore, for testing the effectivity of MNSUH method, the unit hydrograph parameters are calculated by using MNSUH and Mockus method and the results are compared.

II. MATERIAL

In this study, for modifying Nakayasu SUH equations Turkey's 7 small-scale basins were selected. The OAUH datas belong to these basins are taken from KHGM Soil and Water Resources Research Final Reports.

Selected sub-basins are show in Table 1.

TABLE I. SELECTED SUB-BASINS AND LOCATIONS

Name of Sub-Basins	Location of Sub-Basins
Izmir-Menemen-Ulucak	Number 5 Gediz Basin
Konya-Seydisehir-Glabbera	Number 16 Konya Basin
Mersin-Tarsus-Topçu	Number 17 East Mediterranean Basin
Konya-Beysehir-Karabalçık	Number 16 Konya Basin
Adiyaman-Kahta-Harabe	Number 21 Euphrates Basin
Yozgat-Sorgun-Ikikara	Number 15 Kizilirmak Basin
Ankara-Haymana-Catalkaya	Number 12 Sakarya Basin

The OAUH parameters of selected sub-basins shown in Table 1 are taken from KHGM Soil and Water Resources Investigation Result Reports [3, 7, 8, 9, 10, 11, 12].

The selected sub-basins' area (A), length (L) values and observed average unit hydrographs' (OAUH) peak discharge (Q_p), reaction times (t_r), peak time (T_p), unit hydrograph base

time (T_b) and the time of the peak discharge reducing %30 ($T_{0.3}$) values are given in Table 2.

The selected sub-basins geographic locations are shown in Figure 1.

TABLE II. THE CHARACTERISTICS OF SMALL SCALE BASINS AND OBSERVED AVERAGE UNIT HYDROGRAPHS

	Sub-Basins	A (km ²)	L (km)	Q_p (m ³ /s mm)	t_r (h)	T_p (h)	T_b (h)	$T_{0.3}$ (h)
1	Izmir-Menemen-Ulucak	0.34	1.30	0.068	0.69	1.19	5.39	1.04

III. NAKAYASU SUH METHOD

In this study, the NSUH method used for detecting UH parameters such as peak flow, lag time, peak time and base time. The equations given by NSUH method for calculation of these parameters are as follows.

For calculating peak time (T_p) Eq. (1) is used. The peak time is given as a function of lag time (t_g) and effective rainfall duration (t_r) :

$$T_p = t_g + 0.8 t_r \quad (1)$$

The lag time (t_g) is calculated for two different cases. The first case when river length (L) is less than 15 km the lag time (t_g) is calculated by Eq.2:

$$t_g = 0.21 L^{0.7} \quad (2)$$

The second case is when the river length is more than 15 km the lag time (t_g) is calculated by Eq.3:

$$t_g = 0.4 + 0.058 L \quad (3)$$

One of the important parameters of NSUH method is $T_{0.3}$. This means that the time required for reducing the peak discharge up to %30 and this parameter is calculated by Eq.4:

$$T_{0.3} = \alpha t_g \quad (4)$$

In Eq.4, α value is a coefficient of basin characteristics and this coefficient is given as follows [13, 14]:

For common sloped basins: $\alpha=2$

For low sloped basins: $\alpha=1.5$

For high sloped basins $\alpha=3$

Fig 2. Nakayasu SUH parameters

In NSUH method peak discharge (Q_p) is calculated by Eq.5, the peak discharge (Q_p) is given as a function of watershed area (A), rainfall coefficient (C), the unit rainfall (R_0), peak time (T_p), the time required for the reduction peak discharge rate up to 30% ($T_{0.3}$). The Eq.5 is as following:

$$Q_p = \frac{C \cdot A \cdot R_0}{3.6(0.3T_p + T_{0.3})} \quad (5)$$

A unit hydrograph shape consists rising and decreasing limbs. In NSUH method rising limb curve discharge (Q_a) is calculated by Eq. (6):

$$Q_a = Q_p \left(\frac{t}{T_p} \right)^{2.4} \quad (6)$$

The decreasing limb curve discharge (Q_d) is calculated by using given equations for separately three regions. The given equations are as follows:

$$Q_d > 0.3Q_p \rightarrow Q_d = Q_p \cdot 0.3^{\frac{t-T_p}{T_{0.3}}} \quad (7)$$

$$0.3Q_p > Q_d > 0.3^2Q_p \rightarrow Q_d = Q_p \cdot 0.3^{\frac{t-T_p+0.5T_{0.3}}{1.5T_{0.3}}} \quad (8)$$

$$Q_d < 0.3^2Q_p \rightarrow Q_d = Q_p \cdot 0.3^{\frac{t-T_p+1.5T_{0.3}}{2T_{0.3}}} \quad (9)$$

IV. APPLICATION OF NSUH

In order to analyze the usability of NSUH method, seven small scale sub-basins observed unit hydrographs are tested in application. The UH parameters have been calculated by using NSUH method's equations. These calculated parameters given in Table 3. The comparison of the NSUH and OAUH is depicted in Figure 3 to Figure 9. The difference and error ratios between observed UH parameters and parameters calculated by NSUH are given in Table 4.

TABLE III. THE UH PARAMETERS CALCULATED BY NSUH METHOD

Basins		Parameters Calculated by NSUH Method

V. MODIFICATION OF NSUH EQUATIONS

While making modification it is aimed to re-determine the coefficients of equations given by NSUH method by regression analysis.

By using OAUH's of basins, the equations given by Nakayasu were modified for Turkey's small scale basins. The developed new equations are given as following:

Modified Nakayasu equation for t_g is:

$$t_g = 0.388 L^{0.552} \quad (10)$$

The coefficient of basin α is necessary for calculating $T_{0.3}$, but for calculating α no equation is proposed in Nakayasu method. For this reason, it is difficult to determine the α coefficient. To make the method easier to implement, a new α equation has been developed. The developed new equation is given as following:

$$\alpha = -1.933 T_p + 12.279 t_g - 1.485 L + 0.090 A \quad (11)$$

The Q_p equation is determined as follows by using T_p and $T_{0.3}$ values which are calculated by modified equalities.

Modified Nakayasu Equation for Q_p is:

$$Q_p = \frac{(0.9953 A R_0)}{(3.6 (0.3 T_p + T_{0.3}))} \quad (12)$$

In Nakayasu method no formula is proposed for the calculation of UH base time (T_b) value. The T_b value is calculated by using decreasing limb equations. The time value at the point where the decreasing limb curve discharge is zero, at the same time equal to T_b value. For this reason, determining the T_b value is quite difficult and this causes the T_b to be calculated incorrectly. The equation developed for the calculation of T_b value is given as follows:

$$T_b = 2.2 \left(\frac{T_{0.3} + T_p}{t_r} \right)^{1.01} \quad (13)$$

According to new equations, the UH parameters have been calculated. The calculated new values according to modified Nakayasu synthetic unit hydrograph method (MNSUH) for seven basins are shown in Table 5. Also, the comparison of MNSUH and observed values is given in Table 6.

VI. MOCKUS SUH METHOD

The Mockus method, in terms of its practically calculation and the ease of drawing triangular hydrograph is preferred. The Mockus method is applied for drainage areas of up to 30 hours of concentration, if the drainage area has bigger than 30 hours of concentration time, the drainage area is divided into sub-areas and hydrographs to be drawn for each are superposed according to the lag time [16]. According to the Mockus method calculating some unit hydrograph parameters by using following equations.

$$T_c = 0.00032 \frac{L^{0.77}}{S^{0.385}} \quad (14)$$

$$t_p = 0.6T_c \quad (15)$$

$$T_p = \sqrt{T_c + 0.6T_c} \quad (16)$$

$$t_r = 1.67T_p \quad (17)$$

$$T_s = T_p + t_r \quad (18)$$

$$Q_p = \frac{K.A.h_a}{T_p} \quad (19)$$

Here, T_p is the peak time of unit hydrograph, T_c is the concentration time, t_p is the lag time, t_r is the decreasing time, T_s is the base time, K is a coefficient and it is accepted to be 0.208 and h_a basin surface flow height [16, 17].

The calculating UH parameters by using Mockus equations is given in the Table 7, the difference and the error ratio between observed and calculated value are given in Table 8 and the root mean square error (RMSE) of NSUH and MNSUH and Mockus method are given in Table 9.

The comparison of the MNSUH, NSUH, Mockus and OAUH is indicated in Figures 10 to 16.

VII. CONCLUSION

In this study, Turkey's seven small scale basins have been selected. The OAUH parameters of these basins calculated by NSUH method. When the results were examined, it is seen that the error ratios between calculated and observed parameters are high. For this reason, the equations given by Nakayasu method were modified by regression analysis using OAUH data. The determined new equations have been used for calculating the UH parameters.

When the entire outcome was analyzed, it shows that parameters that belong to the unit hydrograph such as Q_p , T_p , T_g , $T_{0.3}$, T_b ; were calculated with a very low error ratio by the modified Nakayasu method. Additionally, when the RMSE value of all methods were analyzed it is seen that the UH shape is perfectly simulated by using MNSUH method.

Additionally, the MNSUH method has no restriction on application, whereas, DSI and Mockus methods have some restriction on the application. DSI method is not applicable on the rising time (T_p) less than 2-hour drainage area and Mockus

method is not applicable on the drainage area which have more than 30 hours of concentration time.

Consequently, it was seen that the modified equations are more effective in calculating the UH parameters and simulating UH's shape. For this reason, the MNSUH method gives appropriate results for Turkey's small scale basins.

It should be considered that; the modified equations can only be used for calculating in similar characteristic basin's UH parameters.

Abstract—Ilisu Dam is one important energy projects in Turkey. After it is completed, it is expected that it will contribute to the country economy approximately \$300 million annually. One of the most remarkable engineering designs of the dam is the conversion of diversion tunnels of 12 m in diameter and about 1 km in length into sluice outlet structure. In this study, the CFD simulation of Ilisu Dam sluice outlet were performed with 1/40 scale. The obtained CFD results were compared with physical model observations conducted by the State Water Works (SWW). A good agreement was achieved between both results, and some useful results of CFD were presented for design of the outlet.

Keywords—Ilisu Dam; Sluice Outlet; CFD.

I. INTRODUCTION

Sluice outlet is a hydraulic structure which is designed to completely discharge the dam when necessary, to reduce the spillway capacity and to release the water to be left to the downstream of the river. The sluice outlet can be of different shapes and lengths depending on the needs or shapes of the dams. An important consideration when designing the sluice way is to prevent cavitation damage. In order to avoid this problem engineers may choose different solutions in the sluice outlet design. Experimental studies are conducted to observe how the cavitation phenomenon will actually have an effect. However, these experiments may be time consuming, costly and require a lot of attention. Instead, using the developed computational fluid dynamics (CFD) is now a more functional and reliable method that has been tested many times. There are many studies exist in the literature that was performed using the CFD. Some of those studies can be seen as follows:

Reference [1] establishes a 3D CFD model of The Dalles Dam forebay. The aim of the model is to investigate the effects of clogging resulting from the accumulation of debris in the 12.3 m section above the turbine intake. The model includes approximately 0.80 million cells consisted from 22 power plant units, two fish turbine units, station services unit and a forebay

bathymetry. The CFD model has quite well simulated the velocity distributions observed in a physical model. Numerical simulations indicated that blocked garbage pits would change velocity distributions around the powerhouse to a significant extent [1]. Reference [2] defines the flow properties at a large opening to improve the discharge calculation for submerged channel gates. To do so, the technical note investigated the upstream and downstream flow characteristics of the channel inlet gates experimentally and numerically by means of a fluid method using average Navier-Stokes two-dimensional simulations by Reynolds [2]. Reference [3] develops a dynamic numerical model to investigate a laboratory experiment. Through analysis and modeling of the observed data, the river water quality and quantity (WQQ) operations under the water channel regulation were examined and the interaction between the WQQ and the regulatory capacity downstream of a water channel was investigated [3]. Reference [4] developed a numerical model to simulate the flow of probable maximum flow (PMF) on a system consisting of an existing service spillway and a new auxiliary spillway. In the study, approach channel geometries consisted from different combinations were simulated. The article demonstrates the successful implementation of a CFD model in the design process of an auxiliary spillway and encourages the hydraulic engineers and CFD modelers for designing the hydraulic structures [4]. Reference [5] investigated CFD model used applications to reveal its limitations and to make some assumptions. At the end, article noted that CFD numerical models are a good way to recognize the hydraulic conditions [5].

A technical report modified a previously computed fluid dynamics model, and it was used to characterize tailrace hydraulic and sluice outlet exit conditions for low total river and low level spillway flows [6]. Reference [7] investigated the preliminary test results obtained from a large scale Deriner Dam of tunnel spillway model are presented. A number of test models have also been carried out for the original and final

project cases. In the article it was seen that the original designed ventilator did not work effectively from the values obtained according to the original project status. For this reason, it became necessary to change the original progeny in terms of location and geometry of the aerator [7].

From the current literature, it can be said that CFD models are valuable, useful and reliable tools for the hydraulic structures. As one can understand that there is limited study about the CFD models of the sluice outlet. This study investigates the working principle of sluice outlet of Ilisu Dam by using CFD model.

II. ILISU DAM AND HPP

Ilisu Dam and Hydroelectric Power Plant (HPP) is one of most important energy project with 1200 MW installed capacity in Turkey. After completed, the total produced energy will be 3833 GWh/year, and it is expected to bring about \$300 million incomes to the economy annually. This energy corresponds to 10% of the hydroelectric energy to be produced in Turkey. The general project characteristics of Ilisu Dam and its sluice outlet structures were given in Table 1 [8], [9].

DT2 derivation tunnel of Ilisu Dam was converted to the outlet structure. DT1 derivation tunnel parallel to DT2 tunnel also were designed as an aeration tunnel for air supply purpose. Two tunnels were connected by a horseshoe cross-section air gallery. The detail of outlet structures converted from DT2 derivation tunnel were showed in the Fig. 2

TABLE 1. ILISU DAM AND HPP PROJECT CHARACTERISTICS

Type of Dam	Embankment, concrete-face rock-fill
Purpose	HP, flood control and irrigation
Status	Under construction
Location	Dargeçit County, between Mardin and Şırnak
River	Dicle River
Construction cost	1.7 billion \$
Height from thalweg	135 m
Length	1.820 m
Dam volume	43,800,000 m ³
Installed capacity	1,200 MW
Average annual energy production	6 x 200 MW Francis-type
Hydraulic head	122.6 m
Annual generation	3,833 GWh
Derivation slope	0.1%
Derivation structures	DT1+DT2+DT3 derivation tunnels
Sluice outlet	DT2 derivation tunnel
Diameter of sluice outlet	12 m
Length of the outlet	1016.1 m
Type of control valve	Sluice valve
Number of control valve	2
Dimensions of control valve	2.65x4.00 m
Spillway type	Service overflow, controlled-chute
Spillway capacity	18,000 m ³ /s

Fig. 1. Details of the sluice outlet converted from DT2 derivation tunnel of Ilisu Dam [8].

III. METHOD

In this study, a three-dimensional (3D) numerical simulation using FLOW-3D software was applied to Ilisu Dam sluice outlet to determine the two-phase (air-water) flow properties. FLOW-3D is a general purpose CFD program which is especially effective free surface flows for one and two phase flows. The program solves the mass continuity and the Navier-Stokes equations as the momentum equation for each element to estimate properties of fluid motions. These equations can be

given as follows respectively for Cartesian coordinate system [10].

$$V_F \frac{\partial p}{\partial x} + \frac{\partial}{\partial x}(\rho u A_x) + \frac{\partial}{\partial y}(\rho v A_y) + \frac{\partial}{\partial z}(\rho w A_z) = R_D + R_S \quad (1)$$

where, V_F is volume fraction, ρ is the density of fluid; R_D is a turbulent diffusion term; R_S is a mass source; A_x , A_y , and A_z are the fractional areas in the x , y and z ; u , v and w are velocity

components. The Navier-Stokes are used to describe three-dimensional fluid dynamics.

$$\begin{aligned} \frac{\partial u}{\partial t} + \frac{1}{V_F} \left[u A_x \frac{\partial u}{\partial x} + v A_y \frac{\partial u}{\partial y} + w A_z \frac{\partial u}{\partial z} \right] &= -\frac{1}{\rho} \frac{\partial p}{\partial x} + G_x + f_x - \frac{R_S}{\rho V_F} (u - u_w - \delta u_s) \\ \frac{\partial v}{\partial t} + \frac{1}{V_F} \left[u A_x \frac{\partial v}{\partial x} + v A_y \frac{\partial v}{\partial y} + w A_z \frac{\partial v}{\partial z} \right] &= -\frac{1}{\rho} \frac{\partial p}{\partial y} + G_y + f_y - \frac{R_S}{\rho V_F} (v - v_w - \delta v_s) \\ \frac{\partial w}{\partial t} + \frac{1}{V_F} \left[u A_x \frac{\partial w}{\partial x} + v A_y \frac{\partial w}{\partial y} + w A_z \frac{\partial w}{\partial z} \right] &= -\frac{1}{\rho} \frac{\partial p}{\partial z} + G_z + f_z - \frac{R_S}{\rho V_F} (w - w_w - \delta w_s) \end{aligned} \quad (2)$$

where; G_x, G_y, G_z are body acceleration components, f_x, f_y, f_z are viscous accelerations components, u_w, v_w, w_w are the components of velocity source; u_s, v_s, w_s are the velocity components at the surface.

A. Physical Model

The experimental studies on the revised design of the sluice outlet structure and aeration tunnel were conducted by State Hydraulic Works in Turkey. In the first design of the Ilisu Dam sluice outlet, the transport tunnels to the sluice outlet vane chamber were planned as ventilation galley providing air flow. However, in the tests and analyzes conducted, it was understood that the air in the narrowing sections would reach a speed as high as 100 m/s and eventually air explosions and operational problems would occur. For this reason, one of the two sluice outlet (DT1) was planned as an air gallery with a diameter of 12 m and a length of about 1000 m, and the air for the DT2 sluice outlet was provided by an air gallery with a horseshoe section here. Different alternatives of this system have been experimentally investigated by DSI with 1/40 model and solution proposal has been introduced. The experimental setup of the outlet and aeration tunnels performed by DSI was showed in Fig. 2.

Fig. 2. Experimental setup of the outlet and aerations tunnels (DSI, 2010)

B. Numerical Model

The 3D numerical model was given in the Fig. 3. Numerical model was divided into 3,900,000 structured 3D hexahedral elements. The simulation duration is approximately 7 hours with two real core xenon processor and 8 GB ram. Two phases model with *renormalized group (RNG)* turbulence model were used in the numerical solution. Numerical model with 12 m diameter of DT1 and DT2 tunnels were scaled by 1/40 scale similar to the experimental model. The dimension of the rectangular sluice section is 2.65x4.00m. The height and width of the horseshoe air tunnel are 4.5 m and 4.20 m respectively.

Fig. 3. Geometry of 3D numerical model

The CFD analysis were performed for 24.75 m of the hydraulic head and 430 m³/s of water outlet discharge with laboratory model dimensions (1/40 scale). The solution convergence was achieved in 5.0 second. The solution convergence curves and water velocity of the sluice flow were illustrated in Fig. 4. As seen at the convergence curves in Fig. 5, the air flow rate in the aeration tunnel is almost steady while approaching to 0.012 m³/s and velocity of 1.2 m/s. This corresponds 121.43 m³/s and 7.58 m/s of prototype values. The air entrainment discharges and average air velocity were observed by DSI as 118.76 m³/s and 7.35 m/s experimentally [8]. The air entrainment rates ($\beta=Q_a/Q_w$) are calculated as 0.303

of experiment, and 0.309 of CFD. The relative percent error between experimental and numerical (CFD) results is approximately 2%. These comparisons were given in Table 2.

TABLE 2. COMPARISON OF EXPERIMENTAL AND CFD RESULTS

	Hydraulic Head, H_t (m)	Water discharge, Q_w (m^3/s)	Air entrainment discharge, Q_a (m^3/s)	Average Air Velocity, V_a	Air entrainment coefficient ($\beta=Q_a/Q_w$)
Experiments	24.75	392	118.76	7.35	0.303
CFD	24.75	392	121.43	7.58	0.309
Error (%)			2.2	3.0	2.0

Fig. 4. Solution of the numerical model with convergence curves.

The maximum velocity of water flow was observed in jet near to impact region at the downstream of sluice gate. The streamlines of the water flow are shown in the Fig. 5. This figure also indicates same the maximum water velocity position.

Fig. 5. Streamlines of the water flow in the sluice outlet

Fig. 6 shows the streamlines of air flow (on the left) and velocity contours at the middle section of aeration tunnel (on the right). It is observed in these figures that the air velocity on the section is irregular and the maximum velocity occurs at the top of the section while the velocity at a lower part of the section was almost zero. The maximum air velocities in the DT2 tunnel were observed near to water surface probably owing to slip velocities between air and water flow.

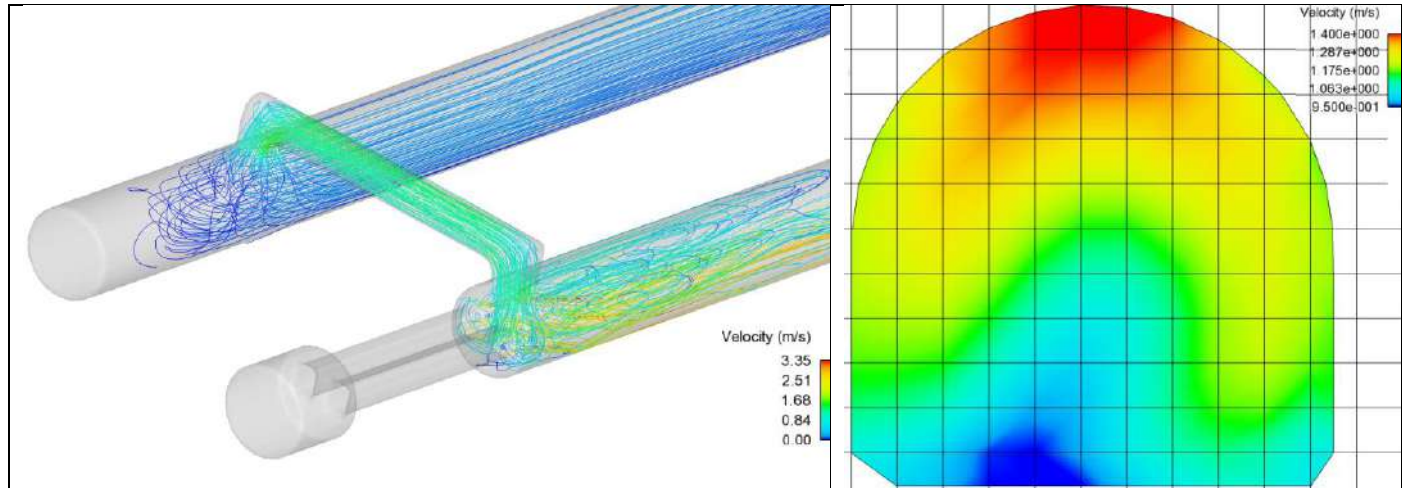

Fig. 6. Streamlines of air flow (on the left), and the velocity distribution at the cross-section of the aeration tunnel (on the right).

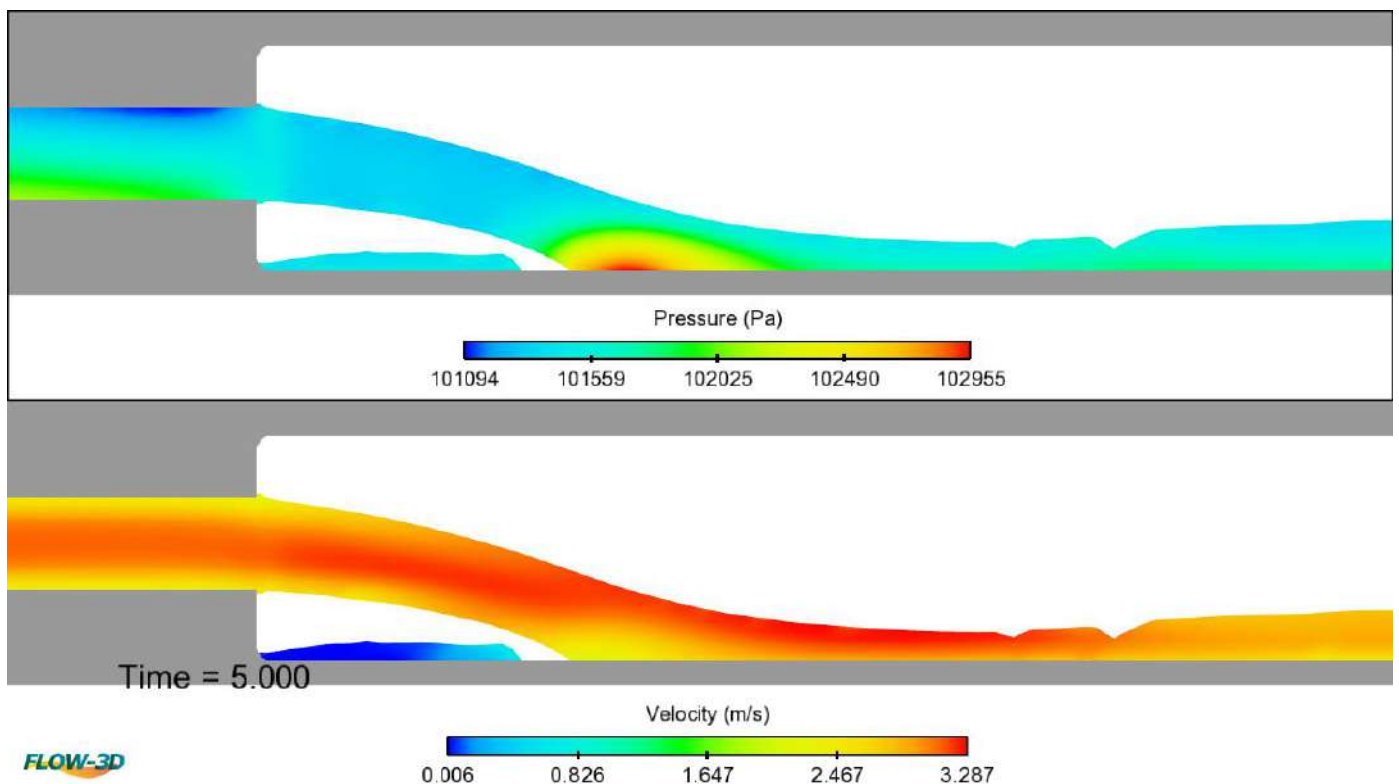

Fig. 7. Pressure and velocity contours of water flow jet downstream of sluice gate.

IV. CONCLUSIONS

In this study, Ilisu Dam's sluice outlet, which have 12 m diameter, was analyzed by using CFD simulation technic, and was discussed. The results of CFD analysis were compared to the experimental tests with 1/40 scale performed by DSI, and a good agreement was achieved in terms of air entrainment by air supply tunnel. The CFD results are reasonably compatible with the experimental observations with the percent errors from 2.00 to 3.00%. The experimental study is more expensive and required more effort than CFD analyses. Bu still, the CFD models need to be calibrated with some experimental data. The calibrated numerical models may be more useful and easier to determine hydraulic characteristics than experimental studies. The results encouraged the further researches for detailing the design of the Ilisu Dam outlet and the other similar projects.

ACKNOWLEDGEMENT

We thanks to Firat University Department of Civil Engineering, the State Water Works (SWW) and IOG Engineering for their valuable contribution.

Abstract— In this study, the roller compacted concrete dams were summarized and two-dimensional nonlinear dynamic analyses of Andiraz Dam which its building is planned in the border of Kastamonu were done with the use of 3 Safety-Based Earthquake (2475-years repetition) and the nonlinear analyses were done with the use of Drucker-Parager elasto-plastic material model. The results for Vertical and Principal Contraction Stress - Duration in the critical points which were considered on the stem of dam were gotten, the dam's stability after the earthquake was evaluated in consideration of the damage areas which were obtained.

Keywords—Roller Compacted Concrete (RCC), Dam, Nonlinear dynamic analysis

I. INTRODUCTION

The great majority of The Roller Compacted Concrete (RCC) dams are built after they are designed in the type of gravity dam. The arch dams are built by RCC and also, there aren't efficient experience savings and common implementations on their motions. In the simplest description, the gravity dam is a mass structure which is offending against the sliding and rollover with its gravity that they will occur as a result of all external loads' effect , which has mostly got right triangle section. The Roller Compacted Concrete (RCC) gravity dam is closely resemble to the concrete gravity dam which is done with the classical concrete casting. The classical concrete gravity dam has got a overcosting structure with the properties which are required in the concrete and the concrete's materials (the requirement for washing aggregate etc.) and with the aspect of building technique. An important saving were gotten in the construction of the Roller Compacted Concrete (RCC) with the similar use of the building machinery and a concrete material which is equivalent with the classical concrete properties in RCC dams was obtained as it was in the

construction of rock-fill or earth-fill dams for the manufacturing, transport, sprawl and compacting zero-slump concrete with roller as a different concrete material. It became possible to build a concrete dam in a short time and with a low cost with this concrete material which provides opportunity for the rollers and other building machinery to get about without sinking. In this case, The Roller Compacted Concrete (RCC) dams got in a race with earth-fill and rock-fill dams and other dam type in terms of the cost.

The analyses in the duration-description field are defined as the mostly effective method to review the dynamic motions of structures which are exposed to the place motion because the equations of motion are analysed by being taken directly as integral in the small time step [1]. The dam's earthquake motion can be calculated in the calculation method during all of the earthquake records that the balance of motion is provided in each of time steps so the temporal change of the stress and deformations can be followed. The dam's dynamic motion can be reviewed in a more realistic way as the foundation rock, reservoir water, main dam and the mutual interaction with each other are modelled in the aforementioned.

An important advantage of the analyses in the duration-description field is that it gives opportunity to the full controlling the performance criteria of Operating-based Earthquake (OBE) and Maximum Design Earthquake (MDE) in the sense of the solution of the linear and non-linear systems. The method provides the valid and reliable results for the cases that the concrete stresses remain within the elastic limits, and also, it is recommended for all of dam designs by the international specifications [1,2]. in the purpose that the dam's motions on the linear limits and the damages that would occur are foreseen.

The vertical construction joints are included in both of the casting concrete and the roller compacted concrete dams and also, the horizontal casting joints which are lower than the tensile and shear strength stem concrete occur during the manufacturing of stem. It is possible to be fractures depending on the repetitive folding on the vertical joints, the horizontal casting joints, the tensile on the corners that concrete-rock contact or stress concentration occurs during the low-level place motion [1]. In this sense, the great majority of deformations will occur on these fractures, and the occurrence of fractures will be prevented as the tensile stresses decrease in the other areas of the dam stem. Thus, it should be expected that there would be a few of main fracture surfaces on the concrete dams in the case of a great earthquake [3].

Two or three dimensional, static or dynamic, elastic or ultra elastic analyses are done on the estimation of RCC Dams' earthquake performance. The potential damage areas are found with the areas of stress concentration as a result of analyses. The reliability of section is determined as the effect of damage areas on the dam stability following the earthquake is examined in the ultra elastic analyses in consideration with the stress limits in the elastic analyses.

The investigations which are required after an earthquake are summarized with the analyses of an earthquake at Figure 1. The critical points are investigated with the linear elastic stress analyses which will be done for OBE, MDE and EED. The section of dams which their criteria aren't provided can be extended or the higher-strength concrete or grout can be used in the areas that they are found as inefficient. The reliability of dam stem would be investigated with the ultra elastic non-linear analyses for the sections that their stress criteria aren't provided as a result of the linear elastic analyses but the ultra elastic motion would be limited. Generally, the ultra elastic analyses which are done in the duration- description field are very hard and complex analyses. These structure models should be used after it is assured that the concrete fracture motion is modelled in these models definitely in a correct way.

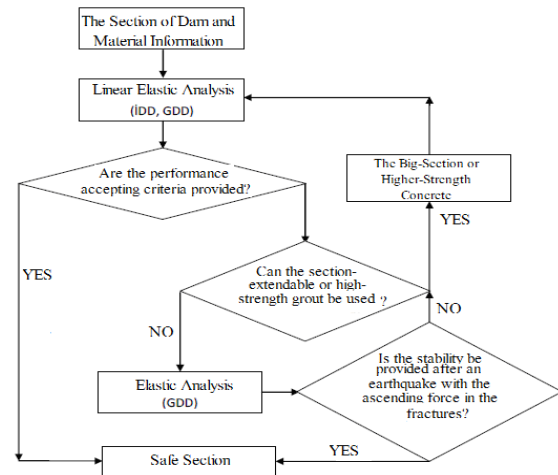

Fig. 1. The flowchart for earthquake investigations

It is necessary to consider the static and dynamic loads in the analyses of earthquake. The results of static and dynamic analyses are directly collected in the linear elastic analyses. The loads are reflected to the models in the ultra elastic analyses according to their occurrence orders. The dynamic loads which affect on the dams, the inertia forces of dams' stem and the hydrodynamic loads arising from the reservoir and tailwater in the source and downstream are the dynamic effects that the reservoir base and if it is available, the filling material would create them. The static loads are the weight of dam, hydrostatic pressure, silt loads which occur on the base of dam and the ascending forces. Hydrostatic and hydrodynamic loads should be considered for the different cases as the minimum and maximum water levels of dams' water level are considered.

In this study, two-dimensional linear elastic dynamic analyses of Andiraz Dam which its construction is planned within the border of Kastamonu were done with the use of 3 MDE Earthquake acceleration records and 3 EED records. It was provided to obtain the total ultra elastic motion duration - the demand capacity rate curves on the same points as the results of vertical and principal tensile stress -duration were obtained on the aforementioned critical points which were considered on the dam's stem.

II. DATA, MATERIAL PARAMETERS AND DYNAMIC LOADS BELONGING TO DAM

II.a. Geometry and Model

The project's area which consists of Andiraz Dam's stem place and the lake area which is within the border of Kastamonu and which will be done on Soganli Small Stream is seen at Figure 2.

Fig. 2. The project's area

Andiraz Dam has got 142 m height at the maximum section, it has got the roller compacted concrete (RCC) filling type, and it has got 10 m crest width. The dam which its geometry at the maximum section is given at Figure 3 was designed as the source's surface was given as vertical and the river mouth's side slope was given as 1D/1Y. Maximum water level takes place lower than 1,3 m crests. The crest depression on the dam's stem, the change in acceleration and the change great principal stress

Fig. 3. Max. stem cross section and the points which are examined in the model

Fig. 4. Dam- foundation - reservoir finite element model

changes in 7 points with points were obtained and the cumulative-aggregation duration -demand capacity curves were obtained.

The model which is done in order that the dam's earthquake motion could be reviewed by the method of finite elements is shown at Figure 4. The model was divided into 1876 elements and the model's right and left sides were chosen as the river mouth at three floors of the dam height at the direction of source and at two floors of the height at the direction of base in order to decrease the effect of limit conditions on the system's dynamic motion. As the reservoir was included to the model as three floors of height at the direction of river mouth, Sommerfeld limit condition wasn't implemented at the end of reservoir. The effect of alluvion layer nearly at 40 m depth on the basement of reservoir to reflect the wave of earthquake was included into the model with the proper parameters. The element of Alluvion was used in the model which was done with the use of ANSYS program, PLANE 42 was used for the base and the dam's stem, FLUID 29 was used for the reservoir

II.b. Material Parameters and Damping

The elasticity module was determined as $E_r = 5.5$ GPa for Granodiorite base rock with the help of the geological evaluations and the laboratory experiments and the base rock was modelled as a linear elastic material. The speed of shear wave at the base rock is nearly 950 m/s, it includes in the B class rock or rocklike ground class bu NEHRP and in A class rock or rocklike ground class bu Eurocode-8. The elasticity module was taken as $E_r = 0.12$ GPa for alluvion nearly at 40 m thickness which is available at the stream bed.

It was seen as efficient in the pre-analyses that RCC target compressive strength is 20 MPa. The target tensile strength which is at the vertical direction on the horizontal joints and which is at the principal direction on the stem concrete was determined in a way which was given at the equations 1,2,3,4 by the criteria of USACE (2000) [4] in consideration that the padstone which will prevent the occurrence of cold joint between the layers in the necessary places will be implemented.

RCC tensile strength for OBE earthquake is

$$\sigma_{tv} = 0.05 \sigma_c = 1.00 \text{ MPa}, \sigma_{tv\text{-dynamic}} = 1.35 \sigma_{tv} = 1.35 \text{ MPa} \quad (1)$$

$$\sigma_{tp} = 0.09 \sigma_c = 1.80 \text{ MPa}, \sigma_{tp\text{-dynamic}} = 1.35 \sigma_{tp} = 2.43 \text{ MPa} \quad (2)$$

RCC tensile strength for MDE and EED earthquakes is

$$\sigma_{tv} = 0.05 \sigma_c = 1.00 \text{ MPa}, \sigma_{tv\text{-dynamic}} = 2.00 \sigma_{tv} = 2.00 \text{ MPa} \quad (3)$$

$$\sigma_{tp} = 0.09 \sigma_c = 1.80 \text{ MPa}, \sigma_{tp\text{-dynamic}} = 2.00 \sigma_{tp} = 3.60 \text{ MPa} \quad (4)$$

σ_{tv} ve $\sigma_{tv\text{-dynamic}}$ shows respectively the statical and dynamic tensile strength at the vertical direction; σ_{tp} ve $\sigma_{tp\text{-dinamik}}$ shows respectively the statical and dynamic tensile strength at the principal direction, on the above statements. The material parameters which were used for the statical and dynamic analyses of Andiraz Dam are seen at Table 1. It was provided that the ground doesn't create an inertia effect as the ground was modelled in a massless form in the finite element model. The rental rate wasn't gotten in order to neglect the radiation effects at the base. Drucker-Prager material model was used for the dam's stem in the non-linear analyses. The non-linear motion of the material occurs as the fracture of concrete in the tensile and as the plasticisation in the pressure in this model. Drucker-Prager approach is a material model that these effects would be considered [5]. This approach was obtained from the generalisation of von mises criterion in a way to include the effects of hydrostatical stress. The flowing surface of Drucker-Prager approach which was stated depending on C cohesion and ϕ angle of internal friction has got a vertical cone form and was presented at Figure 5. This graphical representation shows that the material's motions are different at the tensile and pressure. Their magnitude which is seen at Figure 10 reflects the principal stress. The plastic form changing occurs with the change in the volume for Drucker-Prager approach.

Fig. 5. The flow surface in the principal stress space of Drucker-Prager approach

In the document of USAGE-EP-1110-2-12 which grounds on Fenves and Chopra's studies (1985) [6], it was stated that the finite element which is solved with the help of massless base would be calculated in consideration with the effect of rental rate's three factors (structure-ground-reservoir) which will be used in the concrete dam analyses.

$$\xi = \frac{1}{R_r R_f^3} \xi_1 + \xi_f + \xi_b \quad (5)$$

In this formula, the structural rental rate of the dam which was modified with R coefficient (the rate of soft-base dam period on the rigid-base dam period, the rate of reservoir-filled dam period on the reservoir-free dam period) states the additional rental rate which will be added to the the system's rental rate due to the reservoir while the dam is empty and it states the additional rental rate which will be added to the the system's rental rate due to the base. Chopra and Fenves (1985) [6] thinks that the rock and concrete elasticity rate at 0.26 (for 20 MPa concrete) was determined as the coefficients 1.29 and 1.55 at 100% reservoir level in consideration with alluvion at the basement of reservoir. It was taken as the recommended value at the document of USACE-EP-1110-2-12 and the values were obtained as 3.2% and 15% with the use of the tables that Chopra and Fenves (1995) [6] gave them. The rental rate for all of the system was obtained as 19% as these values were written in their places on the equation. The mode that 90% participation was gotten with the first vibration mode was gotten with the system model analysis and Rayleigh coefficients were calculated as $\alpha = 1,096$ and $\beta = 0,033$ in a way to give 19% rental rate with the use of angular frequencies. System modal analysis was performed to obtain the mode with 90% participation by the first natural vibration mode, and Rayleigh coefficients $\alpha = 1,096$ and $\beta = 0,033$ were calculated to give 19% damping using $\omega_1 = 5,526 \text{ rad/s}$ and $\omega_2 = 6,03 \text{ rad/s}$ angular frequencies.

TABLE I. MATERIAL PARAMETERS

Name of Parameters	The Dam's Stem Concrete	Granodionite	Alluvion	Reservoir
Statcal Elasticity Module (Es) (GPa)	21.2	5.5	0.12	2.02
Poisson Rate	0.02	0.2	0,3	-

Reservoir Sediment Reflection Coefficient	-	-	-	0.8
Sonic Wave Speed (m/s)	-	-	-	1440

III. EULER FORMULATION FOR THE LIQUID STRUCTURE INTERACTION

The structure's motion is stated as the change of location and the motion of liquid is stated as the pressure in the analysis of liquid-structure system with the Euler approach. Two dimensional motion of lineer compressible, non-viscose liquid without rotation can be given under the small-amplitude changes with the wave equation,

$$P_{,xx} + P_{,yy} = \frac{1}{C^2} P_{,tt} \quad (6)$$

x,y,z states the cartesian coordinations, t states time, C states the pressure wave speed in liquid and P_{,ii} states two-time partial derivative by i variable of hydrodynamic pressure. The hydrodynamic pressures which occur in the liquid system as a result of any effects are obtained with the resolution of (6) equation under the proper limit conditions. The limit conditions should determined for the liquid system on the liquid-structure interface, the liquid basement, the liquid surface and the back surface (the condition of wave propagation) that the finite element net is gone of. The liquid system's limit conditions are collectively given at the following:

- 1- On the liquid-structure (dam-reservoir) inter-surface,

$$P_{,n} = -\rho_w \ddot{U}_n \quad (7)$$

- 2- On the liquid (reservoir) surface,

P=0 (If there isn't surface waves on the liquid free surface) (8)

$$P_{,n} = -\frac{P_{,tt}}{g} \quad (\text{If there is surface waves on the liquid free surface}) \quad (9)$$

- 3- On the liquid basement (on the basement of reservoir),

$$P_{,n} = -\rho_w \ddot{U}_{ng} \quad (\text{If the reservoir basement is rigid}) \quad (10)$$

$$P_{,n} = -\rho_w \ddot{U}_{ng} - qP_{,t} \quad (11)$$

- 4- For Sommerfeld wave propagation on the liquid's (reservoir's) back surface,

$$P_{,n} = -\frac{P_{,t}}{C} \quad (12)$$

They are defined as the above ones [7, 8]. As the New magnitudes which are seen at the equation 7~12; n states the liquid's surface external normal, the pressure's derivative in the direction of surface normal, the structure accelerations in the normal direction on the liquid-structure inter-surface, the mass density of liquid, g states the acceleration of gravity, the ground acceleration in the direction of liquid basement external normal, the pressure's one-time derivative to time and q states the reservoir basement rental rate coefficient. As the condition of one-dimensional wave propagation is used in the reservoir basement, q rental coefficient can be given with the equation [9];

$$q = \frac{(1-\alpha)}{C(1+\alpha)} \quad (13)$$

α coefficient shows the rate of wave reflecting from the reservoir basement to the the coming wave.

Hydrodynamic pressures would be obtained as the equation (6) which represents the motion of liquid environment is resolved under the limit conditions whih are given with te equations (7,9,11-12). If the finite element approach is used for the aforementioned liquid equations, the finite element motion equations belonging to the liquid system can be written on the form of matrix as the following;

$$[M_f^p]\{\ddot{P}\} + [C_f^p]\{\dot{P}\} + [K_f^p]\{P\} = -\rho_w[R]^T\{\ddot{U}_{sf}\} + \{F_{fg}\}$$

This shows the liquid mass matrix which includes the effect of surface waves, the liquid rental rate matrix which includes the rental rate which occurs due to the reservoir basement wave absorption effect with the propagation limit condition, the liquid rigidity matrix. It is a matrix related to the liquid-structure interface; it is used to determine the liquid load vector from the accelerations which occur from the structure

environment and the structure vital point additional forces from the pressures which occur in the liquid environment. It shows the structure accelerations on the liquid-structure inter-surface, the liquid load vector which occurs from the ground accelerations on the liquid basement, the hydrodynamic pressure vector and the one-two-time partial derivatives by this vector's time on this equation.

The finite element equations belonging to the dynamic motion of structure environment can be given with the following formula;

$$[M_s]\{\ddot{U}_s\} + [C_s]\{\dot{U}_s\} + [K_s]\{U_s\} = \{F_s\} + \{F_{sf}\} \quad (15)$$

It represents the mass, damping ratio and matrix belonging to the structure environment (dam+base) respectively; and their magnitudes represents the vectors for the acceleration, speed and change of location belonging to the structure environment. The structure's external vector states the additional external load vector which comes to the structure from the hydrodynamic pressures which occur in the liquid environment. The vector can be written as the following;

$$\{F_{sf}\} = [R]^T \{P\} \quad (16)$$

Thus, the common motion equations belonging to the liquid-structure system can be obtained with the combination of (9) and (10) equations as the following;

$$\begin{bmatrix} [M_s] & [0] \\ [M_{fs}] & [M_f^P] \end{bmatrix} \begin{Bmatrix} \{\ddot{U}_s\} \\ \ddot{P} \end{Bmatrix} + \begin{bmatrix} [C_s] & [0] \\ [0] & [C_f^P] \end{bmatrix} \begin{Bmatrix} \{\dot{U}_s\} \\ \dot{P} \end{Bmatrix} + \begin{bmatrix} [K_s] & [K_{sf}] \\ [0] & [K_f^P] \end{bmatrix} \begin{Bmatrix} \{U_s\} \\ \{P\} \end{Bmatrix} = \begin{Bmatrix} \{F_s\} \\ \{F_{fg}\} \end{Bmatrix}$$

Here, it is;

$$[M_{fs}] = \rho_w [R]; [K_{sf}] = -[R]^T \quad (18)$$

IV. DYNAMIC LOADS

EED value was given as 0,636 g at Andiraz Dam's Seismic Hazard Analysis Report. Three acceleration records which were recorded on the Class B rock and rocklike formulations in order to use in the dynamic analyses and these records were scaled with the use of target spectrum specific to the area which was given at the seismic risk analysis report in a way to be EED=0,636g which its safety evaluation earthquake is 2% possibility of exceedance in 50 years (2475-years repetition) the acceleration records of Coalinga earthquake were used for EED-1 record which has got 2% possibility of exceedance in 50 years, Pallsprings earthquake's records were used for EED-2 record and Morgan Hill earthquake's records were used for EED-3 record. 1/3 of the horizontal acceleration record was implemented to the model as the vertical acceleration record in the analyses. The scaled acceleration records are seen at Figure 5.

Fig. 5. The safety-based earthquake accelerograms which are scaled with the target spectrum specific to the area

V. RESULTS OF THE ANALYSIS AND RECOMMENDATIONS

VI.

V.I. The Determination of Structural Performance

The structural performance of concrete weight dams is determined with the linear analysis especially in the time-

description field. The deformations and stresses are calculated in consideration with the various compounds' elastic properties with the linear analyses. The possible damage levels which correspond to the dam's structural performance are determined, using the data. The damage terms which are used for the dam's performance are related to the fracture of concrete which is used

in the dam, the opening of joints and if it is available, the flowing in the equipment [10].

In normal conditions, the linear analyses are efficient for the structure systems which are sized by the design earthquake, which have got a smooth geometry, rigidity and mass distribution. The linear analyses which are done by the elastic methods may not be efficient in the big structure systems such as the drawbridge, towers and concrete dams which it is difficult for these properties to be together. Thus, the deformations, stresses and performance curves from the structural performance parameters which are obtained with the linear analyses to determine the real motions of the kind of structure systems provide to determine the structure's damage level. Namely, it was tried to be determined on what the scale the structure systems' linear analyses are efficient by the damage levels which are gotten from the performance curve.

The demand-capacity rate (TKO) which is seen at Figure 7; it is defined as the rate of the tensile stresses which are obtained at a point which is reviewed on the concrete dam as a result of the linear analysis to the dam concrete's strength stresses. The non-elastic cumulative time is defined as the cumulative total of each time step which exceeds the capacity of concrete tensile stress.

Fig. 7. The linear elastic analysis evaluation diagram [10]

It is considered that the dam motion remains within the elastic area and isn't damaged for the cases that TKO is smaller than 1. It states that the area under the curve on the performance curve which was obtained by the case that TKO is 1 and 2 is efficient for the linear analysis to determine the structure's motion, the area above the curve isn't efficient for the linear analysis and it is necessary to make the non-linear analyses to determine correct fracture sizes which occurs on the concrete stem (USACE 2003). The followings manners which are examined on the linear-elastic calculations which are done for Andiraz dam;

V.II. The Analyses for Earthquakes

As a result of Linear Elastic dynamic analyses which were done for 3 EED records on Andiraz Dam, it was observed that there was a capacity exceedance on 3 numbered point and this point's bottom levels in a way that it is expected on the heel of dam's source. This case was observed much more in Pall Springsearthquake especially as it is relatively. The performance curves came down to the certain damage section for 3 and 4 numbered points at Figure 9 (a). While 6 numbered point which was reviewed at the heel of source came down to the linear area for Coalinga earthquake, it includes in the certain damage area for Pall Springsearthquake. This case can be explained as the duration of Coalinga earthquake was the shorter one respectively. The performance curves which were obtained as a result of the linear analyses show that the non-linear analysis should be done to determine the damage much more correctly, at Figure 9. Thus, the nonlinear- analyses were done with the use of Drucker-Parager Elastic Plastic material model with the material parameters at Table 1. Some results of those analyses are seen at Figure 10-11-12 and 13.

The changes of principle tensile strength respectively in the earthquakes of Coalinga, Pall Springs and Morgan Hill during the earthquake at 6 numbered critical point, the principle stress during the maximum effect and the vertical stress distribution are seen at figures of 10-11-12 (a), (b), (c). The damage areas which occurred on the dam's stem at the end of the earthquake respectively in the earthquakes of Coalinga, Pall Springs and Morgan Hill are seen at the figures 13 (a), (b), (c). While there wasn't seen any permanent damage on the dam's stem at the end of Coalinga earthquake, there were the damaged areas on the dam's source's heel at 3 m thickness and 28 m depth in the earthquake of Pall Springs, at 5 m thickness and 21.3 m depth in the earthquake of Morgan Hill.

Fig. 9. (a) 3-4 and 5 no. points' performance curves under Palm Springs Earthquake (b) The Performance curves under SBE's for 6 no. point

Fig. 10. S1 principal stress changes during the earthquake at 6 no.point under the earthquakes of (a)Coalinga, (b) Palm Springs, (c) Morgan Hill

Fig. 11. S1 principal stress distributions on the critical areas under the earthquakes of (a)Coalinga, (b) Palm Springs, (c) Morgan Hill

Fig. 12. The vertical stress distributions in the critical areas under the earthquakes of (a)Coalinga, (b) Palm Springs, (c) Morgan Hill

Fig. 13. Plastic Damage Distribution at the end of earthquakes; (a)Coalinga, (b) Palm Springs, (c) Morgan Hill

It is seen that 20 MPa target strength which were foreseen with the use of the classical stress analysis methods at the beginning of project studies were property at the end of the analyses. A set of damages were considered to be possible as a design philosophy in EED earthquakes which have got 2% possibility of exceedance in 50 years (2475-years repetition) which were used in this study and the dam's statical reliability after an earthquake was evaluated. Andiraz dam's statical reliability after an earthquake was evaluated in consideration with the damages which occur on the heel of dam's source and it was seen that Andiraz Dam will overcome the seismic loads to be possible with the damages which would be acceptable without getting out of its precision.

Abstract—For planning of water resources based on the demands through the basin, water potential of the basin is required to be analyzed carefully. For an accurate and reliable analysis, complete meteorological and flow data must be obtained which covers a long period of previous years. Because, especially missing flow monitoring data used at the planning stage of water structures have been reported to induce serious hazards at the operating stage. In this paper, completion of data deficient (missing data) obtained from the flow gauging stations (FGS) was performed using regression analyses related to the correlation method. Seydisuyu basin has been selected as the study area. In order to fill data deficient (missing data), linear and non-linear regression equations have been used to identify the missing values without affecting the statistical structure of the original (long) data sets. It is examined by comparison of the original and filling data with flow duration curve. In this way, it has been investigated how statistically it is true. The magnitude of missing part of the data, however, is one of the most important points to be considered in filling the missing values. Especially in case of large amount of missing values, regression method resulted in large deviation when compared with original data. Therefore, instead of using a single method, different methods should be practiced and compared if possible, for completion of missing values. Comparison of the results from different methods would lead the best missing data filling method.

Keywords—Missing flow data; Flow duration curve; Regression analysis; Seydisuyu Basin

I. INTRODUCTION

Meteorological and hydrological data such as evaporation, precipitation, snow, temperature and flow have always been required towards water resources management and planning on the basis of watershed management and researches. Completeness and continuity of these data are extremely important. Except that, meteorological (precipitation, temperature, evaporation, snow, etc.) and hydrological (flow

measurement) data, obtained from different institutions might be deficient belonging to the previous years due to various reasons. Data deficient might come out for a variety of reasons (climatic challenges, transportation challenges, measuring device issues, ...etc.).Comprise of gaps in flow data due to inconvenient climatic conditions creates some serious problems in terms of effectively planning, design and operation of water resources [1,2]. When the literature is analyzed, generally, in flow data, we are met %5-%10, or even %25 of data deficient [3-5]. Due to the mentioned reasons above, there are considerably deficient, specially in hydrological data in our country, Turkey [5]. In hydrology, data deficient can cause some key issues, specially in hydrologic modeling, and design studies in terms of water resources management. There are numerous methods used for completion of deficient data. Among all, the most popular and commonly used ones are interpolation, regression analysis, time-series analysis, artificial neural nets, and hydrologic models [6-10].

Completion of data deficient (missing) might also be practiced using algorithms found in different statistic programs (EM-Expectation Maximization), and using posterior probabilities of the data [11-12].

In addition, data deficient of meteorological and flow measurements having similar watershed characteristics, can also be complemented using different empiric equations such as (M. Turc, Langbein and Coutagne methods) [13,14]. However, besides practicality of the empiric approaches like M. Turc method, we can encounter with important deviations in region adaptation including data deficient of flow, used in the parameters of the method, and the impossibility to obtaining an accurate flow data has been stated correspondingly in the literature [14]. In addition to these methods, using the observed data from an existing stream gaging station, the flow of any

unknown point in the watershed can be estimated applying area ratio method, that is commonly used in literatures. Although different methods are used in completion of flow data deficient, correlation between the data has to be taken into consideration as well. Thereby, possibility of comparison among multiple stations will be provided rather than a single station.

Within this study, flow data belonging to General Directorate of State Hydraulic Works, and General Directorate of Electric Power Resources Survey and Development Administration, has been investigated in Seydisuyu basin, that is a sub-basin of Sakarya river. The high percentage of data deficient, is the main reason for choosing this study area. Accurate completion of the data deficient and usage of the complemented/filled data has become significant in planning water structures.

For this purpose, Seydisuyu basin has been investigated as part of scientific research projects. Totally there are 6 stream gaging stations existing in Seydisuyu basin and its sub-streams. 5 of them are run by General Directorate of State Hydraulic Works and the remaining one is run by General Directorate of Electric Power Resources Survey and Development Administration. Unmeasured months on these stations were determined using regression analysis and flow relationships between the gauges. Also mathematical relationships between these stream gaging stations were found out in this study. Using these mathematical relationships, data deficient in each flow gauging station belonging to unmeasured years, were calculated separately. Accuracy of filling data deficient were compared by evaluation of the original data set.

II. DATA AND METHOD

The research area is Seydisuyu basin, which is a sub-basin of the Sakarya River. Seydisuyu basin is in the Central Anatolian Region, between $38^{\circ}.85'-39^{\circ}.36'$ north latitudes and $30^{\circ}.16'-31^{\circ}.07'$ east longitudes. Water of the basin is discharged into the Sakarya River by Seydisuyu River. Seydisuyu basin is surrounded by Sakarya-Sarisu, Porsuk-Sarisungur, Porsuk-Kalabak in the east, by Buyuk Menderes, Gediz and Porsuk-Sarisungur in the southwest, and by Sakarya-Bardakci and Akarcay basins in the south-east. As the hydrologic basin border, a great part of the basin is in the provincial borders of Eskisehir, and the remaining parts are in the provincial borders of Afyon and Kutahya. Seyitgazi, Mahmudiye districts of Eskisehir province, Kirka town, and 51 other villages are located in the basin. Seydisuyu basin covers an area of 1816.1 km^2 , corresponds to 13% surface area of Eskisehir approximately. Geographical position of the basin in Turkey is given in Figure 1.

Fig. 1. Location of study area

The 53 years of long-term monthly data for the periods 1952-2005 were provided from 3. Regional Directorate of State Hydraulic Works. 5 of the stream gaging stations are belonging to General Directorate of State Hydraulic Works and the remaining one is belonging to General Directorate of Electric Power Resources Survey and Development Administration. Location of the stations in the basin, their coordinates, their precipitation area, the data as obtained and belonging which water year is given in Table 1.

Table 1. Flow gauging stations (FGS) in the study area

FGS No	Province	Coordinate	Elevation (m)	Drainage Area (km^2)	Year

Scarcely, missing of monthly records in the basin belonging to some operated flow gauging stations were indicated as by virtue of climatic challenges and so couldn't have been recorded. Investigations were done extensively with regard to existing condition of raw data, provided from General Directorate of State Hydraulic Works. For this purpose, a database per Microsoft Excel program was constituted.

Data provided from General Directorate of State Hydraulic Works were analyzed. Also the deficient part, based upon the missing dates were determined and drawn graphically in Figure 2. Data belonging to each inspected flow gauging station were

investigated statistically. Regression analysis were applied to examine the relations among the gauges. Microsoft Excel program was practiced on, to determine correlation coefficients which are interpreting the mathematical relationships among the stations and statistical evaluations.

A. Completion of Flow Data Deficient (Missing Data) in the Research Area

Locations of flow gauging stations, used in the research area were given in Figure 2.

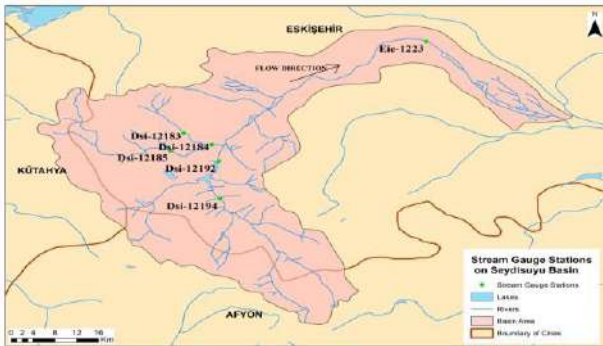

Fig. 2. Flow Gauging Stations (FGS) in the study area

Provided time-related status of monthly flow data for the periods 1952-2005 is given in Figure 3.

When the flow gauging stations are analyzed, considerable deficient could be noticed in the data provided from General Directorate of State Hydraulic Works.

Fig. 3. Time-related status of provided dailyflow measured data results

As it is noticed in Figure 3. , flow gauging data are missing in some specific dates. By investigating whether there is a mathematical relationship between these stations or not, group of stations compatible with each other and could be used for completion of data deficient (missing data), were determined. Data analysis modulus were benefited in Microsoft Excel 2010, to determine these groups and to investigate the mathematical relationships between these stations.

Regression-correlation analysis is performed to determine whether there are relations between two or more variables or not,

and determine the direction and strength of these relations, if exist.

Approximation of the coefficients found as the result of the correlation to 1, shows the higher accuracy of the analysis, and is an indicator of pretty strong hydrologic relation between the stations.

Correlation coefficient is calculated from the equation given as follows.

$$r_x = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2 \sum_{i=1}^n (y_i - \bar{y})^2}} \quad (1)$$

Here; r_{xy} , shows the correlation coefficients related to 2 flow gauging stations, x_i and y_i show flow data measured in the same period, belonging to investigated flow gauging stations, and ... show the average flow values, belonging to flow gauging stations.

Correlations between flow gauging stations is given in Table 2. While the values of correlation coefficients are investigated, the highest relation (correlation coefficients with greater absolute values $|r|$) between two stations are shown with bold colors.

In the calculations towards correlation matrix, data missing of two flow stations belonging to the same date, were shown with dash lines. For estimation of correlation, as shown in Equation 1. , the investigated flow gauging station data must have been recorded at the same date. For this reason, some parts in the correlation matrix, were remained blank or empty.

Table 2. Correlations between flow gauging stations

	dsi-12183	dsi-12185	dsi-12194	eie-1223	dsi-12184	dsi-12192
dsi-12183	1					
dsi-12185	0,452886	1				
dsi-12194	0,52006	0,729207	1			
eie-1223	0,476829	0,417583	0,458892	1		
dsi-12184	0,319158	0,086062	0,249459	0,349014	1	
dsi-12192	-0,06292	-0,34911	-0,17548	-0,08732	0,353843	1

After determination of the stations that have got strong relations with each other (higher absolute R^2 values), linear and non-linear regression analysis were performed/practiced, to present the mathematical statement of relations between these stations. According to data obtained from correlation matrix diagram, relations between flow gauging stations were examined whether it possess a linear or a non-linear structure.

In the analysis, to determine whether there is a linear relation between two stations or not, linear regression was applied. In addition, exponential relation and regression analysis of natural logarithms taken, were practiced on each station separately. To specify the best and proper representations of obtained mathematical relations between station data at the end of performed regression analysis, regression coefficient, r^2 values were calculated. In the calculation of regression coefficient,

$$r^2 = \frac{\sum_{i=1}^n (y_i - \bar{y})^2 - \sum_{i=1}^n (y_i - \hat{y})^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (2)$$

Here; y_i , \hat{y} , \bar{y} , represent recorded flow data, produced flow values with mathematical model, average values of recorded flow data, respectively. Within this study, mathematical relations with the highest r^2 values were taken in consideration (Figure 4). Along the entire time-scale, it is impossible to find both possessing the optimal relation and flow gauging data relevant period of time, by all means. In this case for the deficient time periods, another gauging data containing and possessing second best mathematical data relation, have been used.

Fig. 4. Investigation of relations between stations (DSI-12185 and DSI-12194) and selection of mathematical equations

It is determined optimal mathematical relations located in the basin (study area), for completion of data deficient (missing data) in flow gauging stations.

If the recorded flow data between the years of 1952-2005, belonging to 6 FGS found in Seydisuyu basin, it is specified that there is no data found or recorded at all FGSs in 1961 water year. In this case, completion of data deficient (missing data) at all 6 FGSs in 1961 have been impossible due to nonexistence of recorded data at any of FGSs. Because there is no existing data to reveal a relation between FGSs. For this reason, long-term average flow values were used to complement/fill values of 1961 water year mentioned above. Monthly long-term seasonal average flow values, were estimated according to average values of stations in consideration of each month. For example, the flow values of January 1961, were calculated by averaging January month's value of long-term annual data for the periods 1952-2005 (accepted as flow value of January in 1961). In this manner using long-term average monthly flow values, data deficient of monthly flow values belonging to 1961, were complemented/filled.

B. Accuracy Analysis of Complement/Filled Data

After completion of original monthly flow data in FGSs, continuity curves of original data recorded in FGSs and complemented/filled data deficient, were drawn and compared for the purpose to check and determine whether there has been a difference cause over the characteristics of hydrologic structure in terms of statistics or not.

Fig. 5. Comparison of continuity curves drawn from original flow data of gauge noie-2620, and complemented/filled flow gauge values

Originated flow continuity curves were noticed in Figure 5, using complemented/filled flow values and original recorded data of station no. EİE-1223. As it is noticed in the figure, any important changes have not occurred, in terms of hydrologic characteristics. Thereby, actualized data deficient prediction, meaningfulness of data completion process in terms of statistics and suitability of statistical structure dataset by filling gap process, could be noticed clearly in the figure.

III. RESULT AND DISCUSSION

Within this research, flow gauging data found Seydisuyu basin were investigated. Monthly missing data of the flow gauging stations were estimated/complemented by applying and using correlation method between stations. Correlation method has been widely used and has given satisfactory results in completion/filling of flow gauging data deficient, in the cases if there are few numbers of data deficient. After data deficient completion/filling process, nonoccurrence of any important changes in terms of hydrologic characteristics were noticed. Thus, actualized data deficient prediction, meaningfulness of data completion/filling process in terms of statistics and suitability of statistical structure dataset by filling gap process, were noticed in the method.

However, some inconsequence could occur in completion of data deficient, due to having limited numbers of data and nonproduction of sufficient correlation with other gauging stations. This inconsistency could be noticed easily, by drawing continuity curve.

If we investigate continuity curve of station that have weak correlation after completion of data, considerable effects are clearly noticed on hydrologic characteristics. This is because of insufficiency in number of observations and consisted weak correlation with other stations

As a consequence, to prevent from such type of problems and obtain a satisfactory result in completion of data deficient, it is required to practice, apply and compare various methods.

ACKNOWLEDGMENT

This study has been supported within the context of project no. 1609F626 accepted by Commission of Scientific Research Projects of Anadolu University. In addition, we would like to thank General Directorate of State Hydraulic Works (DSI) for their support.

Abstract — Side weirs, also known as lateral weirs, and overflow dams are free overflow regulation and diversion devices commonly encountered in hydraulic engineering. The lateral loss of water is reducing the sediment transport capacity in the main-channel and the formation of a local sediment deposit in the downstream of weir. The head over the side weir rises and the side overflow discharge as well. The design discharge to be diverted over the weir is increased by this flow-sediment transport interaction. Although there were no studies that scrutinized the scouring depth and geometry that occurs around the labyrinth side weirs in channels with movable bed, there are limited number of studies that examined the scouring geometry around the classical side weir. In the present study, local scour depths formed in the periphery of triangular labyrinth side weir mounted in a live-bed rectangular cross-section straight channel were experimentally investigated under steady state flow and free overflow from the side weir conditions. To provide for live-bed conditions, the sediment was added to bed material in the experiments. A series of experiments were conducted for live-bed scouring conditions (for flow intensity greater than one) to determine the maximum scour depths that occur around the triangular labyrinth side weir with different flow depths, different main channel discharges, different volumetric amounts of sediment feed, different crest heights, different Froude numbers, different flow intensities and using uniform bed material. In the experiments, the dimensions of the scours and sediment deposits that occur upstream and downstream of the weir exhibited a periodic change (increase and decrease). The maximum depth of scour occurred at the downstream end of the triangular labyrinth side weir frequently.

Keywords — *triangular labyrinth side weir; flow intensity; local scour; live-bed scour; sediment transport*

I. INTRODUCTION

A structure, located in a stream bed or built later, could change certain properties of the flow. If these changes in flow could be predicted beforehand, the structure would be designed in a sounder manner, or necessary precautions against the problems that are caused by these changes would be taken. Otherwise, this case leads to damages in the structure or to the failure in fulfilling its function. The scouring observed in the intake structure, scouring formed in the downstream of the spillway, and the scouring occurring in the abutment wall and

midfoot of the bridges and the scouring observed in the downstream of the baffle structures are of major problems encountered in hydraulic engineering.

The decrease in velocity and shear stress due to the lateral over flow causes the realization of a reverse current via creating a stagnation region in the downstream of the side weir. Scouring is formed between the main channel axis in the downstream region of the side weir and the outer bank, as a result of the changes in the shear stress.

Although there were no studies that scrutinized the scouring depth and geometry that occurs around the labyrinth side weirs in live-bed channels, there are limited number of studies that examined the scouring geometry around the classical side weir. Rosier et al. (2011) conducted an experimental research on the geometrical behavior of bed forms in a classical side weir region placed in a rectangular channel [1]. Paris et al. (2012) researched the applicability of De Marchi hypothesis on the determination of discharge capacity of side weirs under subcritical flow regime and live-bed conditions. This study presents experiments demonstrating the relationship between bed morphology and overflow discharge. The experiments were conducted in a main channel with small dimensions (0.30 m x 5 m x 0.30 m) and within a small discharge range (2-12 L/s). Studies reported that De-Marchi approach could be used in live-bed channels [2]. Onen and Agaccioglu (2013) conducted an experimental research examining clear-water scouring and live-bed scouring conditions in rectangular cross-section side weirs with $L = 0.25, 0.40$ and 0.50 m weir opening and $p = 0.07, 0.12$ and 0.17 m crest height from the sand bed in a live-bed 180° curved channel, considering subcritical flow regime and overfall conditions [3].

Since there are limited number of studies in the literature on the change in bottom topography and the scouring problem, which both occur around the labyrinth side weir that are placed in the streams, a complete theoretical basis on this subject was not constituted. Therefore, it is considered that it would be useful to examine the scouring problem, especially in our country that is rich in rivers. The aim of the present study is; to investigate the maximum scouring depth and the bottom geometry in the labyrinth side weirs, under the live-bed scouring conditions.

II. HYDRAULICS OF SIDE WEIR FLOW

The most important function of the side weir is to discharge the excessive water, when the optimum capacity, determined by taking into account the requirement and economy, is exceeded. Side weirs are used in numerous engineering applications. As the water level in the reservoir reaches a level that could damage the dam, side weirs are used to discharge the water (Fig. 1). Although they are built next to the reservoir due to the flow conditions in the reservoir, these weirs act as normal weirs. This condition should be taken into consideration while conducting the hydraulic design.

Fig. 1. Walshaw Dean Reservoir [4]

Figure 2 presents the side weir plan and section. It is stated that; y_1 = flow depth at the upstream end of the side weir at the centerline of the main channel (m), y_2 = flow depth at the downstream end of the side weir at the centerline of the main channel (m), y = flow depth at any point in the main channel (m), Q_1 = main channel discharge (m^3/s), Q_2 = main channel discharge after the side weir (m^3/s), Q_w = total flow over side weir (m^3/s), V_1 = mean approach flow velocity at the upstream of the side weir in the main channel (m/s), V_2 = mean approach flow velocity at the downstream of the side weir in the main channel (m/s), V_s = mean approach flow velocity of the side weir in the collection channel (m/s), B = main channel width (m), L = around a triangular labyrinth side weir of width (m), Ψ = angle of deflection ($^\circ$), p = weir crest height (m), x = longitudinal coordinate (m).

Fig. 2. Plan and section of the side weir flow [5]

III. LABYRINTH WEIRS

Increasing the flow rate that could overflow in a particular lake level or transmitting a constant flow rate by a smaller crest water load is aimed via the labyrinth spillways, through increasing the effective length of the spillway crest. These weirs could be considered as an alternative, which are advantageous in conditions where the space in the upstream is restricted for the reservoir water level that would especially be created by the flood discharge or in conditions where the spillway width is limited due to topography. Labyrinth weirs could be constructed in trapezoidal, triangular, and circular-shaped (Fig. 3). Most preferred type is the trapezoidal-shaped type. Equation (1) is used to find the rate of flow, that pass over the labyrinth weir. Total crest length should be considered instead of the distance "L" in Eq. (1) [6].

$$Q = 1.83.(L-0.2h).h^{3/2} \quad (1)$$

Fig. 3. Labyrinth weirs [7]

IV. THE DETERIORATION OF EQUILIBRIUM IN SEDIMENT TRANSPORTATION

In the case that the amount of solid material transported in an alluvial stream changes locally, changes such as sediment deposit in the bed and scouring could occur. As the amount transported increases scouring is observed, and when decreases, sediment deposit is observed.

The construction of a hydraulic structure such as a weir might cause changes in the stream bed. Such changes in the bed of the stream are observed either as sediment deposit in some parts or as scouring in others, depending on the amount of material that comes from the upstream, on the amount of material that is transported and on the amount of material that is over flown (Fig. 4). Both the sediment deposit and the scouring phenomena continue until they obtain a stable cross-sectional shape. Sediment deposit starts primarily with the sediment deposit of coarse particles, with their departure from the bed the velocity increases and the suspension discharge increases due to the decrease of the mean diameter of the material transported in suspension. Thus, due to the increase in the transported material, equilibrium condition is approximated. On the other hand, as the material coming from the upstream is smaller than the discharge transport capacity, the coarse particles remain in the bed since initially the fine particles in the bed would be scoured. In addition, occurrence of ripples in the bed would as well cause the decrease of the discharge transport capacity. Thereby, either in case of scouring or in sediment deposit, several secondary degree factors accelerate the achievement of the equilibrium condition [8].

Fig. 4. Sediment deposit and scouring observed in the present study

In a bed with cohesionless loose-material, the movement starts when the bed conditions reach a critical value required for movement. The particles that depart the bed due to the bed movement are washed away along the bed by depositing.

Bed shapes encountered in the rivers are as follows:

- a. Ripples
- b. Dunes

- c. Plane bed
- d. Antidunes

The order of the bed shapes provided above is made according to the change depending on the velocity of the flow. In other words, sand ripples occur with lower velocity flows, and as the velocity increases the bed has the shapes of ripple, dune, plane bed and antidune, respectively. Various shapes that the bed could take are given in Fig. 5 [9].

Fig. 5. Bed forms developed in alluvial channels [9]

Ripple and dune formations observed in this study are presented in Fig. 6.

Fig. 6. Ripple and dune formations observed in this study

V. EXPERIMENTAL STUDY

This study was conducted at the Firat University Hydraulics Laboratory using the experimental setup depicted in Figure 7. The experimental setup was 18.20×0.50 m and the side wall of the main channel was made of glass. The slope of the main channel bottom was approximately 0.1%. The collection channel was 0.50 m wide and 0.70 m high. The main channel and collection channel were separated by a steel wall. The section of the collection channel where the side weirs would be installed was built in a circular form with a diameter of 1.30 m to provide free nappe overflow from the labyrinth side weir (Fig. 7).

Fig. 7. Experimental setup plan and longitudinal cross-section: Plan view (a), Longitudinal section (b).

The experiments are conducted in a linear channel with a rectangular cross-section; for a side weir opening of $L = 0.25$ meters, and for triangular labyrinth side weirs, with crest height of $p = 0.07, 0.12$ and 0.16 meters from the sand bed and with an apex angle of $\theta = 90^\circ$. The experiments were carried out under steady flow conditions, and in the case of bed scouring ($V_1/V_c > 1$) for free over flowing condition. The experiments were conducted at a discharge of $50 - 90$ L/s. The flow depth (y_1) was measured at the channel axis at the upstream end of the side weir. The water depth at the main channel axis upstream of the side weir was used as the side weir upstream water depth. Novak and Cabelka (1981) suggested a minimum upstream water depth of 30 mm [10]. Thus, in this study a minimum upstream water depth of 30 mm was used to prevent surface tension affects.

Two sills of 20 centimeters height are placed at the upstream and downstream ends of the main channel, as seen in Figure 8. Quartz sand was placed between the upstream and downstream sills on the main channel. For this sand laid on the channel bed, following values are determined, $d_{50} = 1.16$ millimeters and $\gamma_s = 26$ kN/m³. The parts before the upstream sill and after the downstream sill are made up of sheet metal with an approximate slope angle of 15° , reaching the channel bed. Thus, the provided sand base was protected against deterioration. In order to ensure stable flow conditions (i.e. to provide time-invariant flow conditions), hollow bricks are placed at the upstream part of the channel and in front of the specific points at the end of the collecting channel. The aim is to ensure taking accurate measurements over the weir.

This experimental study was carried out for the labyrinth side weirs placed in the middle part of a linear channel. The bed material was laid 4 meters forth and 4 meters backwards from the center of the side weir, covering 8 meters of the channel. Experiment system application assembly is shown in Fig. 8.

Fig. 8. Experiment system application assembly

Prior to each experiment, the sand was mixed and compacted and the bed was leveled. After the channel bed is compressed and flattened, water was supplied slowly to the channel by turning on the valve very little. As the water slowly flowed over the sand by rising slowly from the ramp in front of the sill of the upstream end of the channel, a thirdsill is placed 20 centimeters above the sill on side of the downstream (i.e., as it should be 40 centimeters high from the channel bed). In such way, deformation the flat shape of the sand in the bed is prevented. Then, it was waited until the depth of water in the next section of the downstream sill of the main channel reached the same water depth in the main channel. After all water level along the channel became even, the requirement flow was attained and the experiment was commenced by slowly removing the thirdsill that prevented the deformation of the shape of the sand in the bed, on the sill at the downstream part. By keeping the flow rate constant, flow height in the channel (y_1) was adjusted to the required level via the radial caps at the end of the channel.

Once the experiment is completed, the valve was slowly turned off, and the thirdsill was placed back on the downstream sill of the channel in order to preserve the topography that was formed on the bed, and thus the discharge of the water from the channel was provided. Consequent to all these processes, maximum scouring depth that occurred at the side weir area was measured via a digital limnimeter. In addition, for the bed topography, bed level measurements were taken at the side weir area at 268 points with particular intervals through the aid of the digital limnimeter. Figure 9 presents the points, at which the bed topography measurements were taken.

Fig. 9. The demonstration of the points of topography measurements at the labyrinth side weirs that were tested: $L = 0.25$ m

Initially pilot experiments were conducted in order to determine the bed load flow for various flow conditions. In case of a moving bed ($V_1/V_c > 1$), since bed ripples occur in a short time, and the bed is constantly in a movement, solid material transportation occurs at a high level, and the amount of the overflow material increases constantly due to the increase in the flow rate (V_1/V_c). Thus, in order to provide the moving bed condition, constant supply of solid material was provided in the channel via the portable machine, which is designed in the Hydraulics Laboratory of the Firat University's Civil Engineering Department, seen in Fig. 10. The velocity of the volumetric amount of sediment feed ($Q_{s,up}$) was adjusted by taking into consideration the " V_1/V_c " values through this machine.

Fig. 10. Portative machine that provide solid material supply to the channel

Side weir properties and flow conditions in this study are presented in Table 1.

Table 1. Side weirs and flow conditions tested in the experiments

Experiment No	p (m)	L (m)	Q_1 (L/s)	y_1 (m)	$Q_{s,up}$ (m ³ /s)	V_1/V_c (-)	F_1 (-)
1	0.07	0.25	50	0.12	0.00075	1.94	0.77
2	0.12	0.25	55	0.16	0.00019	1.52	0.55
3	0.16	0.25	90	0.19	0.20	2.06	0.69

VI. EVALUATION OF THE EXPERIMENT RESULTS

In this section, non-dimensional maximum scouring depth's (d_{smax}/p) change in non-dimensional time (t/t_{max}) was investigated in case of moving bed scouring, for side weirs with $L = 0.25$ meters opening and $p = 0.07, 0.12, 0.16$ meters crest height, and is presented in Figure 11(a-c). For moving bed scouring, " V_1 ", which is the velocity value in the main channel, is selected greater than the " V_c " value, which is the initial velocity of the movement in the bed. The experiments were carried out in the range between $V_1/V_c = 1.0-3.0$ and each experiment were carefully elaborated to be sustained for 1080 minutes. Figure 4 presents the areas in which maximum scouring depths were observed. The experiments pointed out that the duration required to obtain the maximum scouring depth during equilibrium for moving bed scouring is

approximately 480 minutes. For larger " V_1/V_c " values, this duration was around maximum 900 minutes. After this duration, maximum scouring depths were observed to exhibit amplitudes close to the equilibrium scouring depths (Fig. 11). On the other hand, for the same " V_1/V_c " values in side weirs with larger crest heights, scouring depth at the time of equilibrium was observed to be smaller, and the equilibrium time was attained in a shorter duration. Scouring depth-duration graphics for each experiment is presented in Figs. 11 (a-c) and the flow characteristics are presented in Table 1. The tendency of the experiment results is parallel to the change of scouring depth as a function of time graphics in the studies of Tsujimoto and Mizukami (1985) and Yanmaz and Altinbilek (1991), [11 and 12].

a) No.1 experiment

b) No.2 experiment

c) No.3 experiment

Fig. 11. Time-dependent change of the scouring depth for $L=0.25$ m in the maximum scouring area: $p=0.07$ m (a), $p=0.12$ m (b), $p=0.16$ m (c)

Bathymetric contour lines of the bed occurrence as a result of the experiment for $L = 0.25$ meters and $p = 0.07, 0.12$ and 0.16 meters and the related images are presented in Figs. 12 (a-c).

In Figure 12 (a), it is possible to observe that the topography at the interior edge of the channel did not change significantly. Scours and peaks were observed in the labyrinth triangular side weir area placed at the exterior edge. Scouring depth at equilibrium time occurred at a certain distance from the weir area.

a) No.1 experiment

Scouring depth at equilibrium time in Figure 12(b) was formed in an elliptical shape from the center of the downstream of the weir to the downstream end. At the upstream overflow part, a small peak formation was observed. Due to the increasing crest height and decreasing flow rate (V_1/V_c), less material was transported to the collection channel.

b) No.2 experiment

In Figure 12(c), it was observed that the topography at the interior edge of the channel did not alter significantly and small-dimensioned sand ripples were formed. However, at the exterior edge of the channel, it was observed that scours and peaks were formed. Scouring depth was formed with an elliptical shape at the weir's downstream end. Bed ripple formation is observed. Maximum scouring formation is observed at the downstream overflowing part. Due to the large crest height and lower side weir length of the side weir used for this experiment, little amount of material was overflowed.

c) No.3 experiment

Fig. 12. Bed bathymetry and related images for $L=0.25$ m: $p=0.07$ m (a), $p=0.12$ m (b), $p=0.16$ m (c)

VII. CONCLUSIONS

Along a linear, rectangular cross-section channel with a moving bed, in constant flow and free overflowing conditions; following results are obtained from this study, which scrutinized the topographical changes that occur around the side weir and at the main channel bed and the scouring depths at the non-dimensional equilibrium time, in conditions of moving bed scouring in labyrinth side weirs with $L = 0.25$ meters length and $p = 0.07, 0.12$ and 0.16 meters crest height from the sand bed.

- In this experimental study ($V_1/V_c = 1.0 - 3.0$), it was observed that scouring depth became evident after a short duration from the initiation of the experiment and this duration shortened due to the increase of the flowrate.
- For the flow rate $V_1/V_c = 1.52$ value, while usually ripple formation was observed in the bed, mostly dune formations were observed at 1.94 and 2.06 values.
- The transformation of the channel bed from ripple form to dune form, scatterings were observed in the scouring depths due to the changing bed roughness.
- While the duration to reach the maximum value of the scouring pit decreased due to the increase of the side weir crest height, the duration for obtaining the maximum value in larger " V_1/V_c " values increased.
- The place of the scouring pit formation was determined as around the side weir and close to the downstream end. As the " V_1/V_c " value increased, it was observed that the place of the scouring pit was shifted from the downstream end of the side weir to the downstream.
- With the larger values of flow rate (V_1/V_c), scouring depth at the non-dimensional equilibrium time (d_{se}/p) also reached larger values.
- Larger scouring depths were obtained in side weirs with large crest heights.
- When the flow conditions were considerably same, bed scouring started earlier as the side weir crest height decreased, and bed scouring started later as the side weir crest height increased.
- It was determined that scouring shape that occurred in the bed was directly related to the flow rate (V_1/V_c) and non-dimensional side weir crest height (y_1/p) in the rectangular cross-section linear channel, under moving bed flow conditions.
- While the side weir height is 0.07 meters, the shape of the scouring in the bed is formed with circular cross-sections due to the vortex occurrence, and when the side weir crest height increases to 0.12 and 0.16 meters, the scouring was observed to have an elliptical shape.
- It was determined that the scouring depth at non-dimensional equilibrium time (d_{se}/p) changed directly with the increase in flow rate (V_1/V_c) and after a certain period it presented an amplitude around the peak values.

Abstract— Turkey is situated in a seismically active region and exposes to earthquakes at frequent intervals, which cause considerable loss of life and property. Designing earthquake resistant buildings is considerably significant in terms of the durability of buildings against to the earthquake loads. This statement supports the general objective of the study that earthquake resistant design of buildings is a vital need for Turkey. Earthquake is a common and significant research field ranging from social sciences to technical sciences. However, the structural problems are generally seen as an engineering problem even though they can be eliminated through the architectural design phase. This study mainly aims to gain an understanding of the earthquake design issues in the architectural design phase in terms of structural irregularities and after perceiving the problem, develop solutions to the earthquake resistance problems in buildings. The failures which are commonly observed in the reinforced concrete (RC) buildings after earthquakes and the solution suggestions to these problems will contribute to the consciousness in the earthquake resistant architectural design. In this study, structural irregularities, which has a serious effect on earthquake behavior of buildings, have been investigated in detail based on Turkish Earthquake Code 2007. These structural irregularities are examined with the examples of damaged buildings after the Marmara earthquake in 1999 and Van earthquake in 2011. The problems causing structural irregularities are evaluated in detail with their solutions. The detected effective factors or commonly encountered problems on the earthquake performance of buildings are architectural form, configuration of structural elements, aspect ratio, floor openings, projections in plan, cantilevers, differences in the rigidity between floors both in plan and vertical direction, short columns and pounding effect.

Keywords—*earthquake; earthquake resistant design; reinforced concrete buildings; structural irregularities; earthquake architecture*

I. INTRODUCTION

Turkey, with more than 90 percent of its territory located in highly seismic regions. It is an earthquake prone country that has been struck by various devastating earthquakes throughout history. During last century, 22 earthquakes took place with magnitudes greater than 7 with the last Van earthquake in 2011

($M=7.2$). These earthquakes resulted in thousands of deaths and destroying or heavily damaging 500,000 buildings [1]. Therefore, earthquake resistant building design is considerably significant.

If the earthquake effects on existing buildings from the past destructive earthquakes are considered, it can be clearly seen that failures on buildings start at the beginning of the architectural design phase. Therefore, there is a strong relationship between the architectural design of buildings and their earthquake safety. “Earthquake resistant architectural principles are not the provisions that could be inserted by the structural engineer after the completion of architectural design. They should be applied to the project during the architectural design phase” [2]. Architectural Design error cannot be corrected by a mathematical calculation. Therefore, architectural design decisions play an active role in the earthquake behaviour of buildings.

In Turkey, the mainstream construction system is reinforced concrete (RC). Most of the buildings were severely damaged or collapsed after earthquakes (Erzincan earthquake in 1939 and 1992, Marmara earthquake in 1999, Van earthquake in 2011, etc.). These severely damages or collapses are related to many factors such as architectural form, configuration of structural elements, storey number, floor openings, projections in plan, cantilevers, differences in the rigidity between floors both in plan and vertical direction, short columns and pounding effect, etc.

Municipality of Düzce conducted a damage survey in buildings after 1999 Marmara Earthquakes to investigate the relation between storey number of buildings and damage levels. These results are illustrated in Figure 1. It is pointed out that building vulnerability increases remarkably with the increase in the storey number. The percentages of damage levels are given for each storey number separately. Buildings, especially having four or five storeys appear to be more vulnerable than the others [3].

Figure 1. Building damage levels with the number of storeys after 1999 earthquakes in Düzce [3]

After the Marmara Earthquake in 1999, an investigation was made on ten heavily damaged or destroyed buildings [4]. These buildings have been investigated in terms of their structural irregularity mechanism. It is observed that they are all multi-storey R/C skeleton buildings which are commonly used for commercial or dwelling purposes. Based on Bakar's study [4], the structural irregularities on these ten investigated buildings is presented in Table 1. The table draws attention to the torsional irregularity(A1) and soft storey irregularity (B2) and nonparallel axes (A4) which are explained in Turkish earthquake code 2007 (TEC-2007) [5].

Table 1. Structural irregularities on chosen ten buildings after the Marmara Earthquake

	Reviewed Project Number	Existant	Nonexistant
A1	10	-	10
A4	10	2	8
B2	10	-	10

The structural irregularities are described in the Turkish Earthquake Code, 2007(TEC, 2007) [5]. However, in practice it is very significant and required to gain an understanding of the problems in projects at least in terms of structural irregularity, and then manage to solve the problems using problem-oriented solutions. Earthquake is a common and significant research field ranging from social sciences to technical sciences. However, the structural problems caused by an earthquake are generally seen as an engineering problem even though they can be eliminated through the design phase. Safety precautions should have a significant position in architectural design. The safety of a building is strongly related to its architectural design and its structural system [6]. For this reason, architects should have an awareness of the problems about structural irregularities in terms of both problems in plan and structural configuration in order to achieve the reasonable and logical solutions. This study aims to explore architectural problems in earthquake resistant design and then their interaction with structural configuration to emphasize the

architectural failures. Commonly encountered structural irregularities are examined with the examples of damaged buildings after the Marmara earthquake in 1999 and Van earthquake in 2011. The problems causing structural irregularities are examined in detail with their solutions from literature.

II. SEISMICITY OF TURKEY

The Earth that we are living on has witnessed lots of disasters such as earthquakes, floods, storms, and avalanche. Earthquake is a major problem for all human being because of killing thousands each year. The great part of the World is under the threat of earthquakes [7]. Its specific time, location, and magnitude cannot be estimated before it has happened. Based on the long-term seismic records in the World, it is expected that one very strong earthquake will occur each year. Estimated numbers of earthquakes per year are listed depending on their magnitudes below in Table 2.

Table 2. Estimated earthquake frequency in the World [8]

Group	Magnitude	Annual Average Number
Very Strong	$M > 8.0$	1
Strong	$7.0 < M < 8.0$	17
Medium	$5.0 < M < 7.0$	1453
Small	$3.0 < M < 5.0$	143000
Micro	$1.0 < M < 3.0$	1300000
Ultra Micro	$M < 1.0$	

There are three prominent earthquake belts in the world. These are Pacific earthquake belt, mid-Atlantic belt, and the third one is Alp Himalayan earthquake belt which affects the seismicity of Turkey. Nearly 17 % of the world's major earthquakes occur at Alp Himalayan earthquake belt [9]. The 17 August 1999 Kocaeli earthquake with a magnitude 7.4 and the 12 August 1999 Düzce earthquake with a magnitude 7.1 Düzce can be given as the most striking examples occurred on Alp Himalayan earthquake belt. Turkey is a tectonically active country that lies on the Anatolian Peninsula on the Alp Himalayan earthquake belt. Turkey has surrounded three main faults. These are North Anatolian Fault (NAF), East Anatolian Fault and West Anatolian Host Graben system.

Turkey is separated on five earthquake zones according to their risk conditions, of which the 1st and 2nd earthquake zones are the most hazardous ones due to the existence of the high magnitude earthquakes in the past. Seismic Hazard map of Turkey is given in Figure 2. 1st earthquake zone is red coloured regions and 2nd earthquake zone is orange coloured. According to the seismic zone map of Turkey, approximately 96 % of its land is located on considerably risky earthquake zones and 80 % of its population is imposed upon to the large scale earthquakes.

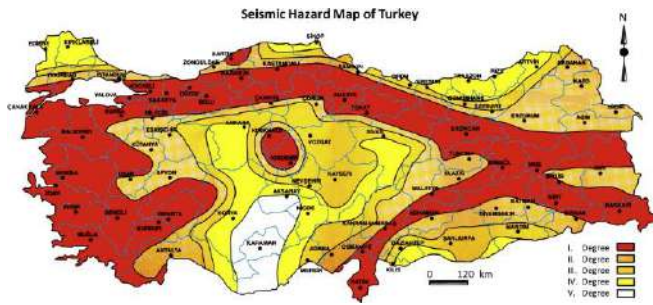

Figure 2. Seismic Hazard Map of Turkey [10]

III. STRUCTURAL IRREGULARITIES

Irregular buildings are defined in the Turkish earthquake code (TEC-2007) as buildings whose design and construction should be avoided because of their unfavorable seismic behavior. Structural irregularities begin in the initial part of the architectural design phase. There are many factors causing structural irregularity and affects adversely earthquake performance of buildings. These are irregular design in plan and vertical direction, discontinuity in mass and rigidity distribution, configuration of structural elements on nonparallel axis, height differences between floors, short columns, pounding effects, etc. [11]. Accordingly, TEC-2007 divides structural irregularities into two main groups: irregularities in plan and irregularities in the vertical direction. Irregularities in plan consist of three different types of structural irregularities, which are torsional irregularity denoted as A1, floor discontinuities denoted as A2 and projections in plan denoted as A3. Irregularities in the vertical direction comprise three types of structural irregularities, which are weak storey denoted as B1, soft storey denoted as B2 and discontinuity of structural elements denoted as B3. These irregularities are explained in Table 3 and Table 4.

Table 3. Irregularities in Plan [5]

A- IRREGULARITIES IN PLAN	
A-1 Torsional Irregularity:	
The case where Torsional Irregularity Factor η_{bi} which is defined for any of the two orthogonal earthquake directions as the ratio of the maximum storey drift at any storey to the average storey drift at the same storey in the same direction, is greater than 1.2 $[\eta_{bi} = (\Delta_i)_{\max} / (\Delta_i)_{\text{ort}} > 1.2]$	
A-2 Floor Discontinuities:	
In any floor; I - The case where the total area of the openings including those of stairs and elevator shafts exceeds 1/3 of the gross floor area, II - The cases where local floor openings make it difficult the safe transfer of seismic loads to vertical structural elements, III - The cases of abrupt reductions in the in-plane stiffness and strength of floors.	
A-3 Projections in Plan:	
The cases where projections beyond the re-entrant corners in both of the two principal directions in plan exceed the total plan dimensions of the building in the respective directions by more than 20%.	

Table 4. Irregularities in Vertical Direction [5]

B- IRREGULARITIES IN VERTICAL	
B1 – Interstorey Strength Irregularity (Weak Storey) :	
In reinforced concrete buildings, the case where in each of the orthogonal earthquake directions, Strength Irregularity Factor η_{ci} , which is defined as the ratio of the effective shear area of any storey to the effective shear area of the storey immediately above, is less than 0.80. $[\eta_{ci} = (\Sigma Ae)_i / (\Sigma Ae)_{i+1} < 0.80]$	
Definition of effective shear area in any storey :	
B2 – Interstorey Stiffness Irregularity (Soft Storey) :	
The case where in each of the two orthogonal earthquake directions, Stiffness Irregularity Factor η_{ki} , which is defined as the ratio of the average storey drift at any storey to the average storey drift at the storey immediately above or below, is greater than 2.0. $\eta_{ki} = (\Delta_i / h_i)_{\text{ort}} / (\Delta_{i+1} / h_{i+1})_{\text{ort}} > 2.0$ or $\eta_{ki} = (\Delta_i / h_i)_{\text{ort}} / (\Delta_{i-1} / h_{i-1})_{\text{ort}} > 2.0]$	
B3 - Discontinuity of Vertical Structural Elements :	
The cases where vertical structural elements (columns or structural walls) are removed at some stories and supported by beams or gusseted columns underneath, or the structural walls of upper stories are supported by columns or beams underneath.	

A. Torsional Irregularity

Various seismic codes define torsional irregularity as a significant irregularity, because of its devastating effects on buildings. The main factors causing torsional irregularity are the architectural form of the building and rigidity distribution in the plan geometry. Earthquake loads act on gravity centre of the structure (G). However, the rigidity centre of the structure (R) responds to these loads (Figure 3). If the eccentricity between these two centres is great, a torsional moment will occur around the centre of rigidity. Therefore, the structure begins to rotate around the rigidity axis [12]. The distance between the center of gravity and the centre of rigidity should be kept as minimum as possible [13].

Figure 3. Working mechanism of Gravity and Rigidity centre

The design of a building is the geometrical arrangement of all the architecture, structure and contents. It should include both appropriate form and the structural distribution. This should be considered in the early design phase by architects. The most appropriate form in terms of earthquake loads is circle and square due to their symmetric and simple plan geometry. Besides, the rectangular form is a suitable alternative solution owing to its simplicity and symmetry provided that the lengths of both short and long edges are close to each other [13]. These simple forms react the same inertia forces under earthquake loads coming from in every direction. Structures which have asymmetric and complex plan geometry such as L, H, T, U, Y, +, have little energy absorbing capacity due to the torsional effects and stress concentrations at notch points on reentrant corners [12-13]. Apart from the simplicity of the plan geometry, irregular rigidity distribution in plan cause torsional irregularity. It can create torsional irregularity despite the regular plan geometry [12-13]. For instance, if shear walls or rigid core are located on one side of the building, flexible and rigid parts occur in the structure. In Figure 4, a heavily damaged building due to the torsional irregularity from 1999 Marmara Earthquake is presented.

Figure 4. A heavily damaged building from 1999 Marmara Earthquake

To prevent the torsional irregularity, complex forms separated into simple forms by using seismic separation joints. The distance between gravity and the rigidity center should be minimized. Symmetry both in the building form and rigidity distribution should be provided. In the complex plan geometries such as L and T types, acute angle reentrant corners should be Strengthened at notch points by vertical structural elements or reentrant corners should be softened.

B. Floor Discontinuities

Some cases such as big holes in the slabs, the existence of the openings adjacent to the vertical structural members, abrupt reduction in the slabs or improper local floor holes prevent the regular distribution of the earthquake loads to the vertical

structural members [12-13]. This type of irregularity also causes torsional irregularity via creating flexible and rigid parts in the building. The reinforcement around the corners and edges of the openings may contribute to the continuity in floors [12]. The rigidity of the columns and beams around the openings should be increased or shear walls should be placed around the openings to balance the rigidity between floors [12]. Openings on the floors should be positioned symmetrically in the plan geometry. Floor openings should be separated by dilatation joints and slabs should be made void-free.

C. Projections in Plan

The projection ratio has significant role on earthquake behaviour of structures. This irregularity which is called projections in plan is the cases where projections beyond the reentrant corners in both of the two principal directions in plan exceed the total plan dimensions of the building in the respective directions by more than 20 % (TEC, 2007). It is illustrated on the Figure 5.

Figure 5. Projections in plan

The buildings which have large projections are seriously damaged from earthquakes [12]. Because, the building wings make different movements on different directions under earthquake loads and stress concentration occurs at the notch points of the building. Therefore, critical shear forces and moments occur in the reentrant corners where the projections connect. There are two alternative solutions to prevent this type of irregularity. The first is to divide building blocks into simple parts by seismic joints (Figure 6). The second is to tie the building wings strongly with a linkage element to reduce torsion[14] (1)

Figure 6. Separating building blocks by seismic joints

D. Soft and Weak Storeys

Weak storey irregularity is a kind of vertical configuration issue in which there is a major reduction in strength of the storey when it is compared with above storey [12]. It can be observed at any storey of a building. However, it frequently occurs at the first storey due to the considerable loads accumulation at the first storey of the building. It is due to the differences in stiffness or flexibility between storeys. All stories of the building should be designed nearly equal in terms of strength or stiffness in order to distribute the earthquake forces homogeneously among stories. However, architectural design issues in a building limit that type of planning. For instance, the ground floors are generally used as shops while the upper stories are used for housing in residential buildings in Turkey. The storey heights are different between the ground floor and above. Thereby, shops are designed as to have large window openings and vertical structural elements inside the shops are removed which is coming from upper floors because of the need to create large areas. Open ground storey such as shops, meeting rooms, banking halls creates remarkable damages in buildings under earthquake loads. Because, while a great storey drift occurs in the ground floor, the upper floors move like a diaphragm. High stress concentration occurs along the connection line between the ground and first floor that leads to distortion or collapse in buildings.

Figure 7. The soft first storey failure mechanism

There are many factors leading to the weak and soft storey irregularity. For instance, buildings with vertical setbacks are one of them. A setback can be defined as an abrupt and major change of strength and stiffness. For that reason, it prepares both soft and weak storey irregularity on the ground floor. It can be visualized like a building having vertical reentrant corners. The building having vertical setbacks suffers from damages in the line of the setback or notch point due to the great stress concentration. The vertical setbacks in the building start making different displacement due to the different natural period of vibration between the typical storey and the storey with setbacks [15]. Their earthquake behaviour is quite complex to predict. Projections which are designed in order to animate the facades of a building cause considerable damage due to the earthquake forces. All storeys should have the same plan geometry [15]. Even though setback exists in a single building block, it can also occur in adjacent buildings having different heights due to the deficiency in the amount of seismic separation joint or having no seismic separation joint.

Cantilevers are another factor that lead to weak and soft storeys. In Turkey, approximately 70 or 80 % of buildings have

constructed with cantilevers [16]. The building shown below in Figure 8 subjected to great earthquake damage due to the insufficient cross sections of columns at ground floor. There are stiffness differences between floors especially related to the heavy closed cantilever and weak columns at the ground floor. For this reason, the columns broke at the ground floor level on connection points and collapsed. The cross sections of the columns should be increased and shear walls should be added on the ground floor. Binders should be increased along the column height, especially on across to the connection points.

Figure 8. Damage due to the heavy cantilevers [Photo by Kutlu Darılmaz]

There are various alternative solutions to reduce or eliminate the negative effects of the weak and soft storey irregularities. Some of them are presented in Figure 9. The cross sections of the columns can be increased on the ground floor or additional columns or shear walls may be added. Open ground floors may be supported additional walls. Bracing elements can be added to the ground floor which contribute to the vertical structural elements for load transfer. Joints should be left between columns and walls.

Figure 9. Solutions for Weak and Soft storey

E. Discontinuity of Vertical Structural Elements

This irregularity is described as the case where vertical structural elements are positioned improperly. Some vertical configurations of structural elements are prohibited in Turkish Earthquake Code (TEC-2007) illustrated in Figure 10. Gusseted columns or the columns which rest on cantilever beams are prohibited. A damaged gusseted building is given in Figure 11. In no case the shear walls should be allowed to rest under the columns and In no case the shear walls should be allowed to rest on the beams. In the case where a column rest on a beam supported with columns at both ends, all internal forces consisting vertical loads and seismic loads from the earthquake direction shall be increased by 50 % at all sections of the all beams and the columns which are adjacent to the beam.

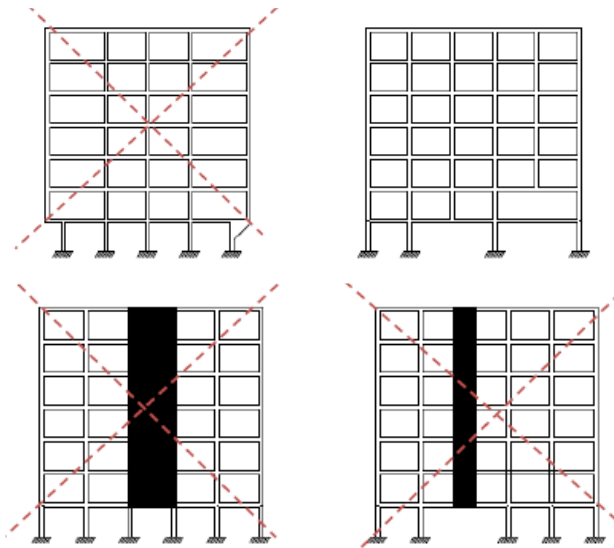

Figure 10. Discontinuity of Vertical Structural Elements

Figure 11. Gusseted column damage [Photo by Elif Çiftçi]

F. Short Column Effect

When a building has both long and short columns in the same storey, the columns expose to different shear forces due to their height differences. The lateral loads firstly come to the long and flexible columns, and then go towards to the short column and accumulate in there. Due to the excessive accumulation of the seismic energy, shear cracks occurs at both ends of the columns. The long and short column having the same cross section show the same displacement under earthquake loads. However, the short columns are more stiff or rigid as it compared with the long column and expose greater earthquake forces than short columns [17]. Mezzanine floors, Mechanical floors, Hillside sides, Graded foundation, Adjacent columns to the openings, Stair landing cause short columns. The damage in these short columns is often in the form of X-shaped cracking that occurs due to shear failures. heavy non-structural walls must be isolated from the columns to prevent the formation of the short column. To prevent short column due to the stair landing, sliding support should be placed between the steps on the intermediate landing (Figure 12).

Figure 12. Sliding support problem

Figure 13. X cracking due to the short column

G. Other irregularities

In a structure, it is desired that beams should begin deforming before columns. Failure in a column can affect the stability of the overall building. However, beams deformation partly affects the building. For that reason, beams need to be made ductile rather than the columns. Sufficient ductility is ensured in the structural members where the damage is estimated to happen under earthquake loads. Plastic hinging at both ends of the columns may initiate a storey displacement or even leading to the overall collapse of the building [6]. The beams should have weakest links instead of columns to prevent plastic hinging in columns. This condition can be provided by correctly sizing the structural members and using sufficient amount of steel in them. In Figure 14, the building is collapsed due to the strong beam-weak column irregularity.

Figure 14. Damage due to the hollow-tile floor slab [Photo by Elif Çiftçi]

Pounding is a damage type in two buildings or different parts of the same building under earthquake loads. It causes hitting the buildings one another. It commonly occurs due to the insufficient seismic gap or no gap between two adjacent buildings. If the size of the seismic gap is insufficient based on the expected storey drifts, pounding between adjacent structures may occur. In Figure 15, the buildings damaged from pounding effect are given.

Figure 15. Pounding effect [Archive of the Istanbul Metropolitan Municipality]

IV. CONCLUSIONS

Architecture is a profession which exists to solve the shelter problems of humanity in a way that is in harmony with nature and the force of nature. The interaction of architectural form and structural configuration has become a serious issue in the building industry because of the poor seismic performance of reinforced concrete buildings in Turkey. Producing earthquake safety environment is one of the duties of architectural design. For that reason, this study aims to explore architectural problems in earthquake resistant design to underline and understand architectural faults, and then its interaction with structural configuration to develop basic knowledge and perspective. In this study, the structural irregularities are investigated comprehensively with solutions suggested in literature and Turkish earthquake code, and then the effective factors on earthquake performance of structures are explored. The detected effective factors or commonly encountered problems on the earthquake performance of buildings are architectural form, configuration of structural elements, aspect ratio, floor openings, projections in plan, cantilevers, differences in the rigidity between floors both in plan and vertical direction, short columns and pounding effect. If the factors causing structural irregularities are investigated, it is observed that many of them can be prevented with the decisions in the early stage of architectural design. Architects are primary responsible from the overall picture observed after earthquakes due to the being the designer of the buildings. It is important to underline that ERD should not be seen just as an engineering calculation issue. Nevertheless, there is still hope for earthquake resistant structures through an understanding of the problems and problem-oriented solutions.

Abstract— The most important principle of the earthquake-resistant design of reinforced concrete structures is that the structural elements must carry both vertical loads and horizontal loads as a whole. For this reason, it is required that the structural elements carry their own weight with sufficient safety and the loads arose from external forces must be transferred safely to the load carrying vertical elements. However, discontinuity of the slabs disturbs the integrity of the structures and causes problems in transferring earthquake loads to the structural elements. In this study, the effect of slab discontinuity in plan on seismic behaviors of multi - storey reinforced concrete structures was investigated by using incremental linear dynamic analysis method. To investigate this irregularity situation, one regular and three irregular multi-storey reinforced concrete building models were selected. Dynamic envelopes of the structures were obtained from the analysis results and compared with each other. Thus, it was observed that the irregular structures subjected to more shear force than the regular structure.

Keywords—reinforced concrete building, slab discontinuity, incremental linear dynamic analysis

I. INTRODUCTION

The earthquake effect is a natural catastrophe that has caused massive devastation on people and the environment. But the main reason of the losses in the earthquakes is that the structures not provided the desired earthquake behavior. While designing the building systems, it is aimed that the buildings resist the earthquake forces at least must be provide life safety level. To provide this performance level, the structure has symmetrical and regular load carrying system. Regular structures; both in practice and in dimensioning, provide simple the calculation and forces are calculated accurately. For this reason, regular construction is the most practical choice for a good design.

Lateral forces are transmitted to the vertical load carrying elements by slabs. It is assumed that the slab behaviors as a rigid diaphragm during the design of structure. But the large openings in the slab invalids rigid diaphragm assumption [1-4]. So, Turkish Seismic Code (TSC-2007) [5] requires some requirements about this irregularity. These requirements are shown in Fig.1. According to code, In any floor

a) The case where the total area of the openings including those of stairs and elevator shafts exceeds 1/3 of the gross floor area,

b) The case where local floor openings which make the safe transfer of seismic loads difficult to vertical structural elements,

c) The cases of abrupt reductions in the in-plane stiffness and strength of floors.

$$A_b = A_{b1} + A_{b2}$$

$$\frac{A_b}{A} > \frac{1}{3}$$

where

A_b shows sum of the openings and A shows gross floor area, respectively.

a)

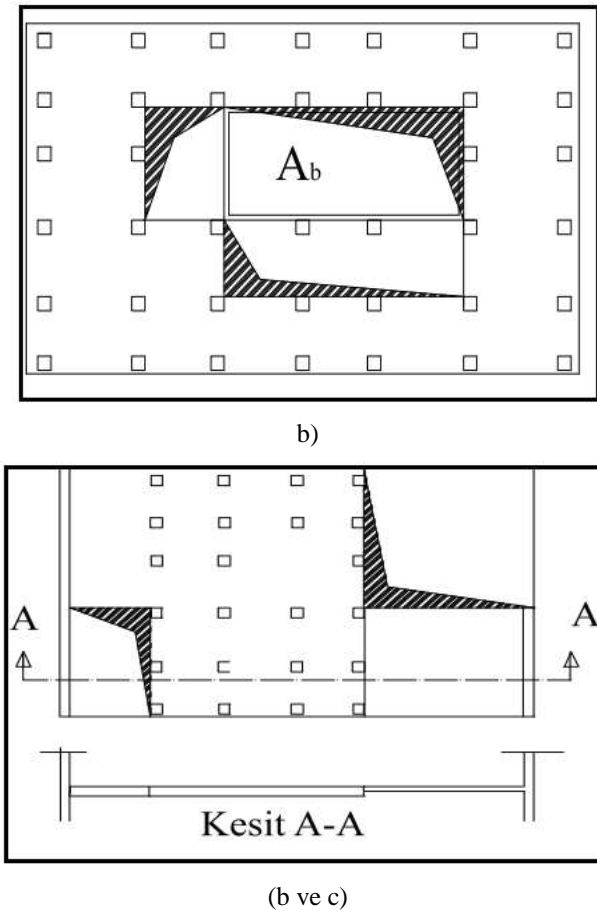

Fig. 1. Slab discontinuity situations defined in TSC

To investigate this irregularity situation, one regular and three irregular multi-storey reinforced concrete building models were selected. Incremental linear dynamic analyses were performed and dynamic envelopes of the structures were obtained from the analysis results. In dynamic analysis, elastic diaphragm assumption was made.

II. NUMERICAL STUDY

A. Selected Building Models

For dynamic analyses three 3D irregular and a regular building models were selected. These models have five stories and height of stories are 3.50 m. The dimensions for columns were selected as 50x50 cm, and dimensions for beams were selected as 30x60 cm. Slab thickness was selected as 13 cm. It was assumed that, the building importance coefficient is 1.0 and, concrete class is C25 and reinforcement steel class is S420. Selected models and rates of slab openings are illustrated in Figs.2-5. In this models, first and end bays are 500 cm and the middle bays are 450 cm in x direction. For y direction first and end bays are 600 cm, the other bays are 500 cm. The dynamic analyses are performed by SAP2000 structural analysis program [6]

B. Earthquake Parameters and Local Site Conditions

Table 1 shows selected earthquake accelerations properties used in dynamic analysis. The seismic records have been selected from the PEER Strong Motion Database [7] and scaled in order to be compatible with the design spectrum according to seismic zones and local site conditions in TSC. Soil classes (from Z1 to Z4) are characterized in term of periods T_A and T_B . The design spectra are given according to local site classes in Fig. 6.

TABLE 1. SELECTED EARTHQUAKE ACCELERATION RECORDS FOR DYNAMIC ANALYSIS

Earthquakes	Station	Direction	Date	Magnitude	PGA (g)
Kocaeli	Sakarya	North-South	August 17,1999	7.4	0.376
Loma Prieta	Corralitos	East-West	October 18, 1989	6.9	0.644
Imperial Valley	El Centro Array	East-West	May 19,1940	7.0	0.313

Fig. 6. Recommended elastic response spectra for ground types Z1 to Z4 (for 5% damping)

Selected earthquake records were scaled in frequency content in order to be compatible with the target design spectrum of four effective ground accelerations and different soil classes (Fig. 7a-d). The records were scaled using SeismoArtif and SeismoSignal programs.

d) Response spectra of the earthquake acceleration records scaled according to the elastic design spectrum for Z4 soil class and effective ground accelerations

b) Response spectra of the earthquake acceleration records scaled according to the elastic design spectrum for Z2 soil class and effective ground accelerations

c) Response spectra of the earthquake acceleration records scaled according to the elastic design spectrum for Z3 soil class and effective ground accelerations

Fig. 7. Response spectra of the earthquake acceleration records scaled according to the elastic design spectrum for four soil classes and effective ground accelerations defined in TSC.

III. ANALYSES RESULTS

Maximum responses of the incremental dynamic time history analyses are given in Figs. 8-10 for the x direction and Figs. 11-13 for the y direction. Dynamic envelopes are obtained according to these responses. Each irregular models are compared with regular building. According to these figures, the correlation coefficient values, are exceed 0.90 for x direction. Also, it is seen that dynamic envelopes of each irregular building models exceed the dynamic envelope of regular building. This situation is a evidence of the irregularity causes more shear forces.

Fig. 8. Comparison of dynamic envelopes of B1 irregular model and Regular model for x direction

Fig. 9. Comparison of dynamic envelopes of B2 irregular model and Regular model for x direction

Fig. 11 Comparison of dynamic envelopes of B1 irregular model and Regular model for y direction

Fig. 10. Comparison of dynamic envelopes of B3 irregular model and Regular model for x direction

Fig. 12 Comparison of dynamic envelopes of B2 irregular model and Regular model for y direction

According to Figs.11-13, the correlation coefficient values are approximately 0.90 for regular building and for the other coefficient exceed the 0.90 for y direction. Seismic actions obtained from the scaled earthquakes follow the same trend and shape to that of the dynamic envelopes, similar to that in the x direction.

Fig. 13 Comparison of dynamic envelopes of B3 irregular model and Regular model for y direction

IV. CONCLUSIONS

In this paper, the effect of slab discontinuity in plan on seismic behaviors of multi-storey reinforced concrete structures was investigated by using incremental dynamic analysis method. To investigate this irregularity situation, one regular and three irregular multi-storey reinforced concrete building models were selected. Dynamic envelopes of the structures were obtained from the analysis results.

According to analysis results, dynamic envelopes obtained from each irregular building models exceed the dynamic envelope of regular building for x and y directions. This situation shows that this type of irregularity causes more shear forces. So, it is should be abstain from the application of this irregularity.

Abstract—This paper presents a new and simple approach to design multiple tuned mass dampers (MTMDs) based on the calibration formulas proposed by Den Hartog for the stiffness and damping of a single TMD. Keeping the mass of all TMD units to be constant and identical, TMD properties are recalibrated based on the natural frequencies of the system on which the number of TMDs is one less than the current system. This is a sequential procedure, where it does not require to do iterations for each step, instead it requires to start from the case with a single TMD, and then move up in numbers one TMD at a time until the desired number is reached. Accuracy and efficiency of the proposed method is shown by numerical examples.

Keywords—Multiple tuned mass dampers; Vibration control; Optimal design

I. INTRODUCTION

To control excessive vibrations of tall buildings, bridges and other civil engineering structures due to environmental loads such as earthquake, wind and traffic loads has been attracted to the interest of many researchers. Research efforts on vibration control of structures have resulted in developing various control devices. Among them, tuned mass dampers (TMDs) consisting of a mass, a spring and a viscous damper is one of the simplest, reliable and low cost control devices.

In 1909, a TMD, which consists of a mass and a spring, was first introduced by Frahm [1]. It has a narrow operation region, and its performance reduces significantly when the exciting frequency varies. Many efforts have been, then, made to obtain optimum parameters of TMDs. Den Hartog [2] proposed a closed form solution to minimize the dynamic response of undamped single degree of freedom (SDOF) system under harmonic loads. Randall et al. [3] proposed numerical optimization procedures for determination of optimum TMD parameters. Fujino and Abe [4] presented a perturbation technique to derive formulas for optimal TMD parameters. Asami et al. [5] gave a series solution for the H_∞ optimization and an exact solution for the H_2 optimization. Ghosh and Basu [6] presented a closed-form expression for optimal tuning ratio of TMDs based on the fixed-point theory of Den Hartog. Brown and Singh [7] proposed a mini-max procedure to design a TMD in the presence of uncertainties in

forcing frequency. Anh and Nguyen [8] carried out an approximate analytical solution for optimal tuning ratio of TMDs by using the equivalent linearization method.

All studies mentioned above are concerned with tuning TMD to a dominant frequency of the main system. However, single TMD is very sensitive to any change in the frequency of TMD and/or the main system. Errors in identifying the main system frequency or in manufacturing TMD lead to the detuning effect. To overcome the detuning due to a frequency deviation, Xu and Igusa [9] proposed to use multiple tuned mass dampers (MTMDs) instead of classic single TMD. They indicated that the use of MTMDs with distributed natural frequencies in a frequency bandwidth can be more effective than a single TMD with the same total mass. This kind of TMD system has also been studied by many researchers [10-15]. The main difference in these studies is the optimization methods and criteria adopted.

Although different techniques exist to obtain optimal tuning parameters, they are not simple as much as Den Hartog's approach. The most useful aspect of Den Hartog's approach is to give simpler, closed form formulas for optimal parameters of classic TMD. The purpose of this paper is to develop a simple design procedure for optimal MTMD devices based on Den Hartog's method.

II. THEORETICAL FORMULATION

A. Governing equations

Consider a single-degree-of-freedom (SDOF) structure with MTMD shown in Fig. 1. The natural frequencies of TMD units are tuned to a frequency range vicinity to the natural frequency of the main structure. Note that total DOFs of the coupled system is $n + 1$ where n is the number of TMD units. The equation of motion for the main structure with MTMD under harmonic excitation is

$$m_s \ddot{x}_s + c_s \dot{x}_s + k_s x_s + \sum_{j=1}^n c_j (\dot{x}_s - \dot{x}_j) + k_j (x_s - x_j) = P e^{i\omega t} \quad (1)$$

and the vertical motion of the j th TMD is

Fig. 1. Main structure – MTMD coupled system

$$m_j \ddot{x}_j + c_j (\dot{x}_j - \dot{x}_s) + k_j (x_j - x_s) = 0 \quad j = 1, 2, \dots, n \quad (2)$$

where over dot denotes differentiation with respect to time t , and m_s , c_s and k_s are the mass, damping coefficient and stiffness of the main structure, respectively, m_j , c_j and k_j are the mass, damping coefficient and stiffness of j th TMD, respectively. x_s and x_j indicate the vertical displacement of the main structure and j th TMD, respectively.

Combining (1) and (2), the equations of motion can be given in the following matrix form:

$$\mathbf{M}\ddot{\mathbf{X}} + \mathbf{C}\dot{\mathbf{X}} + \mathbf{K}\mathbf{X} = \mathbf{F} \quad (3)$$

where \mathbf{M} , \mathbf{C} , \mathbf{K} are the mass, damping and stiffness matrices, $\ddot{\mathbf{X}}$, $\dot{\mathbf{X}}$ and \mathbf{X} are the acceleration, velocity and displacement vectors, respectively. \mathbf{F} is the external force vector. They can be defined as:

$$\mathbf{M} = \text{diag}(m_s \quad m_1 \quad m_2 \quad \dots \quad m_n) \quad (4)$$

$$\mathbf{C} = \begin{bmatrix} c_s + \sum_{j=1}^n c_j & -c_1 & -c_2 & \dots & -c_n \\ -c_1 & c_1 & 0 & \dots & 0 \\ -c_2 & 0 & c_2 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -c_n & 0 & 0 & \dots & c_n \end{bmatrix} \quad (5)$$

$$\mathbf{K} = \begin{bmatrix} k_s + \sum_{j=1}^n k_j & -k_1 & -k_2 & \dots & -k_n \\ -k_1 & k_1 & 0 & \dots & 0 \\ -k_2 & 0 & k_2 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -k_n & 0 & 0 & \dots & k_n \end{bmatrix} \quad (6)$$

$$\mathbf{X} = \{x_s \quad x_1 \quad x_2 \quad \dots \quad x_n\}^T, \quad \mathbf{F} = e^{i\omega t} \{P \quad 0 \quad 0 \quad \dots \quad 0\}^T \quad (7)$$

The normalized displacement amplitude or dynamic magnification factor (DMF) for the main structure under harmonic excitation is [12]:

$$\text{DMF} = \frac{x_1}{x_{st}} = \sqrt{\frac{1}{\text{Re}(z_1)^2 + \text{Im}(z_1)^2}} \quad (8)$$

where

$$\begin{aligned} \text{Re}(z_1) &= 1 - \beta^2 - \beta^2 \sum_{j=1}^n \mu_j \frac{\frac{\beta_j^2}{\beta^2} - 1 + 4\xi_j^2}{\left(\frac{\beta_j}{\beta} - \frac{\beta}{\beta_j}\right)^2 + 4\xi_j^2}, \\ \text{Im}(z_1) &= 2\beta\xi_s + \beta^2 \sum_{j=1}^n \mu_j \frac{2\beta\xi_j}{\left(\frac{\beta_j}{\beta} - \frac{\beta}{\beta_j}\right)^2 + 4\xi_j^2} \end{aligned} \quad (9)$$

where $x_{st} = P / k_s$ is the static displacement of the structure, $\beta = \omega / \omega_s$ is the frequency ratio between the external force and the structure, ξ_s is the damping ratio of the structure, $\mu_j = m_j / m_s$ is the mass ratio, $\beta_j = \omega_j / \omega_s$ is the frequency ratio, and $\xi_j = c_j / 2m_j\omega_j$ is the damping ratio of j th TMD

B. Den Hartog's approach

Tuning parameters for a single TMD are given in this section. Here, we assume that the system given in Fig.1 for $n = 1$ which represents a single TMD. DMF for the main system is

$$\text{DMF} = \frac{x_1}{x_{st}} = \sqrt{\frac{P}{Q}} \quad (10)$$

where

$$\begin{aligned} P &= 4\xi_s^2 \beta^2 + (\beta^2 - \beta_1^2)^2, \\ Q &= 4\xi_s^2 \beta^2 (\beta^2 - 1 + \mu\beta^2)^2 \\ &\quad + [\mu\beta_1^2 \beta^2 - (\beta^2 - 1)(\beta^2 - \beta_1^2)]^2 \end{aligned} \quad (11)$$

with

$$\beta_1 = \frac{\omega_1}{\omega_s}, \quad \beta = \frac{\omega}{\omega_s}, \quad \mu = \frac{m_1}{m_s} \quad (12)$$

Den Hartog [2] gave the followings for the optimal tuning ratio f_{opt} and the optimal damping ratio ξ_{opt} :

$$f_{opt} = \frac{1}{1 + \mu}, \quad \xi_{opt} = \sqrt{\frac{3\mu}{8(1 + \mu)}} \quad (13)$$

C. Proposed design method

It can be obviously seen in Table 1 that the natural frequency of the main structure without TMD is split into two independent modes, when TMD-1 ($n=1$) is attached to it. Therefore, if a MTMD is installed on the main structure, the natural frequency of the main structure without TMD will be split into $n+1$ independent modes. In the approach presented here, MTMD properties are re-calibrated based on the natural frequencies of the system on which the number of TMDs is one less than the current system. This is a sequential procedure, where it does not require to do iterations for each step, instead it requires to start the procedure from the case with a single TMD, and then move up in numbers one TMD at a time until the desired number is reached. For example, the natural frequency of a single TMD attached on the main structure is tuned to that of the structure without TMD. If two parallel TMDs ($n=2$) are attached to the main structure, each TMD is tuned to those of the main system with single TMD ($n=1$). Therefore, we can write the following expressions for the optimal tuning parameters of TMDs:

$$\begin{aligned} \mu &= \frac{\sum_{j=1}^n m_{j,n}}{m_s}, \quad \mu_j = \mu_T = \frac{\mu}{n}, \quad \omega_{j,n} = \frac{\bar{\omega}_{j,n-1}}{1 + \mu_T}, \\ \xi_{j,n} &= \xi_T = \sqrt{\frac{3\mu_T}{8(1 + \mu_T)}}, \quad \beta_{j,n} = \frac{\omega_{j,n}}{\bar{\omega}_{1,0}}, \\ \omega_T &= \sum_{j=1}^n \frac{\omega_{j,n}}{n}, \quad f_T = \frac{\omega_T}{\bar{\omega}_{1,0}}, \quad \Delta_n = \frac{\omega_{n,n} - \omega_{1,n}}{\omega_T} \end{aligned} \quad (14)$$

where m_s is the mass of the main structure, μ is the mass ratio between MTMD and the structure, $\bar{\omega}_{1,0}$ is the natural frequency of the main structure without TMD, $\omega_{j,n}$ is the natural frequency of the j th TMD in MTMD, $\beta_{j,n}$ is the

frequency ratio of the j th TMD, ω_T is the average frequency of MTMD, f_T is the average frequency ratio of MTMD, and Δ_n is the non-dimensional frequency bandwidth of MTMD. In general, $\bar{\omega}_{j,n-1}$ denotes the j th natural frequency of the main structure carrying $(n-1)$ TMD units. In the proposed approach, MTMD system is designed with identical mass ratio (μ_T), i.e., $m_{1,n} = m_{2,n} = \dots = m_{n,n}$, and the stiffness of each TMD unit is adjusted based on $\omega_{j,n} = \sqrt{k_{j,n} / m_{j,n}}$. However, we assume the damping ratio ξ_T units to be constant for all TMDs.

TABLE I. NATURAL FREQUENCIES (RAD/S) OF A SDOF SYSTEM WITH TMD- n

Mode	$n=0$	$n=1$	$n=2$	$n=3$
1	10.000	9.2261	8.9246	8.7487
2	-	10.6263	9.8769	9.5252
3	-	-	10.9031	10.2106
4	-	-	-	11.0721

III. RESULTS

Some illustrative results are presented and discussed. The effectiveness of MTMDs with $n=5$ and 11 designed by the proposed method is compared with that of the optimum TMD-1. Robustness analysis is also performed to understand how the performance of the proposed MTMD and the classical TMD is affected by the changes in the tuning frequency of TMD units. The main system is assumed to be undamped.

Fig. 2 gives the maximum displacement amplitudes of the undamped main system with TMDs in case of the error in the tuning frequency ratio. The abscissa shows the error in the estimated tuning frequencies of TMDs, and the ordinate is the normalized maximum amplitude (DMF) calculated by (8) for $0.5 \leq \beta \leq 1.5$. It can be clearly seen that the robustness of the proposed MTMD system is better than that of TMD-1, which agrees with the literature. As seen, we still have more smooth curves for MTMD devices, especially for greater mass ratio, despite increasing amount of the frequency detuning. That is, MTMD devices are less sensitive to the frequency detuning compared to the classical TMDs. This figure also indicates that the effectiveness of TMD-1 rapidly decreases for lower mass ratio when the error in tuning frequency increases. Finally, increasing the total number of TMD units increases the robustness. However, as reported in the literature, there is almost no difference between the curves for the maximum amplitudes for $n > 7$ as seen in the figure.

Optimal tuning parameters of TMD-5 and TMD-11 obtained by the proposed design method are shown in Table 2, and compared to those of [18]. As seen, the present method gives slightly greater damping ratios, and slightly smaller frequency ratios than those of [18] for MTMDs considered. The frequency bandwidth obtained from the present study significantly larger than that of [18].

Figs. 3 and 4 show comparison of the maximum displacement amplitudes of the primary structure with optimal TMD-5 and TMD-11 devices in case of the frequency

detuning. Here, undamped and damped ($\xi_s = 2\%$) main systems are considered. In the figures, TMD-5* and TMD-11* represent TMD devices designed by [18]. As can be seen from the figures, the effectiveness of TMD-5* and TMD-11* are better than that of MTMDs designed by the present method when the frequency detuning is rather small. However, the effectiveness of TMD-5* and TMD-11* rapidly decrease as the tuning error increases. When the error greater than $\pm 5\%$, their performance in reducing vibration is worst compared to MTMDs proposed in this study. Figs. 3 and 4 also indicate robustness of the proposed MTMDs are better than that of [18].

Fig. 2. Normalized maximum displacement amplitude vs. tuning error for undamped main system with different TMDs

Fig. 4. Normalized maximum displacement amplitude vs. tuning error for damped main system with different MTMDs

IV. CONCLUSIONS

In this paper, a new approach to design MTMD devices with the basis of Den Hartog's optimal criterion is presented. We demonstrated that significantly increased robustness can be obtained when the proposed MTMD is attached to the main system. We have the following conclusions from the study:

- The numerical studies proved that the proposed MTMD is quite effective for suppressing the maximum amplitudes of the main system under external excitation.
- Although the proposed MTMD has the same control effectiveness as the classical single TMD (TMD-1) tuned by Den Hartog's criteria without frequency detuning, it is more robust to the natural frequency changes in TMD units than TMD-1.
- By using the optimization methods, it is extremely difficult to get the optimum parameters of MTMD system theoretically. Thus, the tuned frequency ratio and the damping ratio of TMD units can easily be obtained with through the explicit formulas derived in this study.
- It is interesting to note that the maximum displacement amplitudes of the proposed MTMD is almost

insensitive to $\pm 10\%$ changes in the tuning frequency of TMD units with higher mass ratio.

Abstract—This study presents free vibration of cantilever beams with multiple cracks. The problem is solved analytically by the transfer matrix method (TMM), and is validated experimentally by the operational modal analysis (OMA). Six damage scenarios are considered to study crack effect on the natural frequencies and corresponding mode shapes. Graphs and tables for numerical results are given and discussed. Results show that crack occurrence in a beam significantly changes its dynamic behavior.

Keywords—Crack; Beam; Free vibration; Transfer matrix method; Experimental model

I. INTRODUCTION

Engineering structures are exposed to different types of environmental loads such as earthquakes, wind and traffic loads etc. Over time, stresses and strains due to these loadings lead to reduce in lifetime of the structure, and may cause damages (cracks), which is a serious threat to performance of structure. Early detection of any structural damage is important to prevent structural failures that causes human casualties and financial costs. Thus, an accurate and comprehensive study on structures including cracks are necessary.

Beams are structural elements in which cracks are commonly observed. Therefore, they have been frequently studied by researchers with through different analytical, numerical and experimental techniques. Dimarogonas [1] presented a comprehensive review of various methods in studying structural members with cracks.

Dimarogonas and Paipetis [2] proposed the local flexibility concept to model an open edge crack in a beam, which can be derived from the stress intensity factors in the theory of fracture mechanics. The cracked section in a beam can be replaced by massless rotational springs representing the local flexibility of the crack. Studies on vibrations of cracked beams using the local flexibility concept have generally focused on two main aspects: The first is to estimate the effects of cracks on the eigenparameters of beams as a direct problem, and the second is to detect the location and size of the crack from the measured information as an inverse problem. Direct analysis of beam vibrations in the presence of cracks is, however, required for solution of the inverse problem.

Methods in studying free vibration of beams with cracks are, in general, divided into two main groups: continuous and discrete methods. In continuous methods, the beam is divided into several sub-beams connected by massless springs. Differential equations are, then, solved for each sub-beam individually with considering the boundary and continuity conditions. As a continuous method, the transfer matrix method is an efficient tool for free vibration of cracked beams, and have been widely preferred [3-8]. Viola et al. [9] derived the explicit dynamic stiffness matrix of a cracked axially loaded beam under coupled bending-torsion with considering the effects of the rotatory inertia and the shear deformation. Among discrete methods, the finite element method [10-12] and the discrete element method [13] can be mentioned.

Experimental measurements including ambient and forced vibration tests have also been used to extract the dynamic characteristics of cracked beams during operational conditions as well as to verify their analytical and/or numerical models [14-16]. Experimental measurements can also be used to identify cracks in a beam in inverse problems.

As can be seen in the literature summarized above, there are many studies on cracked beam vibrations using different analytical/numerical and experimental methods. However, the studies on extracting dynamic characteristics of cracked beams by operational modal analysis (OMA), and validating the experimental results with analytical solution are limited. This study presents free vibration analysis of cantilever beams with multiple cracks. The problem is solved analytically by the transfer matrix method (TMM), and is validated experimentally by the operational modal analysis (OMA). The cantilever beam is assumed to obey Bernoulli-Euler theory. Six damage scenarios are considered to study crack effect on the natural frequencies and corresponding mode shapes. Comparative graphs and tables for numerical results are given and discussed.

II. THEORETICAL FORMULATION

A. Analytical model

Consider a cantilever beam with N cracks along its length, and has a rectangular cross-section of width b and height h shown in Fig. 1. The beam is assumed to be connected by

massless rotational springs at cracked section as shown in Fig. 2. Equation of motion for each segment of the beam is given by

Fig. 1. A cantilever beam with multiple cracks.

Fig. 2. Cracked section represented by massless rotational spring.

$$EI \frac{\partial^4 Y_i(x, t)}{\partial x^4} + \rho A \frac{\partial^2 Y_i(x, t)}{\partial t^2} = 0 \quad (i = 1, 2, \dots, N+1) \quad (1)$$

where $Y_i(x, t)$ is the deflection function, EI is the flexural rigidity, ρ is the mass density, $A = bh$ is the cross-sectional area of the beam. Introducing

$$\bar{x} = x / L \quad (2)$$

into (1) yields

$$\frac{EI}{L^4} \frac{\partial^4 y_i(\bar{x}, t)}{\partial \bar{x}^4} + \rho A \frac{\partial^2 y_i(\bar{x}, t)}{\partial t^2} = 0 \quad (i = 1, 2, \dots, N+1) \quad (3)$$

where $Y(x, t) \equiv y(\bar{x}, t)$.

Assuming the solution of (3) as

$$y_i(\bar{x}, t) = X_i(\bar{x}) e^{i\omega t} \quad (i = 1, 2, \dots, N+1) \quad (4)$$

where $X_i(\bar{x})$ denotes the modal shape function, and ω is the natural frequency of the beam, and substituting it into (3) gives the following:

$$\frac{d^4 X_i}{d\bar{x}^4} - \beta^4 X_i = 0 \quad (i = 1, 2, \dots, N+1) \quad (5)$$

where

$$\beta^4 = \frac{\rho A L^4}{EI} \omega^2 \quad (6)$$

Solution of (5) is

$$X_i(\bar{x}) = A_i \sin \beta \bar{x} + B_i \cos \beta \bar{x} + C_i \sinh \beta \bar{x} + D_i \cosh \beta \bar{x} \quad (i = 1, 2, \dots, N+1) \quad (7)$$

where A_i , B_i , C_i and D_i are constants to be determined from the boundary and continuity conditions given by

$$y(0, t) = y'(0, t) = -EI y''(1, t) = -EI y'''(1, t) = 0 \quad (8)$$

$$\begin{aligned} y_i(\bar{x}_i, t) &= y_{i+1}(\bar{x}_i, t) \\ y'_i(\bar{x}_i) &= y'_{i+1}(\bar{x}_i) - (h/L) f(d_i) y''_{i+1}(\bar{x}_i) \\ y''_i(\bar{x}_i, t) &= y''_{i+1}(\bar{x}_i, t) \\ y'''_i(\bar{x}_i) &= y'''_{i+1}(\bar{x}_i) \end{aligned} \quad (9)$$

where $f(d_i)$ is a dimensionless function, which is given by single-sided open cracks as

$$f(d_i) = 2[d_i / (1 - d_i)]^2 (5.93 - 19.69 d_i + 37.14 d_i^2 - 35.64 d_i^3 + 13.12 d_i^4) \quad (10)$$

where $d_i = a_i / h$ is dimensionless crack depth.

Substituting (4) into (9), we have the following:

$$\mathbf{P}_i \mathbf{a}_i = \mathbf{Q}_i \mathbf{a}_{i+1} \quad (i = 1, 2, \dots, N) \quad (11)$$

where $\mathbf{a}_i = \{A_i \ B_i \ C_i \ D_i\}^T$ and

$$\mathbf{P}_i = \begin{bmatrix} \sin \beta \bar{x}_i & \cos \beta \bar{x}_i & \sinh \beta \bar{x}_i & \cosh \beta \bar{x}_i \\ \cos \beta \bar{x}_i & -\sin \beta \bar{x}_i & \cosh \beta \bar{x}_i & \sinh \beta \bar{x}_i \\ -\sin \beta \bar{x}_i & -\cos \beta \bar{x}_i & \sinh \beta \bar{x}_i & \cosh \beta \bar{x}_i \\ -\cos \beta \bar{x}_i & \sin \beta \bar{x}_i & \cosh \beta \bar{x}_i & \sinh \beta \bar{x}_i \end{bmatrix} \quad (12)$$

$$\mathbf{Q}_i = \mathbf{P}_i + \mathbf{S}_i \quad (13)$$

where

$$\mathbf{S}_i = \chi \begin{bmatrix} 0 & 0 & 0 & 0 \\ -\sin \beta \bar{x}_i & -\cos \beta \bar{x}_i & \sinh \beta \bar{x}_i & \cosh \beta \bar{x}_i \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad (14)$$

where $\chi = -\beta(h/L)f(a_i)$. From (11), we have

$$\mathbf{a}_{i+1} = \mathbf{Q}_i^{-1} \mathbf{P}_i \mathbf{a}_i \quad (i = 1, 2, \dots, N) \quad (15)$$

Considering (15), the following relation between the constants of $(N+1)$ th and those of first segment can be written:

$$\mathbf{a}_{N+1} = \mathbf{Q}_N^{-1} \mathbf{P}_N \mathbf{Q}_{N-1}^{-1} \mathbf{P}_{N-1} \dots \mathbf{Q}_1^{-1} \mathbf{P}_1 \mathbf{a}_1 = \mathbf{T} \mathbf{a}_1 \quad (16)$$

where \mathbf{T} is the transfer matrix.

Using the first two conditions of (8) into (7) gives $D_1 = -B_1$ and $C_1 = -A_1$. Substituting the latter two of (8) into (7) gives

$$\mathbf{W} \mathbf{a}_{N+1} = \mathbf{0} \quad (17)$$

where

$$\mathbf{W} = \begin{bmatrix} -\sin \beta & -\cos \beta & \sinh \beta & \cosh \beta \\ -\cos \beta & \sin \beta & \cosh \beta & \sinh \beta \end{bmatrix} \quad (18)$$

Substituting (16) into (17) gives

$$\mathbf{Z} \mathbf{a}_1 = \mathbf{0} \quad (19)$$

where $\mathbf{Z} = \mathbf{W} \mathbf{T}$. Re-calling $D_1 = -B_1$ and $C_1 = -A_1$ and rearranging equation (19), we have

$$\begin{bmatrix} Z_{11} - Z_{13} & Z_{12} - Z_{14} \\ Z_{21} - Z_{23} & Z_{22} - Z_{24} \end{bmatrix} \begin{bmatrix} A_1 \\ B_1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \quad (20)$$

Equation (20) has real roots different from zero when the determinant of its coefficient matrix is zero. Thus,

$$\det \begin{bmatrix} Z_{11} - Z_{13} & Z_{12} - Z_{14} \\ Z_{21} - Z_{23} & Z_{22} - Z_{24} \end{bmatrix} = 0 \quad (21)$$

which gives a characteristic equation as $f(m, \bar{x}_i, d_i) = 0$ depending on natural frequencies, crack size and location. Using the roots β_n ($n = 1, 2, \dots$) of the characteristic equation into (6), the natural frequencies of beam can be obtained from

$$\omega_n = \frac{\beta_n^2}{L^2} \sqrt{\frac{EI}{\rho A}} \quad (22)$$

For modal shape functions, constants \mathbf{a}_i for each segment can, then, be obtained from (20) for $i = 1$ and (15) for $i = 2, 3, \dots$

B. Experimental model

Three steel cantilever beams are constructed for laboratory tests. A typical representation of the model is shown in Fig. 3. The beam has uniform rectangular cross-section along its length. In experimental measurements, B&K3560 data acquisition system with 17 channels, B&K8340-type uni-axial accelerometers and uni-axial signal cables are used as test equipment. Six sensitive accelerometers are located on the laboratory model to extract natural frequencies and corresponding mode shapes of the beam shown in Fig. 4.

Measurements are performed during 10 minutes for all cases (damaged and undamaged) considered. Frequency range, FFT analyzers and Multi-buffer are selected to be 0-800Hz, 800 lines and 100 averages, 50 size and 500m update, respectively. The signals from the accelerometers are recorded on the computer with applying FFT process in PULSE [17] software. This transformed data is, then, filtered by the weight functions in OMA [18] software. Modal parameters are obtained by Enhanced Frequency Domain Decomposition (EFDD) method in frequency domain which gives the spectral density functions of the signals in each channel. Natural frequencies and modal damping ratios are, then, determined using the spectral density functions.

Damage-5 vs. Damage-6	1.14	5.63	0.00	5.46	0.00	3.59

III. RESULTS

Comparisons between the calculated and measured values are given. Material properties are $E = 206\text{GPa}$ and $\rho = 7800\text{kg/m}^3$. Free vibration analyses are performed for six damage scenarios in Table 1. Analytical results are obtained through a computer code written in MATLAB environment.

Tables 2-4 show the first six natural frequencies of the cantilever beam for all cases considered. As can be seen, the natural frequencies decrease with increasing the damage severity. This is more notable when the crack depth increases, i.e., between Damage-3 and Damage-4 cases. Results obtained from TMM and OMA slightly differ. This may be from several reasons such that: (a) fixed support condition at left-end cannot be provided exactly in laboratory environment, and (b) the beam cross-section, thus the flexural rigidity, cannot be uniform along the beam length. The modal updating, which is already out of the scope of this study, is therefore required. Fig. 5 shows the spectral density functions obtained from OMA. In there, the peak points which are selected manually show natural frequencies of the beam.

Modal Assurance Criterion (MAC) is used to establish the correlation between the measured and the calculated results, which is defined by

$$\text{MAC}(X_a, X_e) = \frac{|X_a^T X_e|^2}{(X_a^T X_a)(X_e^T X_e)} \quad (23)$$

where X_a and X_e denote analytical and experimental mode shapes. MAC values are greater than 90% means the mode shapes are good correlated [19]. Figs. 6 and 7 show MAC values between analytical and experimental mode shapes for undamaged and Damage-6 cases, respectively. As seen, the correlation between the calculated and measured mode shapes are very good, which verifies the laboratory measurements performed.

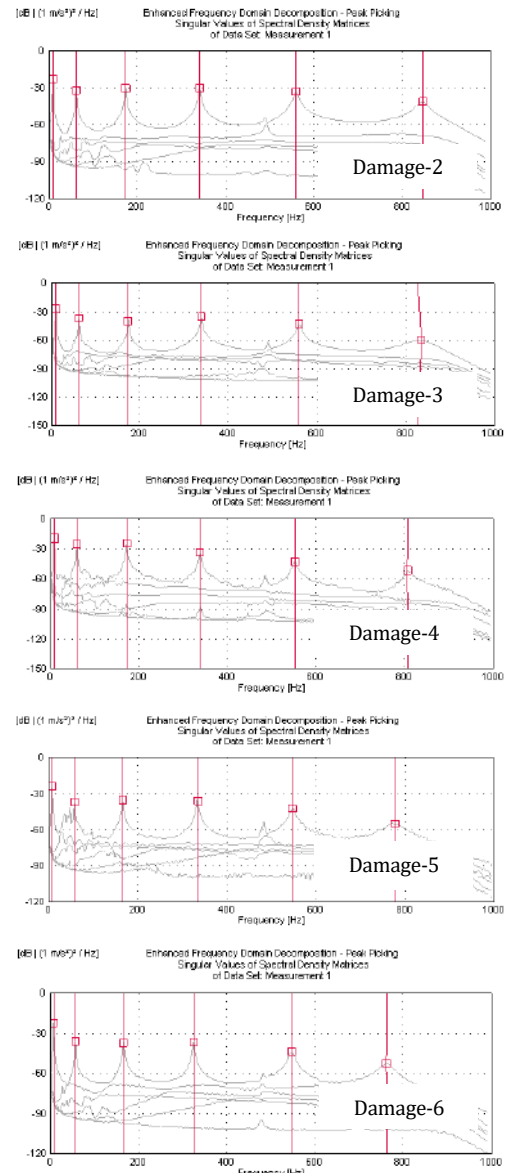

Fig. 5. Singular values of spectral density matrices.

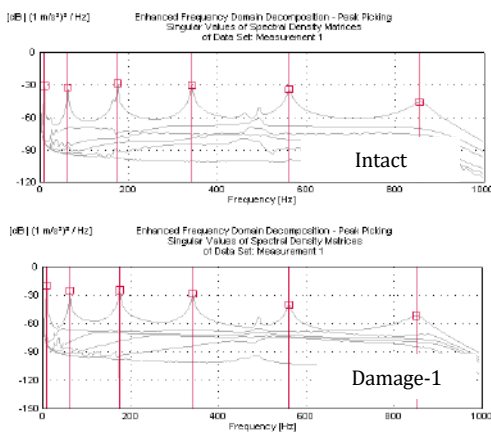

Fig. 6. MAC values between analytical and experimental mode shapes for undamaged case.

Fig. 7. MAC values between analytical and experimental mode shapes for Damage-6 case.

IV. CONCLUSION

Free vibration of cracked cantilever beams is considered by analytical and experimental methods. Results are in good agreement. The followings can be drawn from the study:

- Natural frequencies are strongly affected by crack presence in the beam.
- Crack depth is more effective on the natural frequencies compared to the number of cracks.
- Operational modal analysis is very suitable for experimental analyses of cracked beams. For more accurate results, modal updating should be recommended.
- Transfer matrix method gives the frequency equation to solve the inverse problem for damage detection. However, the solution is required more symbolic computation and thus computing time when the number of cracks increases.

Abstract—A finite element model based on the first-order shear deformation theory for free vibration and buckling of functionally graded beams is presented. The present element has five nodes and ten degrees-of-freedom. Material properties vary continuously through the beam thickness according to the power-law form. Governing equations are derived with employing Lagrange's equations. Natural frequencies and buckling loads are calculated numerically for different end conditions, power-law indices, and span-to-depth ratios. Accuracy of the present element is demonstrated.

Keywords—Functionally graded materials; Finite element method; Free vibration; Buckling; First-order shear deformation theory

I. INTRODUCTION

Functionally graded materials (FGMs) are special composites formed of two or more constituents with a continuous spatial variation. They are usually made of a mixture of ceramics and metals, and can thus resist high-temperature environments while keeping their strength. Therefore, they have been preferred in different applications in aerospace, marine, mechanical, and civil engineering. Increasing demand to FGMs necessitates to well understand the mechanical behavior of such structures.

Compared to functionally graded plates and shells, research on functionally graded beams (FGBs) are relatively less. Bending, buckling and vibration problems of FGBs were solved by different analytical and numerical methods based on various beam theories. Among analytical works, we can mention the followings: Aydogdu and Taskin [1] investigated free vibration of simply-supported FGB based on classical, parabolic and exponential shear deformation theories. Sina et al. [2] developed a novel beam theory different from the classical first-order shear deformation theory to analyze free vibration of FGBs. They assumed the lateral normal stress of the beam is zero. Thai and Vo [3] studied bending and free vibration of FGBs based on various higher-order shear deformation theories. They considered higher-order variation of transverse shear strain through the depth of the beam with

satisfying stress-free boundary conditions. Nguyen et al. [4] developed the first-order shear deformation theory for statics and free vibration of axially loaded FGBs with rectangular cross-section. They derived the improved transverse shear stiffness from the in-plane stress and equilibrium equation, and thus the shear correction factor was obtained analytically. In the foregoing works, researchers used Navier's method to solve governing equations. With the aid of the method of Lagrange multipliers, Şimşek [5] studied free vibration of FGBs considering different higher-order beam theories. A higher-order theory with the assumption of hyperbolic distribution of transverse shear stress was proposed by Nguyen et al. [6] for vibration and buckling analyses of FG sandwich beams. Li and Batra [7] derived analytical relations between the critical buckling load of a FGM Timoshenko beam and that of the corresponding homogenous Bernoulli-Euler beam subject to axial compressive load.

Finite element method (FEM) is one of the mostly used numerical method in analyses of structures. Some authors developed different finite element models based on various beam theories in analyzing FGBs. Chakraborty et al. [8] proposed a beam element based on the first-order shear deformation theory to study the thermoelastic behavior of FGBs. They considered the static, free vibration and wave propagation problems to highlight the difference of FGM beam with pure metal or pure ceramic beams. Based on the classical beam theory, Alshorbagy et al. [9] developed a two-noded, six degrees-of-freedom finite element to investigate free vibration of FGBs. Their element can consider the material graduation in both axial and transversal direction. Kapuria et al. [10] presented a finite element model based on a third-order zig-zag theory for dynamic analysis of layered FGBs. They also gave some experimental results for validation of their proposed theory. Vo et al. [11] developed a finite element model for vibration and buckling of FG sandwich beams based on a refined shear deformation theory. In the formulation, they considered the bending and shear components of transverse displacement as C^1 -continuous whereas the axial displacement is C^0 -continuous. Most recently, Vo et al. [12,13] presented a two-noded C^1 -

continuous beam element with six degrees-of-freedom per node for static, buckling and vibration analyses of FG sandwich beams based on a quasi-3D theory. They considered both shear deformation and thickness stretching effect in the analyses.

This study aims to develop an accurate and simpler finite element model based on the first-order shear deformation theory for vibration and buckling of FGBs. Material properties within the beam vary continuously through the thickness according to the power-law form. The beam element proposed here has five nodes and ten degrees-of-freedom. Governing equations of motion are derived by using Lagrange's equations. Accuracy of the element is validated through comparisons with the results available for buckling loads and natural frequencies of FGBs with different end conditions, power-law indices, and span-to-depth ratios.

II. THEORY AND FORMULATION

A. Material properties

Fig. 1 shows an isotropic, nonhomogeneous elastic beam with length L and rectangular cross-section of $b \times h$. The beam is loaded by an axial compressive force N at its ends. The beam is assumed to be composed of a mixture of two constituents such as ceramic and metal, which are located at its top and bottom surfaces, respectively. Material behavior obeys Hooke's law. The gravity is not considered. Material properties vary continuously through-the-thickness according to the power-law rule given by

$$P(z) = (P_c - P_m) \left(\frac{z}{h} + \frac{1}{2} \right)^k + P_m \quad (1)$$

where k is the non-negative power-law exponent, P_m and P_c are the corresponding material properties of the metal and ceramic constituents, e.g., Young's modulus E , Poisson's ratio ν , and mass density ρ , respectively.

B. Finite element model

Fig. 2 shows a five-noded beam finite element with four equally spaced nodes and a node at the middle. It has ten degrees-of-freedom including three axial, four transversal and three rotational displacements which are measured at neutral axis of the beam. The nodal displacement vector can thus be given as:

$$\mathbf{u} = \{u_1 \ u_2 \ u_3 \ w_1 \ w_2 \ w_3 \ w_4 \ \phi_1 \ \phi_2 \ \phi_3\}^T \quad (2)$$

where u , w and ϕ are the axial and the transverse displacements, and the total bending rotation of the cross-sections at any point on the neutral axis, respectively. Note that ϕ is assumed to be geometrically unrelated to the slope $\partial w / \partial x$ to account for the shear deformation.

According to the first-order shear deformation theory, the displacement field can be given by

Fig. 1. Geometry and coordinate system of a functionally graded beam

Fig. 2. Ten degrees-of-freedom beam element

$$\begin{aligned} U(x, z, t) &= u(x, t) - z\phi(x, t), \\ W(x, z, t) &= w(x, t) \end{aligned} \quad (3)$$

where t denotes time. The strain-displacement relations are given by

$$\begin{aligned} \varepsilon_{xx} &= \frac{\partial U}{\partial x} = \frac{\partial u}{\partial x} - z \frac{\partial \phi}{\partial x} = u_{,x} - z\phi_{,x}, \\ \gamma_{xz} &= \frac{\partial U}{\partial z} + \frac{\partial W}{\partial x} = \frac{\partial w}{\partial x} - \phi = w_{,x} - \phi \end{aligned} \quad (4)$$

where ε_{xx} and γ_{xz} are the normal and shear strains, respectively. $(\cdot)_{,x}$ denotes the derivative with respect to x . Since the material behavior obeys Hooke's law, the constitutive relations can be written as

$$\sigma_{xx} = E(z)\varepsilon_{xx}, \quad \tau_{xz} = KG(z)\gamma_{xz} \quad (5)$$

where σ_{xx} and τ_{xz} are the normal and shear stresses, respectively. K is the shear correction factor, $E(z)$ is the Young modulus, and $G(z) = E(z) / [2(1 + \nu(z))]$ is the shear modulus.

The strain energy of the beam can be given by

$$U = \frac{1}{2} \int_0^L \int_A (\sigma_{xx}\varepsilon_{xx} + \tau_{xz}\gamma_{xz}) dA dx \quad (6)$$

where A is the cross-sectional area of the beam. Substituting (4) and (5) into (6) yields

$$U = \frac{1}{2} \int_0^L \{ A_0 (u_{,x})^2 - 2A_1 u_{,x} \phi_{,x} + A_2 (\phi_{,x})^2 + B_0 [(w_{,x})^2 - 2w_{,x} \phi + (\phi)^2] \} dx \quad (7)$$

where the stiffness coefficients are defined as

$$[A_0, A_1, A_2] = \int_A E(z) [1, z, z^2] dA, \quad B_0 = \int_A KG(z) dA \quad (8)$$

The work done by the axial compressive force N can be expressed as

$$V = \frac{1}{2} \int_0^L N (w_{,x})^2 dx \quad (9)$$

The kinetic energy is obtained by

$$T = \frac{1}{2} \int_0^L \int_A \rho(z) (\dot{U}^2 + \dot{W}^2) dA dx \quad (10)$$

where dot denotes the derivative with respect to time. Taking the derivative with respect to time in (3), and substituting the result into (10) gives

$$T = \frac{1}{2} \int_0^L [I_0 (\dot{u})^2 - 2I_1 \dot{u} \dot{\phi} + I_2 (\dot{\phi})^2 + I_0 (\dot{w})^2] dx \quad (11)$$

where the inertia coefficients are

$$[I_0, I_1, I_2] = \int_A \rho(z) [1, z, z^2] dA \quad (12)$$

Assume the solutions to $u(x, t)$, $w(x, t)$ and $\phi(x, t)$ as

$$u(x, t) = \sum_{i=1}^3 \varphi_i(x) u_i(t), \quad w(x, t) = \sum_{i=1}^4 \psi_i(x) w_i(t), \quad \phi(x, t) = \sum_{i=1}^3 \theta_i(x) \phi_i(t) \quad (13)$$

where $\varphi_i(x)$, $\psi_i(x)$ and $\theta_i(x)$ are the shape functions, and $u_i(t)$, $w_i(t)$ and $\phi_i(t)$ are the generalized nodal displacements. Since the axial displacement of a point not on the neutral axis is a linear function of both u and ϕ , the degree of polynomials for $\varphi_i(x)$ and $\theta_i(x)$ must be the same order. In addition, since the shear strain is a linear function of both the rotation $\phi_i(t)$ and the slope $\partial w / \partial x$, the degree of

polynomial for $\psi_i(x)$ must be one order higher than that for $\varphi_i(x)$ and $\theta_i(x)$ to ensure compatibility. A cubic polynomial for $\psi_i(x)$ and quadratic polynomials for $\varphi_i(x)$ and $\theta_i(x)$ are selected for consistency, which are obtained by the Lagrange interpolation formula (see Appendix A).

The governing equations of motion can be obtained by Lagrange's equations. Letting

$$L = T - (U + V) \quad (14)$$

which is the Langragian functional, Lagrange's equations are defined by

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}_i} \right) - \frac{\partial L}{\partial q_i} = 0 \quad (15)$$

in which q_i denote the generalized coordinates corresponding to unknowns u_i , w_i and ϕ_i . Substituting (7), (9) and (11) into (14) with considering (13) leads to

$$\mathbf{m} \ddot{\mathbf{u}} + (\mathbf{k} - N\mathbf{g}) \mathbf{u} = \mathbf{0} \quad (16)$$

where the element mass (\mathbf{m}), stiffness (\mathbf{k}), and geometric stiffness (\mathbf{g}) matrices are defined as

$$\mathbf{m} = \begin{bmatrix} \mathbf{m}^{11} & \mathbf{0} & \mathbf{m}^{13} \\ \mathbf{0} & \mathbf{m}^{22} & \mathbf{0} \\ \mathbf{m}^{13} & \mathbf{0} & \mathbf{m}^{33} \end{bmatrix}, \quad \mathbf{k} = \begin{bmatrix} \mathbf{k}^{11} & \mathbf{0} & \mathbf{k}^{13} \\ \mathbf{0} & \mathbf{k}^{22} & \mathbf{k}^{23} \\ \mathbf{k}^{13} & \mathbf{k}^{23T} & \mathbf{k}^{33} \end{bmatrix}, \quad (17)$$

$$\mathbf{g} = \begin{bmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{g}^{22} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{bmatrix}$$

C. Free vibration and buckling problem

For the beam with length of L , matrix equation of motion can be written as

$$\mathbf{M} \ddot{\mathbf{U}} + (\mathbf{K} - N\mathbf{G}) \mathbf{U} = \mathbf{0} \quad (18)$$

where \mathbf{M} , \mathbf{K} and \mathbf{G} are the global mass, stiffness and geometric stiffness matrices, respectively. \mathbf{U} is the vector of unknowns. For free vibration of the beam without axial loading, ignoring \mathbf{G} matrix and assuming $\mathbf{U} = \mathbf{U}_0 e^{i\omega t}$ in (18), we have the following eigen-value problem:

$$(\mathbf{K} - \omega^2 \mathbf{M}) \mathbf{U}_0 = \mathbf{0} \quad (19)$$

where ω denote the natural frequencies of the beam. For buckling analysis, ignoring \mathbf{M} matrix and assuming $\mathbf{U} = \mathbf{U}_0 e^{\lambda x}$, the stability equation becomes

$$(\mathbf{K} - \lambda \mathbf{G})\mathbf{U}_0 = \mathbf{0} \quad (20)$$

where $\lambda = N_{cr}$ are the buckling loads. The natural frequencies and buckling loads of the beam can be obtained by non-trivial solutions of (19) and (20).

III. RESULTS AND DISCUSSION

Some numerical examples are given and discussed for validation of the present element. A FG beam composed of aluminum (Al) as metal and alumina (Al_2O_3) as ceramic is considered for which $E_m = 70\text{GPa}$, $\rho_m = 2702\text{kg/m}^3$, $\nu_m = 0.3$, $E_c = 380\text{GPa}$, $\rho_c = 3960\text{kg/m}^3$, and $\nu_c = 0.3$ [5]. Boundary conditions for the beam are assumed to be clamped-clamped (C-C), simply supported (S-S) and clamped-free (C-F). The shear correction factor is $K = 5/6$ for the first-order shear deformation theory. Natural frequencies and critical buckling loads are given in the following normalized form:

$$\bar{\omega}_n = \frac{\omega_n L^2}{h} \sqrt{\frac{\rho_m}{E_m}}, \quad \bar{N}_{cr} = N_{cr} \frac{12L^2}{E_m h^3} \quad (21)$$

Fig. 3. Convergence of the present element for FGBs with different boundary conditions ($L/h = 5$, $k = 1$)

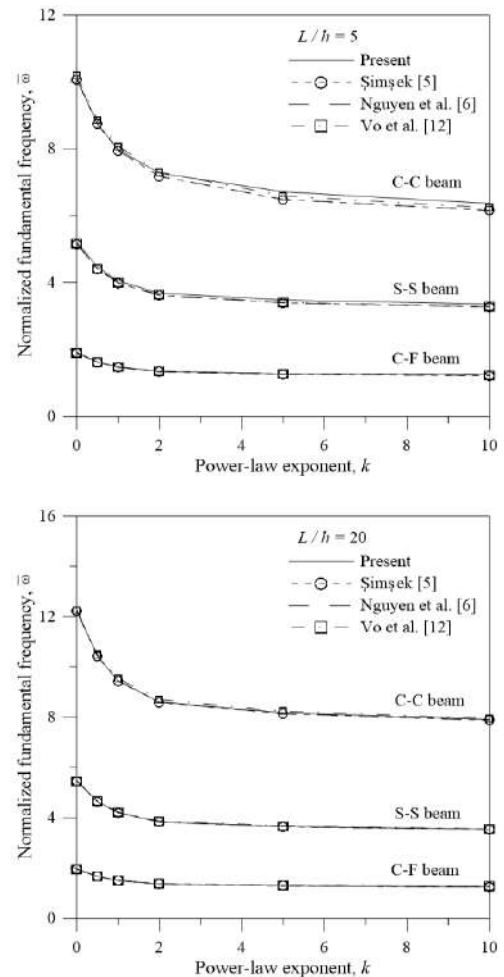

Fig. 4. Variation of the normalized fundamental frequency of FGBs with the power-law exponent

Convergence study is first carried out for the present element. Fig. 3 shows the normalized fundamental frequencies

and critical buckling loads of FGBs with different end conditions for $L/h = 5$ and $k = 1$. As seen in the figure, the present element rapidly converges when the number of elements increase. Twelve elements seem to be enough for the desired accuracy in numerical calculations.

Variation of the normalized fundamental frequencies and critical buckling loads of FGBs with the power-law exponent are given by Figs. 4 and 5, respectively. In these figures, the fundamental frequencies and buckling loads obtained from the present model are compared to the results of different higher-order beam theories such as parabolic shear deformation theory [5], higher-order shear deformation theory with a hyperbolic distribution of shear stress [6], Reddy-Bickford beam theory [11] and a quasi-3D theory including thickness stretching effect [12]. Note that Refs. [5] and [6] gave analytical solution while the others gave finite element solution. As can be seen, the fundamental frequencies and buckling loads computed by the present element agree well with the reference solutions for all beams considered. Although the present element is based on simpler beam theory compared to other theories considered, we have quite satisfactory results for the fundamental frequencies and the buckling loads. This result furtherly validates our element's accuracy in calculation of natural frequencies and critical buckling loads of FGBs. Greater frequencies and buckling loads are obtained for C-C beams than the others. As can also be seen, the power-law exponent has significant effect on both the fundamental frequencies and buckling loads, both of that decrease when the power-law exponent increases.

Fig. 6 gives variation of the normalized fundamental frequencies and critical buckling loads of FGBs with the slenderness (L/h) for $k = 1$. Here, $\nu_m = \nu_c = 0.3$ is considered. Logarithmic (base 10) scale is used for the abscissa, i.e., L/h values, in graphical representation. As seen, the fundamental frequencies and the buckling loads increase with increasing the slenderness. This result agrees with the literature. C-C beams seem more sensitive to change in the slenderness compared to the others.

Fig. 5. Variation of the normalized buckling load of FGBs with the power-law exponent

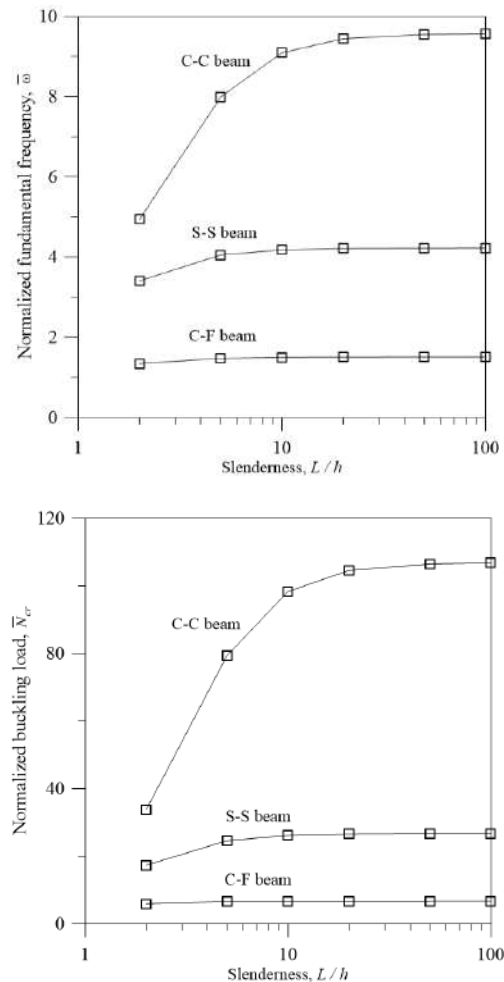

Fig. 6. Variation of the normalized fundamental frequency and critical buckling load of FGBs with the power-law exponent ($k = 1$)

IV. CONCLUSION

A five-noded, ten degrees-of-freedom finite element based on the first-order shear deformation theory is presented for free vibration and buckling analyses of FGBs. Element matrices are derived with the aid of Lagrange's equations. Some numerical results are given for the aim of verification. According to the results of this study, the present model can accurately predict the natural frequencies and the critical buckling loads of FGBs with different end conditions. Accuracy and performance of the present model in computation is well enough.

Abstract—In this study, frictionless contact problem for a functionally graded (FG) layer under gravity is considered. The top of the FG layer is subjected to normal tractions over a finite segment and rested on a rigid foundation. The graded layer is modeled as a non-homogenous medium with a constant Poisson's ratio and exponentially varying shear modules and density. The problem is considered for two cases namely continuous and discontinuous contact. For continuous contact, the problem is solved analytically using plane elasticity and integral transform techniques. The critical load that causes first separation and contact pressures are investigated for various material properties and loadings. The problem is reduced to a singular integral equation using plane elasticity and integral transform techniques in case of discontinuous contact. Obtained singular integral equation is solved numerically using Gauss-Jacobi integration formulation and an iterative scheme is employed to obtain the correct separation distance. The separation distance and contact pressures between the FG layer and the foundation are analyzed for various material properties and loading. The results are shown in tables and figures. It is seen that decreasing stiffness and density at the top of the layer results in an increment both critical load in case of continuous contact and separation distance in case of discontinuous contact.

Keywords—Continuous contact; discontinuous contact; functionally graded layer; Gauss-Jacobi

I. INTRODUCTION

Problems, in which body forces neglected the layer bends and the contact area between the layer and the subspace, will diminish to a finite size independent of the magnitude of the applied load. However, particularly in large scale structures and layered media, in practice clearly this may not be the case, that is, in such problems the contact area is expected to depend on the applied load and furthermore away from the loading region the layer will remain in contact with the subspace because of gravity [1].

An examination of the related literature shows that studies involving layers or coatings with body forces have consisted of homogeneous materials [1-3] whereas studies involving FG layers or coating [4-6] have neglected body forces. Therefore, this study aims to solve the continuous and discontinuous contact problem of an FG layer resting on a rigid foundation by taking the body force the body force of the FG layer into account. Further, the calculations are made under the assumption that the FG layer is isotropic and the shear modulus and mass density exponentially vary along the direction of the layer's thickness.

II. FORMULATION OF THE PROBLEM

As shown in Fig. 1, a symmetric plane strain problem that consists of an infinitely long functionally graded (FG) layer of thickness h resting on a rigid foundation is considered. Poisson's ratio is taken as constant, the shear modulus and the density depend on the y -coordinate only as follows:

$$\mu(y) = \mu_0 \exp(\beta y), \quad \rho(y) = \rho_0 \exp(\alpha y), \quad 0 \leq y \leq h, \quad (1a,b)$$

where μ_0 and ρ_0 are the shear modules and the density of the graded layer at $y=0$, β and α are the non-homogeneity parameter controlling the variation of the shear modules and the density in the graded layer, respectively.

The top of the layer is subjected to a distributed load $q(x)$ over the segment $|x| \leq a$. It is assumed that the contact surfaces are frictionless and is to be the plane of symmetry with respect to external loads as well as geometry, for simplicity. Clearly, it is sufficient to consider one half (i.e. $x \geq 0$) of the medium only.

B. Discontinuous Contact

a separation
ation in the
id assuming
 $x < b$, the

Fig. 1. Geometry and loading of the contact problem

A. Continuous Contact

If the load is sufficiently small, then the contact between the FG layer and the rigid foundation becomes continuous and the boundary conditions can be as follows.

$$\sigma_y(x, h) = q(x)H(a - |x|), \quad \tau_{xy}(x, h) = 0, \quad (2a, b)$$

$$v(x, 0) = 0, \quad \tau_{xy}(x, 0) = 0, \quad 0 \leq x < \infty \quad (2c, d)$$

The problem is solved analytically using plane elasticity and integral transform techniques and following equations can be obtained.

$$\frac{1}{\lambda_{cr}} = \frac{\alpha h}{\exp(\alpha h) - 1} \frac{2 \exp(-\beta h)}{\pi(a/h)} * \int_0^\infty \frac{1}{\xi \Delta F} \sum_1^4 [F_{j1} S_1 \exp(n_j y)] \sin \xi a \cos \xi x d\xi \quad (3)$$

where, S_1 is a known function, F_{j1} ($j = 1, \dots, 4$) are obtained functions applying boundary conditions, λ_{cr} is the critical load that causes to first separation and defined as:

$$\lambda_{cr} = \frac{P_{cr}}{\rho_0 g h^2} \quad (4)$$

in which, P_{cr} is the critical resultant force of the distributed load that causes to first separation, g is gravitational acceleration, and h is the height of the layer. The separation of the FG layer occurs at $x = 0$ symmetry axis and the critical load, λ_{cr} , that cause to first separation can be found equating Eq. (4) to zero at $y = 0$.

$$\sigma_y(x, h) = q(x)H(a - |x|), \quad \tau_{xy}(x, h) = 0, \quad (5a, b)$$

$$\frac{\partial v(x, 0)}{\partial x} = f(x), \quad \tau_{xy}(x, 0) = 0, \quad 0 \leq x < \infty, \quad (5c, d)$$

$$\sigma_y(x, 0) = 0 \quad -b < x < b \quad (5e)$$

in which, v is the vertical displacement and $f(x)$ is the derivative of v with respect to x . Single-valuedness for vertical displacement requires that satisfies the following condition.

$$\int_{-b}^b f(x) dx = 0 \quad (6)$$

The problem is reduced to a singular integral equation using plane elasticity and integral transform techniques given as follows.

$$\frac{1}{\pi} \int_{-1}^1 \phi(s) \left[\frac{1}{t-x} + \frac{b}{h} k_1 \right] ds + \frac{1}{a/h \exp(\beta h)} \frac{\lambda}{\pi} k_2 - \frac{\exp(\alpha h) - 1}{\alpha h} = 0 \quad (7)$$

III. NUMERICAL SOLUTION OF THE PROBLEM

Using following dimensionless quantities, the numerical solution of the continuous and discontinuous contact problem can be simplified.

$$t = sb, \quad dt = bds, \quad x = rb, \quad (8a-c)$$

$$w = \xi h, \quad dw = h d\xi, \quad (8d,e)$$

$$\phi(s) = \frac{4\mu_0}{(\kappa+1)} f(t) \quad (8f)$$

Expressions for critical load factor (3), singular integral equation (7) and single-valuedness condition (6) become:

$$\frac{1}{\lambda_{cr}} = \frac{\alpha h}{\exp(\alpha h) - 1} \frac{2 \exp(-\beta h)}{\pi(a/h)} *$$

$$\int_0^\infty \frac{1}{w \Delta F} \sum_1^4 [F_{j1} S_1 \exp(n_j y)] \sin\left(w \frac{a}{h}\right) \cos\left(w \frac{x}{d}\right) dw \quad (9)$$

$$\frac{1}{\pi} \int_{-1}^1 \phi(s) \left[\frac{1}{t-x} + \frac{b}{h} k_1 \right] ds + \frac{1}{a/h \exp(\beta h)} \frac{\lambda}{\pi} k_2 - \frac{\exp(\alpha h) - 1}{\alpha h} = 0 \quad (10)$$

$$\frac{b}{h} \int_{-1}^1 \phi(s) ds = 0 \quad (11)$$

Since $f(t)$ or $\phi(s)$ is an odd function, i.e. $f(t) = -f(t)$, (11) is automatically satisfied. In addition, one may notice that because of the smooth contact at the point $s = -1$ and $s = 1$, the function $\phi(s)$ equals zero at the both ends. Hence, the index of the integral equation is -1 and the solution may be sought as described by Erdogan and Gupta [7] using appropriate Gauss-Jacobi integration formulas.

IV. RESULTS

The height of the graded layer is taken as 1 whereas the Poison's ratio of the graded layer is taken as 0,25. Note that all quantities are normalized.

As it is seen from Eq. (1a), the top of the layer becomes stiffer if non-homogeneity parameter β increases or vice versa. Similarly, it can be observed from Eq. (1b), the top of the layer becomes heavier if non-homogeneity parameter α increases. In addition, the layer can be assumed as homogenous for non-homogeneity parameters $\beta = 0.001$ and $\alpha = 0.001$.

Table 1 shows the comparison of λ_{cr} in case of continuous contact and b/h in case of discontinuous contact between the values reported in [1] and obtained in this study for homogenous layer, i.e. $\beta = 0.001$ and $\alpha = 0.001$. It can be

seen that values of b/h and λ_{cr} in this study are approximately the same value given by Civelek and Erdogan [1].

TABLE 1. THE COMPARISON OF λ_{cr} IN CASE OF CONTINUOUS CONTACT AND b/h IN CASE OF DISCONTINUOUS CASE ($a/h = 0.01$).

	λ_{cr}	b/h		
		$\lambda = 1.2$	$\lambda = 2.0$	$\lambda = 4.0$
Civ.and Erd. [1]	1.088	0.28	0.96	2.35
This study	1.088625	0.287155	0.970928	2.387936

Table 2 shows the variation of critical load factor λ_{cr} for various non-homogeneity parameters β and α . It is seen from this table that λ_{cr} increases for increasing α if others are fixed β . Similarly, increasing β results in an increase at load factor λ_{cr} .

TABLE 2. THE COMPARISON OF λ_{cr} IN CASE OF CONTINUOUS CONTACT AND b/h IN CASE OF DISCONTINUOUS CASE ($a/h = 0.01$).

	$\alpha = -1.0$	$\alpha = -0.5$	$\alpha = 0.001$	$\alpha = 1.00$
$\beta = -1.0$	0.660946	0.822824	1.046125	1.796639
$\beta = -0.5$	0.672888	0.837691	1.065026	1.829100
$\beta = 0.001$	0.687798	0.856253	1.088625	1.869630
$\beta = 0.5$	0.705887	0.878772	1.117255	1.918800
$\beta = 1.0$	0.727571	0.905767	1.151576	1.977743

The effect of load factor λ and non-homogeneity parameter α on contact pressure in case of continuous contact are shown in Figs. 2 and 3, respectively. It can be seen from these figures that the lowest pressure occurs on the symmetry axis and pressure becomes zero for critical load factor. In addition, the effect of the loading decreases moving away from the symmetry axis and goes to a definite value that corresponds to the weight of the layer and changes with mass density, i.e. ρ_0 and α .

Fig. 2. The effect of λ on contact pressure in case of continuous contact ($a/h = 0.01$, $\kappa = 2.0$)

Fig. 3. The effect of α on contact pressure for $\lambda = \lambda_{cr}$ in case of continuous contact ($a/h = 0.01$, $\kappa = 2.0$)

Table 5 shows the variation of half contact distance b/h between the FG layer and the rigid foundation for various non-homogeneity parameters β and α in case of discontinuous contact for a constant load factor, λ . It can be seen from the table, b/h decreases with increasing β for a fixed value of α . Similarly, increasing α results in a reduction of half separation distance.

TABLE 3. THE VARIATION OF b/h FOR THE VARIOUS NON-HOMOGENEITY PARAMETER β AND α IN CASE OF DISCONTINUOUS CONTACT ($a/h = 0.01$, $\lambda = 4$).

	$\alpha = -1.0$	$\alpha = -0.5$	$\alpha = 0.001$	$\alpha = 1.0$
$\beta = -1.0$	4.751669	3.308814	2.436338	1.208481
$\beta = -0.5$	4.238259	3.226682	2.406783	1.195486
$\beta = 0.001$	4.115861	3.186628	2.387936	1.182186
$\beta = 0.5$	4.042882	3.156730	2.371358	1.167690
$\beta = 1.0$	3.985572	3.129293	2.354350	1.151203

The effect of load factor λ and α on contact pressure in case of discontinuous contact are shown in Figs. 4 and 5, respectively. Similar to continuous contact case, the effect of the loading decreases moving away from the symmetry axis and goes to a definite value that shows the weight of the layer and changes with mass density, i.e. ρ_0 and α . It can be seen from these figures that the biggest pressure occurs near the end of the separation. Moreover, they increase for increasing α and λ .

Fig. 4. The effect of λ on contact pressures in case of discontinuous contact ($a/h = 0.01$, $\kappa = 2.0$)

Fig. 5. The effect of α on contact pressure in case of discontinuous contact ($a/h = 0.01$, $\kappa = 2.0$)

V. CONCLUSIONS

In this paper, the continuous and discontinuous contact problem of FG layer resting on a rigid foundation is considered. The top of the FG layer is subjected to normal tractions over a finite segment. The calculations are made under the assumption that the FG layer is isotropic and the shear modulus and mass density exponentially vary along the direction of the layer's thickness.

For continuous contact, the problem is solved analytically using plane elasticity and integral transform techniques. The critical load that causes first separation and contact pressures are investigated for various material properties. It is seen that the critical load increased with increasing non-homogeneity parameter α . In addition, the lowest pressure occurs on the symmetry axis.

For discontinuous contact, the problem is reduced to a singular integral equation using plane elasticity and integral transform techniques. Obtained singular integral equation is solved numerically using Gauss-Jacobi integration formulation. The effect of the non-homogeneity parameters α and loading on the separation distance b/h and on the contact pressure are investigated using a parametric study. It is seen that, the separation distance decreases with increasing non-homogeneity parameter α . In addition, the biggest pressure occurs near the end of the separation and increase for increasing α and λ .

It was also seen that, the effect of the loading decreases moving away from the symmetry axis. The contact pressure goes to a definite value that corresponds to the weight of the layer and changes with mass density, *i.e.* ρ_0 and α .

Abstract—Optimum design of plane steel frame are studied including corrosion effect on steel cross-sections by using harmony search algorithm. The stress constraints according to AISC-LRFD specifications (American Institute of Steel Construction- Load and Resistance Factor Design), geometric size (column-column and column-beam) constraints, top displacement and inter story drift constraints are applied to the steel frame optimization. Optimum sections are carried out from a profile list including 128 W profiles taken from AISC. A program was developed in MATLAB programming to interact with SAP2000-OAPI (Open Application Programming Interface). Harmony search algorithm method is selected in the design optimization. Optimum designs of a five-story frame carried out for two different cases with/without corrosion effect in industrial site. The results show that corrosion effect plays an important role in the minimum weight of optimum designs.

Keywords—Optimum design, harmony search algorithm, corrosion effect, plane steel frame

I. INTRODUCTION

Minimum weight design of steel frames according to required specifications is very significant subject for structural engineering. In this study, optimum design of plane steel frames are researched for two different cases namely with and without corrosion effect on steel cross sections in industrial site. Stochastic algorithm methods such as genetic algorithm, harmony search algorithm, particle swarm optimization, ant colony algorithm, artificial bee algorithm, bat inspired algorithm, teaching learning optimization methods exist in literature. In this study a basic stochastic technique, Harmony Search Algorithm, is selected for optimum solutions. This

algorithm mimics musical harmony processes. Analyses in the method are conducted by harmony matrix (HM). Values in harmony matrix are updated by harmony memory consideration rate (HMCR) and pitch adjustment ratio (PAR). This algorithm method has been widely studied by many researchers in recent years. A basic study of a new structural optimization based on harmony search algorithm was carried out in 2004 [1]. Optimum design of geometrically non-linear steel frames with semi-rigid connections using a harmony search algorithm was studied in 2009 [2]. Optimum design of steel sway frames to BS5950 using harmony search algorithm was researched in 2009 [3]. Harmony search algorithm was used for minimum cost design of steel frames with semi-rigid connections and column bases in 2010[4]. Optimization of trusses under uncertainties with harmony search was carried out in 2011 [5]. Optimum design of geometrically nonlinear steel frames with semi-rigid connections using improved harmony search method was studied in 2011 [6]. Optimum design of steel space frames under earthquake effect using harmony search was researched in 2016 [7]. Harmony search method was used for optimum design of steel space frames including soil-structure interaction in 2016 [8]. This method was also used in a comparative study on optimum design of multi-element truss structures in 2016 [9].

This study presents optimum designs of a five story plane steel frame in industrial site. Optimum designs of the steel frame are performed for two different cases with and without corrosion effect. A program was developed in MATLAB programming to interact with SAP2000-OAPI to get optimum solutions for both cases. The results obtained from analyses

show that corrosion effect in industrial site increases minimum structural weight and plays very crucial role in optimum designs.

II. THE FORMULATION OF OPTIMUM DESIGN

The discrete optimum design for minimum weight of plane steel frame is determined as below,

$$\min W = \sum_{k=1}^{ng} A_k \sum_{i=1}^{nk} \rho_i L_i \quad (1)$$

where W is the weight of the frame, A_k is cross-sectional area of group k , ρ_i and L_i are density and length of member i , ng is total number of groups, nk is the total number of members in group k .

The objective function $\varphi(x)$ is calculated as below,

$$\varphi(x) = W(x) \left(1 + P \sum_{i=1}^m c_i \right) \quad (2)$$

where P is a penalty constant, $\varphi(x)$ is objective function, c_i is constraint violations. The constraint violations are calculated as follows;

$$g_i(x) > 0 \rightarrow c_i = g_i(x) \quad (3)$$

$$g_i(x) \leq 0 \rightarrow c_i = 0 \quad (4)$$

The stress constraints for the frame are incorporated as specified in AISC-LRFD [12], geometric size (column-column and column-beam) maximum lateral displacement and inter-storey drift constraints are calculated as below,

$$\begin{aligned} \text{for } \frac{P_u}{\phi P_n} \geq 0.2 \\ g_{il}(x) = \left(\frac{P_u}{\phi P_n} \right)_{il} + \frac{8}{9} \left(\frac{M_{ux}}{\phi_b M_{nx}} \right)_{il} - 1.0 \leq 0 \quad \begin{matrix} i = 1, \dots, nm \\ l = 1, \dots, nl \end{matrix} \end{aligned} \quad (5)$$

$$\begin{aligned} \text{for } \frac{P_u}{\phi P_n} < 0.2 \\ g_{il}(x) = \left(\frac{P_u}{2\phi P_n} \right)_{il} + \left(\frac{M_{ux}}{\phi_b M_{nx}} \right)_{il} - 1.0 \leq 0 \quad \begin{matrix} i = 1, \dots, nm \\ l = 1, \dots, nl \end{matrix} \end{aligned} \quad (6)$$

where nm is the total number of members, nl is the total number of loading conditions, P_u is the required axial strength, P_n is the nominal strength, M_{ux} is the required flexural strength about major axis, M_{uy} is the required flexural strength about minor axis, M_{nx} is the nominal flexural strength about major axis, M_{ny} is the nominal flexural strength about minor axis, ϕ

is resistance factor for compression (0.85) and for tension (0.90), ϕ_b is resistance factor for flexure (0.90).

Column-to-column geometric constraints are determined as below,

$$g_n(x) = \frac{D_{un}}{D_{ln}} - 1 \leq 0 \quad n = 2, \dots, ns \quad (7)$$

where D_{un} is the depth of upper floor column, D_{ln} is the depth of lower floor column.

The beam-to-column geometric constraints are defined as below,

$$g_{bb,i}(x) = \frac{b_{fbk,i}}{b_{fck,i}} - 1 \leq 0 \quad i = 1, \dots, n_{bf} \quad (8)$$

where n_{bf} is number of joints where beams are connected to the flange of column, $b_{fbk,i}$ and $b_{fck,i}$ are flange widths of the beam and column, respectively.

Displacement constraints are calculated as below,

$$g_{jl}(x) = \frac{\delta_{jl}}{\delta_{ju}} - 1 \leq 0 \quad \begin{matrix} j = 1, \dots, m \\ l = 1, \dots, nl \end{matrix} \quad (9)$$

where δ_{jl} is the displacement of j^{th} degree of freedom under load case l , δ_{ju} is the upper bound, m is the number of restricted displacements, nl is the total number of loading cases.

Inter-storey drift constraints are calculated as below,

$$g_{jil}(x) = \frac{\Delta_{jil}}{\Delta_{ju}} - 1 \leq 0 \quad \begin{matrix} j = 1, \dots, ns \\ i = 1, \dots, nsc \\ l = 1, \dots, nl \end{matrix} \quad (10)$$

where Δ_{jil} is the inter-storey drift of i^{th} column in the j^{th} storey under load case l , Δ_{ju} is the limit value, ns is the number of storey, nsc is the number of columns in a storey.

Corrosion tests are available in the literature for a period of two years on structural steel in industrial site [13]. The results of this literature study [13] are used in optimum design of plane steel frame including corrosion effect. Corrosion effects on steel cross section surface are presented in Fig. 1.

Fig. 1. Corrosion effect on a steel profile surface

The well-known bilogarithmic equation for the effect of atmospheric corrosion in an industrial site is as follows,

$$C = At^B \quad (11)$$

where C is the weight loss in terms of thickness (μm), t is the exposure time (months) and A, B are constants [13].

III. HARMONY SEARCH ALGORITHM METHOD

Harmony Search Algorithm, a basic stochastic algorithm method, is developed by some procedures which mimics musical harmony processes. Analyses in optimization are conducted harmony memory matrix (HM) and each row in this matrix represents a structural model. Harmony memory matrix is defined as

$$H = \begin{bmatrix} x_1^1 & x_2^1 & \dots & x_{n-1}^1 & x_n^1 \\ x_1^2 & x_2^2 & \dots & x_{n-1}^2 & x_n^2 \\ \dots & \dots & \dots & \dots & \dots \\ x_1^{HMS-1} & x_2^{HMS-1} & \dots & x_{n-1}^{HMS-1} & x_n^{HMS-1} \\ x_1^{HMS} & x_2^{HMS} & \dots & x_{n-1}^{HMS} & x_n^{HMS} \end{bmatrix} \quad (12)$$

Harmony Memory Size (HMS) in here expresses a specified number of solutions. Harmony memory consideration rate (HMCR) and pitch adjustment ratio (PAR) are two important operators to get a stronger harmony memory matrix for better solutions. They are defined as below,

$$\begin{cases} x_i^{nh} \in \{x_i^1, x_i^2, \dots, x_i^{HMS}\} \text{ with probability of } HMCR \\ x_i^{nh} \in X_{st} \text{ with probability of } (1 - HMCR) \end{cases} \quad (13)$$

$$\begin{cases} \text{Yes, with probability of } PAR \\ \text{No, with probability of } 1 - PAR \end{cases} \quad (14)$$

Detailed information about the process and the steps of harmony search algorithm can be found from the studies of [1-4]. In this study, a computer program is developed in

MATLAB [10] to interact with SAP2000 OAPI [11]. A flowchart of Harmony Search Algorithms is shown in Fig.1.

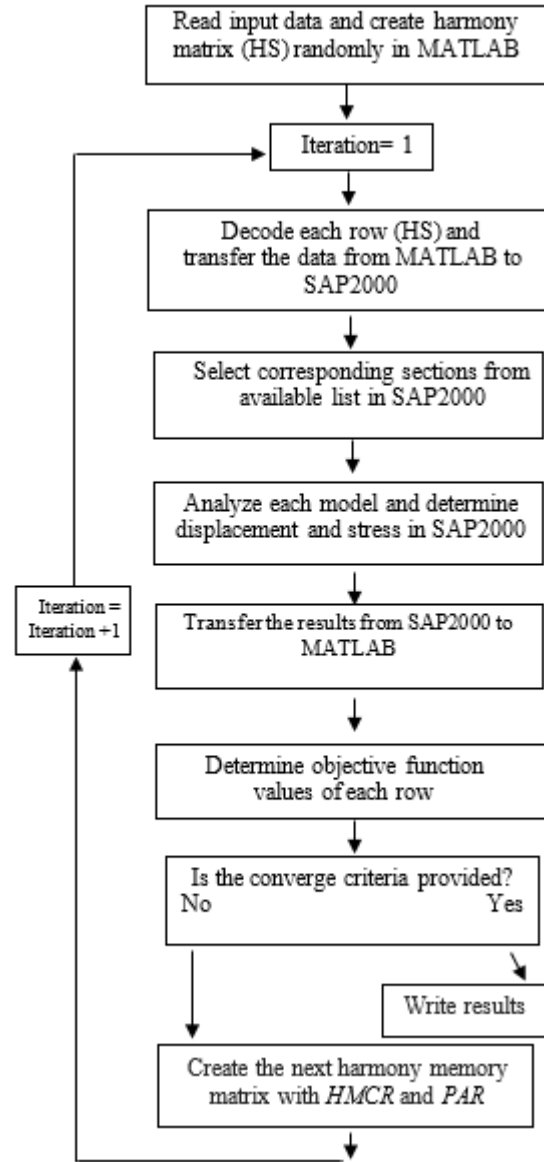

Fig. 2. Flowchart for the optimum design procedure of plane steel frame

IV. DESIGN EXAMPLE: 25-MEMBER PLANE STEEL FRAME

Figure 3 presents a five story steel plane frame structure consisting of 25 elements. All members are collected in 9 groups as given in Table 1. The figure also shows loading information. The top displacement as being the maximum lateral displacement and inter story drifts are restricted 4.375 cm and 0.875 cm (height/400), respectively. Optimum cross sections are selected from a specified list including 128 W

taken from AISC. The material properties are $E=200$ GPa, $f_y=250$ MPa and $\rho=7.85$ ton/m³. Optimum solutions for both cases are also given Table 1. Moreover, their design histories are shown Fig.3.

TABLE 1. Optimum Solutions

Group No	Member No	Case 1 without corrosion effect	Case 2 with corrosion effect

Weight (kN)		56.91	59.14
Top displacement (cm)		3.27	3.41
Max. inter story drift (cm)		0.86	0.86

Fig. 3. 25-member plane steel frame

Fig. 3. The design histories of both solutions

Table 1 shows that the minimum weight of 25-member plane steel frame for the case of without corrosion effect is 56.91 kN. On the other hand, this minimum value for the case with corrosion effect is 59.14 kN. Therefore, it indicates that corrosion effect in industrial site increases the minimum structural weight by about 3.92%. Table 1 also shows that the maximum inter story drift values for both cases are very close to limit value of 0.875 cm. This results expresses that inter story drift constraints play very active role in the optimizations process.

V. CONCLUSIONS

This study presents optimum designs of plane steel frame consisting of 25 members in industrial site for two different cases with and without corrosion effect. The stress constraints according to AISC-LRFD, geometric size (column-column and column-beam), maximum lateral displacement and inter-story drift constraints are considered on the optimum design of plane steel frame. A program is coded in MATLAB programming incorporated with SAP2000-OAPI to carry out optimum solutions. Although, the minimum weight for the case without corrosion effect is 56.91 kN, the weight for the case with corrosion effect becomes 59.14 kN. In other words, the minimum steel weight increases by about 3.92% if necessary precaution against corrosion is not taken on the surface of steel profile. The analysis results also show that inter story drift constraints are very important determinants in the optimum designs.

Evolutionary Optimization of Continuous Structures Under Impact Load

Sedat SAVAS

Firat Univ. Eng. Faculty
Civil Eng. Dept.
Elazig/TURKEY
ssavas@firat.edu.tr

Abstract— In this study, the evolutionary topological design of two and three dimensional structural systems under impact load. Impact effect was performed with a macro program prepared in the ANSYS LS-DYNA package program. Materials used in construction systems were considered homogeneous and von-mises stresses were taken into account. These stresses have been used as constrains. The purpose of the program is to gradually remove elements from a structural element under a certain impact load and to optimize the construction by controlling the extreme maximum stress increments that the element will bring to the structure and making a homogeneous stress distribution.

Keywords— *impact load; optimisation; evolutionary; ls-dyna; shape optimisation*

I. INTRODUCTION

Mankind observed the nature around him and was influenced by him and guided him. Instinctively, energy has been found in behaviors that make economic use and maximize comfort. Finding and using rollers and levers is a testament to the desire to maximize people's mechanical efficiency. Thus, simply developing and using a system is not enough. As time goes by, creating the best and most suitable systems has become the main purpose. In the optimization process, it is tried to get the best results (the lightest, the cheapest, the most efficient, the fastest, etc.) according to the current constraints of a job done.[1,2,3]

II. EVALUATION OF EVOLUTIONAL STRUCTURE OPTIMIZATION (ESO) METHOD

A. ESO method

In recent years, many structural optimization methods have been developed. Analytical and numerical methods are generally used as optimization methods. But the analytical methods are left to numerical methods due to the fact that the structures are becoming ever more complex systems and because of the financial reflection of the increase in accounting time [4,5]. The numerical method can also be called the programming method and this method is a branch of the numerical mathematics field. Generally it is made up of iterative operations.[6]

The topological design of continuous structures is an important part of structural optimization. It is possible to obtain a more economical design with topological optimization and new optimization methods are used for this. These come at the beginning of evolutionary optimization methods[7].

In recent years, many algorithms have been developed for evolutionary optimization. The basic principle of these algorithms is adaptation to external conditions. Evolutionary structural optimization (ESO) has been developed as an example of these methods [8]. With this method, there is an answer to the questions such as how the objects will be shaped or the best possible structural performance of an object. The ESO method has also been shown to be able to solve size, shape and topology optimization problems.

To avoid inefficiency in structural optimization, a full-strength design concept has been developed. At full strain design phase, each component is exposed to a maximum or minimum permissible limit value. When the stresses of all the structural components are about the same, the final structure becomes fully stretched and a fully stressed design is achieved [theoretical approaches]. Equally stressed state in the literature is also called full stress. Often optimization algorithms consist of loops aimed at redesigning to achieve a full-stretch state.

B. Basic Concepts of ESO Method

1. Operating sequence

The ESO method presented in this study uses a finite element analysis package program (ANSYS LS-DYNA) as the calculation technique. At the end of each analysis, the computer determines the FEA results and then applies simple ESO rules to remove the ineffective material.

The ESO method is an application of topology optimization and it is based on a process that involves briefly describing the inefficient material in a more economical way by gradually removing it from the structure [ESO]. The ESO method is conceptually simple and easy to implement when compared with other optimization methods [9,10]. This is why there are no complicated mathematical operations and

equations. It consists of systematically removing ineffective elements and making the system fully stressed.

2. Basic Concepts of ESO Method

In general engineering design analysis, the minimum weight or volume is used as the objective function. Differences can be seen in the constraints. For the purpose of use of the structure, as a limit depending on the environmental conditions and the economic conditions; Stiffness, thickness, frequency etc. can be used. Design variables also vary according to the algorithm or material to be used, but mostly variables such as number of elements, element thickness, and element volume are used [11,12].

In the conventional ESO method, von Mises stresses are used as extraction criterion (i.e., constraints). However, it has been found appropriate to use principal stresses as substitution criterion for von Mises stresses when the system is available in both tension and pressure elements [13]. For this reason, principal stresses have been used as limitations in obtaining optimum structures in our works.

Primarily, each element has principal stresses σ_{11} and σ_{22} . The extraction criterion is applied according to the zones where the pressure or tensile stresses dominate the structure. In areas where pressure stress is dominant, the elements subjected to tensile stress ($\sigma_{22} \leq 0.0$ and $|\sigma_{22}| \gg |\sigma_{11}|$) are removed. In contrast, in areas where tensile stress is effective, pressure stressed elements are removed ($\sigma_{11} \geq 0.0$ and $|\sigma_{11}| \gg |\sigma_{22}|$). We use this element extraction algorithm to create the kernel of the ESO method.

The above operation continues in each cycle until the effect of the multiplication event begins and ends. The time period for this event is divided into certain intervals. In our work, this interval is 50 pieces. These tensile values are compared in each range, and the largest tensile stresses and minimum stresses are determined in the structure. In each range, these stress values are compared and the largest tensile stresses and minimum stresses are determined in the structure.

The algorithm described above can be expressed mathematically. Such an expression is shown in equations (3.5) and (3.6), where pulling or compressive stress is dominant.

$$|\sigma_{11}^e| \leq FF_i \times |\sigma_{11, \max}|, \sigma_{22}^e \leq 0.0 \quad (3.5)$$

Equation (1) is used as the criterion that pressure stress is dominant and tensile stressed elements are to be removed.

$$|\sigma_{22}^e| \leq FF_i \times |\sigma_{22, \max}|, \sigma_{11}^e \geq 0.0 \quad (3.6)$$

In these equations, $|\sigma_{11, \max}|$ and $|\sigma_{22, \max}|$ the absolute maximum stresses of the elements, and FF_i represents the subtraction rate which will result in fewer elements subtracted at each iteration. The steady state, that is to say the end of the iterations, the cycle of the element analysis and the removal of the element are continued until it comes to the condition that no element is removed. But in the present iteration, the evolutionary ratio (EF) becomes active when there are no more elements to be removed, and the EF constant number is added to the subtraction rate FF_i .

$$FF_{i+1} = FF_i + EF, \quad i = 0, 1, 2, 3, \dots \quad (3.7)$$

The new finite element analysis cycles are created with this increased removal rate and the removal process continues until the new steady state is reached.

III. OPTIMIZATION APPLICATIONS WITH ESO METHOD

A. Example of steel sphere drop on Michell beam

As the ESO application, the michell beam example shown in Figure 3.1 which is frequently used in structural optimization problems is used. The structure width L is an anchored joint with height H , fixed on the left. It has been found that the optimum height $H = 2L$ is obtained by calculations made from analytical paths.

In order to obtain such a structure using the evolutionary structure optimization method, the model shown in figure 3.2 is used. Taking into consideration that the model has a predictable final design size, our initial model has been chosen to be a rectangular shape larger than $2L \times L$ dimensions.

The design area in Figure 3.2 is divided into four-node dotted plane stress elements of 50×150 equally dimensioned Beam thickness is chosen as 1mm. Young's modulus $E = 100$ GPa and Poisson's ratio $\nu = 0.3$.

A steel sphere is dropped at a rate of 5 m / sec to the junction of the elements in the beam center. The shapes obtained after the impact are given below.

Fig 3.1 Michell beam

Fig 3.2. Beam geometry at 50. iteration

Fig 3.3 Beam geometry at 150. iteration

B. Example of a 20x20 cube falling under the influence of gravity

In this example, a cube made of concrete was dropped onto a 1.5 m dense steel plate. The gravitational acceleration is 9.81 m/s^2 . Cube element density is 2.5 t/m^3 . As a result of this fall effect, the new geometries connected to the iteration that is happening in the system are given below.

Fig 3.6.a. Cube element geometry at 200. iteration

Fig 3.6.b. Cube element geometry 200. iteration

Fig 3.6.c. Cube element geometry at 200. iteration

Fig 3.6.d. Cube element cross section at 200. iteration

SUMMARY AND CONCLUSION

Evolutionary method optimization of a structure under impact load is performed for the first time in literature reviews. Due to the length of the solution and the theory of evolution, it is disadvantageous to use too many end elements. However, due to the necessity of solution accuracy, the number of elements is not reduced and indirectly the reduction of the solution time is not possible. The system is forced to fully stretch by the Eso method. The figures after the calculation are given in detail in this study. As can be seen from the second sample we gave, when the cube element was forced to fully stressed, there was a more than half reduction in volume. The result of the calculation is the result of the shape, The same impact effect occurs with a smaller volume.

Abstract - This study aims to investigate the transient response of homogeneous, isotropic and elastic stepped circular arches under various in-plane dynamic loads in the Laplace domain. The effect of shear deformation is taken into consideration. The governing equations are first obtained in the time domain. Laplace transform is then applied and the obtained canonical form of the first order ordinary differential equations has been solved by the Complementary Functions Method (CFM) in the transformed domain. The fifth-order Runge–Kutta (RK5) method has been applied for the numerical solution of the obtained differential equations. The solutions obtained are transformed to the time domain by an appropriate inverse numerical Laplace transform method. A computer program is coded in Fortran for the forced vibration of the considered structures. Verification and exactness of the written program is performed by comparing the results of the present methods and results of ANSYS which is a commercial finite element program. It is emerged that present method is highly accurate and efficient compared to conventional step by step integration methods.

Keywords— *Two-Point Boundary Value Problems; Complementary Functions Method (CFM); Inverse Laplace Transforms; Stepped Circular Arches.*

I. INTRODUCTION

Extensive practical applications of arches in many engineering fields have attracted considerable attention of researchers in determining the static and dynamic behavior of those crucial engineering structures. Several investigators

studied the forced vibrations of in-plane loaded circular arches with uniform cross-sections but there are few studies addressed to dynamic response of arches with stepped cross-section.

The static behavior of isotropic elastic in-plane rods is investigated by Haktanır [1] with stiffness matrix method based on the CFM and fourth-order Runge–Kutta numerical method. Bayhan [2] studied the static behavior of planar frames with members of circular axes with the aid of both transfer and stiffness matrix methods. The CFM is used for the bending analysis of circular planar systems, helicoidal stair cases axisymmetric shell structures, and cylindrical vault structures under static loadings by Bozkurt [3]. Yildirim, İnce and Kiral [4] investigated the static response of compound planar frames with members of linear and circular axes by stiffness matrix method. The stiffness matrixes and force vectors of the frame members with circular axes, under planar loads and perpendicular loads to plane, were calculated by transfer matrix method. The dynamic behavior of isotropic, anisotropic, elastic and viscoelastic cylindrical helical rods under time dependent loads is investigated by Çalım [5] in the Laplace domain. The obtained solutions transformed to the time domain by using a proper inverse Laplace transform method. Kırac [6] examined the dynamic behavior of composite straight rods subjected to time dependent loads in the Laplace domain theoretically. The free vibration was considered as a special case of forced vibration. In the formulations, the effect of the rotary inertia, axial and shear deformations were taken into account. The

ordinary differential equations obtained in canonical form in the Laplace domain were solved numerically by the CFM to calculate the dynamic stiffness matrix. Aktan [7] studied the free vibration of in-plane circular beams. The Timoshenko beam theory was used and the effect of the rotary inertia was considered. Çoban [8] investigated the dynamic analysis of curved beams using mixed finite element method with Gâteaux derivative. Akkurt [9] investigated the dynamic behavior of straight and circular rods resting on elastic foundation in the Laplace domain. Karaca [10] studied the static and dynamic analysis of circular Timoshenko rods which are loaded in-plane and out-of-plane. The longitudinal vibrations of elastic bars were investigated using the Gâteaux differential method and the mixed finite element method by Ecer [11]. Manolis and Beskos [12] and Beskos and Narayanan [13] analyzed the dynamic responses of a straight beam. Huang, Teng and Leissa, [14] investigated the dynamic response of circular arches with dynamic stiffness method and the Laplace transform. Huang, Tseng and Lin [15] combines the dynamic stiffness method with the Laplace transformation to obtain the transient responses of an arch with variable curvature while the dynamic stiffness matrix and equivalent nodal force vector for an arch with variable curvature is formulated based on a series solution. Temel, Aslan and Noori [16] investigated the forced vibration of isotropic-elastic planar curved rods in Laplace domain with the CFM. The dynamic and static analysis of in-plane and out of plane loaded curved structural elements is examined by Aslan [17] in Laplace Domain, while RK5 algorithm is used for the solution of differential equations based on the CFM.

Tüfekci and Özdemirci [18] investigated the free in-plane vibration of stepped circular arches. The effects of axial extension, transverse shear deformation and rotatory inertia are included in the governing equations. The solution was obtained exactly by using the initial value method.

When the cross-section of the arch is considered to be stepped, the literature regarding to the forced vibration of circular arches is rare. However, to the best of authors' knowledge the transient analysis of elastic stepped circular arches using the unified approach of Laplace transform and the CFM has not been reported yet. In present research, the forced vibration of in-plane stepped circular arches has been analyzed under various types of dynamic loads by Laplace transform method and the CFM for the first time. The CFM is a numerical solution method which transforms a two point boundary value problem to a system of initial value problems. For the solution of initial value problems RK5 is applied in this research. The application of Laplace Transform, with respect to time, to partial differential equations, converts them to ordinary differential equations in the transformed domain. Thus the numerical solution of partial differential equations in the Laplace domain can be done easily. To transform the obtained solutions in the Laplace domain to the time domain an efficient inverse Laplace transform method has been used. The results of the present method are compared with those solutions obtained by ANSYS, the finite element program which analyses the dynamic response of structures by conventional step by step

integration method. The comparison of the results demonstrate the accuracy and exactness of the present study.

II. GOVERNING EQUATIONS

The time and location depended partial differential equations of in-plane loaded stepped circular arches under dynamic loads are given as follows:

$$\frac{\partial U_t}{\partial \phi} = U_n + r \frac{T_t}{EA(\phi)} \quad (1)$$

$$\frac{\partial U_n}{\partial \phi} = -U_t + r\Omega_b + r \frac{T_n \alpha_n}{GA(\phi)} \quad (2)$$

$$\frac{\partial \Omega_b}{\partial \phi} = r \frac{M_b}{EI_b(\phi)} \quad (3)$$

$$\frac{\partial T_t}{\partial \phi} = r\rho A(\phi) \frac{\partial^2 U_t}{\partial t^2} + T_n - rp_t \quad (4)$$

$$\frac{\partial T_n}{\partial \phi} = r\rho A(\phi) \frac{\partial^2 U_n}{\partial t^2} - T_t - rp_n \quad (5)$$

$$\frac{\partial M_b}{\partial \phi} = r\rho I_b(\phi) \frac{\partial^2 \Omega_b}{\partial t^2} - rT_n - rm_b \quad (6)$$

$$A(\phi) = \pi h(\phi)^2 \quad (7)$$

$$I_b(\phi) = \frac{\pi h(\phi)^4}{4} \quad (8)$$

Here, E , ρ , $h(\phi)$, $A(\phi)$, $I_b(\phi)$, α_n and r indicate the modulus of elasticity, mass density, radius of the cross-section, cross-section area, the moment of inertia, shear correction factor and radius of curvature respectively.

The unknown column matrix, $\{Y(\phi, t)\}$, for the forced vibration of in-plane loaded stepped circular arches is given as:

$$\{Y(\phi, t)\} = \{U_t, U_n, \Omega_b, T_t, T_n, M_b\}^T \quad (9)$$

The Laplace transform of a time-dependent function $f(t)$ is the function " $\bar{F}(s)$ ".

$$L[f(t)] = \bar{F}(s) = \int_0^{\infty} f(t) e^{-st} dt \quad (10)$$

where s is the Laplace variable also known as operator variable in the Laplace domain. The Laplace transform of first and second derivatives with respect to time are as follows:

$$L\left[\dot{f}(t)\right] = s\bar{F}(s) - f(0) \quad (11)$$

$$L\left[\ddot{f}(t)\right] = s^2\bar{F}(s) - sf(0) - \dot{f}(0) \quad (12)$$

Applying the Laplace transform to equations (1-6), converts these partial differential equations to variable-coefficient ordinary differential equations. Thereby, the governing ordinary differential equations of the dynamic behavior of in-plane loaded stepped circular arches can be obtained in the Laplace domain as follows:

$$\frac{d\bar{U}_t}{d\phi} = \bar{U}_n + r \frac{\bar{T}_t}{EA(\phi)} \quad (13)$$

$$\frac{d\bar{U}_n}{d\phi} = -\bar{U}_t + r\bar{\Omega}_b + r \frac{\bar{T}_n\alpha_n}{GA(\phi)} \quad (14)$$

$$\frac{d\bar{\Omega}_b}{d\phi} = r \frac{\bar{M}_b}{EI_b(\phi)} \quad (15)$$

$$\frac{d\bar{T}_t}{d\phi} = rs^2\rho A(\phi)\bar{U}_t + \bar{T}_n - r\bar{p}_t \quad (16)$$

$$\frac{d\bar{T}_n}{d\phi} = rs^2\rho A(\phi)\bar{U}_n - \bar{T}_t - r\bar{p}_n \quad (17)$$

$$\frac{d\bar{M}_b}{d\phi} = rs^2\rho I_b(\phi)\bar{\Omega}_b - r\bar{T}_n - r\bar{m}_b \quad (18)$$

Where the terms shown by (\bullet) indicates the Laplace transform of the quantities.

$$\begin{aligned} L\left[\rho A(\phi) \frac{\partial^2 U_t}{\partial t^2}\right] &= \rho A(\phi) \left[s^2 \bar{U}_t - s U_t(\phi, 0) - \frac{\partial U_t(\phi, 0)}{\partial t} \right] \\ L\left[\rho A(\phi) \frac{\partial^2 U_n}{\partial t^2}\right] &= \rho A(\phi) \left[s^2 \bar{U}_n - s U_n(\phi, 0) - \frac{\partial U_n(\phi, 0)}{\partial t} \right] \\ L\left[\rho I_b(\phi) \frac{\partial^2 \Omega_b}{\partial t^2}\right] &= \rho I_b(\phi) \left[s^2 \bar{\Omega}_b - s \Omega_b(\phi, 0) - \frac{\partial \Omega_b(\phi, 0)}{\partial t} \right] \end{aligned} \quad (19)$$

The second and third terms on the right-hand side of the equation (19) are the initial conditions given for $t=0$; in present study those terms are assumed to be zero.

III. COMPLEMENTARY FUNCTIONS METHOD

The matrix notation of the ordinary differential equations (13-18) obtained in the Laplace domain is given below:

$$\{\bar{Y}(\phi, s)\} = \{\bar{U}_t(\phi, s), \bar{U}_n(\phi, s), \bar{\Omega}_b(\phi, s), \bar{T}_t(\phi, s), \bar{T}_n(\phi, s), \bar{M}_b(\phi, s)\}^T \quad (21)$$

$$\frac{d\{\bar{Y}(\phi, s)\}}{d\phi} = [\bar{A}(\phi, s)]\{\bar{Y}(\phi, s)\} + \{\bar{F}(\phi, s)\} \quad (20)$$

Here ϕ is independent variable and s is the Laplace transform parameter. The state vector for in-plane stepped circular arches is given by equation (21).

The CFM is based on the principle of the solution of equation (20) with the help of the initial conditions. This method is basically the reduction of two-point boundary value problems to initial-value problems. The general solution of Eq. (20), is given by

$$\{Y(\phi, s)\} = \sum_{m=1}^n C_m [\bar{U}^{(m)}(\phi, s)] + \{\bar{V}(\phi, s)\} \quad (22)$$

Where $[\bar{U}^{(m)}(\phi, s)]$ is the complementary solution such that its m^{th} component is equal to 1, whereas all the others are zero. $\{\bar{V}(\phi, s)\}$ is the inhomogeneous solution with all zero initial conditions, the integration constants C_m will be determined from the boundary conditions at both ends.

The results, obtained in the Laplace domain, are transformed to the time domain with the help of modified Durbin's numerical inverse Laplace transform method given by Durbin [19] and Temel, Çalim and Tütüncü, [20].

IV. NUMERICAL EXAMPLES AND DISCUSSIONS

A fixed-ended isotropic stepped circular arch, shown in figure 1.a, is now considered under a point dynamic load applied to its midpoint. Material properties density, $\rho=7850 \times 10^{-6}$ kgf/cm³, Poisson's ratio, $\nu = 0.3$, and modulus of elasticity, $E=2.1 \times 10^6$ kgf/cm². Three types of time depended point loads, shown in figure 1.b, with the amplitude $p_0 = 1$ kgf are implemented to the arch. The radius of the cross section of the arch ($h(\phi)$) is considered to be;

$$h(\phi) = \begin{cases} 0.5 & , \quad -\frac{\pi}{6} < \phi < \frac{\pi}{6} \\ 1.0 & , \quad \frac{\pi}{6} \leq \phi \leq \frac{\pi}{4} \\ 1.0 & , \quad -\frac{\pi}{4} \leq \phi \leq -\frac{\pi}{6} \end{cases}$$

Here the flexural rigidity and cross section of arch is;

$$EI_b(\phi) = E \frac{\pi h(\phi)^4}{4}; \quad A(\phi) = \pi h(\phi)^2$$

The boundary conditions of fixed-end and symmetric point are given as follows:

$$\phi = 0 \rightarrow \begin{cases} U_t = 0 \\ \Omega_b = 0 \\ T_n = -p/2 \end{cases} \quad \phi = \phi_0 \rightarrow \begin{cases} U_t = 0 \\ U_n = 0 \\ \Omega_b = 0 \end{cases}$$

The equations (13-18) given in canonical form are solved numerically in the Laplace domain by the CFM. The results are compared with those obtained from ANSYS. Comparisons are shown in the graphics. In this problem the effect of shear deformation is taken into account.

(a)

(b)

Figure 1: (a) Fixed –ended circular stepped arch; (b) Dynamic loads.

The geometric properties of the arch are as follows:

Shear correction factor $\alpha_n = 1.11$, radius of curvature of the circular arch $r = 100$ cm and $\phi_0 = \pi/4$.

$$h = 0.5\text{cm} \rightarrow \begin{cases} A = 0.7854\text{cm}^2 \\ I_b = 0.0491\text{cm}^4 \end{cases}$$

$$h = 1.0\text{cm} \rightarrow \begin{cases} A = 3.1416\text{cm}^2 \\ I_b = 0.7854\text{cm}^4 \end{cases}$$

Laplace transforms of the step load, sinusoidal load and the Heaviside's unit function load are available in closed-form. The vertical U_n displacement and M_b bending moment of the midpoint of the arch under a point step load obtained by present method is presented in Figs. 2 - 3 respectively.

Figure 2: U_n Vertical displacement of the midpoint of the arch versus time under a point step load.

Figure 3: M_b Moment of bending versus time at the arch midpoint under a point step load.

The M_b bending moment results obtained by the present study at the fixed-end of the arch subjected to a point step load is presented in Fig. 4.

Figure 4: M_b Moment of bending versus time at the arch fixed-end under a point step load.

A uniaxial element with tension, compression and bending capabilities is used to analyze the circular arch problem in ANSYS. Time varying results of the vertical U_n displacement and M_b bending moment of the symmetric point and M_b bending moment under a point step load at the fixed support are given in Figs. 5 – 7.

Figure 7: M_b Moment of bending versus time at the arch fixed-end under a point step load.

The problem has been solved for various time increments as transform parameters ($dt=2.8E-2$ sec., $N = 64$), ($dt=1.4E-2$ sec., $N = 128$), ($dt=7.0E-3$ sec., $N = 256$) and ($dt=3.5E-3$ sec., $N = 512$). It is apparent that results obtained for a coarse time increment along with fewer Laplace transform parameters overlap the results obtained with finer increments and higher parameters. This indicates the efficiency and exactness of the present method.

As it is obvious in the figures above the accuracy of the results of conventional numerical time integration methods depends on the appropriate selection of the optimum time increment. Thus a small time increment is needed to acquire efficient results.

The comparison of present study and conventional step by step time integration methods for various time increments and stepped cross section given in Figs. 8 – 10 show the U_n vertical displacement, M_b bending moment at the midpoint and bending moment at the fixed supported end of the arch for a step load respectively.

Figure 5: U_n Vertical displacement of the midpoint of the arch versus time under a point step load.

Figure 6: M_b Moment of bending versus time at the arch midpoint under a point step load.

Figure 8: Comparison of U_n vertical displacement versus time at the arch midpoint for step load.

Figure 9: Comparison of M_b Moment of bending versus time at the arch midpoint for step load.

Figure 10: Comparison of M_b Moment of bending versus time at the arch fixed-end under a point step load.

It can be seen that time increments of $3.5E-3$ sec. and finer had to be considered for consistent results in ANSYS. An exact match is obtained by using a coarse time increment of $2.8E-2$ sec. in the present method as opposed to much finer increment of $3.5E-3$ sec. in Newmark method.

To examine the dynamic response of this structure under different time depended loads the impulsive triangular dynamic point load is implemented to the stepped circular arch. Solutions are obtained in the similar manner as step load and comparisons are given in Figs. 11 - 13.

Figure 11: Comparison of U_n vertical displacement versus time at the arch midpoint under point impulsive triangular load.

Figure 12: Comparison of M_b Moment of bending versus time at the arch midpoint under point impulsive triangular load.

Figure 13: Comparison of M_b Moment of bending versus time at the arch fixed-end under point impulsive triangular load.

Given figures include the results obtained by present method and ANSYS. The comparison show that an exact match is obtained by using a coarse time increment of $2.8E-2$ sec. in the present method as opposed to much finer increment of $3.5E-3$ sec. in ANSYS.

The behavior of isotropic stepped circular arch is examined under Heaviside's unit function step point load by proposed method. The results are given in Figs. 14 - 16.

Figure 14: U_n vertical displacement versus time at the arch midpoint under point Heaviside's function step load.

Figure 15: M_b Moment of bending versus time at the arch midpoint under point Heaviside's function step load.

Figure 16: M_b Moment of bending versus time at the arch fixed-end under point Heaviside's function step load.

V. CONCLUSION

In this paper, the transient analysis of stepped circular arches made up of linear elastic materials is investigated under various types of time depended loads. The dynamic behavior of such structures is examined by the unified method of Laplace transform and the CFM as the effect of shear deformation and is considered. RK5 algorithm is used for the numerical solution of the initial value problems. The governing equations of the related problem are first obtained in the time domain. Laplace transform is then applied and the set of simultaneous linear algebraic equations are solved by the CFM in the Laplace domain for a set of Laplace parameters. The solutions obtained are transformed to the time domain using an efficient inverse numerical Laplace transform method. For the suggested model, a computer program is coded in Fortran. Results of the presented method are compared with those obtained from ANSYS.

The accuracy of the results of conventional step by step time integration method depends on the appropriate selection of the optimum time steps. By using the presented method, highly accurate results can be obtained, even with a coarse time steps. It is manifest that combination of Laplace transform and the CFM is far more efficient than the conventional step-by-

step time integration methods. Laplace transformation gives a time-independent boundary-value problem in spatial coordinate which is then solved by the CFM. The numerical examples has proved that the suggested procedure is highly accurate and efficient compared to various other numerical methods available in the literature and it can be easily applied to the stepped circular arches.

Abstract—In this study, stochastic analysis of isolated and nonisolated highway bridges under spatially varying ground motion are examined. Spatially varying earthquake ground motion model includes incoherency, wave passage and site response effect. Incoherency effect is taken into account in the scope of this study. Site response effect is not taken account in the analyses. Soil, supported bridge, is assumed to be homogeneous and soft. Two different incoherency models are used analysis to represent incoherency effects. These are Harichandran and Vanmarcke, and Uscinski incoherency models. Triple Concave Friction Pendulum (TCFP) bearing system is used as a frictional pendulum system. Utilization of this isolation system is more effective than other frictional pendulum and conventional isolator systems against severe earthquake. The means of the maximum responses of displacement and internal forces of bridge deck are investigated. These responses are consisted by quasi-static, dynamic and total of internal forces and displacements. The results of these stochastic analyses are also compared with the results of under uniform ground motion. Analysis results revealed that using TCFP bearing on Highway Bridge reduces means of maximum values of total axial force, shear force and bending moment of deck by 85%, 81% and 86%, respectively. Generally, the results from stochastic analysis demonstrated that using Harichandran and Vanmarcke incoherency model is more effective than Uscinski incoherency model and using uniform ground motion at isolated and nonisolated bridges.

Keywords—spatially varying earthquake ground motion; seismic isolation; triple friction pendulum bearing; incoherency effect; highway bridge

I. INTRODUCTION

Highway Bridge is an important transportation network. This type of structures should be protected against effect of severe earthquake. This detrimental effect can be decreased if the fundamental period of structure is lengthened or energy dissipating of bridge is increased. Hence, different types of seismic isolation systems are used to protect structure against detrimental effects of severe earthquake.

Some researchers study to indicate that TCFP bearing system is more effective than other sliding systems on severe earthquake [1-3]. Dynamic response analysis of long span isolated and nonisolated bridges subjected to spatially varying

ground motions were investigated by [4]. [5] performed a study of spatially varying ground motions on stochastic response of isolated bridge with friction pendulum bearing systems. [6] compared stochastic response of isolated and nonisolated cable-stayed bridge with double concave friction pendulum (DCFP) bearing subjected to spatially varying ground motion. [7] performed an analysis of multiple support seismic response of Bosphorous Bridge for various random vibration methods.

While stochastic responses of bridges isolated with different sliding systems have been investigated, TCFP bearing system is not taken into account so far. Aim of this paper is comparing incoherency models at isolated and nonisolated with TCFP bearing under spatially varying ground motion.

II. MATERIAL AND METHOD

TCFP bearing system is to be effective in severe earthquake ground motion. These system used as an isolation device installed between deck and pier in this study. To determine parameters of TCFP bearing, a sample design proposed by [8] is used. Properties of TCFP bearing are given in Table1. Stochastic analyses of isolated and nonisolated bridge are performed under spatially varying ground motion by taking into account only the incoherence effect. The incoherency effect results from reflections and refractions of seismic waves through to the soil during their propagation. Incoherency effect is examined by considering the Harichandran and Vanmarcke and Uscinski models. Also, in the case of uniform ground motion is used for compare results of incoherency models. The soil which is under all supports is homogeneous and soft soil.

Harichandran and Vanmarcke model proposed by [9] is defined as

$$\gamma_{lm}(\omega) = A \exp \left[-\frac{2d_{lm}}{\alpha\theta(\omega)}(1-A+\alpha A) \right] + (1-A) \exp \left[-\frac{2d_{lm}}{\theta(\omega)}(1-A+\alpha A) \right] \quad (1)$$

Where, d_{lm} is the distance between support points l and m . Also, $\theta(\omega)$ is defined as

$$\theta(\omega) = k \left[1 + \left(\frac{\omega}{2\pi f_0} \right)^b \right]^{-\frac{1}{2}} \quad (2)$$

Where A , α , k , f_0 ve b are 0.636, 0.0186, 31200, 1.51 Hz. and 2.95 respectively proposed by [10]. Second incoherency model, Uscinski, is proposed by [11] and defined as

$$|\gamma_{lm}(\omega)|^k = \exp \left[\left(\frac{\alpha d_{lm} \omega}{v_s} \right)^2 \right] \quad (3)$$

Where α and v_s are dimensionless inconsistency parameter and shear wave velocity, respectively. In this study, value of α/v_s is taken as 2×10^{-4} [12-13].

Incoherency effect decreases with increasing frequency and distance between supports. Incoherency effect is equal to one for all frequency and distance between support at case of uniform ground motion [14].

TABLE I. PROPERTIES OF TCFP IN ALL CASES

$\mu_1 = \mu_4$ upper bound	0.096	0.069	0.081
$\mu_2 = \mu_3$ upper bound	0.061	0.016	0.035
μ upper bound	0.083	0.049	0.064

III. NUMERICAL EXAMPLE

In order to investigate the stochastic response of isolated bridge with TCFP bearing and nonisolated highway bridge, two dimensional analytical model used by [14] is selected as a numerical model (Fig.1).

Stochastic analyses of isolated and nonisolated bridges are examined for spatially varying ground motion by taking only incoherency effect. Soil supported bridge assumed to be homogeneous and soft soil. For these purpose two different incoherency models are used for analysis to represent incoherency effects. These are Harichandran and Vanmarcke and Uscinski incoherency models. Also, analysis results of bridge under uniform ground motion is showed to comparison results of incoherency effects. The

analyses are carried out computer code SVEM [15] that is the modified to include a TCFP bearing system's behavior. The first 15 modes and %5 damping ratio are selected for analyses. The periods obtained from analyses for isolated with TCFP bearing and nonisolated bridges are given in Table II.

The analyses results show that using TCFP bearing may length period of the highway bridge. Means of maximum values of quasi-static, dynamic and total axial forces of the deck of the isolated and nonisolated bridges are compared in Fig. 2.

Mean of maximum quasi-static, dynamic and total axial forces of the deck of the isolated and nonisolated bridges are calculated for Harichandran and Vanmarcke, Uscinski incoherency models and uniform ground motion are compared in Fig. 2. Using TCFP bearing decreases values

Fig. 1. Selected Highway Bridge and its model

TABLE II. THE PERIODS OF ISOLATED AND NONISOLATED BRIDGE

Mode	Period (s)	
	Isolated	nonisolated
1	3.6607	1.1929
2	1.0310	0.8144
3	0.7700	0.6844
4	0.5964	0.5784
5	0.3028	0.2739
6	0.2799	0.262
7	0.2419	0.2354
8	0.2123	0.2136
9	0.2003	0.205
10	0.1718	0.1698
11	0.1378	0.1357
12	0.1297	0.1301
13	0.1239	0.1258
14	0.0866	0.0862
15	0.0585	0.0583

of maximum of quasi-static, dynamic and total normal forces of bridge deck by 82%, 65% and 85%, respectively. While the values of quasi-static and total axial forces increase the middle of the bridge length, these forces decreases towards abutment. While Harichandran and Vanmarcke incoherency model is the most effective for quasi-static and total axial forces, it is least effective for dynamic axial force both seismic isolated and nonisolated bridges.

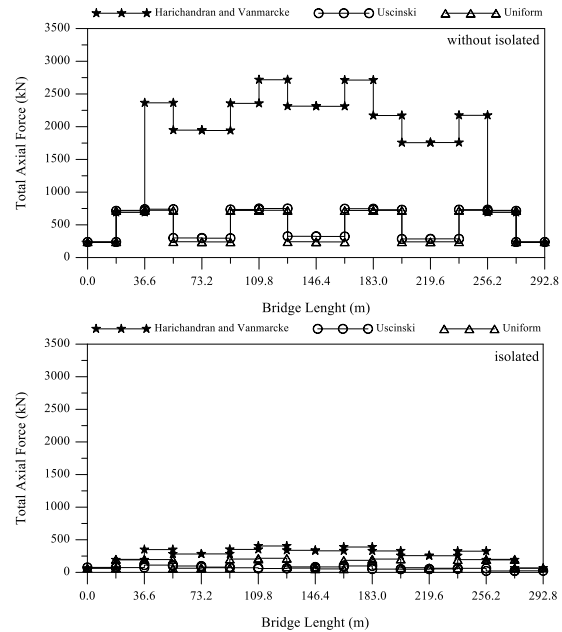

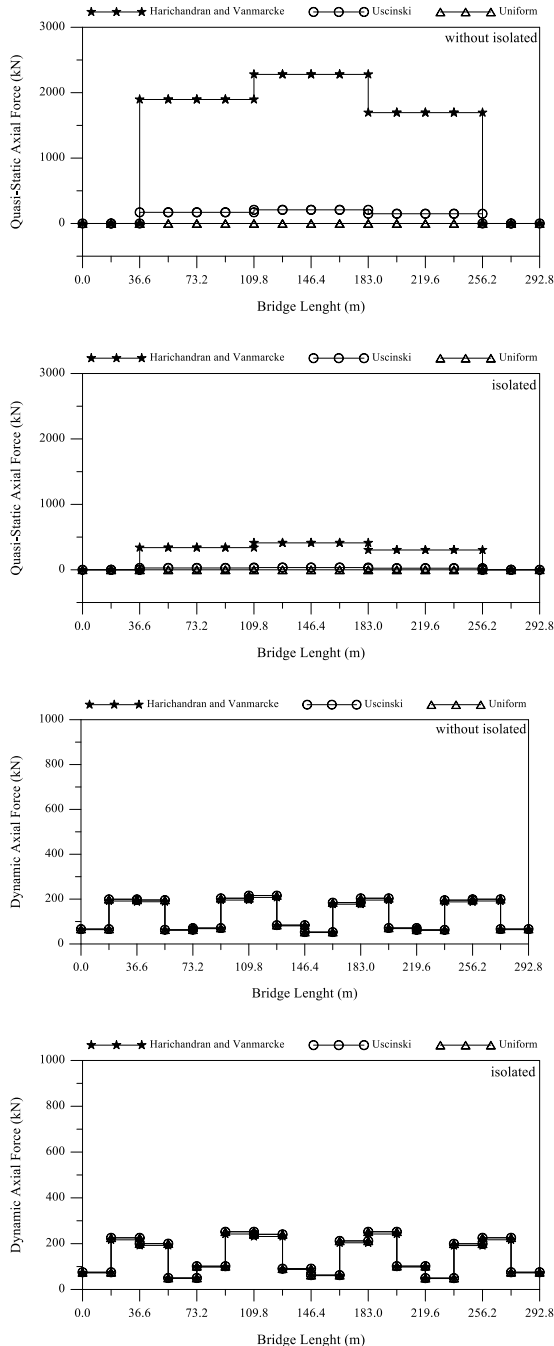

Fig. 2. Mean of maximum axial forces of the deck isolated and nonisolated

Mean of maximum quasi-static, dynamic and total shear forces of the deck of the isolated and nonisolated bridges are calculated for Harichandran and Vanmarcke, Uscinski incoherency models and uniform ground motion are compared in Fig. 3. Using TCFP bearing decreases values of maximum of quasi-static, dynamic and total shear forces of bridge deck by 93%, 68% and 81%, respectively. Harichandran and Vanmarcke incoherency model is more effective than Uscinski model and uniform ground motion for quasi-static and total shear forces at nonisolated bridge. The values obtain from the stochastic analyses considering Harichandran and Vanmarcke and Uscinski models and uniform ground motion are nearly same for dynamic shear forces.

Means of maximum quasi-static, dynamic and total bending moment of the deck of the isolated and nonisolated bridges are calculated for Harichandran and Vanmarcke, Uscinski incoherency models and uniform ground motion are compared in Fig. 4. Using TCFP bearing decreases values of maximum of quasi-static, dynamic and total bending moment of bridge deck by 92%, 74% and 86%, respectively. While Harichandran and Vanmarcke incoherency model is the most effective for quasi-static and total bending moment, case of uniform ground motion is more effective than considering Harichandran and Vanmarcke and Uscinski incoherency models for dynamic bending moment both seismic isolated and nonisolated bridges.

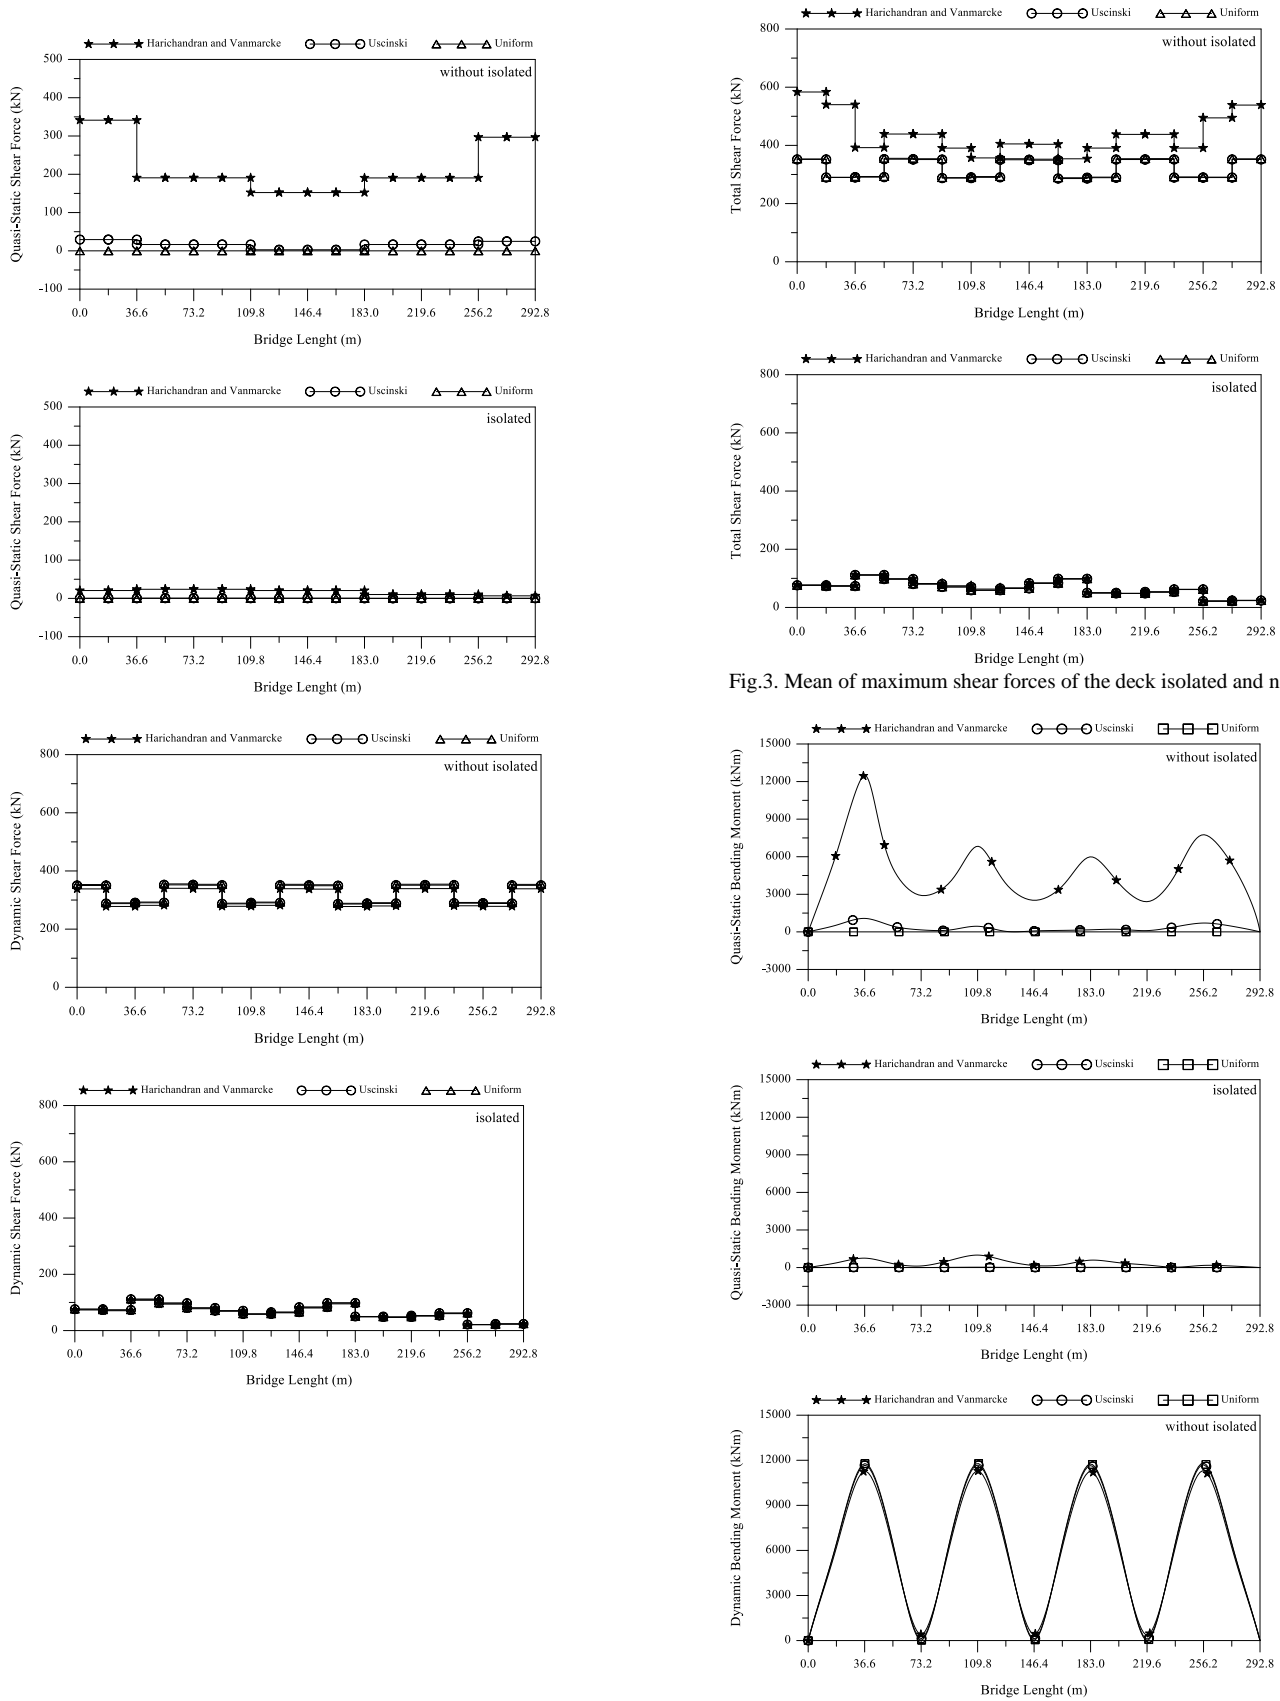

Fig.3. Mean of maximum shear forces of the deck isolated and nonisolated

Means of maximum quasi-static, dynamic and total displacements of the deck of the isolated and nonisolated bridges are calculated for Harichandran and Vanmarcke, Uscinski incoherency models and uniform ground motion are compared in Fig. 5. Using TCFP bearing increases values of maximum of quasi-static, dynamic and total shear forces of bridge deck by 27%, 150% and 37%, respectively. The displacements of bridge deck obtained from stochastic analysis for situation of uniform ground motion are nearly similar to these obtained for Uscinski incoherency model in all graphics. The displacements of deck obtained from stochastic analyses for Harichandran and Vanmarcke are 4.2% smaller than those from analysis for Uscinski incoherency model and situation of using uniform ground motion.

Fig.4. Mean of maximum bending moment of the deck isolated and nonisolated

Fig.5. Mean of maximum horizontal displacement of the deck isolated and nonisolated

CONCLUSION

This study outlines an investigation of the stochastic response of an isolated with TCFP bearing and nonisolated highway bridge. Only the incoherency effect is taken into account in the spatially varying ground motion. Site response effect is not taken account in the analyses. Soil, supported bridge, is assumed to be homogeneous and soft. The stochastic analyses are performed for isolated and nonisolated bridge, separately. In the stochastic analysis, Harichandran and Vanmarcke, and Uscinski incoherency models are taken into account, separately. Also, uniform ground motion which has infinite velocity is used for comparing results. The conclusions drawn from this paper can be written as:

- The value of the periods of the bridge significantly lengths when TCFP bearing system is used.
- The results from stochastic analyses indicated that TCFP bearing decreases element forces of highway bridge deck by 65% to 93%.
- While Harichandran and Vanmarcke incoherency model is the most effective for quasi-static and total axial forces, it is least effective for dynamic axial force both seismic isolated and nonisolated bridges.
- Harichandran and Vanmarcke incoherency model is more effective than Uscinski model and using uniform ground motion for total shear forces on nonisolated bridge. Using difference incoherency models may not influence responses of shear forces of the isolated bridge.
- Harichandran and Vanmarcke incoherency model is more effective than Uscinski model and using uniform ground motion for total bending moment on nonisolated bridge. Using difference incoherency models may not influence responses of bending moment of the isolated bridge.
- Considering to incoherency effect may not influence displacement of bridge deck under spatially varying

ground motion in both seismically isolated and nonisolated highway bridge.

Abstract—The objective of this study is to solve a smooth continuous contact problem between a functionally graded layer and a homogeneous half-plane. The problem is considered under the assumption of plane strain. The half-plane is homogeneous, while the functionally graded layer is inhomogeneous with its shear modulus and mass density changing arbitrarily along the thickness direction. The functionally graded layer is indented by a rigid cylindrical punch subjected to a concentrated normal force. Since the contact between the two bodies is assumed to be frictionless, then only compressive normal tractions can be transmitted in the contact area. By using the Fourier integral transform and the boundary conditions, the problem is reduced to a singular integral equation in which the contact half-width and the contact pressure under rigid punch are unknown. The integral equation is solved numerically by making use of appropriate Gauss-Chebyshev integration formula. The presented numerical results illustrate the influences of the inhomogeneity parameters, load ratio and punch radius on the contact pressure distribution under rigid punch, initial separation load and initial separation distance between functionally graded layer and homogeneous half-plane.

Keywords—contact pressure; functionally graded layer; initial separation load; initial separation distance.

I. INTRODUCTION

The concept of functionally graded materials (FGMs) was proposed in 1984 by Japanese material scientists to prepare thermal barrier materials [1]. Then, FGMs were used in electromagnetic engineering, aerospace and many other fields. Since many of potential applications of functionally graded materials (FGMs) involve contact problems, studies to apply the FGM concept to contact mechanics have attracted the attention in the recent years. Some of these studies are summarized below:

Guler and Erdogan [2–4] applied the singular integrate equation method to solve the two-dimensional contact problem of functionally graded coatings. The sliding contact problem of a graded coating using piecewise linear model for different indenter geometries was examined by [5–7]. Two-dimensional frictionless contact problem of a coating structure consisting of a surface coating, a functionally graded layer and a substrate

under a rigid cylindrical punch was studied by [8]. The problem of a functionally graded coated half-space indented by an axisymmetric smooth rigid punch was investigated by [9]. The thermoelastic frictional contact of functionally graded materials with arbitrarily varying thermoelastic properties was examined by [10]. A theoretical analysis of two-dimensional frictionless sliding contact over orthotropic piezoelectric materials indented by a rigid sliding punch was carried out by [11]. The contact problem for a functionally graded layer supported by a Winkler foundation was solved by [12]. A semi-analytical algorithm for the determination of the contact half width and surface pressure which results from both adhesive and non-adhesive contact problems involving functionally graded materials was presented by [13]. A frictional receding contact plane problem between a functionally graded layer and a homogeneous substrate was solved by [14]. Double receding contact plane problem between a functionally graded layer and an elastic layer was studied by [15]. Frictional receding contact analysis of a layer on a half-plane subjected to semi-infinite surface pressure was examined by [16]. The analytical and finite element solution of plane contact problem of a rigid cylindrical punch sliding over a functionally graded orthotropic medium was investigated by [17].

In this study, the frictionless contact problem for a functionally graded layer resting on a homogeneous half-plane is considered using linear elasticity theory. The problem is reduced to a Cauchy-type singular integral equation in which the unknowns are contact half-width and contact pressure using Fourier integral transforms. The numerical results for the contact pressure distribution under punch, initial separation load and initial separation distance between functionally graded layer and homogeneous half-plane are calculated for various values of the material inhomogeneity parameters, load ratio and punch radius.

II. PROBLEM DESCRIPTION AND FORMULATION

Consider the plane strain problem as shown in Fig. 1. Medium 2 is a homogeneous half-plane and medium 1 is the functionally graded layer with a thickness h . The functionally graded layer and homogeneous half-plane occupy, respectively,

the domains $-h \leq y \leq 0$ and $y \leq -h$. A normally concentrated force P acts on the rigid punch. The shear modulus of the functionally graded layer and homogeneous half-plane are given by $\mu_1(y)$ and μ_2 , respectively. Poisson's ratio ν is taken constant in both the functionally graded layer and the homogeneous half-plane. Where applicable, the germane quantities are reckoned per unit length in the z -direction.

The shear modulus and mass density of the functionally graded layer vary in the thickness direction, i.e. in y -direction. This variation is presented by two exponential functions in the following form:

$$\mu_1(y) = \mu_0 e^{\beta y}, \quad (1)$$

$$\rho_1(y) = \rho_0 e^{\gamma y}, \quad (2)$$

where μ_0 and ρ_0 are the shear modulus and mass density at the top surface of the functionally graded layer, respectively. β and γ are arbitrary non-zero constants characterizing the material inhomogeneity.

For functionally graded layer, the general expressions of the stress and displacement fields can be obtained as [18]

$$\sigma_{1y} = \frac{2\mu_0 e^{\beta y}}{\pi(\kappa_1 - 1)} \int_0^\infty \sum_{j=1}^4 A_j C_j e^{n_j y} \cos(\xi x) d\xi, \quad (3)$$

$$\tau_{1xy} = \frac{2\mu_0 e^{\beta y}}{\pi} \int_0^\infty \sum_{j=1}^4 A_j D_j e^{n_j y} \sin(\xi x) d\xi, \quad (4)$$

$$v_1(x, y) = \frac{2}{\pi} \int_0^\infty \sum_{j=1}^4 A_j m_j e^{n_j y} \cos(\xi x) d\xi, \quad (5)$$

where

$$m_j = \frac{(3\beta + 2n_j - \beta\kappa_1)[n_j(\beta + n_j)(\kappa_1 + 1) - \xi^2(\kappa_1 + 3)]}{\xi[4\xi^2 - \beta^2(\kappa_1 - 3)(\kappa_1 + 1)]}, \quad (6)$$

$$n_1 = -\frac{1}{2} \left(\beta + \sqrt{4\xi^2 + \beta^2 - 4\xi\beta i \sqrt{\frac{3-\kappa_1}{\kappa_1+1}}} \right), \quad (7)$$

$$n_2 = -\frac{1}{2} \left(\beta - \sqrt{4\xi^2 + \beta^2 - 4\xi\beta i \sqrt{\frac{3-\kappa_1}{\kappa_1+1}}} \right), \quad (8)$$

$$n_3 = -\frac{1}{2} \left(\beta + \sqrt{4\xi^2 + \beta^2 + 4\xi\beta i \sqrt{\frac{3-\kappa_1}{\kappa_1+1}}} \right), \quad (9)$$

$$n_4 = -\frac{1}{2} \left(\beta - \sqrt{4\xi^2 + \beta^2 + 4\xi\beta i \sqrt{\frac{3-\kappa_1}{\kappa_1+1}}} \right), \quad (10)$$

$$C_j = [(\kappa_1 + 1)m_j n_j + \xi(3 - \kappa_1)], \quad (11)$$

$$D_j = [n_j - \xi m_j]. \quad (12)$$

Fig. 1. Geometry and loading condition of the problem

For homogeneous half-plane, the general expressions of the stress and displacement fields can be obtained as [19]

$$v_2(x, y) = \frac{2}{\pi} \int_0^\infty \left[-B_1 + \left(\frac{\kappa_2}{\xi} - y \right) B_2 \right] e^{\xi y} \cos(\xi x) d\xi \quad (13)$$

$$\frac{1}{2\mu_2} \sigma_{2y}(x, y) = \frac{2}{\pi} \int_0^\infty \left[-\xi(B_1 + B_2 y) + \left(\frac{1 + \kappa_2}{2} \right) B_2 \right] e^{\xi y} \cos(\xi x) d\xi \quad (14)$$

$$\frac{1}{2\mu_2} \tau_{2xy}(x, y) = \frac{2}{\pi} \int_0^\infty \left[\xi(B_1 + B_2 y) + \left(\frac{1 - \kappa_2}{2} \right) B_2 \right] e^{\xi y} \sin(\xi x) d\xi \quad (15)$$

Boundary conditions relating to continuous contact case of the problem can be written as

$$\tau_{1xy}(x, 0) = 0, \quad (0 \leq x < \infty), \quad (16)$$

$$\sigma_{1y}(x, 0) = \begin{cases} -P(x) & (0 \leq x < a) \\ 0 & (a \leq x < \infty) \end{cases}, \quad (17)$$

$$\tau_{1xy}(x, -h) = 0, \quad (0 \leq x < \infty), \quad (18)$$

$$\tau_{2xy}(x, -h) = 0, \quad (0 \leq x < \infty), \quad (19)$$

$$\sigma_{1y}(x, -h) = \sigma_{2y}(x, -h), \quad (0 \leq x < \infty), \quad (20)$$

$$\frac{\partial}{\partial x} [v_1(x, -h) - v_2(x, -h)] = 0, \quad (0 \leq x < \infty), \quad (21)$$

$$\frac{\partial}{\partial x} [v_1(x, 0)] = f(x), \quad (0 \leq x < a), \quad (22)$$

where subscripts 1 and 2 indicate related to functionally graded layer and homogeneous half-plane, respectively. a and $p(x)$ are the contact half-width of the rigid punch and the unknown contact pressure under rigid punch. $f(x)$ is the derivative of the profile of the rigid punch; one may write

$$f(x) = \frac{x}{R}, \quad (23)$$

where R is the punch radius.

By making use of the boundary conditions (16-21), unknown constants A_j ($j=1, \dots, 4$) and B_i ($i=1, 2$) can be obtained in terms of the unknown function $p(x)$. By substituting the values of these constants into (22), after some routine manipulations and using symmetry condition $p(x)=p(-x)$, one may obtain the following singular integral equation:

$$\int_{-a}^a \left[\frac{1}{t-x} + k_1(x, t) \right] p(t) dt = -\frac{4\pi\mu_0}{1+\kappa_1} \frac{x}{R}, \quad (24)$$

where

$$k_1(x, t) = \int_0^\infty \left(\frac{4}{1+\kappa_1} Z(\xi) - 1 \right) \sin \xi(t-x) d\xi, \quad (25)$$

$$Z(\xi) = \sum_{j=1}^4 (-\xi A_j m_j). \quad (26)$$

For a complete solution of the problem an additional condition is needed. The contact pressure $p(x)$ must satisfy

$$\int_{-a}^a p(t) dt = P, \quad (27)$$

where P is the resultant compressive force.

In order to calculate initial separation load and distance between functionally graded layer and homogeneous half-plane, the contact pressure $\sigma_{1y}(x, -h)$ needs to be evaluated. In the case including the body force of the FG layer, $\sigma_{1y}(x, y)$ can be obtained as [20]

$$\sigma_{1y}(x, y) = \left[\frac{2\mu_0 e^{\beta y}}{\pi(\kappa_1 - 1)} \int_0^\infty \sum_{j=1}^4 A_j C_j e^{\beta_j y} \cos(\xi x) d\xi \right] + \left(\frac{e^{\gamma y} - 1}{\gamma} \rho_0 g \right), \quad (28)$$

where g is acceleration of gravity.

Substituting the values of A_j ($j=1, \dots, 4$) into (28), after some manipulations, the contact pressure $\sigma_{1y}(x, -h)$ can be obtained as

$$\sigma_{1yg}(x, -h) = \frac{\rho_0 g (e^{-\gamma h} - 1)}{\gamma} + \frac{1}{\pi h} \int_{-a}^a k_2(x, t) p(t) dt, \quad (29)$$

in which $k_2(x, t)$ is given by [20]. To simplify the numerical analysis, the following dimensionless quantities are defined:

$$x = aw, \quad t = a\eta, \quad (30)$$

$$g(\eta) = \frac{p(a\eta)}{(P/h)}, \quad \lambda = \frac{P}{\rho_0 g h^2},$$

Using these quantities, (24), (27) and (29) can be written as

$$\int_{-1}^1 \left[\frac{1}{\eta - w} + \frac{a}{h} k_1(w, \eta) \right] g(\eta) d\eta = -\frac{4}{1+\kappa_1} \frac{\mu_0}{(P/h)} \frac{(a/h)}{(R/h)} w, \quad (31)$$

$$\frac{a}{h} \int_{-1}^1 g(\eta) d\eta = 1, \quad (32)$$

$$\frac{\sigma_{1y}(x, -h)}{P/h} = \frac{(e^{-\gamma h} - 1)}{\gamma h} \frac{1}{\lambda} + \frac{1}{\pi h} \int_{-1}^1 k_2(x, a\eta) g(\eta) d\eta. \quad (33)$$

The contact pressures are zero at the edges of the contact because of the smooth contact at the end points. Thus (31) has an index -1 [21]. Its solution may be expressed as

$$g(\eta) = G(\eta)(1-\eta^2)^{1/2}, \quad (-1 \leq \eta \leq 1). \quad (34)$$

Using appropriate Gauss-Chebyshev integration formula, (31-32) are replaced by

$$\sum_{i=1}^N \Gamma_i \left[\frac{1}{\eta_i - w_j} + \frac{a}{h} k_1(w_j, \eta_i) \right] G(\eta_i) = -\frac{4}{1+\kappa_1} \frac{\mu_0}{(P/h)} \frac{(a/h)}{(R/h)} w_j, \quad (j=1, \dots, N+1), \quad (35)$$

$$\frac{a}{h} \sum_{i=1}^N \Gamma_i G(\eta_i) = \frac{1}{\pi}, \quad (36)$$

where

$$\Gamma_i = \frac{1 - \eta_i^2}{N + 1}, \quad (i = 1, \dots, N), \quad (37)$$

$$\eta_i = \cos\left(\frac{i\pi}{N + 1}\right), \quad (i = 1, \dots, N), \quad (38)$$

$$w_j = \cos\left(\frac{2j - 1}{N + 1} \frac{\pi}{2}\right), \quad (j = 1, \dots, N + 1). \quad (39)$$

In (35) the additional equation is equivalent to consistency condition of the integral equation. It may be shown that the $(N/2 + 1)$ -th equation in (35) is automatically satisfied. Thus, (35) and (36) provide $N + 1$ algebraic equations to determine $N + 1$ unknowns, which are $G(\eta_i)$, $(i = 1, \dots, N)$, and the contact half-width (a). The system of equations is linear for $G(\eta_i)$, but nonlinear in terms of the variable (a). Therefore, an iteration scheme had to be used to obtain this unknown. In this iterative procedure, firstly N equations $[j = 1, \dots, (N/2), (N/2 + 2), \dots, (N + 1)]$ are chosen from (35). After predicting value for (a), $G(\eta_i)$ ($i = 1, \dots, N$) are calculated using previously determined N equations. If the chosen (a) and obtained $G(\eta_i)$ values ensure (36), the solution would have been found. Otherwise, $G(\eta_i)$ values are recalculated after predicting new (a) value.

To determine the initial separation load and the initial separation distance between the functionally graded layer and the homogeneous half-plane, (33) needs to be equalized to zero. Using this equation, the initial separation load and the initial separation distance can be determined together.

III. RESULTS AND DISCUSSION

This section presents the numerical results generated by using analytical procedures whose details are provided in Section II. We take into consideration four cases of functionally graded layer, a stiffer layer with $\beta h < 0$, a softer layer with $\beta h > 0$, the heavier layer with $\gamma h < 0$, the lighter layer with $\gamma h > 0$ from the top surface of the functionally graded layer to that of the bottom surface.

Fig. 2 illustrates the effect of the punch radius R/h on the normalized contact pressure under rigid punch. From this figure, it can be concluded that increasing the value of punch radius results in a reduction of the peak value of contact pressure. The effect of the load ratio $\mu_0/(P/h)$ on the normalized contact pressure under rigid punch is shown in Fig. 3. The results of Fig. 3 reveal the fact that for increasing values of the load ratio, the peak value of the contact pressure increases. Fig.

4 depicts effect of the inhomogeneity parameter (βh) on the normalized contact pressure under rigid punch. It is seen that as the inhomogeneity parameter (βh) increases in the positive sense, i.e. as the rigidity of the layer decreases from top to bottom, the peak value of the normalized contact pressure decreases. It can also be seen from this figure, negative values of the inhomogeneity parameter (βh) increases in absolute value, i.e. as the rigidity of the layer increases from top to bottom, the peak value of the normalized contact pressure increases.

Fig. 5 shows the normalized contact pressure distribution between functionally graded layer and homogeneous half-plane for various values of punch radius. It is clearly evident from this figure that as punch radius increases, the initial separation load and distance between functionally graded layer and homogeneous half-plane increase. The normalized contact pressure distribution between functionally graded layer and homogeneous half-plane for various values of load ratio is given in Fig. 6. Examination of Fig. 6 indicates that, the initial separation load and distance between functionally graded layer and homogeneous half-plane decreases for increasing values of load ratio. The normalized contact pressure distributions between functionally graded layer and homogeneous half-plane for various values of inhomogeneity parameter (βh) is presented in Fig. 7. As can be seen in the figure, the inhomogeneity parameter (βh) increases in the positive sense, i.e. as the rigidity of the layer decreases from top to bottom, the initial separation load decreases and the initial separation distance increases. Besides, the opposite effect can be obtained when negative values of the inhomogeneity parameter (βh) increases in absolute value. Fig. 8 shows the normalized contact pressure distribution between functionally graded layer and homogeneous half-plane for various values of inhomogeneity parameter (γh). It is observed that as the inhomogeneity parameter (γh) increases in the positive sense, i.e. as the functionally graded layer becomes lighter, the initial separation load between functionally graded layer and homogeneous half-plane decreases. Besides, the initial separation distance between functionally graded layer and homogeneous half-plane is not affected by the change in the inhomogeneity parameter (γh).

Fig. 2. Effect of the punch radius R/h on the normalized contact pressure under rigid punch ($\kappa_1=\kappa_2=2$, $\mu_0/(P/h)=100$, $\beta h=-0.6931$, $\mu_0=1$, $h=1$, $\mu_h/\mu_2=1$)

Fig. 3. Effect of the load ratio $\mu_0/(P/h)$ on the normalized contact pressure under rigid punch ($\kappa_1=\kappa_2=2$, $R/h=500$, $\beta h=-1.3863$, $\mu_0=1$, $h=1$, $\mu_h/\mu_2=1$)

Fig. 4. Effect of the inhomogeneity parameter βh on the normalized contact pressure under rigid punch ($\kappa_1=\kappa_2=2$, $R/h=100$, $\mu_0/(P/h)=500$, $\mu_0=1$, $h=1$, $\mu_h/\mu_2=1$)

Fig. 5. Normalized contact pressure distribution between functionally graded layer and homogeneous half-plane for various values of punch radius R/h ($\kappa_1=\kappa_2=2$, $\mu_0/(P/h)=100$, $\gamma h=-1.0986$, $\beta h=-0.6931$, $\mu_0=1$, $h=1$, $\mu_h/\mu_2=1$)

Fig. 6. Normalized contact pressure distribution between functionally graded layer and homogeneous half-plane for various values of load ratio $\mu_0/(P/h)$ ($\kappa_1=\kappa_2=2$, $R/h=500$, $\gamma h=-1.0986$, $\beta h=-1.3863$, $\mu_0=1$, $h=1$, $\mu_h/\mu_2=1$)

Fig. 7. Normalized contact pressure distribution between functionally graded layer and homogeneous half-plane for various values of inhomogeneity parameter βh ($\kappa_1=\kappa_2=2$, $R/h=100$, $\mu_0/(P/h)=500$, $\gamma h=-1.0986$, $\mu_0=1$, $h=1$, $\mu_h/\mu_2=1$)

Fig. 8. Normalized contact pressure distribution between functionally graded layer and homogeneous half-plane for various values of inhomogeneity parameter γh ($\kappa_1=\kappa_2=2$, $R/h=100$, $\mu_0/(P/h)=500$, $\beta h=-0.6931$, $\mu_0=1$, $h=1$, $\mu_h/\mu_2=1$)

IV. CONCLUSION

The conclusions drawn from this study can be written as:

- As the punch radius increases, the peak value of contact pressure under punch decreases, the initial separation load and distance between functionally graded layer and homogeneous half-plane increase.
- As the load ratio increases, the peak value of contact pressure under punch increases, the initial separation load and distance between functionally graded layer and homogeneous half-plane decrease.
- As the functionally graded layer becomes stiffer, the peak value of contact pressure under punch increases, the initial separation load increases and the initial separation distance decreases.
- As the functionally graded layer becomes softer, the peak value of contact pressure under punch decreases, the initial separation load decreases and the initial separation distance increases.
- As the functionally graded layer becomes heavier, the initial separation load increases
- As the functionally graded layer becomes lighter, the initial separation load decreases.
- The initial separation distance is not affected by the fact that the functional graded layer is heavier or lighter.

Abstract—This paper aims to present adopted material properties of masonry elements to historical mosque and bridge structures. The importance of this study is to adopt correct material properties with reliable reference according to material types and structure types.

Keywords—material properties; historical structures; historical mosques; historical bridges

I. INTRODUCTION

Historical structures are the most important part of civilization where constructed. Therefore, these cultural heritages of the urban population should be protected through centuries against external extreme loads. Conservation of cultural heritages are commonly considered as suitable restoration. However, with developing numeric analysis tools, it is possible to estimate global behavior of a historical structures available and after restoration situation under severe loads like earthquake. Structural characteristics of a historical monument mostly depend on the availability of local construction materials during construction era [1]. Moreover, it is difficult to determine the engineering properties of materials adopted to the historical structures due to the lack of experimental data and forbidden destructive test by authorities [2]. For this reason, indirect methods are developed to evaluate historical structures to reveal information related to available conditions. These indirect assessment methods are based on visual inspection, geometrical and crack pattern survey, surface decay mapping, radar, geoelectric and ultrasonic testing. Listed indirect methods are not convenient for the assessment of historical masonry structure alone. In addition, these methods cannot be substituted by destructive testing [3]. These are necessary to understand the damages and their causes and carry out a first interpretation of the phenomena [4].

During the analytical modelling, defining incorrect or uncertain material properties causes unavoidable wrong results. For a typical masonry heritage, the most difficult step is defining input parameter to quantify the material properties of masonry and mortar assembly. When developing a (FE)

models, especially for historic masonry structure, it is possible to define imprecise input parameters that can result in unrealistic models and erroneous solutions [5]. Indefinite references or insufficient material data force researcher to use wide range of data with lower boundary and upper boundary [6]. The aim of using upper and lower boundary material data is to adapt randomly selected engineering property due to insufficient material data for modelled structure. The reliability of the selected material properties depends mostly on model calibration of the FE model. Basic philosophy of model calibration is to compare dynamic identification test result of investigated structure with FE model of the same structure on the base of natural vibration period and frequencies. The success of model calibration depends not only on selecting the correct comparative quantitative but also in updating the correct quantitative. Thus, if the extreme use of the FE model is to assess damage in historical structures, the engineering properties must be adapted well to represent linearity and nonlinearities. Model calibration includes engineering judgment and self-intuition about selecting calibration parameters. Moreover, the unforeseen dependencies or correlations of parameters possibly arise among the calibrated inputs. If these dependencies or correlations are strong, this will raise the problem of the calibration of one parameter compensating for imprecision in another [5]. Besides, purchasing accelerometer always not possible due to extreme cost of test set up and non-destructive application. For listed reason above, it is very important to define certain and robust material properties for investigated historical structures.

This study presents 14 different study composed of mosques and bridges.

II. STRUCTURE TYPES

A. Mosques

Mosques are one of the most prominent religious structures in the history. Nearly all dominated sultans let to construct mosque to shown power. Many of the available mosques are still in use. For this reason, response of their behavior against

external loads needs to be assessed. Koçak and Köksal (2010) investigated seismic behavior of Little Hagia Sophia with FE modelling. Adopted material properties were suited with destructive and non-destructive methods [7] and addressed to Aköz and Yüzer (1995) [8]. Teomete and Aktaş (2010) implemented destructive tests on historical masonry and brick elements of an historical Urla Kamanlı mosque in İzmir Turkey [9]. Demir and İlki (2014) studied on material properties and characterization of single layer and multi-layer Küfeki stone in other words limestone which is commonly used to construct mosques [10]. Demir and İlki (2014) characterized the multi layered Küfeki stone in other words limestone according to sample dimensions 40x30 cm, 40x26 cm and 40x20 cm respectively [10]. Altunışık et al. (2015) assessed the performance of Kaya Çelebi Mosque in Turkey. For this purpose, dynamic modal analysis and seismic spectral analysis were performed on model [11]. Material properties were adopted by Altunışık et al. (2015) addressed to Can et al. (2012) [12], Dal-Cin and Russo (2014) [2014] and Saloustros (2015) [14]. Cakir et al. (2015) modelled and analyzed Erzurum Lala Pasha Mosque. For this purpose, firstly material characterization was implemented and then FE model was prepared. Compressive strength and tensile strength of materials were obtained from experimental characterization. However, elasticity modulus and density adapted from literature [15]. Nohutcu et al. (2015) studied Hafsa Sultan Mosque in Turkey. In their study, ultrasonic pulse velocity was used to obtain mechanical properties of granite and stone. Homogenization approach was used to determine mechanical properties of FE model [16]. Nohutcu et al. (2015) obtained mechanical properties by using ultrasonic pulse velocity test and then these values evaluated as bigger to adapt complete model of masonry elements [16]. Güllü and Karabekmez (2016) investigated seismic behavior of 125 years old Gaziantep Kurtuluş mosque. Material properties were adopted from literature [17]. Elasticity modulus, poisson ratio and compressive strength values were obtained from predicting with genetic algorithm by Baykasoğlu et al. (2008) [18]. Tensile strength value is adopted like $1/f_c$. İlerisoy and Soyuk (2012) studied on Şehzade Mehmet mosque to assess seismic performance [19]. Adopted material properties was addressed to similar studies by Kaya et al. (1998) [20]. Addressed reference contains a numeric study related to Süleymaniye mosque. Altunışık et al. (2016) studied on seismic safety of Kaya Çelebi mosque [21]. Material properties were adopted from Can et al. (2012) [12], Dan Cin and Russo (2014) [13] and Saloustros et al. (2015) [14]. Mangia et al. (2016) assessed seismic performance of Eltihatun Mosque located in Tunceli province. Adopted material properties obtained from literature on the base of medium hard masonry elements [22]. These properties can be seen in Table 1. There are eight mosques and experimental studies related to mosque. Material properties of these investigated mosques can be seen in Table 1.

The numbers in bracked demonstrates calibrated parameters

B. Bridges

There are many historical bridges either restored or non-restored in our country. A few of these bridges were studied by researchers. Hacıfendioglu et al. (2015) assessed seismic behavior of masonry arch Kurt bridge in Turkey against blast induced ground motion [23]. Material properties of bridge adopted from Sevim et al. (2011) [24]. Güllü and Jaf (2016) modelled a historical arch bridge with two different boundary condition approach. One of them is soil structure interaction and other of them is with fixed base boundary condition [25]. Material properties were adopted from similar study by Ural and Doğangün (2007) [2]. However, Ural and Doğangün estimated material properties on the base of their experiences for the same arch bridge. Altunışık et al. (2015) modelled a historical arch bridge called as Göderni bridge. Adopted material properties were obtained from laboratory test results. Sayın (2016) performed nonlinear dynamic analysis on a historical masonry arch bridge called as Nadir bridge [27]. The source of adopted material parameters is unknown. Sevim et al. (2011) presented earthquake response of historical masonry arch bridge [24]. Adopted material properties were referenced to similar studies by Frunzio et al. (2001) [28], Tokar and Unay (2001) [29] and Brencich and Sabia (2008) [30].

III. STATISTICAL ANALYSIS

This section contains statistical evaluation and correlation of Young's modulus and compressive strength of historical masonry material. The most common and used masonry materials are limestone and brick. Statistical evaluations are performed on these materials to easily obtain missing parameters with a known parameter.

A. Limestone

Limestone is of the most used material among historical masonry structures. Even if material properties are more abundant while compared with other materials, abrasion factor and environmental interference change the material properties of this material based on local conditions.

Figure 1. Young's modulus versus compressive strength of Limestone

As seen from the Figure 1, correlation between the Young's modulus and compressive strength is polynomial. This correlation can be defined with an equation indicated in the figure above. The confidence percent is 74.53%. This equation is proposed to determine unknown parameter with known one.

B. Brick

Brick is one another abundant material after stone masonry. One of the most important property of brick is more consistent than stone masonry. Because, while plotting the data and fitting the best curve to this material type, none of the data was ignored.

Figure 2. Young's modulus versus compressive strength of brick

The best fitted curve between the Young's modulus and compressive strength is polynomial as seen in Figure 2. Confidence percent is 73.37%.

IV. DISCUSSION

After the FE modelling procedure, one of the most important key point is to define correct parameter of historical heritage. Many researchers are missing a few important parameters like poison ratio, compressive strength or tensile strength. However, each parameter has own importance. Ural and Doğangün (2007) [2] investigated changing mechanical properties of infill and arch material parameters on the seismic performance of historical masonry arch bridge. However, Ural and Doğangün adopted material properties on the base of their experiences and considered intervention of material by external natural events. Güllü and Jaf (2016) [25] modelled a historical masonry arch bridge with soil structure interaction (SSI) and without SSI and then addressed Ural and Doğangün related to material properties of Mataracı bridge located at Trabzon. But, Ural and Doğangün performed sensitivity analysis on the base of masonry arch and infill material properties. Moreover, Ural and Doğangün considered natural intervention on mechanical properties of material [2]. Güllü and Karabekmez (2016) obtained material properties of investigated mosque by prediction with genetic algorithm on the base of in-situ testing [17]. Mangia et al. (2016) obtained material properties from literature referenced to medium strong masonry elements. Indeed, this assumption does not reflect actual behavior of the historical mosque [22]. Sayın (2016) implemented a numeric study on a historical Nadir bridge to assess seismic performance of the bridge [27]. However, adopted material properties has not been addressed to any reference. In addition, the used material type is not clearly presented in the study. This unknown information decrease reliability of the study. One

another example is randomly selected material properties on the base of self-experience like Ramos et al. (2010) performed model calibration on historical masonry tower before starting structural analysis [31]. However, randomly 1000 MPa elasticity modulus was selected for FE model of the historical tower. This random selection was implemented on the base of self-experience and high confidence of dynamic identification. However, due to high instrumentation cost, dynamic identification is always not possible for researcher.

V. CONCLUSION

The purpose of this paper is to present material properties of historical structures. Mosques and bridges were considered for this study. Moreover, this study limited with national historical structures. Recently, there are numerous study revealed by investigators that seek for performance evaluation of historical structures. However, reliability of these investigations depends completely on the adopted material properties of the investigated structure. External intervention is nearly impossible on historical monuments in order not to disturb available property of value. For this purpose, reliable references are required especially for numeric model of the investigated monument. Correct material properties that adapted to numeric model is indispensable to implement risk assessment of any type of historical structure. This study collected all material properties of investigated historical structures either with destructive or non-destructive testing evaluation. Moreover, this study includes experimental tests to determine engineering properties of the historical element or structure. This paper has contributions to the literature on the base of listed aspects;

1. Before performing a numerical assessment of a historical structure, precise material properties should be adopted to the structure with the same material and the structural type.

2. In an investigated structure, material properties of all element type cannot be the same properties. Vault, arch and wall element of the same model may contain different material properties even if these element type composed of the same material.

3. Adopted material properties can be calculated by different approaches like homogenization. This calculated property reflects overall behavior of brick and mortar unit. While calculating these parameters, selected material properties of the unit and mortar should be selected on the base of individual characterized elements.

4. Adopted material properties should simulate structural intervention and restoration well.

Abstract--The basic functions expected from any structure are generally sufficient rigidity, ductility and stiffness. In this study, the effect of steel ducts with high ductility level on the performance of steel structures was investigated. For this purpose, calculations were made using five different types of central steel curtains for steel flues of any hospital building. Period, frequency, modal addition rates, displacement and rotation values are calculated and compared for each different central steel screen. The aim of the study is to be informed about the central steel slabs with high ductility level and to have information about which of the most suitable central steel slabs will be chosen.

Keywords--Ductility; High Ductility; Steel Structures; performance; Steel Cross Braced Frame

I. INTRODUCTION

Rigidity, ductility and strength must be sufficient to ensure that the earthquake loads are transmitted continuously and safely to the foundation of the earthquake loads as well as in each of the elements constituting the earthquake loads at the same time [1]. Adequate rigidity, strength and ductility are at the top of the principles considered in the design of earthquake-affected structures. In the regulation of the structural bearing system, the material strength, the ductility and

stiffness concepts in the elements are important parameters. These parameters need to be built into the structure.

Generally, ductile conveying systems are the foreground in the depressive structure design. However, it is emphasized that the selection of the regular carrier system in the horizontal and vertical sections and the encouragement to be shown in the junctions of the elements.

Ductility is defined as the extent of displacement of a section, of an element or of a carrier system, without significant change in external load, beyond the elastic limit, and the system ductility rate is proportional to the linear shape changes of the total shape changes in the displacement order. The result of the system ductility ratio taking large values ensures that the structure can change its nonlinear shape sufficiently before migration.

Central crossed structures are very popular for medium height structures. Design and production are simple and the required horizontal stiffness and strength can be obtained with low cost. The horizontal stiffness of the central steel cross curtains is provided by vertically positioned cage beams. This lattice behavior is obtained by crossing the column and the beams [2], [3], [4].

In this study, calculations were made in the case of using five different centric steel braced frames for a steel chimney belonging to a structure designed as a hospital building. The results were compared and recommendations were made.

II. METHODOLOGY

Structural engineering is the science and art of designing and making, with elegance and economy, buildings, bridges, frameworks and other similar structures so that they can safely resist the forces to which they may be subjected. The main purpose of structural design is to produce suitable structure. We must consider not only the initial cost, but also the cost of maintenance, damage and

failure. Thus, the optimum design of a structure requires a general view on the total process.

The design of steel seismic resistant structures took a dramatic turn after the last Californian and Japanese events. The heavy damage observed as a result of these earthquakes was never before recorded in the history of building design. These events gave rise to a general effort all over the world to improve the seismic resistance of steel structures. A comprehensive program started to evaluate both the design specifications and detail

rules. In this perspective, clear attention has been paid to the evaluation of local ductility erosion at the level of sections [2].

A ductility is a measure of the ability of a section, an element, or a carrier system to deform beyond the elastic limit, without significant change in external load. The numerical definition of the system ductility ratio is the ratio of the total shape change to the linear shape change during the displacement.

The two most important features of steel are energy absorption capacity under ductility and repeated inelastic loading. In terms of behavior against depression, horizontal load carrier systems of steel buildings are separated into two classes in terms of ductility level [1].

In Turkish Seismic Code, DBYBHY-2007, based on their behaviour against seismic events, the lateral load bearing systems of the steel constructions are classified in two sections based on their ductility.

a. *Systems with High Ductility*

b. *Systems with Low Ductility*

Based on this, the classifications are further divided to

- *Frames with High Ductility,*
- *Shears with Steel Cross Beam Bars with High Ductility,*
- *Shears with Outer Steel Cross Beam Bars with High Ductility,*
- *Frames with Standard Ductility” and*
- *Shears with Steel Cross Beam Bars with Standard Ductility,*

to form a list with five different titles with descriptions in seismic activity regulations.

In this study, centric steel braced frames with high ductility level are shown in Figure 1. The lateral load carrying capacity of these systems is large, along with their bending strength. Obviously, these shear wall systems can be interpreted as earthquake walls in a reinforced concrete structure.

Fig. 1. Centric Steel Braced Frames with High Ductility

III. NUMERICAL APPLICATIONS

As a numerical application, a steel chimney of hospital structure was analyzed. In the project, the steel chimney was transferred to the rectangular truss system. The steel chimney has an area of 3,125 m² and a span of 2.5 m. The building height is 12 m. 150 * 150 * 5 mm was used for the structural system columns and 60 * 60 * 4 mm box

profiles were used for the beams and bracing members (Figure 2).

Fe37 steel was used as material. In Fe37 steel $\sigma_{saf} = 14.1 \text{ kN/cm}^2$, $\sigma_{yield} = 24 \text{ kN/cm}^2$, $\sigma_{weld} = 11 \text{ kN/cm}^2$ were taken.

In calculations, truss span $L = 2,50 \text{ m}$, truss space $L' = 1,25 \text{ m}$ and number of truss were two. The wind load is taken as $q = 0.8 \text{ kN/m}^2$ from TS498 Specification [5].

Fig. 2. Steel Chimney Plan

The steel chimney was modeled and analyzed in the SAP2000 package program [6]. It is modeled as a 12-storey structure while modeling a 12 m high chimney system. Five different centric

steel braced frames were used in this study. Centric steel braced frame types considered in the study are taken from the SAP2000 program and shown in Figure 3.

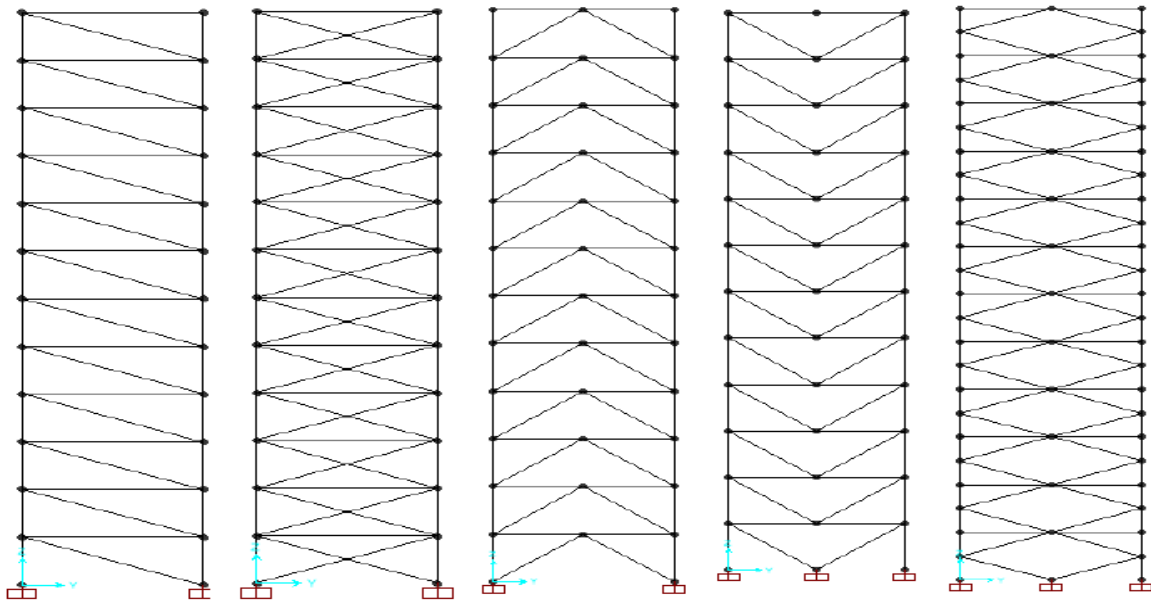

Fig. 3. SAP2000 model of Centric Steel Braced Frames

In the dynamic analysis of the chimney system, the seismic parameters and function values shown in Figure 4 are entered. Period, frequency

and eigenvalues are calculated for each braced type with these values.

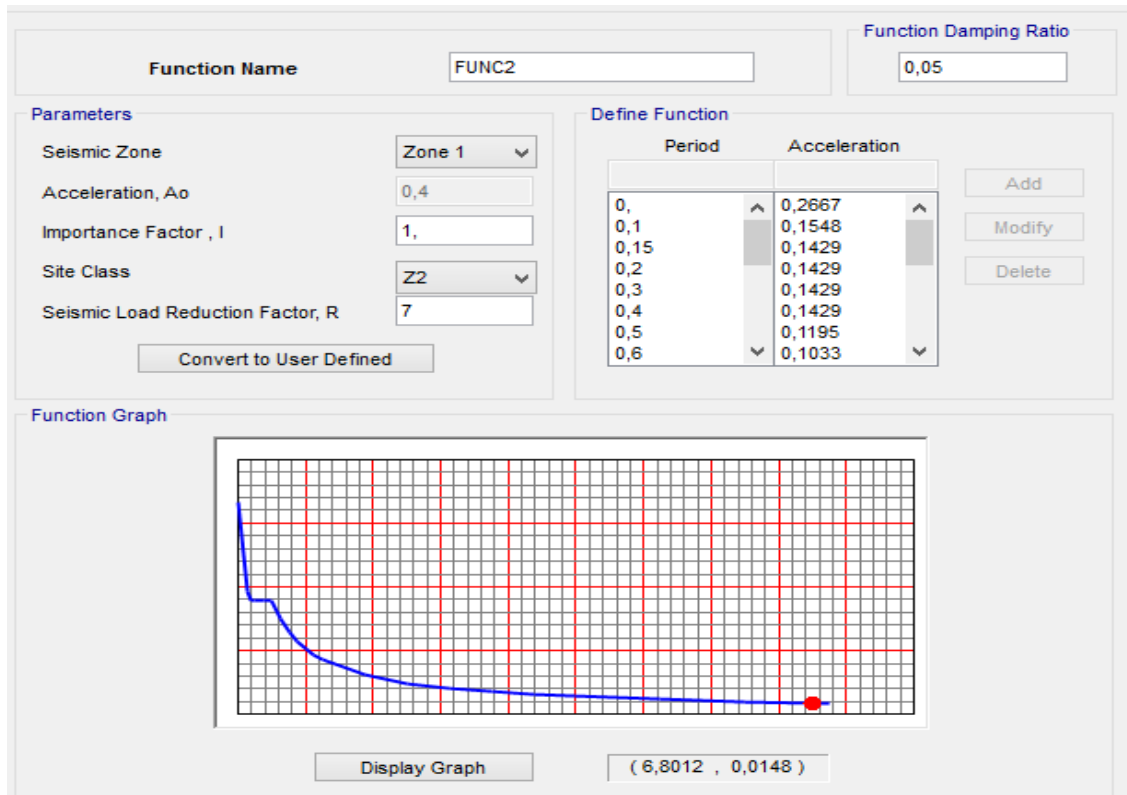

Fig. 4. Seismic parameters in SAP2000 program

The displacements and rotations calculated in the SAP2000 program for the five different steel

braced frames given in Figure 3 above are presented in Table 1.

TABLE 1. Displacements and rotations of centric steel braced frames

FRAME TYPE	Displacements [mm]			Rotations [rad]		
	U _x	U _y	U _z	R _x	R _y	R _z
Diagonal Bracing	10,40	-0,10	-0,70	0,00000	0,00095	-0,00013
X-Bracing	8,90	0,27	-0,70	0,00000	0,00090	-0,00010
Inverted V-Bracing	8,20	0,00	-0,50	0,00000	0,00082	0,00000
V-Bracing	10,70	0,00	-0,70	0,00000	0,00100	0,00000
K-Bracing	8,90	0,00	0,60	0,00000	0,00090	0,00000

As shown in Table 1, the maximum lateral displacement is calculated as $U_x = 10.7$ mm at the top of the steel chimney. In the specifications, displacement is generally given as $U_x \leq \Delta_{\max} =$

$H/300$ limit. From here, if the constraint is checked, $U_x = 10.7 \text{ mm} \leq \Delta_{\max} = 12000/300 = 40 \text{ mm}$ will be seen.

IV. RESULTS

In this study, the effect of five frames with high ductility level centric steel braced frames were investigated. Horizontal displacement values occurring in the building under lateral loads (earthquake and wind loads) are given in Table 1. The limitation given by the specifications is provided with confidence. That is, the frame with high ductility level centric steel braced frames is provided with a rigidity of about four times.

Nearly the same performance was achieved with five types of centric steel braced frames applied to lateral displacements.

With the classic Moment-resisting frames, larger lateral displacements are obtained and displacement limits can not be achieved.

Finally, it is concluded that the systems providing the best limitations for earthquake performance and specifications are high ductility level centric steel braced frames.

Abstract—In this paper, continuous and discontinuous contact problems for layers loaded by symmetrical distributed loads whose lengths are $2a$ on an elastic semi-infinite plane is solved using finite element method. The elastic layer also subjected to uniform vertical body force because of effect of the gravity. Thickness in z direction is taken to be unit. It is assumed that the contact surfaces are frictionless, only normal tractions can be transmitted through the contact areas. The contact along the interface between elastic layer and half plane is continuous if the value of load factor is less than a critical value. In continuous and discontinuous contact cases, the stress distribution on the contact interface are plotted for different dimensionless quantities. The finite element method of the problem is constituted using ANSYS software and analysis of the problem is carried out. Finally, the results obtained from the finite element solution are verified by comparison with the analytical results. (*Abstract*)

Keywords—mechanic, continuous contact, discontinuous contact, elasticity, half plane, finite element analysis.

I. INTRODUCTION

Since contact problems have possible application to a variety of structures of practical interest such as foundation grillages, pavements in roads and runways, railway ballasts and other structures consisting of layered media, there has been an increasing attention on the contact problems. There is large body of literature concerned with contact problems both analytically [1-9] and numerically [10-15].

Except for these papers, El-Borgi et al. investigated a receding contact problem between a functionally graded layer and a homogeneous substrate and they studied the effect of the material nonhomogeneity parameter and the thickness of the graded layer on the contact pressure and on the contact lengths. Kahya et al. studied a receding contact problem for an anisotropic elastic medium consisting of a layer and a half plane and they obtained contact stresses and contact lengths for

different fibre orientations. A double receding contact axisymmetric problem between a functionally graded layer and a homogeneous half plane is solved Rhimi et al.. Effects of surface tension on axisymmetric Hertzian contact problem and they obtained helpful results to characterize and measure the mechanical features of soft materials or biomaterials through micro-indentation. El-Borgi et al. considered a frictional receding contact problem between a functionally graded layer and a homogeneous semi-infinite plane and they analyzed the effect of friction coefficient and nonhomogeneity factor on the contact pressure distribution and contact lengths. Gun and Gao presented a quadratic boundary element formulation for continuously nonhomogeneous, isotropic and linear elastic functionally graded material contact problems with friction. Yan and Li analyzed double receding contact problem between functionally graded layer and elastic layer. Li et al. are presented fundamental contact solutions of a magneto-electro-elastic half space indented by a smooth and rigid half infinite punch. Comez studied moving contact problem for a rigid cylindrical punch and a functionally graded layer and he obtained an effect of relative moving velocity for contact problem of functionally graded layer.

In this paper, continuous and discontinuous contact problem for infinite layer on an elastic semi-infinite plane is solved using FEM. The load which will occur by initial separation and the bigger values than this load, the stress distribution on the contact surfaces are plotted for different dimensionless quantities. Finally, the results obtained from FEM are verified by comparison the analytical results.

II. DEFINITION OF THE PROBLEM

Fig. 1. Geometry and loading of the contact problem

In this paper continuous and discontinuous contact problems for layers on an elastic semi-infinite plane is solved using finite element method. Layers are loaded by symmetrical distributed loads whose lengths are $2a$ and thickness in z direction is taken to be unit. It is assumed that the contact surfaces along the interfaces is frictionless, only normal tractions can be transmitted through the contact surfaces, body forces of elastic layer is taken into account and body force of semi-infinite plane is neglected.

As shown in Fig. 1, consider the symmetric plane strain problem consist of an infinitely long homogeneous layer of thickness h in smooth contact with semi-infinite plane. μ_1 , ν_1 and ρ_1 are the shear modulus, poisson ratios and density of a layer respectively. Similarly μ_2 , ν_2 and ρ_2 are the shear modulus, poisson ratios and density of a half space respectively.

III. THE FINITE ELEMENT SOLUTION

The finite element method is a numerical method for solving problems of engineering and mathematical physics. In this method, problem divides into simpler parts that are called finite elements and the model transform into large system of equations. With recent developments in computer technology and package programs for FEM solution of large system of equations is fulfilled.

In this study, the finite element analysis is performed by ANSYS software program. The geometrical model is created with the standart tools in ANSYS software. Because of the problem exhibits symmetry in geometry, material proportions and loading, only half of the problem is modeled. The geometry and the applied load are shown symmetrically in Fig. 2. The layer and semi-infinite plane are considered as linear elastic and isotropic. In the analysis, geometric properties are taken as $L = 12m$ (length of the layer in x direction), $h_1 = 1m$ (thickness of the layer in y direction). Other parameters are choosen such that $p_0/\rho gh$, μ_1/μ_2 , κ_1/κ_2 . Are compatible with analytical values.

Fig. 2. Schematic model of the contact problem (symmetric finite element model)

PLANE183 element is used for the modeling elastic layer and semi-infinite plane. PLANE183 element consist of eighth nodes having two degrees of freedom: translations in the nodal x and y directions. Frictionless surface-to-surface 2D contact elements are used to model the interaction between the contact surfaces: CONTA172 and TARGE169. CONTA172 is used to represent contact. Target surfaces is defined by TARGE169 for the associated contact elements CONTA172. Several numerical solution methods have been proposed to solve the variational equation of elastic contact problem, including penalty method, augmented Lagrangian method, Lagrange multiplier method method and augmented Lagrangian multiplier method. These methods incorporated to general finite element analysis (FEA) technology, are applied to solve the contact problem that involves complex geometry shapes. In the penalty method, the accuracy of the solution depends on the choice the penalty parameter. Too small a penalty parameter may cause unacceptable error in the solution. Also the penalty method suffers from ill-conditioning as the penalty parameter becomes large. The augmented Lagrangian method is an iterative series of penalty methods. The contact tractions (pressure and frictional stresses) are augmented during equilibrium iterations so that the final penetration is smaller than the allowable tolerance. Compared to penalty method, the augmented

Fig. 3. Deformed shape after finite element analysis.

Lagrangian method usually leads to better conditioning and is less sensitive to the magnitude to contact stiffness. The Lagrange multiplier method introduces new unknowns for each constraint. Therefore, it always increases the dimension of the system equations to be solved. For large scale problems where the contact surface consist of a large number of nodes, the number of unknowns introduced by the Lagrange multiplier method is also large. This increases the CPU time to solve the problem. For the augmented Lagrangian multiplier method, both penalty parameters and Lagrangian multipliers are applied, and penetration is admissible but controlled by allowable tolerance [28]. In this study, Augmented Lagrangian method is used as the contact algorithm. And the deformed shape after analysis is shown in Fig. 3

IV. CONCLUSIONS

In this paper, continuous and discontinuous contact problem for infinite layer and semi-infinite plane is solved by using finite element method and results obtained from finite element method are verified by comparing with analytical results in literature. Note that all quantaties are dimentionless.

Fig. 4-5 shows contact stress distributions for the continuous contact cases. It can be seen that the initial separation point x_{cr} seems to increase as a/h increases.

Fig. 4. Contact stress distributions for the cases of continuous ($e=e_{cr}$) for the first loading condition. ($\mu_1/\mu_2 = 1/3$, $e_{cr} = p_0/(\rho_0 gh)$)

Fig. 5. Contact stress distributions for the cases of continuous ($e=e_{cr}$) for the second loading condition. ($\mu_1/\mu_2 = 3$, $e_{cr} = p_0/(\rho_0 gh)$)

Fig. 6. Contact stress distributions for the cases of discontinuous ($e > e_{cr}$) for the first loading condition. ($\mu_1/\mu_2 = 1/3$, $e_{cr} = p_0/(\rho gh)$)

Fig. 7. Contact stress distributions for the cases of discontinuous ($e > e_{cr}$) for the first loading condition. ($\mu_1/\mu_2 = 1/3$, $e_{cr} = p_0/(\rho gh)$)

The variation of the normalized contact stress $\sigma_y(x,0)/(\rho gh)$ between the infinite layer and semi-infinite plane is shown Fig. 5-6. As it can be seen in graphics, there are three regions in the discontinuous contact between the layer and semi-

infinite plane. These are the continuous contact region, separation zone, and the discontinuous contact region where the effect of the external load (P) decreases and disappears infinitely. If the a/h increases, initial separation point occurs a longer distance from the origin and separation zone decreases for similar material proportions.

Finally, based of the comprasion of numerical values obtained from finite element solution and analytical solution in literature [11], difference between finite element solution and analytical solution in literature is in a acceptable range.

MS EXCEL Macro Applications of Finite Difference and Integration Method for Simply Supported Rectangular Plates Under Sinusoidal Load

Sedat SAVAŞ

Firat Univ. Eng. Faculty
Civil Eng. Dept.
Elazig/TURKEY
ssavas@firat.edu.tr

Abstract— In this study, an elastic plate under sinusoidal loading was compared with the finite differences and integration methods. This question type, which is one of the common examples in the literature, is available with various methods. In this study, Microsoft Excel excel macro program, VBA, has written program codes for both finite element method and integration method. The difference between the results of these programs and the CPU time is calculated.

Keywords— *Finite Difference Method; Integration Method; Elastic Plate ; microsoft Exell Macro*

I. INTRODUCTION

Numerous calculations have been made up to now on the solution of elastic plates. These studies were carried out by varying the dimensions of the elastic plaques from time to time and changing the loading conditions applied on the bases, changing the boundary conditions at the bases. In this study, four edges under sinusoidal loading resolve a simple supported elastic plate problem [1]. These solutions were compared with manual solutions and also within themselves.

In this analysis, VBA programming language in Microsoft Excel is used. The reason for choosing this applet is that it is easy to access and is easy to implement by every engineer. In addition, the ability to read data from the file and write data to the file is easier, as well as the wide selection of graphics. However, the CPU time is not the performance seen in other programming languages .

II. SINUSOIDAL LOAD UNDER ELASTIC PLATE

A. System geometry and loading condition

In the coordinate system given 2.1, the rectangular plate with long side a, short side b is simply supported. We assumed that the sinusoidal load distributed over surface of rectangular plate is given by the expression

$$q = q_0 \sin\left(\frac{\pi x}{a}\right) \cos\left(\frac{\pi y}{a}\right) \quad (1)$$

in which q_0 represents the intensity of the load at the center of the plate.

Fig 2.1. Rectangular plate

III. INTEGRATION METHOD

Generally, numerical approximation methods require reaching in several steps of solving by dividing time or space region into specific intervals, or in most cases require successive iteration solutions [2,3,4]. Numerical methods developed for this reason. They have various advantages or disadvantages in terms of the computational needs they require, the time spent on the solution or the CPU (Central Processing Unit) time, the stability of the equations, the number of node points used, the preprocessing for problem solving, and most importantly the time spent on this solution.

In this method, Elastic curve equation for (1) equation loading condition ;

$$\frac{\partial^4 w}{\partial x^4} + 2 \frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = \frac{q}{D} \quad (2)$$

The differential equation (2) for the deflection surface in this case becomes;

$$\frac{\partial^4 w}{\partial x^4} + 2 \frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = \frac{q_0}{D} \sin\left(\frac{\pi x}{a}\right) \cos\left(\frac{\pi y}{a}\right) \quad (3)$$

in which the quantity D, taking the place of the quantity EI in the case of beams, is called the flexural rigidity of the plate. The boundary conditions for simply supported edges are

$$w=0 \quad M_x=0 \quad \text{for } x=0 \text{ and } x=a$$

$$w=0 \quad M_y=0 \quad \text{for } y=0 \text{ and } y=b$$

we can represent the boundary conditions in the following form:

$$w=0 \quad \frac{\partial^2 w}{\partial x^2} = 0 \quad \text{for } x=0 \text{ and } x=a$$

$$w=0 \quad \frac{\partial^2 w}{\partial y^2} = 0 \quad \text{for } y=0 \text{ and } y=b$$

All boundary conditions are satisfied if we take for deflections the expression;

$$w = C \sin\left(\frac{\pi x}{a}\right) \cos\left(\frac{\pi y}{a}\right) \quad (4)$$

in which the constant C must be chosen so as to satisfy Eq. (3). Substituting expression (4) into Eq. (3), we find

$$\pi^4 \left[\frac{1}{a^2} + \frac{1}{b^2} \right]^2 C = \frac{q_0}{D} \quad (5)$$

and we conclude that the deflection surface satisfying Eq. (3) and boundary conditions is

$$w = \frac{q_0}{\pi^4 \left[\frac{1}{a^2} + \frac{1}{b^2} \right]^2 D} \sin\left(\frac{\pi x}{a}\right) \cos\left(\frac{\pi y}{a}\right) \quad (6)$$

In the light of these equations, we have applied this equation to find the displacements along the entire plate surface with the aid of the program we have done in excel macro.

Step of program:

- 1- Once plates surface is defined.
- 2- The plate lengths are divided into equal parts
- 3- Cyclic increments are made in the x and y directions

- 4- These values are placed in the equation
- 5- Program is stopped

IV. FINITE DIFFERENCE METHOD

Boundary value problems do not have many definite and closed solutions. Approximate solutions are available for this. Approximate methods are divided into characters. Some agrees with the provision of boundary conditions, but requires that the differential equation be precisely met. In the second group of methods, there is approximation in the presence of the differential equation, even if the boundary conditions are precise. The finite difference method is a method that can be applied to almost every other form entering this second group[].

It is possible to approximate the derivative of a function $y = f(x)$ at a certain set of discrete points, using known values. Similarly, approximate partial derivative formulas can be given for multivariable functions of type $z = f(x, y)$. Considering the definition of derivative, advanced difference approach, backward difference approach and central difference approach are emphasized.

Fig. 2.2. The derivation of $f'(x)$ at point P using forward and backward and central differences

Advanced difference formula:

$$f'(x_0) = \frac{f(x_0 + \Delta x) - f(x_0)}{\Delta x} \quad (7)$$

Back difference formula:

$$f'(x_0) = \frac{f(x_0) - f(x_0 - \Delta x)}{\Delta x} \quad (8)$$

Central difference formula:

$$f'(x_0) = \frac{f(x_0 + \Delta x) - f(x_0 - \Delta x)}{2\Delta x} \quad (9)$$

The theory of elasticity is a branch of the theoretical physics, and the strain and shape changes that occur in elastic bodies under the influence of the objective external loads are calculated precisely by moving from a certain set of differential equations. In this case, the vehicle used for the solution is the differential equation theory[3].

The principal equation of plane elasticity theory;

$$\Delta(\sigma_x + \sigma_y) = \Delta\Delta F = \frac{\partial^4 F}{\partial x^4} + 2 \frac{\partial^4 F}{\partial y^2 \partial x^2} + \frac{\partial^4 F}{\partial y^4} = 0 \quad (10)$$

From the boundary conditions:

$$F_s = M(s) \text{ and } \left(\frac{dF}{dn} \right) = -Q_t(s) \quad (11)$$

Here;

F_s : Stress function,

$M(s)$: Static moment,

Q_t : It is the trace of the boundary value forces on the tangent.

The way to solve the problem of boundary value:

- Equation (11) calculates the values of the den function at the boundary precisely,
- The coefficients of the finite difference are calculated
- We extend the function to the outside of the region to be calculated,
- Divide the calculated shape into the desired number of node points to form the finite difference equations,
- Since the gauss-elimination method is used, conversion of the results to square matrix
- By solving these results into a matrix format.

V. SUMMARY AND CONCLISION

In this study, an elastic plate finite difference method and a generalized computer program were used to obtain the elastic plate deflection graph for a complex loading situation of the geometry. The results were compared and the solutions were made. In the comparison made, 0.01 percent error was observed between the integration method and the final difference method. Displacement graphics have topped. The reason is that The number of segment is excessive. But the solution time is ten times more in the finite difference method.

Abstract— Structures are exposed to various dynamic effects such as earthquake, wind and traffic load. It need to be taken various measures for surviving the structures under dynamic loads. Taking the appropriate measures depends on the well-known of dynamic behavior of existing structures. This behavior of the structure can be known through analytical or experimental methods. In the analytical methods, many acceptance is made in finite element modeling of the structure and it is considered that the created model represents its existing case. However, it is rather difficult to fully represent of the existing structure with the accepted assumptions. In experimental methods, the dynamic characteristics of the structure (natural frequencies, mode shapes and damping ratios) are determined for the present case. Using these dynamic characteristics, the existing analytical model of the structure can be updated and the evaluation of the structure according to this new model can be made more realistic. In this study, analytical and experimental analyses of the minaret of Firat University Engineering Campus Mosque were carried out. The finite element model has been updated depending on the dynamic characteristics obtained from the experimental analysis.

Keywords— Dynamic characteristics; Reinforced concrete minaret; Analytical model; Environmental vibration data; updating of finite element model.

I. INTRODUCTION

As depending on the fast progress of the technology, the produced electronic devices enable easy observation of the behaviors of living things and also enable observation of the behaviors of the structures [1]. The analysis of the acceleration signals obtained with the help of accelerometers gives some

information about the structure. By comparing the results obtained for different situations, it can be determined whether there is any change in the behavior of the structure. Experimental Modal Analysis method is widely used for this purpose [2]. The basis of experimental modal analysis studies, which have application scope in many engineering disciplines, is based on the 1940s. At early times, non-practical approaches was mostly used since transformers measuring dynamic forces were simple. In the 1960s, the modern era of experimental modal analysis began as depending on the development of digital computers and Fast Fourier Transforms [3].

Structures are exposed to various dynamic effects such as earthquake, wind and traffic load. It need to be taken various measures for surviving the structures under dynamic loads. Taking the appropriate measures depends on the well-known of dynamic behavior of existing structures. While the dynamic characteristics of the structures (natural frequencies, mode shapes and damping ratios) are used to determine its dynamic behavior with using the mode superposition method, it also helps to control the accuracy of the analytical model. These characteristics cannot be at the expected values due to cracking, fatigue, collapse of support in the structures and/or workmanship faults during construction [4]. Therefore, it is considered that using of the dynamic characteristics obtained from analytical methods in determining dynamic response of the structures can be given incorrect results. Since experimental methods are applied on the current state of the structures, dynamic characteristics obtained by these methods reflect the current situation. Updating of analytical models of structures

with respect to results of experimental methods will lead to more realistic results [5-7].

There are many studies on determining the dynamic characteristics of structures based on experimental measurements [8-14]. In these studies, the dynamic characteristics of many structures such as minaret, tower, mosque, church, etc., which are constructed as reinforced concrete/masonry, are determined.

II. EXPERIMENTAL METHOD

Vibration is the behavior of structures under initial conditions or under applied external loads. Basically, there are two types of vibration, free and forced vibration [7,15]. Free vibration occurs under the initial conditions of the structure and ends with the effect of damping after a while. In this type of vibration, the fundamental frequency is the smallest frequency and usually the most effective frequency of the structure. If an external load is applied to the structure, the name of this vibration is the forced vibration. As long as the structure is exposed to external load, vibration of the structure continues [16]. The experimental method to be used varies depending on whether vibration is known or not. If the numerical values of vibration applied to the structure are known, Conventional Modal Analysis (CMA) method, if the numerical values of the vibration are unknown and the structure vibrates under of environmental effects, Operational Modal Analysis (OMA) method is used. OMA method are not needed expensive devices when compared to CMA method at large volume structures for artificial excitation [5,17].

OROS-OR36 Multichannel Noise and Vibration Analyzer is used in the experimental measurements based on the OMA method (Figure 1).

Fig. 1. OROS-OR36 Multichannel Noise and Vibration Analyzer

III. NUMERICAL APPLICATION

In this study, theoretical and experimental analyses of the minaret of Firat University Engineering Campus Mosque (Figure 2) were carried out. This minaret had built as reinforced concrete.

A. Theoretical Analysis

The analytical model of the selected reinforced concrete minaret was created with shell elements by using SAP2000 finite element package program. In the initial analytical model, the modulus of elasticity of the concrete was taken as $11 \cdot 10^3$ MPa (Figure 3). The values of first three frequencies obtained

from the modal analysis using the initial analytical model are 2.30, 2.45 and 8.77, respectively.

Fig. 2. Minaret of Firat University Engineering Campus Mosque

Fig. 3. Finite element model of Minaret

B. Experimental Analysis

1) *Creating Experimental Model:* OMA method were used in the experimental measurements of the structure. Measurements were taken with the accelerometers attached to 4 different points of the structure. The measurement points on each floor are selected as points having the same coordinates in the "x" and "y" directions. 8 accelerometers were totally used for the measurement without reference as two accelerometers each of which are placed in x and y directions for each point (Figure 4).

Fig. 4. The accelerometer system for measurement without reference

2) *Experimental Measurement and Updating Analytical Model*: After the preliminary tests of structure carried out, (finite element model solutions and in-situ wide frequency range measurements), the measurement frequency range, time and other parameters were determined. The Modal Indication Function was created by processing raw signals obtained from measurements. With the help of this function, first three frequencies were selected and values of that are 2.15, 2.32 and 9.56 Hz, respectively. Mode shapes with related these frequencies were given in Figure 5-6.

Fig. 5. Selected frequencies from modal indication function

The compatibility of analytical and experimental modes was controlled by a criterion called Modal Assurance Criteria (MAC). This criterion [16] is defined by the (1) equation.

$$MAC(\psi_a, \psi_d) = \frac{|\psi_a^T \psi_d|^2}{(\psi_a^T \psi_a)(\psi_d^T \psi_d)} \quad (1)$$

where ψ_a and ψ_d refer to analytical and experimental mode shape, respectively. If the analytical and experimental mode shapes are entirely the same, the MAC value must be 1, otherwise this value must be less than 1.

In comparison of the initial analytical model solutions and experimental results (Table I), the frequency and MAC values

were seen to be compatible for both method. It was also given experimental damping ratios in Table I. It is thought that differences between analytical and experimental frequencies can be minimized if the initial model of the structure is updated. The minaret mass is considerably known. There is more uncertainty in stiffness. Factors affecting the stiffness can be expressed as concrete elasticity and boundary conditions. Here, elasticity module of concrete was updated as 10×10^3 MPa. Modal analysis of the updated analytical model was performed and, the first three frequencies and mode shapes were presented in Table II and Figure 7, respectively. Now, the frequency and MAC values of first two modes for the updated analytical model are closer to the results of the experimental method.

Fig. 6. Mode shapes for selected frequencies

TABLE I. COMPARISON OF INITIAL ANALYTICAL MODEL SOLUTIONS AND EXPERIMENTAL RESULTS

Mode Number	Analytical Frequencies (Hz)	Experimental Frequencies (Hz)	Experimental Damping Ratios (%)	MAC (%)
1	2.30	2.15	4.09	96.281
2	2.45	2.32	3.29	91.841
3	8.77	9.56	2.89	90.419

TABLE II. COMPARISON OF UPDATED ANALYTICAL MODEL SOLUTIONS AND EXPERIMENTAL RESULTS

Mode Number	Updated Analytical Frequencies (Hz)	Experimental Frequencies (Hz)	MAC (%)
1	2.24	2.15	96.366
2	2.34	2.32	95.898
3	8.58	9.56	90.397

Fig. 7. The first three modes obtained using updated analytical model

IV. RESULTS

In this study, dynamic characteristics of a reinforced concrete minaret were determined by using Operational Modal Analysis (OMA) method and the analytical model of this minaret was updated. The analytical model solution was obtained by using SAP2000 finite element package program. Modal analysis of the analytical model was performed to find the dynamic characteristics and the first three frequencies were obtained at the range of 2.30-8.77 Hz.

The OROS-OR36 Multichannel Noise and Vibration Analyzer was used for experimental measurements. In these measurements, the first three frequencies are in the range of 2.15-9.56 Hz and the damping ratios related to these frequencies are in the range of 2.89-4.09%.

In comparison of the initial analytical model solutions and experimental results, the frequency and MAC values were seen to be compatible for both method. Differences between analytical and experimental frequencies can be minimized if the initial model of the structure is updated. The minaret mass is considerably known. There is more uncertainty in stiffness. Factors affecting the stiffness can be expressed as concrete elasticity and boundary conditions. Here, elasticity module of concrete was updated. The first three frequencies of the modal solutions of the updated model were obtained in the range of 2.24-8.58Hz. For the frequency and MAC values of first two modes, modal solution of the updated analytical model are closer to the results of the experimental method.

It has also been shown in this study that the dynamic characteristics of structures can be obtained using experimental methods and the analytical models can be updated according to the results of the experimental methods.

Abstract — Masonry structures are commonly used in many countries. Load bearing masonry walls are the most important structural element in the masonry structures. In this study, a computer program was written in MATLAB for linear elastic analyses of masonry walls. In addition, a mesh program which meshes the wall as two dimensional model was written in MATLAB. These models were constituted with macro modeling approach. Three different load cases were applied to two dimensional masonry model with opening. The obtained results from the linear elastic analysis were compared with ANSYS software results.

Keywords —masonry walls; linear elastic behaviour; finite element method

I. INTRODUCTION

Masonry is the oldest building material that still finds wide use in today's building industries [1]. Masonry structures are the construction systems where walls, comprised of mortar and masonry units such as briquette, brick, stone and adobe, are used as load bearing system. Undoubtedly, the most important structural element for masonry structures is the load bearing walls. These structures are commonly used in many countries all over the world. The most important characteristic of masonry construction is its simplicity. Laying pieces of stone, bricks or blocks on top of each other, either with or without cohesion via mortar, is a simple, though adequate, technique that has been successfully used ever since remote ages [2]. Half of the existing building stock is consist of masonry structures in Turkey [3]. The vast majority of these structures are located in the rural areas and neighborhoods around the city.

Masonry structures prefer over other structural systems because the relevant materials can be easily obtained and their construction and workmanship are easier. For this reason, the ratio of masonry structures increase to 82% in rural regions [4]. Masonry structures can be divided into three groups as confined, unreinforced and reinforced masonry structures. These structures are commonly constructed as to be unreinforced masonry in Turkey. These structures are constructed with traditional techniques using locally available materials. Nearly no engineering services are used in these buildings.

II. MODELING OF MASONRY

Masonry is a material which exhibits distinct directional properties due to the mortar joints which act as planes of weakness. In general, the approach towards the numerical representation of masonry can focus on the micro-modeling of the individual components, unit (brick, block, etc.) and mortar, or the macro-modeling of masonry as a composite [5]. Depending on the level of accuracy and the simplicity desired, it is possible to use one of the modeling strategies. Three different strategies which called detailed micro modeling, simplified micro modeling and macro modeling are used for modeling the masonry structure. One modeling strategy cannot be preferred over the other because different application fields exist for micro- and macro-models.

In the detailed micro-modelling, the material specifications of the masonry units and the mortar, i.e., the modulus of elasticity, density and Poisson ratio are evaluated separately.

The masonry units are widened by as much as half of the mortar layer in the simplified micro-modelling. Thus, the mortar layer is neglected, and the masonry units are separated from each other with interface lines.

Macro-modelling is an equivalent material model that assumes the construction elements to be a composite without any exception among stone, brick and mortar. These modeling strategies are given in Figure 1.

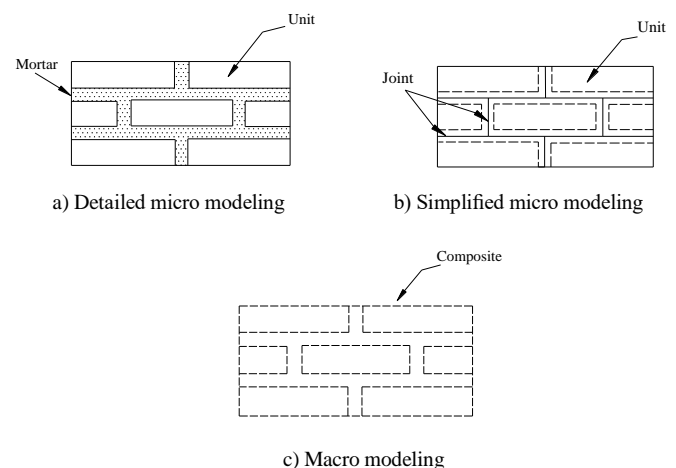

Fig. 1. Modeling strategies of masonry structures (Lourenço, 1996)

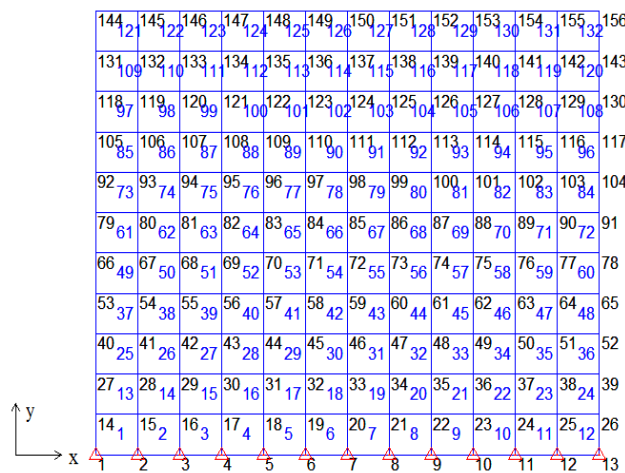

III. LINEAR ELASTIC ANALYSES

In this study, linear elastic analyses of a masonry wall was performed. For this purpose, a program that can perform linear analyses of masonry walls was written in MATLAB. The program was named as masonry-lin. Also, a mesh program was written in MATLAB that can draw the wall with and without opening and prepare the necessary information as input file for the masonry-lin [6]. The mesh program is modelled the masonry wall as two dimensional by means of the macro modelling approach. Node coordinates, element and node numbers, element connectivity, restrained nodes and material properties are prepared with the mesh program as the input file for the masonry-lin.

Finite element mesh of the wall with and without opening created by the mesh program is presented in Figure 2. In this figure, black and blue numbers on the wall show node points and element numbers, respectively.

a) with opening

b) without opening

Fig. 2. Finite element mesh of the masonry wall

The masonry-lin. uses this input file and starts the analysis. It calculates displacement, stress and strain values of the node points. In finite element implementation, finite element model

of the masonry wall is constructed using quadrilateral elements, with four nodal points and two degrees of freedom on each nodal point. Element stiffness matrixes were found using 2x2 Gauss integration rule. The flow diagram of the masonry-lin. is presented in Fig. 3.

Fig. 3. Flow diagram of the masonry-lin.

Three different load cases were applied to two dimensional masonry model with opening. The base nodes of the wall were fixed in x and y directions at all load cases. For first and second load case, single load is applied at horizontal and vertical direction, respectively. For third load case, these two single loads are applied together to the masonry wall model. Value of the single load is considered as 50 kN. The modulus of elasticity, mass per volume and Poisson's ratio for the masonry unit is considered as 5×10^3 Mpa, 1.2 t/m^3 , and 0.20, respectively. The dimension of the masonry wall used in the analysis is shown in Figure 4.

For first load case, the single load was applied in the x direction at nodal point 119. For second load case, the single load was acted in the negative y direction at nodal point 125. For third load case, these two single loads were applied at the same nodes and at the same directions (Fig. 5).

Fig. 4. Dimension of the masonry wall

Deformed and undeformed shape of the masonry wall for three different load cases obtained the masonry-lin. is shown in Figure 5. In this figure, solid blue and dashed green lines show the undeformed and deformed shape of the masonry wall.

Fig. 5 Undeformed and deformed shape of the masonry wall with different load cases

Displacement values of the node point 131 obtained from the masonry-lin. and ANSYS software under first, second and third load cases is presented in Table 1.

Also, the masonry-lin. can calculate the maximum and minimum principal stress of the node points. Maximum and minimum principal stress values of the node point 117 under first, second and third load cases is presented in Table 2.

Table 1. Displacement values of the node point 131

Load cases	Masonry-lin.		ANSYS	
	x (mm) direction	y (mm) direction	x (mm) direction	y (mm) direction
First load case	1.285	-0.277	1.285	-0.277
Second load case	-0.0542	-0.0104	-0.0542	-0.0104
Third load case	1.233	-0.282	1.233	-0.282

Table 2. Maximum and minimum principal stress of the node point 117

Load cases	Masonry-lin.		ANSYS	
	max. principal stress (kPa)	min. principal stress (kPa)	max. principal stress (kPa)	min. principal stress (kPa)
First load case	144.24	-141.06	144.24	-141.06
Second load case	84.45	-94.17	84.45	-94.17
Third load case	227.60	-232.95	227.60	-232.95

IV. CONCLUSIONS

In this study, a computer program was written in MATLAB to perform linear elastic analyses of masonry walls. Furthermore, a mesh program which meshes the wall as two dimensional was written in MATLAB. These masonry walls were constituted with macro modeling approach. Three different load cases were applied to these walls. Accuracy of the results obtained from the masonry-lin. were compared with ANSYS software results.

Abstract— Chemical composition of the Fırat River bank sediments which are located between Palu and Keban Dam Lake show that the Fırat River's sediments can be named as sub-litharenite and felspar litharenite. Pb isotope composition ratios of the studied sediment samples show that the natural weathering of the local lithologic units is to be more effective on the river sediment chemistry than anthropogenic effects. Average of $^{206}\text{Pb}/^{207}\text{Pb}=1,205$ ratio of the river sediments shows that the sediments are mostly between natural lead values which come from the mafic volcano-sedimentary rocks. The units have characterization of Plio-Quaternary Palu Formation, Upper Miocene Çaybağı Formation, and Upper Cretaceous Elazığ Magmatic rocks. Physico-mechanic experiments show that the sediments of the Fırat River have 2.6 gr /cm^3 specific weight and sediments' content of optimum bitumen is 4.6 % and their kind of combination's stability value is 2300 kg.

The sample sediment (P39) has taken from the east side of the East Anatolian Fault Zone, and has different chemical features from the other samples. The sample sites from P39 to P50 have physical-mechanical features of clay size fraction due to the superficial water circulation within fault zone, and increase on the sedimentation of clay minerals because of abundance of suspension matter within the river water. According to the all results, the whole sediment samples which have taken from the sample site from P1 to P39 (East Anatolian Fault Zone) are suitable for aggregate and asphalt as construction industry raw materials in terms of stability and fluxing.

Abstract— A new additive material composed of sugar beet molasses and fly ash was synthesized in laboratory conditions. It was called as molasses-based fly ash compound (MFAC) and used to modify the base bitumen of 50/70 penetration grade with different concentrations from 1% (w/w) to 8% (w/w). The effects of MFAC on the rheological properties of the base bitumen were investigated through penetration, softening point, dynamic shear rheometer (DSR) and bending beam rheometer (BBR) tests. The short and long term ageing of the bitumen samples for DSR and BBR applications were performed with rolling thin film oven test (RTFOT) and Pressure aging vessel (PAV). Also, Marshall tests were carried out in order to determine the effects of the additive on bituminous mixture properties. According to the BBR test results, MFAC was found to improve the creep stiffness (S) of the base bitumen by 14 % indicating the better performance of the modified bitumen at low temperatures.

I. INTRODUCTION

Pavement types are generally flexible, rigid and composite feature on road haulage. Flexible pavements are the most preferred pavement versions nowadays. They are exposed to the deterioration due to environment, climate and traffic. These deformations are rutting, fatigue, stripping and low temperature crackings. Studies on the modification made by using additives are very important to bituminous mixtures behave as expected [1]. Bitumen may show different performances depend on conditions during the production-service and rheological properties, even though they have the same physical characteristics. The bitumen stress-strain relationship is

dependent on the amount and the duration of application of the load because of the rheological material [2]. Aging is very important due to the bitumen becoming brittle. Separation of volatile components from bitumen, mixing-laying processes and wide aggregate surface area cause oxidation of aging. Hardening of bitumen that occur during mixing and laying is provided on the laboratory conditions by RTFOT. Performance and behavior of bituminous mixtures are related to loading time and temperatures. In consideration of these factors, DSR method is applied to samples. The studies show that additive materials improves the resistance against distortion. $G^*/\sin\delta$, the rutting parameter, can be successfully improved by the styrene-butadiene-styrene (SBS) modification [3,4,5]. Additionally, SBS has a positive impact on mechanical properties of the bituminous mixtures [6,7,8]. Ethylene vinyl acetate (EVA) increases the penetration index of bitumen and Marshall stability of bituminous mixtures [4,9]. Rubber is used to improve adhesion properties and viscoelastic characteristics of bitumen [10,11]. Low density polyethylene (LDPE) increases in softening point and a decreased in ductility data, so it developed rutting resistance of bitumen [12]. Phenol-formaldehyde is increased Marshall stability, softening point, viscosity, though heat sensitivity, penetration, surface energy, stripping are decreased [13]. Polyethylene terephthalate (PET) modification enhance low temperature performance and fatigue resistance of bitumen and the Marshall stability, stripping resistance of bituminous mixtures [14]. Organomontmorillonite is a kind of clay. It was stated that Organomontmorillonite affected the rheological behavior and aging properties of bitumen [17]. The purpose of the study is to investigate the modification of the bitumen and bituminous mixtures with molasses-based fly ash compound (MFAC).

Fly ash is puzzolanic material. It can be extensively used construction industry. Fly ash is usually gray in colour and may become darker according to the amount of unburned carbon. Fly ash which is round consists of very fine particles[15]. Sugar beet molasses are an organic waste material which includes approximately 50% sugar. Sugar beet molasses use in fertilizer industry, in ethanol production, in animal food, etc. It approximately consists of 25% water. Sugar beet molasses and fly ash hasn't been used as a bitumen modifier before when they are together. The additive material was called molasses-based fly ash compound (MFAC) which was obtained in the laboratory condition using fly ash and sugar beet molasses. Various tests were performed on laboratory as penetration, softening point, dynamic shear rheometer (DSR) and bending beam rheometer (BBR) test, rolling thin film oven test (RTFOT) and Pressure aging vessel (PAV).

II. MATERIALS AND METHODOLOGY

A. Bitumen

50/70 penetration grade bitumen was obtained from General Directorate of Highways in this study. The basic properties of the base bitumen of 50/70 penetration were summarized in **Hata! Başvuru kaynağı bulunamadı..**

Table 1. Basic Properties of the Base Bitumen

Penetration, 25 °C, 100 g, 5 s, 0,1 mm	61.8	ASTM D5
Softening Point (°C)	54.6	ASTM D36
Flash Point (°C)	271	BS EN 22592
Specific Gravity, 25 °C, (g/cm ³)	1.028	ASTM D70
Viscosity, 140 °C(Pa.s)	0.212	ASTM D4402
130 °C(Pa.s)	0.336	ASTM D4402

B. Aggregate

Basalt aggregate was supplied from Islamdag quarry of Ordu/Turkey. The specific gravity of each aggregate portion was given in Table 2. Aggregate gradation used and local gradation limits were shown in Figure 1 to prepare Marshall samples. The average value of type II is used for wearing courses in Turkey.

Table 2. Specific Gravity of Each Basalt Aggregate Portion

Aggregate Portion	Specific Gravity
Coarse aggregate, bulk	2.551
Apparent	2.633
Fine aggregate, bulk	2.691
Apparent	2.712
Filler, bulk	-
Apparent	2.598

Figure 1 Aggregate gradation and specification limits

C. Preparation of MFAC and Modified Bitumen

Fly ash, molasses and caustic were used and a new material was developed in laboratory condition. A heater and reactor equipped were used in this synthesise study of the MFAC(Figure 2). Additive materials were mixed in the heater by a magnetic stirrer at 100°C.

Figure 2 Equipment of MFAC synthesizing

Features of using molasses and fly ash were shown in Table 3 and

Table 4. The molasses used in the modification of the base bitumen were supplied from sugar refinery in Ankara, Turkey.

Table 3. Features of using molasses

Property	Value
Density	1g/cm ³
Physical state	Semifluid
Saccharose	48%
Invert sugar	1.6%
Inorganic oxides	25.3%
H2O	25.1%

Table 4. Chemical Properties

Features	Standard limits
$\text{SiO}_2 + \text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$	Min. 70%
MgO	Max. 5%
SO	Max. fr 5%
Moisture	Max. 3%
Loss on ignition	Max. 10%

Different concentration of MFAC was added to the base asphalt between 1% and 8% by weight of the base bitumen. The synthesis process was carried out at 120°C during 20 minutes mixed in oil bath.

III. RESULT AND DISCUSSION

Penetration and softening point tests are ones of the parameters used to relate any bitumen. The impacts of the MFAC on the softening test and penetration of the original bitumen are pointed out in Figure 3. Penetration values generally increase and softening points decrease. Because these parameters are related converseley to each other.

Figure 3. Penetration and softening point test results

Marshall Stability test method is one of the most important test methods base and modified bitumens. 5% value is the optimum content of base bitumen aggregate combinations. These test results are pointed to Table 5. According to the results Marshall stability value only increased on 2% (w/w) additive concentration. Specification limit values are $3 < V_a < 5$. V_{air} of 0% concentration value has slightly exceeded these limit values, but sample has provided V_{air} limits to work with MFAC.

Table 5. Marshall Stability Test Results

%	Stability(kg)	Specific gravity	V_a %	VMA%	V_f %
0	1010	2.283	5.06	14.8	65.9
2	1041	2.294	4.61	14.41	68
3	967	2.302	4.25	14.1	69.8
5	916	2.288	4.86	14.64	66.8
8	910	2.288	4.83	14.62	66.9

DSR tests are performed to determine high temperature properties of bitumen. DSR test were conducted at 64°C and 70 °C to unaged and RTFO aged binders. They are shown that Figure 4 and Figure 5. Complex shear modulus(G^*) and phase angle(δ) were determined and were calculated $G^* \sin \delta$ at different temperatures after PAV. $G^* \sin \delta$ and additive concentration graphics were in Figure 6. $G^* \sin \delta$ parameter is minimum 1.00 kPa on base bitumen because of rutting to decrease minimum. In the other words, $G^* \sin \delta$ parameter should be higher than 1 kPa for unaged specimen. $G^* \sin \delta$ should't be lower 2.2kPa for aged specimen after RTFO test. Specification limit values are delivered at 64 °C temperature in Figure 4.

Figure 4. $G^* \sin \delta$ Results Before RTFO

Figure 5. After RTFO $G^*/\sin\delta$ results

$G^*\sin\delta$ value represents fatigue parameter in Figure 6. The fatigue crack according to superpave specifications shouldn't exceed to 5000kPa.

Figure 6. After PAV $G^*\sin\delta$

Creep stiffness(S) and creep ratio(m) are determined through BBR test. These test results at (-12) °C and(-18) °C are indicated in Table 6.

Table 6. BBR Results

	Creep stiffness, S(Mpa) (-12) °C	Creep rate, m (-12) °C	S/m (-12)°C	Creep stiffness, S(Mpa) (-18) °C	Creep rate, m (-18) °C	S/m (-18)°C
0%	222	0.323	687.30	507	0.229	2213.97
1%	210	0.330	636.36	501	0.259	1934.36
2%	191	0.339	563.42	414	0.277	1494.58
3%	202	0.337	599.40	444	0.264	1681.81
4%	190	0.345	550.72	395	0.271	1457.56
5%	207	0.334	619.76	463	0.263	1760.45
6%	197	0.333	591.59	447	0.272	1643.38
7%	209	0.324	645.06	446	0.267	1670.41
8%	206	0.342	602.33	458	0.264	1734.84

Creep stiffness(S) of measured at the BBR test according to Superpave specification is limited at a maximum of 300 MPa. Creep rate (m) have to be higher than 0.3. Creep stiffness(S) and creep rate(m) are suitable accordance with limits in Table 6. S and m parameters point to resist low temperature cracking. Smaller "S" and larger "m" is better of resisting to low temperature cracking[16]. The most increase

rate of m and the maximum reduction rate in S is 4% concentration value at (-12) °C. The increase in Marshall stability was at a 2% concentration. S and m rate of change at 2% are almost similar to 4% result at (-12) °C. These situation supports the increase in Marshall stability. 2% is more economical than 4% concentration. If S/m parameter is smaller than other results, cold weather performance is better than another concentration.

IV. CONCLUSION

Synthesized materials, namely MFAC, were used to modify base bitumen. In this study, 50/70 penetration of bitumen was used to modify process. Penetration and softening point tests are inverse of each other. If lower softening point and higher penetration is test results, $G^*/\sin\delta$ parameters of unaged specimen increase in DSR. Original and short term ageing parameters show that rutting.

According to the BBR test results, MFAC was found to improve the creep stiffness (S) of the base bitumen by 14 % indicating the better performance of the modified bitumen at low temperatures. As a result, using MFAC modified bitumen in cold and rainy regions, in heavy motor and peak- hour traffic highways will supply increase for highway pavement performance.

ACKNOWLEDGMENT

General Directorate of Highways and Gazi University are thankfully acknowledgment for the laboratory facilities.

Abstract--The present study aimed to examine the resistance of pure hot mixes and those prepared with 4% of three different polymers two types of SBS (styrene-butadiene-styrene) and one type of EVA (ethylene-vinyl-acetate) against permanent deformation. Samples were prepared with application of vibration so that they would have 4% void ratio using a roller compactor and without this application. The effect of vibration application during sample preparation on the wheel track formation was also assessed in the current study. Wheel track tests demonstrated that use of additives increased the resistance of hot mixes against wheel track formation. It was also determined that the most effective additive was EVA. Furthermore, it was determined that application of vibration during sample preparation increased the resistance of specimens against permanent deformation.

Keywords-- Wheel Tracking;

I. INTRODUCTION

Two basic components of bituminous hot mixes (BHM) are aggregate and bitumen and aggregates used in BHMs consist 90-95% of the total BHM weight. 1.6 billion tons of bituminous hot mix is produced every year worldwide. For this purpose, approximately 1.5 billion tons of aggregate is used. Environmental damages caused by highway construction are those resulting from construction activities (CO₂ emissions, use of nature lands, change in current conditions and ecological balance, change in natural structure) and the damages caused by the material utilized for construction (destruction of natural lands, technological equipment causing chemical pollution, noise and vibration) [1].

One of the most encountered deformations observed with bituminous hot mixes, permanent deformations occur as a result of two basic conditions. The first occurs due to the inappropriate construction of the base course or the asphalt base course. In the second condition, while there is no deformation in lower layers, the permanent deformation (wheel tracks) form on the wearing course [2].

Wheel track formation is frequently observed on pavement courses in hot temperatures and on roads where heavy vehicle traffic is present. Deformations cause expensive rehabilitations or reconstruction, as well as new material needs, resulting in harming the environment again.

To improve the features of BHMs, postponing expensive rehabilitation and reconstructions, additive substances are utilized. Polymers used as the most common additive substances used in modification of bituminous binders are grouped in four categories of plastomers, elastomers, fibers and pavements. To improve the features of bitumen, selected polymer should form a new bond in bitumen, chemically reacting with bitumen. Obtaining a high performance polymer modified bitumen is dependent on the better distribution of the polymer in bitumen and the chemical structure of the bitumen [3]. Most frequently used bitumen additives are styrene-butadiene-styrene (SBS) from the elastomer group and ethylene-vinyl-acetate (EVA) from the plastomer group [4]. Several studies demonstrated that resistance against ageing [5], permanent deformation [6], low temperature fractures [7], and moisture damage [8] increased by the use of SBS modified bitumen. EVA especially increases resistance against permanent deformation [9], [10].

It is possible to adjust the polybutadiene structure of SBS block copolymers using a special catalyzer. Thus, it is possible to obtain an SBS with the same molecular weight, but with a shorter polymer chain. This means low viscosity, and a better and more homogenous mixture with bitumen [11], [12].

It is of utmost significance to prepare bituminous hot mixes in laboratory environment reflecting the field conditions, for the accuracy of the design and accurate determination of the material that would be applied in the field. In the present study, bituminous hot mix samples containing pure bitumen and bitumen modified by three different additives (two types of SBS and one type of EVA) were prepared using roller compactor. The mixes were compacted with and without vibration to create the same void ratio. Afterwards, wheel track tests were conducted on these mixes. Thus, the effect of mix preparation method on permanent deformation performance of the mixes was assessed.

II. MATERIAL AND METHODOLOGY

Limestone type aggregate procured from Karayazı region in Elazığ province in Turkey was used in the study. Properties of the aggregate is presented in Table 1 and the gradation selected according to Superpave method is given in Figure 1. Triangular signs depict control points, closed field shows forbidden zone, and square signs show utilized gradation points in Figure 1.

PG 58-35 bitumen procured from TÜPRAŞ refinery was used as the main binder in the present study. Two different types of SBS produced by Shell Corporation (Kraton D 1101 and Kraton MD 243) and EVA produced by Arkema Corporation (Evatane® 2805) were used as additives. A four-bladed mixing head was used in

preparing modified bitumen. Pure bitumen and additives were mixed in a special mixer for 60 minutes at 180°C temperature and 1000 rpm.

To evaluate the effect of these additives on the performance of bituminous hot mixes, all additives were used at a rate of 4% (Table 2). Dynamic shear rheometer (DSR) and beam bending rheometer (BBR) test results for pure and with 4% SBS D1101 (MB_{SBS-D}), SBS MD243 (MB_{SBS-M}), and Evatane® 2805 (MB_{EVA}) bitumen are presented in Table 3. It was determined that the performance levels for MB_{SBS-D} and MB_{SBS-M} modified bitumen were similar (PG 70-34), and the low temperature value for MB_{EVA} modified bitumen was one level higher (PG 70-28).

Rotational viscometer tests were conducted on unaged pure and modified bitumen under 135°C and 185°C temperatures to determine the workability of the binders and aggregate mixing and compacting temperatures. For workability, the viscosity values for the binders should be below 3 Pa.s (3000 cP) at 135°C [13]. Furthermore, it is required that the viscosity value of bituminous binders during mixing with aggregate should be 170 ± 20 cP, and during compacting it should be 280 ± 30 cP [14]. Utilizing the viscosity-temperature graphs plotted in the study, aggregate mixing and compacting temperature for each binder was identified. Results of viscosity tests are displayed in Table 4.

Data presented in Table 4 shows that all binders met the workability criterion. Furthermore, using additives increased viscosity values and mixing and compacting temperatures rose as a result. Modification indices were obtained by division of viscosity values of modified bitumen by viscosity value of pure binder. As could be seen in Table 4, the highest modification index value was

obtained with MB_{EVA} modified bitumen at both 135°C and 165°C temperatures. This situation indicates that more energy would be required in the plant during mixing with aggregate with EVA use.

During preparation of bituminous hot mixes, aggregate and bitumen were heated to mixing temperature and mixed using a special mixer. Non-compacted samples were placed in trays 21-22 kg per square meter and aged for a short period of time for 4 hours in an incubator at 135°C. Then, the mixtures were heated to mixing temperatures and compacted using a 1.25° angle gyratory compactor for 100 revolutions. The design was determined based on the volumetric properties of bitumen content mixtures. It was determined that design bitumen content increased with modified bitumen use. Volumetric properties of mixtures in design bitumen content and Superpave specification criteria are presented in Table 5. It was confirmed that all mixtures met Superpave specification criteria.

III. WHEEL TRACK TESTS

Wheel track formation on pavement layer was examined in the study. The tests were conducted based on EN 12697-22 standard B procedure to examine the wheel track resistance of samples that contained pure PG 58-34, 4% SBS-D, SBS-M and EVA modified binders. Since maximum aggregate grain diameter was 19 mm according to the standard, sample height was selected as 6.0 cm. Initially 30.5 * 30.5 * 6 cm plate samples were compacted using rolling compactor so that they would have 4% air void ratio. Some samples were compacted with application of vibration, and the others were compacted without. Required BHM amount for plate samples was determined using the following equation:

$$M = 10^{-6} * L * l * e * \rho_m * ((100 - v) / 100) \quad (1)$$

where M is sample weight (kg), L is inner length of the mold (mm), l is the inner width of the mold (mm), e is the final height of the sample (mm), ρ_m is the maximum density of the bituminous mixture (kg/m³), and v is the void ratio of the sample (%).

In wheel track experiment the samples were tested at 60°C temperature. The device took 27 deformation

measurements, out of which one was taken from the center of the sample, and 13 were taken from the left of the center and right of the center. At the end of 10,000 wheel revolutions, wheel track depths were determined using the average of these 27 values. For each mixture sample, two samples were tested and average of the values were taken. According to EN 12697-22 standard, the test is terminated either after 10,000 load repetitions or when 20 mm wheel track depth is formed. In mixtures containing pure binder, 20 mm wheel track depth was obtained after 2,940 load repetitions and the test was ended. The tests conducted with modified bitumen were terminated after 10,000 load repetitions. The relationship between wheel track depth and number of load repetitions in mixtures prepared with vibration is presented in Figure 2, while relationship between wheel track depth and number of load repetitions in mixtures prepared without vibration is displayed in Figure 3. The load that caused 20 mm deformation in mixtures prepared with pure binder is displayed with a dashed line.

Fig. 2. The wheel track depth-number of load repetition relationship in mixtures prepared with vibration.

Fig. 3. The wheel track depth-number of load repetition relationship in mixtures prepared without vibration.

It was determined that wheel track values for mixtures prepared with MB_{SBS-D} and MB_{SBS-M} were close to each other as displayed in Figures 2 and 3. Comparison of mixtures prepared with modified bitumen showed that the lowest wheel track value was obtained with the mixture prepared with MB_{EVA}, and the highest wheel track value was obtained with the mixture prepared with MB_{SBS-D}. Deformation values for 5,000 and 10,000 load repetitions are presented in Table 6.

As could be observed in Table 6, wheel track depths for 5,000 and 10,000 load repetitions in mixtures prepared without vibration and using EVA modified bitumen were 18.5% and 22.7% lower than the mixture prepared using SBS-D modified bitumen, respectively. Furthermore, wheel track depths for 5,000 and 10,000 load repetitions in mixtures prepared using EVA modified bitumen were 15.3% and 20.3% lower than the mixture prepared without vibration using SBS-D modified bitumen, respectively.

As could be observed in Table 6, wheel track depths for 5,000 and 10,000 load repetitions in mixtures prepared with vibration and using EVA modified bitumen were 18.1% and 19.1% lower than the mixture prepared using SBS-D modified bitumen, respectively. Furthermore, wheel track depths for 5,000 and 10,000 load repetitions in mixtures prepared with vibration and using EVA modified bitumen were 15.7% and 19.9% lower than the mixture prepared using SBS-M modified bitumen, respectively.

As a result of vibration application, wheel track formation in mixes prepared using SBS-D modified bitumen decreased 5.7% after 5,000 load repetitions and 6.8% after 10,000 load repetitions. As a result of vibration application, wheel track formation in mixes prepared with SBS-M modified bitumen decreased 5.1% after 5,000 load repetitions and 4.3% after 10,000 load repetitions.

TABLE 6. WHEEL TRACK VALUES FOR MIXTURES UNDER DIFFERENT LOAD REPETITIONS

Mixtures prepared without vibration				
Deformation (mm)	Mixture type (according to used binder)			
	PG 58-34	MB _{SBS-D}	MB _{SBS-M}	MB _{EVA}
@5000 load cycles	-	2.63	2.56	2.22
@10000 load cycles	-	3.08	3.02	2.51
Mixtures prepared with vibration				
Deformation (mm)	Mixture type (according to used binder)			
	PG 58-34	MB _{SBS-D}	MB _{SBS-M}	MB _{EVA}
@5000 load cycles	-	2.48	2.43	2.10
@10000 load cycles	-	2.87	2.89	2.41

As a result of vibration application, wheel track formation in mixes prepared using EVA modified bitumen decreased 5.4% after 5,000 load repetitions and 4.0% after 10,000 load repetitions.

Overall consideration of mixes showed that vibration application decreased wheel track formation. This finding demonstrated that, although the mixes had the same volume, the mix compacted better as a result of implementation of vibration. As a result of comparison of additive types, values obtained after 10,000 load repetitions showed that the mix affected by vibration the most was the one prepared with SBS-D and the mix affected by vibration the least was the one prepared with EVA based on permanent deformation. It was observed that compacting especially the SBS-D modified bitumen using vibration was more significant for wheel track formation.

IV. RESULTS

In the present study, initially the effect of three different bitumen additives (SBS-D, SBS-M and EVA) on the resistance of bituminous hot mixes against wheel track formation was examined. Later on, the effect of vibration application on the preparation of wheel track samples was attempted to be identified. Additive ratio was kept constant at 4% for all additives. Thus, the convenient comparison of all additive types was aimed. In the field, vibrating rollers are used to compact bituminous hot mixes. A roller compactor with vibration capabilities was used to obtain compatible samples with the field conditions. Samples were prepared using modified bitumen both by using and not using vibration. Wheel track tests were conducted on these samples to assess the effects of vibration.

It was determined that performance levels for modified bitumen that contained SBS-D and SBS-M equal to 4% of bitumen weight were PG 70-34, and the performance level of those that contained EVA were PG 70-28. It was identified that design bitumen content of the

mixes prepared with SBS-D, SBS-M and EVA modified bitumen were 5.27%, 5.35%, and 5.07%, respectively.

Wheel track samples that contained pure and modified bitumen with 4% void ratio consistent with the field applications were prepared with roller press. Samples were prepared both using vibration and without using vibration. It was determined that mixes prepared with EVA modified bitumen had the lowest wheel track depth for both vibration applied and not vibration applied mixes. Furthermore, it was identified that wheel track values for mixes prepared with SBS-D and SBS-M modified bitumen were similar. It was also determined that vibration applied mixes displayed lower wheel track formation when compared to mixes that were not applied vibration.

It was determined that vibration was more effective especially in mixes prepared with SBS-D modified bitumen. It was considered that this condition was due to better compacting of the mixes as a result of vibration. To determine the compatibility of vibrated and non-vibrated samples with the field conditions, it would be beneficial to compare the test results for samples obtained from the field with the test results for the samples prepared at the laboratory in the future.

Abstract—In order to evaluate the bearing capacity of pavement system on steel bridge deck and the rationality of pavement structure design, and accumulate empirical data for the theoretical design of pavement system, a static loading test was carried out on the Zhoupu Pond Bridge with the asphalt pavement of double-layer SMA (Stone Matrix Asphalt), under 3 groups 51 loading conditions, and the surface strains were tested, as well as the temperature. According to the test results, it is concluded that: for the transverse surface strain corresponding to the in-between position of two diaphragms, it was almost not affected by the traffic loading outside the diaphragms; when the loading began to cross the adjacent diaphragm, the transverse surface strain began to change, and the measuring point was under lateral pressure; when the loading just acted on the measuring point or was located within the range of 0.2m, the transverse strain reached the maximum value and the point was objected to tension strain; when the loading was far away, the measuring point was compressed. For the longitudinal strain corresponding to the diaphragm, it was not affected when the loading was out of the range of 0.4m away the diaphragm; when the loading just acted on the diaphragm, the longitudinal strain reached a maximum. The transverse and longitudinal strain values corresponding to the web were greater than those of corresponding to the U-rib edge, and the former was 10 times and 5 times that of the latter, respectively.

I. INTRODUCTION

The asphalt pavement on steel bridge deck with large flexibility is in more complicated and challenging stress condition than the ordinary asphalt pavement, that is because that apparent stress or strain concentrations appear in the ribs and across beam joint under heavy vehicle loads [1]. Besides, the factors, such as the high temperature, waterproof and interlayer binding, aggravate the deformation of asphalt pavement on the steel bridge deck, different from the general asphalt concrete pavement.

Due to the complexity and variability of materials' composition and nature, the impact randomness of environment and load factors, and the quality instability of non-factory construction, it is very difficult for the purely mechanical method to learn the real response of actual pavement structure. Moreover, although the long-term performance observation

could systematically summarize the performance development in the entire life cycle, it is really a long process which costs lots of manpower, material and financial resources as well as analysis difficulty with many influencing factors. As a result, information monitoring in asphalt pavement on testing bridges with intelligent sensors gradually becomes a hot issue [2].

Researches on the testing bridge about the pavement on steel bridge deck started relatively early abroad. Hameau and Esslinger obtained the strains of pavement and steel deck through a two-span continuous compound beam test [3]. In England, a similar test section as same as the Severn Bridge was built in a heavy traffic artery in 1963, and after 10 years observation, TRRL (Transport and Road Research Laboratory) concluded that the guss-asphalt (GA) was suitable for the environment there. In 1976, Japan Longpu steel bridge test was conducted and the pavement composed of GA as the lower layer and the modified dense-graded asphalt mixture as the upper layer was thought to be the best. In order to choose the pavement system for the Esplanade Bridge in Sweden in 1993, eight pavements were paved on the test bridge of BD1337 and then observation and investigation were done in the following four years [4]. In China, the test research of asphalt pavement on steel bridge deck began from the Humen Bridge. And then, relevant units built indoor ring or straight models of orthotropic steel bridge deck, and through accelerated loading tests compared the performance of different pavement structures, mainly relates to the relevant research work of literatures [5]~[12]. The research group of Runyang Yangtze River Highway Bridge used strain gauges to measure the strains before and after the pavement construction [4, 13]. Wu et al. conducted a loading test on a steel bridge to measure the strains at different asphalt layers [14].

In order to measure the surface strains of asphalt pavement on the steel bridge deck, a loading test was conducted on a typical steel bridge, and FBG (Fiber Bragg Grating) strain sensors and temperature sensors were laid to monitor the whole real-time mechanical performance. This paper summarized the development and change rules for dimensional static strains on the top surface of asphalt pavement on the steel bridge deck.

II. TEST OVERVIEW

A. Pavement Structure

Zhoupu Pond Bridge is a steel-box girder bridge with a single span, a part of Lin Hai highway (A20~A30). Its length is 35km, with eight lanes in two-way. The total design thickness of asphalt pavement on the steel bridge deck is 10cm, and the structure is shown in Table I. The performance of materials and structures all meet the specification requirements (JTJ 052-2000, JTG E42-2005 and JTG E40-2007).

TABLE I. ASPHALT PAVEMENT STRUCTURE

Structure Layer	Paving Material
Upper layer	5cm SMA-13 (modified by high viscosity asphalt)
Tack coat	Modified emulsified asphalt (0.4kg/m ² ~0.6kg/m ²)
Lower layer	5cm SMA-13 (modified by high viscosity asphalt)
Waterproof adhesive layer	Reactive waterproof adhesive layer
	Covered by 3mm~5mm diabase gravel (covering rate of 50%~60%)
	1mm epoxy asphalt binder layer
Steel deck	Surface treatment with epoxy zinc-rich paint

B. Strain Measurement

The stress pattern of asphalt pavement on steel bridge deck is different from general asphalt concrete pavement, that is, under vehicle loads, negative bending moment exists in the pavement surface of the top of rib (such as box girder), and then the maximum tensile stress or strain appears on the surface of the pavement layer.

In the case of static force, the vehicle load is the most harmful to the pavement system on bridge deck. According to previous studies, the general failure mode of bridge deck pavement system is "from top to bottom", because the existence of stiffened rib structure leads to excessive tensile strain on the top surface of the pavement. For structural damage analysis of pavement system on steel deck (such as fatigue cracking, low-temperature cracking and so on) and functional damage (such as rutting, shoving, passing and bulging etc.), it is more effective to learn under the most unfavorable conditions. Under static loads, in order to analyze the most unfavorable longitudinal and transverse load positions, it is necessary to consider the geometric characteristic of stiffened rib and orthotropic steel deck, and the relative location effect of the vehicle load and transverse stiffener on the pavement.

In this paper, two transverse and two longitudinal strain sensors are arranged on the surface of asphalt pavement, which are used to test the transverse and longitudinal strain values of the pavement structure under different loading conditions. Layout scheme of the strain sensors is shown in Fig. 1. Transverse and longitudinal sensors are arranged on the asphalt

surface corresponding to the bridge structure of in-between position of two diaphragms and the intermediate diaphragm, respectively; besides, a group of transverse and longitudinal sensors is placed corresponding to the U-rib edge, another group corresponding to the web.

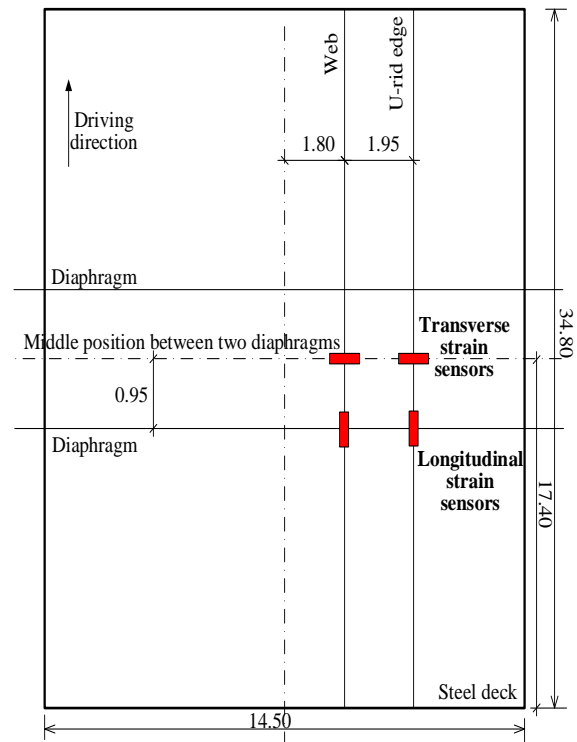

Fig. 1. Layout scheme of strain sensors (unit: m)

The strain sensors are lamellar FBG ones, named by QSS100B, with the measuring range of $\pm 1500\mu\epsilon$. The strain collection system is FBG8600. The strain of FBG sensor expressed by ϵ can be determined through the following Equation (1).

$$\epsilon = \frac{(\Delta\lambda - \alpha_T \Delta T)}{\alpha_\epsilon} \quad (1)$$

Where, $\Delta\lambda$ is the change of central wavelength, α_ϵ is the sensitivity coefficient, α_T is the temperature correction coefficient calibrated with structure, ΔT is the change relative to calibration temperature (20°C).

C. Temperature Measurement

Because of the asphalt, asphalt concrete and so on are temperature sensitive materials, whose deformations are greatly affected by temperature. Therefore, in order to accurately describe and analyze strains on the asphalt pavement, it needs simultaneous temperature acquisition in the strain measuring process. Furthermore, in order to analyze the temperature field on the steel bridge, and to make the temperature compensation for the corresponding strain value, the temperature test is required. Temperature sensors are arranged on the pavement surface, under the upper layer, under the lower layer, and on the upper and lower surfaces of steel

deck. Besides, another temperature sensors hung on the handrail to collect the air temperature at the same time. Due to the space limitations, this paper just analyzes the pavement surface temperature and air temperature which are closely related to the surface strains in the following sections. Customized Pt100 sensors are selected to measure temperature, with the measuring range of $-200^{\circ}\text{C} \sim 650^{\circ}\text{C}$, and the accuracy is 0.01°C .

D. Loading Parameters

The vehicle parameters in the loading test are shown in Table II.

TABLE II. VEHICLE PARAMETERS IN THE LOADING TEST

Parameter	Weight /kg		Area per Wheel / cm^2	Pressure /MPa	Distance /m	
	Left	Right			Between front-rear axles	Wheel clearance of rear-axle
Front-axle	1,450	1,455	22×16.5	0.40	4.70	1.75
Rear-axle	5,470	4,850	22×16.5	0.70		

The static loading test is divided into three groups of 51 conditions, and each group includes 17 conditions expressed by the imaginary lines in Fig. 2 (Group 1 taken for the example). The first group: the right tire center of the front-axle is located on the longitudinal loading line of the U-rib edge, and the distance from left tire center of the front-axle to the strain sensors corresponding to the web surface is 30cm; the second group: the centers of left and right tires of rear-axle are coincided with the web and U-rib edge, respectively; the third group: the left tire center of the front-axle is coincided with the longitudinal loading line corresponding to the web, and the right tire center of the front-axle keeps the distance of 30cm away from the surface strain sensors corresponding to the U-rib edge. In every loading condition, the loading vehicle flames out and remains stationary for 5min at least.

Fig. 2. Static loading conditions (Group 1, unit: m)

III. RESULT ANALYSIS

A. Temperature Test Results

The air temperature and the pavement surface temperature during 12:00~13:00 reach the maximum values of 30.5°C and 40.7°C, respectively, and the both at 2:50 reached the lowest values of -20.8°C. So, the pavement surface bears 10°C higher than the air temperature, which is an ordeal for the high-temperature performance of asphalt pavement. In the temperature-rise period, from 7:00 to 13:00, the pavement surface temperature is higher than air temperature. In the temperature-decrease period, that is, from 14:30 to the next day at 7:00, pavement surface temperature is higher than air temperature, too. Temperature rate curves show that the rising and decreasing rate of pavement surface temperature is slightly larger than that of air temperature. The former is about 1.5 times of the latter.

B. Strain Test Results

The strain test results are shown in Fig. 3. According to the test results under different static loading conditions, it is concluded that:

- For the transverse surface strain corresponding to the in-between position of two diaphragms, it was almost not affected by the traffic loading outside the diaphragms; when the loading began to cross the diaphragm, the transverse surface strain began to change, and the measuring point was under lateral pressure; when the loading just acted on the measuring point or was located within the range of 0.2m, the transverse strain reached the maximum value and the point was objected to tension strain; when the loading was far away, the measuring point was compressed.
- For the longitudinal strain corresponding to the diaphragm, it was not affected when the loading was out of the range of 0.4m away the diaphragm; when the loading just acted on the diaphragm, the longitudinal strain reached a maximum.
- The transverse and longitudinal strain values corresponding to the web were greater than those of corresponding to the U-rib edge, and the former was 10 times and 5 times that of the latter, respectively.

Abstract— Demand for sustainable pavements increases day by day in asphalt paving industry. Warm Mix Asphalt (WMA) technology has begun to be an interesting topic for researchers owing to sustainability and environmental issues. Within the scope of this study, the effect of an organic WMA additive was evaluated in terms of mixture characteristics and performance. The fundamental and rheological properties of bitumen samples involving organic WMA additive were determined by conventional bitumen tests and dynamic shear rheometer (DSR). Mixtures modified with organic WMA additives were produced according to Marshall mix design method and the optimum bitumen content of the samples were determined. Following the determination of optimum bitumen content, the effect of the organic WMA additive was investigated in terms of indirect tensile stiffness modulus, fatigue and creep behaviour. Hamburg wheel tracking device was also applied to evaluate the permanent deformation characteristics of WMA mixtures in comparison to Hot Mix Asphalt (HMA) mixtures. The results appraised the effect of the organic WMA additive on rheological and performance characteristics of bituminous mixtures.

INTRODUCTION

Most of the field pavement practices around the world consist of conventional hot mix asphalt (HMA). For the last decade, implementing of warm mix asphalt (WMA) technologies has gained popularity in Europe and in some other countries as well as in the USA. The goal of WMA technologies is to obtain required strength and durability which is equivalent to or even better than HMA pavements [1]. The use of WMA technologies offers many benefits to asphalt industries. Many studies have common sight about the various advantages of the utilization of WMA technologies. These advantages are all originated from the major feature of WMA additives which is reducing the viscosity of the bitumen [2]. This reduction results in increasing workability and ease of use, ecological benefits due to less emissions and reduction in costs due to less energy use. In terms of workability, the reduced viscosity helps the aggregates to be coated more easily [3, 4]. When discussing about environmental benefits, there are serious worries about the greenhouse gases emissions in HMA pavement applications. Due to lower application temperatures of WMA mixes, the emission of carbon dioxide (CO₂) and other so called greenhouse gases are lowered in comparison with HMA mixes [5]. Besides, the evaporation of less heavy components of

bitumen occurs less than conventional applications. This causes less odours in asphalt plants, therefore provides more pleasant working conditions. Builders comments also indicate that the fumes are rather less in WMA production in comparison with HMA production [6]. The fuel consumption of WMA technologies is rather less than conventional HMA mixtures. Energy consumption for WMA production has been reported as 60–80% of HMA production [4]. Some studies have also reported the range of 20–35% of savings in burner fuel with use of WMA technologies [5]. In asphalt industry, a common way of achieving lower application temperatures in order to produce WMA is the utilization of WMA additives. All of the current WMA additives facilitate lowering of production temperature by either lowering the viscosity and/or expanding the volume of the bitumen at a given temperature [7, 8]. There are many kinds of WMA additives, these additives are categorized as chemical, zeolite or organic additive etc. Organic WMA additives those are the most common as aforementioned, WMA additives used to improve workability by reducing the viscosity of bitumen [9]. By lowering the viscosity, asphalt can be produced at lower temperatures compared to conventional HMA. Organic WMA additives are reported as resistance improvers against permanent deformation by composing crystallized structures after cooling [10].

In this research, WMA mixture has been prepared with an optimum rate of organic WMA additive that is based on the recommendation of manufacturers. The mechanical performances of the samples were evaluated by Marshall stability test. Following, WMA samples involving organic WMA additive; indirect tensile stiffness modulus (ITSM) and fatigue behaviour of WMA were analyzed and compared with control specimens (HMA). Hamburg wheel tracking device was also used to determine the rutting performance of WMA mixture.

EXPERIMENTALS

Materials

In this study, 50/70 penetration grade base bitumen provided from Aliğa/Izmir petroleum refinery was used. In order to characterize the properties of the base bitumen, conventional tests such as: penetration test, softening point test, Rolling Thin Film Oven Test (RTFOT) and etc. were conducted. These tests were performed in conformity with the relevant standards. Results are presented in Table 1.

TABLE 1. PROPERTIES OF BASE BITUMEN

The aggregates used in this study consist of a mix of basalt and limestone aggregates provided from Dere Madencilik Inc. quarry located in Belkahve/Izmir. The mix gradation of basalt and limestone was intentionally chosen to provide desired performance in conformity with Turkish specifications concerning the Type 1 wearing course. Basalt plays the role of strengthening constituent as coarse aggregate while limestone participates in the fine aggregate framework. Table 2 presents the final gradation chosen for basalt–limestone aggregate mixture. The properties of the aggregate were investigated by several tests such as specific gravity, Los Angeles abrasion resistance, sodium sulphate soundness, fine aggregate angularity and flat and elongated particles. Test results conducted on both aggregate types are presented in Table 3.

Sasobit® is an organic WMA additive which is product of Sasol Wax Inc. It is a long-chain aliphatic polymethylene hydrocarbon produced from the Fischer-Tropsch (FT) chemical process with a melting temperature of 120°C. The longer chains help keep the wax in solution, which reduces bitumen viscosity at typical asphalt production and compaction temperatures. Based on the literature, dosages for organic additive ranged from 1.0% to 4.0% by weight of the bitumen [11–13]. In this research, the organic additive content was chosen as 3.0% based on the past research [14]. Organic additive added to the virgin bitumen at 120°C and mixed by using the high shear mixer for 10 minutes.

TEST METHODS

Conventional bitumen tests

The base bitumen and the bitumen sample containing organic additive were subjected to the following conventional bitumen tests; penetration, ring and ball softening point, thin film oven test (TFOT), penetration and softening point after TFOT as well as the storage stability test determined by the difference in softening point test results taken from the top and bottom of the tube (ASTM D5-06 2006; ASTM D36-95 2000; ASTM D 1754-97 2002) [15–17]. In addition, the temperature susceptibility of the bitumen samples has been calculated in terms of penetration index (PI) using the results obtained from penetration and softening point tests [18].

The viscosity defined as resistance of a fluid to flow is significant since it affects the workability of the bitumen [19]. Brookfield viscometer was employed to inspect the mixing and compaction temperatures of the mixtures in according to ASTM

D4402-06 [20]. The test was performed at 135°C and 165°C and the temperatures corresponding to bitumen viscosities 170±20 mPa.s and 280±30 mPa.s were chosen as mixing and compaction temperatures respectively.

Mechanical Properties

The effect of organic WMA additive on the mechanical properties of WMA has been determined by Marshall mix design method (ASTM D3549) in terms of stability, flow and air void content as well as by indirect tensile stiffness modulus test and indirect tensile fatigue test [21-24]. The tests were conducted on WMA samples at recommended contents and on HMA as control samples. Asphalt concrete specimens were prepared with a compaction effort of 75 blows simulating heavy traffic loading conditions. The ITSM test is a non-destructive test that is used to evaluate the relative quality of materials and study the effect of temperature and loading rate. The ITSM Sm in MPa is defined as below [23];

$$Sm = F(R + 0.27)/LH \quad (1)$$

Where F is the peak value of the applied vertical load (repeated load, N), H is the mean amplitude of the horizontal deformation (mm) obtained from five applications of the load pulse, L is the mean thickness of the test specimen (mm), and R is the Poisson's ratio (assumed as 0.35). The test was performed by way of a universal testing machine (UTM) in deformation-controlled mode. The magnitude of the applied force was adjusted by the system during the first five conditioning pulses such that the specified target peak transient diametral deformation was obtained. An appropriate value was chosen to ensure that sufficiently high signal amplitudes were obtained from the transducers which would produce consistent and accurate results. Accordingly, this value was selected as 5 mm for this test. The rise time, which is measured from the origination of load pulse and denotes the duration of the applied load rising from zero to the maximum value, was set at 124 ms. The load pulse application was adjusted to 3.0 s. ITSM tests were conducted at three different temperatures (20 °C, 25 °C and 30 °C).

The indirect tensile fatigue test is one of the constant stress test that characterizes the fatigue behaviour of the mixture [25]. In this study, the fatigue test was performed in a controlled stress mode based on BS DD AFB standard [24]. The UTM was also used for this purpose. The loading frame was housed in an environmental chamber to control temperature during the test. The desired load level, load rate and load duration were controlled by a computer. The deformation of the specimen was monitored through linear variable-differential transducers (LVDTs). The LVDTs were clamped vertically onto the diametrical side of the specimen. A repeated dynamic compressive load at 350 kPa was applied to specimens at 20°C, 25°C and 30°C test temperatures, across the vertical cross-section along the depth of the specimen using two loading strips 12.5 mm in width. Finally, the resulting total deformation corresponding to the applied force was measured.

Rheological Properties

The DSR test was performed on WMA samples by using a Bohlin Gemini II DSR rheometer to evaluate their rheological characterization. The test was performed under controlled stress loading conditions using low (0.01 Hz) and high (10 Hz) frequency sweeps at temperature between 30 °C and 80 °C (for every 10 °C). The stress amplitude for all the tests was confined within the linear visco-elastic response of the bitumen.

Rutting test

The loss of pavement serviceability is a common result from rutting which is defined as the formation of the longitudinal depressions under the wheel paths caused by the progressive movement of materials under traffic loading in the asphalt pavement layers [26]. The Hamburg wheel tracking device is designed to evaluate the rutting characteristics of bituminous mixtures by dint of aggregate structure, bitumen properties, moisture susceptibility and adhesion between bitumen and aggregates. The test is carefully contemplated to simulate bearing capacity of pavement under actual wheel tracks.

The working principle is to roll a steel wheel with a specified diameter over a bituminous mixture specimen with a standard thickness for a specified number of wheel passes. The test measures the depth of rut after the specified number of passes is reached. Various organizations may define their own specifications with different testing conditions such as specimen dimensions, wheel diameter, rolling length, applied load and temperature. Within this context, there are many devices designed to carry out the task under various conditions.

The test device used within the scope of this study, was an electronically powered device which rolls a steel wheel (capable of using rubber wheel) with a diameter of 203 mm and width of 50 mm over a well compacted specimen with dimensions of 430×280×50 mm. The device is capable of making about 50 passes in minute over the specimen's surface by rolling length of 230 mm. The applied load was chosen as 710 N by default as per EN 12697-22 standard test method [27]. Prior to compaction of the specimens, HMA and WMA mixtures were carefully mixed at their pre-defined mixing temperatures using a mixer capable of mixing adequate amount of materials at desired temperature. The Hamburg wheel tracking device comes with a roller compactor in order to compact mixtures within standard molds to fit in wheel tracking device frames. The roller compactor also makes it convenient to prepare specimens with desired thickness (50 mm) with specified air voids (4%). The amount of loose mix to reach the desired compacted bulk specific gravity corresponding to 4% air voids considering mold dimensions was calculated and poured into compaction molds. After cooling the specimens at room temperature, the specimens were subjected to 30.000 passes of wheel tracks. In this study, two specimens of HMA and WMA were prepared and tested for right and left wheels. The rut depth was measured and recorded for right and left wheels simultaneously by an electronic system at every 5.000 passes while the test was running.

RESULTS AND DISCUSSIONS

Conventional test results

The conventional properties of the bitumen prepared with organic additive are presented in Table 4. As depicted in Table 4, the addition of the organic WMA additive decreased the penetration values and increases the softening point values.

As seen in Table 4, WMA sample exhibits higher penetration index values (which is an indicator of reduced temperature susceptibility) compared to base bitumen. Asphalt mixtures containing bitumen with higher PI are more resistant to low temperature cracking as well as permanent deformation [28]. Storage stability test indicate that, the bitumen samples with WMA additive is much more storage stable compared to HMA.

As depicted in Table 4, the additive reduce the viscosity of bitumen which indicates that, WMA additives increase the workability and make relatively reductions for mixing and compaction temperatures. The viscosity of results related to WMA additive 135°C and 165°C are drawn at semi logarithmic figure and the temperature corresponds to compaction and mixing range is also summarized in Table 5. Based on the Table 5, it can be seen that, the addition of organic WMA additive reduced the mixing and compaction temperature between 10-15°C.

TABLE 4. CONVENTIONAL PROPERTIES OF BASE AND ORGANIC WMA MODIFIED BITUMEN

Test	Base bitumen	Bitumen including Organic WMA Additive

Results of Mechanical Properties

In this study, the optimum bitumen content related to HMA mixture as well as WMA mixture containing organic WMA additive were determined by the Marshall mix design method,

retrieved directly as the bitumen content corresponding to 4% air voids on content–air voids graphic based on second degree polynomial trend lines. The optimum bitumen content for HMA mixture and WMA mixture containing organic WMA additive were determined as 4.76%, and 4.25% respectively. The ITSM values at 20°C, 25°C and 30°C temperatures for HMA and WMA mixtures containing organic WMA additive are shown in Fig. 1. As depicted in Fig. 1, the ITSM values of WMA are higher than HMA mixtures at all tested temperatures. The ITSM values of HMA mixtures and WMA mixtures containing Organic WMA additive have significantly decreased by increase in temperature.

Figure 1. ITSM values of HMA WMA mixtures including organic WMA additive

The variation of load cycle numbers by temperature change is given in semi-logarithmic graphs in Fig. 2. As presented in Fig. 3, the load cycle numbers which caused the specimens to be cracked declined considerably as the temperature increased.

Figure 2. Variation of load cycle numbers by temperature change

The deformation of the specimens was monitored through linear variable–differential transducers (LVDTs) during the indirect tensile fatigue test. The graphs for the load cycle number corresponding permanent deformation are given in Fig. 3 for HMA and WMA mixtures at 20°C temperature. As shown in Fig. 3, HMA and WMA mixtures were cracked at approximate values of 4.3 mm, 4 mm deformation strains respectively. The specimens prepared with organic WMA additive could withstand higher load cycles and have cracked at lower deformation strains.

Figure 3. Permanent deformations corresponding load cycle numbers

Results of Rheological Properties

The variation of complex modulus (G^*) of the base bitumen and the bitumen samples involving variable content of organic WMA additive at low (0.01 Hz) and high frequency level (10 Hz) and at six different temperatures are presented in Figs. 4a and 4b. As depicted in Figs. 4a-4b complex modulus increases by the decrease of temperature. An increment in G^* indicates higher elastic part, thus an improved elastic behaviour. Besides, G^* increases with increase in frequency. This is due to the rheological behaviour of the bitumen samples since bitumen under shorter loading times (high frequency level) exhibit elastic behaviour. G^* values of the samples involving organic WMA additive are greater than G^* of base bitumen for all temperatures and frequencies as seen in Figs. 4a and 4b.

Figure 4a. Complex Modulus of organic WMA additive at 0.01 Hz.

Figure 4b. Complex Modulus of organic WMA additive at 10 Hz.

Rutting Test Results

The Hamburg wheel tracking test was performed in accordance with EN 12697-22 standard [27]. The rut depths at 50°C are presented in Figure 5. Results are given as percent values indicating the ratio of actual rut depth over the total thickness of tested specimen (50 mm). The real rut depths (mm) are obtainable by halving the percent values. The rut depths at 50°C of HMA and WMA mixtures involving organic WMA additive were determined at each 5.000 passes initiating at 5.000 and ending at 30.000.

Figure 5. The rut depth % values corresponding number of passes for HMA and WMA mixtures including Organic WMA Additive

As expected the rut depth values typically increased with increase in the number of passes. Based on each number of passes, WMA mixture involving organic additive performed better than HMA mixture in terms of rut depth.

CONCLUSIONS AND RECOMMENDATIONS

Lowering mixing and compaction temperatures and consequently the reduction of energy costs as well as emissions are the dominant advantages of utilization of WMA technologies. The utilization of organic WMA additive helps in the reduction of viscosity values which in turn reduces the mixing and compaction temperatures.

The results obtained from Marshall design demonstrated that the optimum bitumen content decreases by WMA additive. This reduction can be described as an advantage of using organic WMA additive in terms of initial cost.

ITSM values regarding HMA mixture and WMA mixture showed that the utilization of organic WMA additive increases the stiffness of mixtures. The ITSM values of all mixtures tested within the scope of this study significantly decreased by increase in temperature. As well as PI values of bitumen containing organic additive exhibited that the use of WMA additive potentially improves the temperature susceptibility.

When evaluating the load cycle numbers which caused the specimens to be cracked, WMA additive improves the repetitive loading strength of bituminous mixtures. The load

cycle numbers of all mixtures significantly decrease by increase in temperature. Taking into consideration the deformation strains, WMA mixture exhibits better performance under constant loading cycles. The utilization of organic WMA additive improves the ability of asphalt pavements against permanent deformation and increases the rigidity of bituminous mixtures. The formation of crack in lower deformation levels as a result of repetitive loading is an indicator for brittle susceptibility level of a specimen.

Detailed investigation performed by DSR test at low and high frequency level and at different temperatures indicated that, the complex modulus value increases with increase in frequency and decreasing temperature. Increment in G^* is attributed to improved elastic behaviour of the sample.

In the light of findings from rutting test, it is possible to consider that the organic WMA additive improves resistance to rutting characteristics of bituminous mixtures. Organic WMA additive has structural modification effects on bituminous mixtures.

Abstract— One of the most common reasons for deterioration in concrete pavements are thermal strains which occurs due to daily temperature changes. Additional strains occur due to thermal differences between bottom and top layers of concrete covers.

Even if thermal related cracks do not cause fundamental structural problems in its initial development stage, these cracks could increase due to freeze and thaw of the rigid pavement. Consequently, the drained water in the base layers cause deteriorations in base ground and other layers.

The most common used concrete pavement class in Turkey and around the world C30 class concrete was poured in accelerated pavement test laboratory facility in 1/1 scale ratio conditions and thermal measures were daily taken from the edge and middle of the 5 m by 4.5 m and 150 mm thick concrete plate section. Thermal variations through the 150 mm thickness were measured every 50 mm depth by the thermocouples in summer and winter.

In recent years, an Albedo device, which is an innovative method for determining the amount of reflection of sunlight coming to the surface of the pavement, is used. Reflections from the surface of concrete slabs were recorded with the Albedo device while temperature measurements were taken in this study. In this study, it was investigated how the temperature which occurs on the surface of a concrete pavement of C30 standard progressed along the thickness. Finally, thermal data were entered in ANSYS finite element models and afterwards strains were computed.

Keywords- Thermal stresses, ANSYS, Daily temperature, Thermal cracks, Albedo

I. INTRODUCTION

Concrete pavements are used as an alternative to asphalt pavement, especially in roads exposed to heavy vehicle traffic. This type of coating is suitable for use even in the case where the subgrade layer is weak due to its advantages such as high strength, long life, less maintenance and repair.

Concrete pavements are exposed to formations such as expansion and shrinkage due to seasonal temperature cycling and daily temperature changes. These physical changes cause a number of problems in concrete pavements. Concrete pavements can be constructed using reinforcement and/or joints so that they can be used smoothly with expansion and contraction problems during service life.

While the concrete surface expands in hot weather and shrinks in cold weather. The difference in temperature between the bottom and the top surface of the concrete coatings causes thermal stresses in the concrete. As the plate thickness increases, the temperature difference between the surfaces increases.

Although the temperature distribution in concrete pavements depends on the weather conditions, the impact angle of the sun's rays on the pavement surface can also affect the temperature distribution. The amount of reflection from the pavement surface of the sun's rays can be determined with the Albedo device. At this point, the temperature distribution obtained during the pavement thickness and the sun rays reflected from the surface can be found.

Considering the literature studies, it has been found that there are significant stresses in concrete roads due to thermal stresses. These stresses have been found in the literature with modeling of land studies or end-elements. It is seen that the nonlinearity of the temperature distribution along the depth in the concrete coatings is more stressed than the linearity.

A. Temperature Effect in Concrete Pavements

Experimental and numerical studies are widely used to determine the temperature distribution in concrete slabs. Measurements must be taken in the field conditions in order to remove the temperature profile of the concrete pavement. The temperature distribution along the pavement thickness is measured and recorded and displayed by thermocouples placed at different depths [1, 2, 3]. This data is accurate for short-circuited readings, but can lead to significant errors due to zero point deviations for long-run thermocouple readings. At the same time, these data can lead to misleading results because in situ observations cannot cover areas with special conditions that are affected by heat transfer between the pavement and the environment [1, 2, 4].

It would be useful to compare the measurements taken from the field with analytical solutions or computer models. After the measurement results are clarified, the extra internal stresses introduced into the concrete pavement are investigated. The temperature distribution that occurs in concrete pavement creates internal stresses that will result in increased curl and shrinkage of the pavement. It is accepted that the temperature distribution during the design and analysis of concrete pavement is linear across the layer thickness. However, when field measurements are taken, it can be seen that there is a nonlinear distribution.

In a study by Huang in 1993, it was determined that the temperature difference between the lower and upper surface of the pavement reached a maximum of 0.5-0.6 °C/mm during the day, and reached up to half of this value at nights [5]. Zhang et al. found that the linear temperature distribution in the pavement produced excessive tensile stresses and observed that the nonlinear distribution caused an increase of about 75% compared to the linear one by forming the maximum tensile stress [6]. Tensile stresses can occur as flexural and shrinkage stresses in concrete slabs. These curling and shrinkage stresses cause damage in rigid pavement. Since the shrink-covered concrete forms significant stresses at early ages, the capillary cracks formed along the pavement after turning on the road are transformed into continuous cracks [7].

B. Relationship Between Surface Temperature and Albedo

Albedo, or solar reflectance, is the ratio of reflected solar radiation to the total amount that falls on that surface, known as incident solar radiation. Albedo values range from 0, for perfect absorbers, to 1, for perfect reflectors. In pavement structures,

the topmost surface is the only layer which affects albedo. Therefore, pavement type selection should also include a consideration of albedo where heat generation is a concern. If concrete and especially asphalt surfaces coated with 'cool material', its surface temperature and heat absorption can be reduced. Therefore the use of high albedo urban surfaces is an inexpensive measure that can reduce summertime temperatures [8].

The term of solar reflectance is the ability of a material to reflect solar energy from its surface back into the atmosphere. Some previous studies related to cool materials, Pearlmutter et al. showed that light-colored walls would reflect more short-wave radiation and generate a slightly higher heat gain for pedestrians based on a pedestrian-centered conceptual model [9]. Brender and Lindsey conducted experiments in Las Vegas and observed hotter interior temperatures (5°C at maximum) in the conduit over a white roof as compared to dark-colored roofs [10]. And results of experiments by Li implied that the temperature of the building Wall would be heated up by the reflected energy from the pavement surface, which could be at maximum ≈ 2 to 5°C higher around noon [11].

Subsequently, the increased temperature makes air conditioning units work harder, accelerates the heat aging of the membrane, damages surrounding building components, and causes heat discomfort for pedestrians. This effect causes potential problems for the high density urban areas where building components are in close proximity to each other [11]. For example, increasing the albedo from 0.15 to 0.5 would substantially impact the comfort of people standing on the more reflective pavement, increasing the temperature they feel by 3 to 6°C [12]. Taha et al. measured the albedo and surface temperatures of various materials used in urban surfaces and found that white elastomeric coatings that have an albedo of over 0.72, were 45 °C cooler than black coatings with an albedo of 0.08 [13].

Various studies have been performed to understand better the thermal performance of paving materials. Berg and Quinn reported that in mid-summer, white painted roads with an albedo close to 0.55 have almost the same temperature with the ambient environment, while unpainted roads with albedo close to 0.15 were approximately 11 °C warmer than the air [14]. Asaeda et al. have reported the experimental results of a study where the impact of various pavement materials used commonly in urban environments were tested during the summer period. They found that the surface temperature, heat storage and its subsequent emission to the atmosphere were significantly higher for asphalt than for concrete and bare soil [15].

C. Methods of Analyzing Stresses Due to Temperature Distribution

Wastergaard first demonstrated that heat exchange in concrete produces stress [16]. The assumption of a linearly distributed temperature distribution over its pavement depth is widely accepted in the prediction of curvature stresses in concrete pavement subjected to curling [17]. The idea that Wastergaard's thermal stresses along the concrete slab has been reduced to the final dimensions by Bradbury and that the thermal stress to be formed when the temperatures of the lower and upper surfaces of the slab are known is precisely defined [18]. Subsequent work has shown that the exposed edge surfaces of the concrete pavements have a nonlinear temperature distribution, rather than a linear, since they can be easily affected by the heat flow in the upper surface.

Channakesava et al. made a nonlinear static analysis of concrete pavements in 1993. He used a spring element to place the ground layer under the concrete cover which he designed as a three-dimensional solid element. Analyzes were carried out under thermal load and wheel load to observe fractures caused by nonlinearity in concrete. After determining that the joints are close to each other, the bond has been replaced by a dowel bar [19]. Zaman et al. developed an algorithm using the finite element method to determine the dynamic responses in rigid airport pavement exposed to shrinkage caused by temperature change and traffic overhead. The concrete plate is defined as a thin plate element and is placed on a viscoelastic base layer which is uniformly formed by spring elements. He studied the effect of joint spacing and temperature distribution on the basis of his work [20].

II. MATERIAL AND METHOD

A. Experimental Study

Within the scope of this study, 5 different concrete plates were utilized. Three of these plates are 150 mm thick and two of them are 200 mm thick. It is separated by grouting between plates and its dimensions are 4.5x5 meters. The compressive strengths of the plates are 25, 30 and 35 MPa. We used a 150 mm high plate with a compressive strength of 30 MPa.

Temperature measurements were taken using a K-type thermocouple at 50 mm intervals along the depth of the selected concrete plate from the edge of the joint and from the center of the plate near the joint (Fig.1.).

Fig.1. Settlement of concrete pavements

The temperature of the concrete pavement was set separately in May and January. Temperature measurements taken separately from the edge and center of the plates were recorded at intervals of 15 minutes (Fig.2). At the same time the air temperature is recorded and the measurements are confirmed to be correct.

Fig.2. Datalogger settlement

In the course of the study, Albedo was placed and reflections were recorded as the sunlight hits the cover (Fig.3). The effect of the temperature of the pavement surface of the sunlight was recorded. According to the data of the General Directorate of Meteorology between 1950 and 2015, the maximum sunshine duration of Trabzon province was determined as May-June and the minimum sunshine duration was determined as December and January [21]. The time of study is set according to this calendar.

Fig.3. Albedo device

B. Finite Element Model

This part of the work is concerned with the process of preparing and analyzing the finite element model. ANSYS 14.5 Workbench interface is used when finite element modeling is done [22]. Boundary conditions and geometric modeling steps constitute a significant part of the finite element operation. Analyses made to determine the thermal stresses occurring in concrete pavements are the basis of the study.

Finite element modeling includes steps such as geometry creation, material model preparation, mesh and boundary conditions. The geometry of the model is based on the measurements of the concrete plate in the laboratory environment. For concrete plate material properties, "Concrete" element was selected and concrete elasticity modulus, density, poisson ratio, thermal expansion coefficient and thermal conductivity coefficient values were entered as in Table 1. After the concrete slab was formed, mesh analysis was carried out to separate it into finite elements, and then 'fine mesh' was made after the most appropriate mesh sizes were determined.

TABLE 1. PROPERTIES OF CONCRETE ENTERED IN ANSYS

Modulus of elasticity of concrete, MPa	32000
Poisson ratio	0.2
Thermal expansion coefficient, C^{-1}	1.3×10^{-5}
Density, kg/m^3	2300
Thermal conductivity coefficient, W/mK	0.72

III. RESULT AND DISCUSSION

A. Temperature Measurements

The temperatures of the concrete pavements are measured via thermocouples placed along the depth. Measurements were taken in May and January. The temperature distribution on the cover could be watched in both summer and winter seasons. The data taken from the edge region and center of the pavement are shown in Figures 4-11.

Fig.4. Temperature distribution on surface in May

Fig.5. Temperature distribution on bottom in May

Fig.6. Temperature distribution along the thickness of the plate center in May

Fig.7. Temperature distribution along the thickness of the plate edge in May

Fig.8. Temperature distribution on surface in January

Fig.9. Temperature distribution on bottom in January

Fig.10. Temperature distribution along the thickness of the plate center in January

Fig.11. Temperature distribution along the thickness of the plate edge in January

It is known from the literature that surface expansion occurs when the temperature of the coating surface is higher than the temperature of the bottom. The expansion occurring in the concrete pavements causes elongation in the joints. The amounts of elongation were not determined experimentally but tried to be determined with the models created by the finite elements method.

Because the thickness of the coating is 150 mm, which is a thin value, the temperatures in the pavement are close to each other. But in some days the temperature differences between the pavement surface and the bottom have increased. When the Fig 4 and 8 are examined, it is seen that the temperatures formed on the pavement surface are very close to the ambient temperature. It was observed that the temperatures at the center of plate surface provided this condition, while the temperature changes at the edge region were more shifting. This is because there is more air flow at the edge of the pavement.

This is not evident during the pavement depth. On the contrary, the temperatures taken along the thickness of the plate center and the plate edge are close to each other. It is seen that

the difference between the ambient temperature and the lower surface of the pavement increases.

B. Albedo Measurements

Albedo is the ratio of the amount of sunlight reflected from the pavement surface to the amount of sunlight coming from the pavement surface. The daily albedo values of the pavements are calculated in this way.

The average of all values was calculated as 0.24, with a minimum of 0.18 and a maximum of 0.36 for the albedo values during the 30-day May-June period on the concrete pavement (Table 2).

TABLE 2. ALBEDO VALUES DURING THE 30-DAY MAY-JUNE PERIOD

Day	Albedo	Day	Albedo	Day	Albedo
1.	0.18	11.	0.21	21.	0.18
2.	0.20	12.	0.20	22.	0.20
3.	0.20	13.	0.22	23.	0.20
4.	0.25	14.	0.21	24.	0.25
5.	0.25	15.	0.20	25.	0.25
6.	0.23	16.	0.32	26.	0.23
7.	0.23	17.	0.34	27.	0.36
8.	0.22	18.	0.32	28.	0.22
9.	0.23	19.	0.21	29.	0.23
10.	0.22	20.	0.22	30.	0.22

Albedo measurements vary depending on the amount of incoming and reflected sunlight. As can be seen in Figure 12, the albedo values are very close to each other in May, when the number of sunny days is high, while the albedo value decreased by about 10% in January when the number of sunny days is low.

Fig.12. Albedo values in May and January

C. ANSYS Analysis

The temperature data obtained in the laboratory environment were analyzed and the temperature differences on the upper and lower surfaces of the concrete pavement were examined within 30 days. The days when the temperature difference was maximum were determined and the temperature differences formed during those days were applied to the concrete pavement. The reason why the process performed in this step is the highest temperature difference occurring on the upper and lower surfaces of the coating is that it causes the maximum curling stress.

Total displacement amounts in concrete plates were determined and the elongation amounts in the "x" and "y" directions were determined (Figure 13). As a result of the analyzes, it is seen that the maximum amount of displacement is 0.48 mm. In addition, it was observed that the maximum tensile stresses were determined as the regions where the tensile strength of concrete was not exceeded. The sample temperature distribution in the coatings is as shown in figure 14.

Fig.13. Thermal stresses in concrete plate

Fig.14. Temperature distribution along pavement thickness

IV. CONCLUSION

In this study, it was investigated how the temperature which occurs on the surface of a concrete pavement of C30 standard progressed along the thickness. Furthermore, the reflections from the surface of concrete slabs were recorded with the Albedo device while temperature measurements were taken, experimentally. Finally, thermal data were entered in ANSYS finite element models and afterwards strains were computed. The conclusion drawn from the results obtained in this study are as follows:

- It was observed that the temperatures at the center of plate surface provided this condition, while the temperature changes at the edge region were more shifting. This is because there is more air flow at the edge of the pavement.
- Especially when the temperature measurements taken in the summer months are examined, it is seen that the ambient temperature is closer to the pavement temperatures. But in winter this difference has increased considerably.
- The albedo values are very close to each other in May, when the number of sunny days is high, while the albedo value decreased by about 10% in January when the number of sunny days is low.
- According to AASHTO standards, the width of expansion joints in concrete casings is recommended as 20 mm and more. This situation leads to the problem of Hydro pumping and presents very negative conditions in terms of driving comfort. It has been shown that a gap of 1-2 mm is sufficient at joints where 20 mm joint opening is excessively large in these working conditions.
- The results obtained without this work can be compared later by adapting to thicker concrete slabs. In addition, the amount of expansion in joints will be measured experimentally.

Abstract—In this study; the special problems of the Eastern Black Sea region related to rock fall are examined and solution proposals are presented. The subjects to be considered during the construction stages of the projects to be applied in the field and the methods and materials used during the manufacturing have been examined through the sample projects. The study also includes information about the innovative steel barriers of neighborhood of Güney in Maçka District which have been tendered and completed in the same period, and the tender and acceptance stages of compacted soil reinforced embankment walls of neighborhood of Yesilyurt in Araklı are presented.

The study includes information on how approximate costs are initially calculated and the rates of bidding. Later, the difficulties encountered during the manufacturing process will be examined. According to these difficulties, the experience gained about the selection of the type of production, preparation before and after manufacture, extra costs, etc. will be shared. Finally, at the end of the manufacturing, unit length costs, energy capacities and other aspects will be examined and a general comparison will be made. As a result of the studies, it has been found that the domestic product (Reinforced Soil Embankments) saves 3 times cheaper than compared to the innovative steel barriers. Furthermore, the steel barriers have at least 5-10 times less energy absorption capabilities than the embankment walls. However, according to the conditions of the region, it is necessary to find suitable land type for the construction of the embankment wall or to take precautions with extra costs.

Keywords—Rockfall, Steel barriers, Domestic products, Embankment walls, Gabions

I. INTRODUCTION

In our country, many settlement centers, dams and transport networks are experiencing rockfall events. In particular, the Eastern Black Sea region is one of the places where this situation is most experienced. The settlements in which the rock falls have been made up of generic villages and neighborhoods, some of them being provincial and district centers. In case the rockfall is dangerous and frequent, the disaster exposed area announcement is made pursuant to the Law no. 7269 on the aids to be made with the measures to be taken in the event of a disaster. Accordingly, the region was declared a disaster exposure, housing and urban development is prevented. However, there are no obstacles to the creation and operation of the transportation network. This situation threatens the safety of life and goods, especially sustainability in highways. Falling rock masses disrupt the road superstructure and lead to long-term closing of the traffic.

There are many methods to solve the problem in rocky areas. In particular, there are studies to ensure the stability of rocks, with or without bullion steel grid nets and / or ropes, or to ensure that with steel barriers, which are energy absorption features. Both of these methods are of foreign origin and in particular almost all of the energy mitigation steel barriers are imported. The most important reason for this is that imported products are patented and experimental works are carried out abroad. The reason for doing this work is to provide domestic alternative energy absorbers (especially embankment walls) as an alternative to imported products, aiming to ensure the residential safety and sustainability of road traffic. In this study; special problems of the zone related to rockfall have been examined and suggestions for solutions have been mentioned. Particularly focused on alternative methods for the protection of local roads and houses in the area exposed to rockfall. The issues to be

considered during the construction of the projects to be applied in the field and the methods and materials used during manufacturing have been examined through the sample projects [1].

Slope currents and rock fall events are common in our country's highway transportation line. For this reason, rock improvement projects have become one of the frequently used methods in our country day by day. There are a number of considerations that must be taken into account during the project. First of all, the probability of falling rocks should be assessed under regional conditions and the physical characteristics of the rocks likely to fall should be well defined. These definitions should be supported with information gained from experience so that they can be made nearest to the truth. Rockfall; can be defined as rocks separated from the main rock due to physical or chemical reasons or risk of separation, rolling down the road edge through the slope or the palms of the ground with factors contributing to the initial movement of the rock such as soil structure, humidity, precipitation regime, vegetation cover, sudden temperature changes, volcanic mobility and seismicity [2]. The most important reason for rock falls is cracks on the rocks. The likelihood of falling rocks varies with different types of cracks. Rock falls occur in the form of superficial rash or fall of block rocks, caused by deep instabilities along the slope [3]. Types of instability give information about the dimensions of the rocks. Dimensions are used to calculate rock weights and help determine the type of measure to be selected. Furthermore, the speed, energy and jump heights that the moving rocks have during motion must be known during the projecting phase. Keeping rocks that are likely to fall in place using various technical methods, stopping without any danger in case of a fall, or ensuring that they fall controlled and safely, form different types of rock reclamation projects. Rock rehabilitation studies in Turkey are being implemented by many public institutions and organizations, especially DSİ, General Directorate of Highways, AFAD. Generally, we can gather applied methods under four headings.

A. Surface Coating with Steel Nets (Wire Net)

This method is used in rubble, debris flowed slopes and areas where instabilities do not form large blocks. In particular, rocks which act on large area but do not have excess mass are kept in place by surface coating method. In case of falling rocks on steep slopes, if they gained energy or speed of the rock cannot be prevented by other methods, the surface coating method should be preferred and the rocks should be stopped before moving. In this method, rocks are allowed to flow in certain sizes from slopes wrapped with steel mesh as figure 1. In the areas where this method is applied, nets should be examined periodically. Since the fatigue effect of the so-called Debris on the steel web of the broken rock materials will cause the net to break, the material that accumulates in the net must be cleaned. Steel nets are reinforced with steel ropes and bolts. The steel net tensile strength capacity, which is important for steel network

calculations, is that it can carry three loads. These loads are: the load of the steel net and the ropes, the load of the breakage rocks and the snow load.

Fig. 1. Rockfall Mitigation with nets at Maçka made by Trabzon AFAD

B. Gabions (Embankment walls)

If the rocks that are likely to fall have a very high value of energy or speed to gain during the movement, construction of earthed walls should be preferred. A well-designed earthed structure can reach very high energy absorption capacities thanks to the on-site soil. Moreover, the distortions and deformations caused by the impact of the rocks affect the earthed walls less than other methods. Also, this method is quite advantageous in terms of cost compared to other methods. However, it is difficult to be preferred due to the effects of implementation difficulties, location and material selection. It works as a retaining wall with the material placed inside [4, 5].

C. Cleaning and Stacking

In some of the areas where rock rehabilitation works are carried out, rocks are divided into small pieces due to physical reasons. Since some slopes do not have much slope gradient, rather than covering with steel mesh, which is more costly, rocks are being rehabilitated by clearing the rocks along the slope and stacking them at appropriate locations. The medium sized rocks randomly scattered in the ground can be crushed by hand crushers to get rid of the burden and can be stacked in location.

D. Energy Breaker Barrier/Embankments Systems

It is not always possible to apply surface coating systems and stabilization methods with technical, topographical, practical or economic reasons in large scale and difficult terrain (land) conditions. In such situations, Energy Breaker Barrier or embankments Systems, which will be placed on the slope surfaces in the proper direction and position as the most effective and efficient solution against the rock falls, are at the forefront. The primary role of these barrier or embankment systems is to absorb the energies of large rock blocks that will fall from the hillside or slope surfaces and stop the rockfall. The capture nets in barrier systems are made up of materials with specific height,

length and energy absorption capacity. In these barriers with energy absorption effect, steel nets, which have an absorption characteristic, are stretched between the steel posts made of various angles. There are some difference between steel barrier and embankments given at Table 1. The following three main points should be taken into account when designing this system:

- The energy that the rock will gain during the fall
- Speeds at which the rock will gain during the fall (Max. 30 m/sec)
- Bounce movements that the rock can make during the fall

According to these three main criteria, dimensional drawings and cross sections prepared previously are examined and barrier placement is made at the most suitable location. The location where the barrier is placed directly affects the barrier dimensions (height and width). Since this affects cost, it is very important to select the location where the barrier will be placed [6].

TABLE I. COMPARISON BETWEEN EMBANKMENTS AND BARRIERS [7]

Feature	Reinforced soil embankment	Rockfall barrier
Energy absorption capacity	Much more than 5000 kJ	Up to 5000 kJ in the current market
Resistance to multiple impacts	Yes	Variable depending on barrier type
Downslope deformation after impact	Negligible	Not negligible
Ability to intercept high speed impacts	Can withstand impact velocities up to 50 m/sec	Tested up to 25 – 30 m/sec
Maintenance required for low-energy impact	Negligible to none	Variable depending on impact, barrier type, and barrier manufacturer
Installation tolerances (geometric) of the structure	There are no specific geometric requirements	Barrier must be installed within specific geometric requirements
Required slope topography for installation	Suitable for slopes with medium to low gradient	Can be installed on any type of slope
Cost of installation of the structure	Cost efficient for energies greater than approx. 3000 kJ	Cost efficient for energies below approximately 4000 kJ
Environmental compliance	Potential LEED compliance and blending with landscape by vegetating embankment facing	Structure is likely transparent to a distant observer

II. THE PROBLEMS ENCOUNTERED WHEN DESIGNING ROCKS IN THE REGION

Deep valley: The topography of the region consists of deep valleys. The rocks with the risk of falling are located near settlements but on rough terrain that is difficult to access. For this reason, during the project work, these rugged terrains create various difficulties in terms of transportation. In addition, alternative measures should be taken in advance by considering that a rock part that is accidentally fell while working in these areas will cause loss of life and property in the settlements or transportation located below.

Vegetation: There are dense vegetation in the Black Sea Region. This makes it difficult to project and conduct rehabilitation works. As seen figure 2, rocks that are in danger of falling do not appear due to dense vegetation, which makes mapping and projecting works difficult. Because the accuracy of the project is directly proportional to the mapping detail, also mapping cannot be done due to the systems that are flown to the developed technology in the region, so traditional methods should be applied carefully. In addition, it is difficult to work by preserving the trees in the forest during construction. This should be taken into account during the projecting phase.

Fig. 2. Dense vegetation cause not appear rocks.

Climate: Continuous rainfall in the zone creates various difficulties during the projecting and construction works. This situation both prolongs the manufacturing process and requires extra precautions. For example, during the rock rehabilitation work on a dry creek bed in Şalpazarı Çetrik neighborhood, due to heavy rainfall the water of the river has high flow rate information has become necessary to add to the project [8].

Site selection : The lack of flat areas in the region affects the project and construction of rehabilitation work. Since expropriation is not carried out, applications are usually carried out in treasury land, forest area or pasture. This makes it difficult to select the most suitable location for manufacturing. While the project is being carried out in limited flat land belonging to the citizen, there is also a problem of persuasion of the citizen. Figure 3 shows us treasury land, that made by villagers. This area is the only part of area suitable for cultivation

Fig. 3. Trabzon Çaykara, some villagers make stone wall with difficult conditions for farming.

Slope cleaning: Rocky areas with high risk of falling before manufacturing are very common in the Black Sea Region as well as in the general areas where rock breeding works are to be carried out. These slopes need to be pre-cleaned or fixed as they may fall during manufacturing and may cause accidents. During the projecting phase these rocks must be identified and added to the metric figure 4. Some rocks rest against the buildings. The precautions to be taken during the cleaning of these rocks, which are rested and dangerous to the houses, must be considered during the projecting phase.

Fig. 4. Before making preventive structure, pre-cleaning and fixed

III. RESULTS AND DISCUSSION

In this report will compare two protective structure made by Trabzon Provincial Directorate of Disaster and Emergency Directorate. One of structure made at Maçka disaster (Steel barrier) and the other made at Araklı disaster (Soil compacted reinforced wall).

A. Pre-tender Works

The two neighborhoods where the rock rehabilitation work was done were declared as the area affected by the disaster and details given in the Table 2 . 19 residences in Maçka and 24 residence in Araklı were determined to be affected. In addition, hazelnut gardens, fruit trees, stables, poultry houses, outbuildings and various public buildings (roads, electricity / telephone / water lines, schools, health clinic, etc.) are also included in the areas exposed to the disaster. When these structures are taken into account, as shown in Table 2, the total estimated cost of the site where the rock is to be emerged [8]. Rock treatment is planned in three neighborhoods at the same time in Maçka district. In this study, manufacturing in the Güney Neighborhood will be examined. In the project prepared for the rehabilitation of the affected area in the Güney Neighborhood, it was decided to construct a rock barrier with a height of 80 m and a capacity of 500 Kjoules and a height of 2 m. At Yeşilyurt Neighborhood in Araklı District, it was decided to construct a earthed barrier with a length of 3 m a length of 212 m and a capacity of at least 7500 Kjoule in accordance with the type of production. Approximate costs of manufacturing and contract costs are given in Table-2. According to this table, it is seen that the cost of transporting the citizens living in the affected areas to another region is considerably high. However instead of this, making rock fall protection structures works yield 15-20 times more profitable. According to this information, it has been observed that the embankment wall is 3 times more profitable than the steel barriers, although it can

be absorbed by at least 15 times more energy, 1.5 times higher and 2.65 times longer.

TABLE II. ARAKLI-MAÇKA PRETETIVE STRUCTURE COMPARISON

B. Projecting

The rock improvement project work consists of three phases.

The first is detailed dimensional drawing studies and preparation of critical sections, the second is the preparation of rock-related geotechnical data that can be fall down, and finally the determination of precautions. These steps were followed in two studies conducted in the province of Trabzon. After mapping, Trabzon Provincial Directorate of Disaster and Emergency Directorate made the necessary inspections in the field, and in consequence of these examinations, the cross sections of the routes are desired, where the rocks have fallen before and the elevation has occurred rapidly. Various details about the rock that can be fallen have been prepared, and the largest rock sizes that can be fallen according to the crack type are estimated. Finally, the highest energy, bounce heights and speeds were determined using statistical programs related to rock treatment on the computer. With program outputs, best routes (Economic and safety) were chosen. The dimensions of the measures to be used and the energy capacities have been chosen to remain in the safe zone.

C. Manufacturing Practices and Challenges

The production started after the delivery of the place to the company that took the tender. The manufacturing stages were checked and accepted by the Disaster Emergency Directorate.

Situations during manufacturing:

- Due to the fact that the Steel Barriers are of foreign origin, it took a certain period of time for the material to come to Turkey and to leave warehouses. This disadvantage has not been found on the embankment wall. Moreover, it is obvious that the same problems will be experienced again when a possible project is going to increase in steel barriers. Grounding barriers are completely domestic production barriers. It is also produced at about 3 times less cost than steel barriers.
- The steel barriers need to be anchored in a sound manner. The stability of anchors is directly related to the work of energy dampers. The anchor, which is located at 2 anchorage bases made in Maçka, has prevented the dampers from working due to the excessive load coming from the place. Embankment walls do not need base courses.
- The ground floor of the embankment walls is quite wide. It has almost one-to-one dimensions with its length. The

height of the embankment wall made in Araklı as the figure 5 is 3 meters and the width is 3.5 meters. In addition to this broadness, it is also necessary to have a specific area for the accumulation of rocks falling on the part facing the

Location/ Number of House	Height and length (m)	Energy absorption capacity (KJoule)	Approx. cost of rock treatment (TL)	Contract cost of rock treatment (TL)	Estimated cost of transfers of citizens (TL)	Profit. Ratio (times)
Maçka/19 Steel Bar.	2 - 80	500	250.612,80	141.190,30	2.175.000,00	15,404
Yeşilyurt/24 Rein. Soil. Embankm.	3-240	Min. 7500	157.411,01	156.880,00	3.000.000,00	19,122

source rock. In other words, it is necessary to place at least 6 meters of a tilting structure at a height of about 3 meters. This distance can go up to 7-8 meters to run the excavator. In regions where flat land, such as the Black Sea region, is rarely found, especially in areas where there is hardly any reclamation, construction of a soil barrier create problems or is made on fill.

Fig. 5. Compacted soil and reinforced embankment wall at Araklı Yeşilyurt

- Araklı Yeşilyurt project was planned to create a flat area 7 meters wide before slope. Approximately 1.5 to 2 meters of this area is filling. The embankment wall was required to straighten 8 meters of the slope by pulling in 1 meter to avoid putting it directly on the end of this dolman. In the future, it has been decided that reinforced concrete retaining walls should be added to the project under filling, in order to make the soil flow and filling pavement more comfortable during operation.
- In embankment walls, the material used must be small. More energy damping and different seating durability can be achieved. However, the soil-clay material in the nearby environment is filled with small stones. For this reason, it was subjected to screening process. The sieve was not used at the desired level due to the precipitation of the area and the fact that this work corresponds to the autumn winter months. Precipitation has prevented the removal of material.

- Embankment walls need to be compacted well. The 3 meter high wall was built on the 4 layers. Each layer is 75 cm and subjected to a compression process at every 25 cm. However, especially in the areas close to the tools used for compaction cannot enter the compression is not exactly wanted.
- Embankment walls consist of galvanized steel hexagonal wire and erosion cover. A triangular shaped frame is used to mount the walls at the desired angle.
- Steel barriers are stretched with ropes. This causes some loss in size as seen figure 6. This loss should be taken into account during the projecting phase.
- Steel barriers work by energy damping of parts called disparator during rockfall. After a rockfall has occurred, it may be necessary to change the disaster according to the damage level. For this reason, quality control is required. Moreover, since disparators are patented products abroad, they cannot be imitated without permission and thus constitute foreign dependence. Because embankment walls have a lot of energy capacities, they usually need to be cleaned for a certain period of time as they accumulate material behind them.
- Because the embankment walls are greening, they can be harmonious with nature. Climate and vegetation cover our region in a short time without using this method. The

citizens planted hazelnut trees in the highest elevations. Steel barriers take up less space in nature, but they cannot fully conform to nature.

Fig. 6. Lose of height steel barriers

- Because the ground walls are 240 meters long, it is divided into 3 for the citizen's animals to go to the grassland. In order to make such a production in steel barriers extra material is needed, so it is necessary to inform the foreign origin factory in advance.

IV. CONCLUSIONS

Grounding walls are native, fast-reachable, environmentally compatible barriers that do not have the burden of increasing work. They are about 3 times cheaper than steel barriers. However, there are at least 10 times more energy damping capacities. The main disadvantage of grounding walls is that they must have a flat surface of at least 6-7 meters in width. The steel barriers can be manufactured only by foundation without any leveling work. Grounding walls should be preferred in order to prevent the growth of the current open due to domestic production. However, if the ruggedness and physical conditions of the manufacturing area are not available, steel barrier alternatives should also be considered.

Abstract---Daily changing temperature causes significant thermal stress and deformations in concrete pavement. These stresses are important parameters included durability of pavement and are significantly depended on thermal difference (i.e. difference in temperature between upper and lower surface plane) and surface temperature of pavement. The surface temperature of the pavements has a great influence on the temperature profiles, displacements and thermal stress. When increase the albedo value, the surface temperatures of the concrete pavements reduce. For this reason, the surface temperature can be reduced and the thermal stress can be reduced by increasing the albedo value of the pavements.

Keywords- concrete pavement; thermal stress; albedo; displacement

I. INTRODUCTION

The pavement surface temperature is critical to the pavement deterioration [1-4]. High daily temperature amplitude developed in a rigid pavement causes structural defects such as warping and curling [2, 5-7]. Curling stresses result from linear thermal difference in the whole thickness of slab. It is assumed that temperature remains constant in the normal middle plane of pavement whereas temperature at the top of slab is different from its bottom. These two major components of thermal stresses are combined by algebraic addition to obtain the overall stress in the slab due to temperature variations [8].

Traditionally, deformation behavior of a concrete slab due to temperature differential along its depth is referred to as curling. Many researchers have made an effort to evaluate the temperature gradient (or termed temperature differential between the top and bottom of a slab) during daily times and the corresponding motions of curling in actual concrete slabs [9, 10]. Several former studies [11-13] have shown that temperature gradients along the slab depth are typically nonlinear, with greater daily temperature fluctuations at the

top surface than at the bottom. If the temperature and moisture gradients are nonlinear, the slab tends to deform in accordance with its compensation plane (or a sectional average plane) as each concrete element along the depth should meet the linear continuity condition [13]. Balbo and Severi [14] have documented the influence of weather conditions on daily and seasonal variations in temperature through the slab depths in a hot and wet tropical climate in Brazil. It was found that the night-time temperature differentials were not as extreme as the daytime differentials.

Especially in hot summer months, the surface temperature of concrete covers can reach 50-55 °C. As a result, the positive temperature difference (ΔT_+) varies from 15 to 20 °C for pavements with a thickness of 20 cm, and this difference in temperature can cause cracks due to thermal stress [15]. In order to prevent overheating of the coating surfaces, it has become especially popular to coat the surface of the coatings with materials having high solar albedo for the last 20 years. Thus, "cool pavements" with low surface temperature were obtained. Albedo is a technical name to describe the fraction of incident reflected sunlight. Albedo, also known as solar reflectance, is the percentage of the solar radiation reflected by a surface with respect to the total incident solar radiation falling on the surface [16]. Boriboonsomsin and Reza, 2007 have observed the use of cool paving materials or 'cool pavements' has been identified as one strategy that can help to decrease pavement surface temperature. One method of creating a cool pavement is to increase the solar reflectance or *albedo* of its surface. This can be achieved by many existing paving technologies.

Surface albedo plays an important role in the thermal-energy behavior of pavements and other ground surfaces and their resultant impact on humans and the environment. Bretz *et al.* [17] showed therefore that significant energy saving and increased comfort levels of urban areas can be reached through solar-reflective and high-albedo materials,

by estimating the achievable increases in albedo for different surfaces.

In this study, the change of thermal expansion is observed by modeling with finite element method (FEM) and compared with 3 different formulas widely used in the literature. While these models are being built, the maximum of the previously measured surface temperature measurements is used. As a result of the analyzes, the surface temperature measurements of the albedo high values of the coatings, the layer temperature distributions, the horizontal displacement amount and the thermal stresses were lower than the measurements and analyzes in the conventional concrete coating. Similarly, stress values calculated with 3 different formulas give consistent results when compared to FEM. The results show that the application of a concrete road design with low surface temperature can reduce thermal stresses and deformations by increasing the coverage albedo value.

II. CLIMATE CONDITIONS OF THE REGION

In order to better understand the effect of the Albedo effect on the surface temperature and the temperature distribution, it was decided to carry out the measurement in July, taking into consideration the average daily sunshine periods and the monthly maximum temperature values of the region from 1950 to 2015 belonging to the General Directorate of Meteorology. This is mainly due to the highest sunshine duration in July, and it is estimated that the albedo values and effect will be observed more efficiently and that the surface temperature will rise to the maximum level since the daily temperature value in the same month is 37 °C and the second highest month in the year. As shown in Fig. 1, the daily sunshine duration has reached its maximum annual value in 10 hours and July.

Fig.1. Values of Trabzon the monthly maximum temperature and the average daily sunlight hours [18].

III. CREATION OF 3D MODELS

A. Determination of Surface Temperature

The temperature values taken from the concrete roadways in the campus area of the KTU campus were measured for 10 days of albedo in August and a maximum of 48.1 °C (A1 concrete pavement, albedo value 0.18) at 15:00 on day 7 as a result of surface temperature measurements, was measured as 38.3 °C (A2 painted with high-reflected materials, albedo value 0.29) (Fig. 2).

This study was performed with a single-headed pyranometer in the form of albedo measurements in accordance with ASTM E1918. The CMA6 parameter provides solar reflectance (W/m^2) of the surfaces 50 cm above the area to be measured, as specified in the standard.

These temperature values are entered as the surface temperature in the created 3D models. Thus, in summer, the natural temperature of the concrete surfaces will be subjected to 3D modeling and performance analysis of the road pavement under field conditions.

Fig.2. Daily surface temperature values (A1: Concrete pavement, A2: Painted-Concrete pavement)

B. Design of Layers

The concrete plate is designed to sit on a foundation layer geometrically as shown in Fig. 3 with the ANSYS 3D finite element analysis program. Analysis of 3D models was done as ANSYS-Linear. CONCRETE plate The CONCRETE element in the ANSYS material library is selected and the pre-set values in it are used. For the basal plate, SOLID element design is done according to the parameters in Table 1 in linear-elastic form. $f = 1.5$ between the foundation layer and the concrete plate is defined as the friction coefficient. The subbase values used in the study are

taken from the literature. No experimental work has been done for this.

TABLE 1. PARAMETERS OF LAYERS

	Thickness (m)	Modulus of layer (MPa)	Poisson ratio	Coef. of thermal expansion ($1/^\circ\text{C}$)	Thermal conductivity ($\text{W/m}^\circ\text{C}$)	Density (kg/m^3)
Concrete	0.2	30000	0.2	1.0E-05	2.5	2400
Subbase	0.5	2900	0.3	7.0E-06	0.05	2100

Fig.3. 3D model top view (a) and A-A sectional view (b)

IV. THERMAL ANALYSIS OF PLATES

A. Determination of Temperature Profile

The solutions for both surface temperatures were linearized according to the basic heat conduction equation in Equation (1). Finally, the base temperature of the substrate with a surface temperature of 48.1°C decreased to a minimum of 29.69°C (Fig. 4). For this layer, $\Delta T1 = 18.41^\circ\text{C}$ was obtained. The same solution was obtained at a temperature of 26.88°C for the second surface with a surface temperature of 38.3°C and $\Delta T2 = 11.42^\circ\text{C}$. With a temperature difference of about 10°C between the two surfaces, $\Delta T2$ is 38% lower.

$$\rho C \frac{\partial T}{\partial t} = k \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} \right) \quad (1)$$

Where:

T: Surface Temperature ($^\circ\text{C}$)

t: Time (second)

ρ : Density (kg/m^3)

C: Specific heat ($\text{J/kg } ^\circ\text{C}$)

k: Thermal conductivity ($\text{W/m } ^\circ\text{C}$)

Fig.4. Temperature profiles

B. Analysis of Thermal Stress-Displacement

Firstly, the maximum displacement amounts of concrete plates for $\Delta T1$ and $\Delta T2$ were analyzed Fig. 5. The linear relationship between the bed temperature distribution and the displacement amount is shown in Fig. 6. The maximum horizontal displacement at $\Delta T1$ was 1.4 mm, while at $\Delta T2$ it decreased by about 42% to 0.8 mm.

Fig.5. Plate displacement cross-section (for $\Delta T1$)

For the mathematical solution of the displacement calculation; $\Delta L = L \alpha t (\Delta T)$ (2)

Where:

L= Plate size (m) (where 6 m in x direction is used)
 α_c = Concrete thermal expansion coefficient (1/°C)
 ΔT = Temperature profil (°C)

Fig.6. Relationship between plate temperature distribution and displacement (for 6 m direction)

Secondly, the thermal stresses between the two layers are investigated depending on the ΔT temperature difference

The thermal stress is calculated as:

$$\{\sigma\} = [D](\{\epsilon\} + \{\epsilon_t\}) \quad (3)$$

Where;

$\{\sigma\}$ = Stress vector
 $[D]$ = Elastic matrices
 $\{\epsilon\}$ =Total strain vector; $\{\epsilon\} = \Delta T \{\alpha\}$
 $\{\alpha\}$ = Thermal stress vector

Because the analysis represents tensile stress, "Max. Principal Stress" is considered. 4.51 MPa and 2.61 MPa for ΔT_1 and 2.81 MPa and 1.68 MPa for ΔT_2 , respectively, were obtained with the maximum and minimum principal stress sequences. Similar to the displacement change, the maximum tensile stress of ΔT_2 , which has a low surface temperature, is also 35% lower in the case of tensile elongation. Piotr notes that ΔT values for concrete slabs with a layer thickness of 20-25 cm exceeded 20 °C and that thermal stresses reached critical levels in the concrete they were using in studies conducted in 2014 [8] and IRC 2002 [15]. In this study, the tensile strength of the CONCRETE element in the ANSYS material library is 5 MPa. In the present analysis, the maximum tensile stress is 4.51 MPa,

and the tensile stresses do not cause cracking in concrete casings. However, the use of lower strength concrete can lead to cracks due to thermal expansion if the temperature difference $\Delta T \geq 20$ °C is increased to high values.

Fig.7. Relationship between plate temperature distribution and stress

Max and Min prime stresses are analyzed as shown in Fig. 7 The tensile strengths of the concrete road are compared with the finite element thermal stresses calculated by using 3 different formulas in the literature.

1. Westergaard, 1927 [2];

In 1927, Westergaard conducted the first extensive research to find the thermal expansion of concrete slabs. In this study, we have obtained the following formula as the temperature distribution will be linear in the layer.

$$\Sigma_x = \Sigma_y = \sigma_0 = \frac{E \alpha T}{(1-\mu)} \quad (4)$$

Where;

E= Elasticity modulus
 α = Thermal expansion coefficient
T= Linear average temperature ($\Delta T/2$)
 μ = Poisson ratio

Westergaard's formula is arranged in the following manner for a finite plate of length L, so that the maximum prime stress (σ) at the center of the plate is assumed.

$$\Sigma = \sigma_0 \left[1 - \frac{2(\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda)}{\sin 2\lambda + \cos 2\lambda} \right]; \quad (5)$$

$$\lambda = L/(l\sqrt{8}); \quad l = \sqrt[4]{\frac{Eh^3}{12(1-\mu^2)k}} \quad (6)$$

2. Bradbury, 1938 [20];

Bradbury calculated the thermal stress formula Winkler calculated the elastic plate in contact with the basic conditions, depending on the boundary condition coefficient, as follows.

$$\Sigma = \frac{CE\alpha\Delta t}{2} \text{ (Plate edge tensions), (7)}$$

$$\sigma = \frac{E\alpha\Delta t}{2} \left(\frac{C_x + \mu C_y}{1 - \mu^2} \right) \text{ (Internal stresses) (8)}$$

C, C_x, C_y : Boundary condition coefficient (Takes values according to plate dimensions)

3. Iwama, 1963[19];

As a result of the research I have conducted, I have calculated 30% of the internal stresses in the concrete plate of 20-25 cm thickness. Thus, we found that the daily nonlinear thermal stress distribution accounts for 70% of the total total stress. This formula, found by Iwama, has been used in the design of concrete roads in Japan for 40 years.

$$\Sigma = 0.7 \frac{E\alpha\Delta T}{(1 - \mu)} \quad (9)$$

The results obtained from the calculated calculations are given in Table 2.

TABLE 2. THEMAL STRESS VALUES OF ALL ANALYSIS

	$\Delta T1$				$\Delta T2$			
	ANSYS	(Westergaard, 1927)	(Bradbury, 1937)	(Iwama, 1964)	ANSYS	(Westergaard, 1927)	(Bradbury, 1937)	(Iwama, 1964)
Thermal Stress (MPa)	4.51	4.01	3.97	2.80	2.61	2.06	1.92	1.44

C. Relationship between Thermal Stress and ΔT

The difference between the thermal stresses in the thermal stress analyzes and in the calculations obtained by the three different formulas seems to be seen in Fig.8. As can be seen, analyzes made with the ANSYS program have obtained thermal stresses greater than the other 3 calculation methods for $\Delta T1$ and $\Delta T2$ temperature differences. Especially the tensile strengths obtained with the Westergard and Bradbury formulas are almost the same.

Fig.8. Relationship between plate temperature distribution and stress

V. CONCLUSION

In this study, the sheet temperature distribution (ΔT) of the different surface reflectance properties of concrete slabs with the same properties and accordingly the variation of thermal stresses under daily temperature variation were investigated. The main purpose of the work is to keep the thermal stresses at a level that will not crack and to reveal the plate temperature difference (ΔT) that will provide it. The following results were obtained from the study;

- As the surface reflectivity of concrete coatings increases (Albedo), the surface temperature decreases and accordingly the layer temperature difference decreases. Thus, an increase of approximately 0.1 of albedo has reduced the surface temperature by almost 10 °C. Similarly, Albedo's 0.1 increase increased the sheet temperature distribution (ΔT) by about 7 °C.
- In the displacement analyzes performed on the plates, the maximum horizontal displacement at $\Delta T1$ was 1.4 mm, while at $\Delta T2$ it decreased by about 42% to 0.8 mm. According to the results obtained, as the albedo increases, it is seen that the horizontal displacement is reduced.
- As the layer temperature increased in the analyzes performed, the tensions obtained for both ANSYS and 3 different formulations tended to increase parabolically. The analysis with ANSYS showed an increase of 63% from $\Delta T1$ to $\Delta T2$, while the thermal stress increased from 2.61 MPa to 4.51 MPa by 72%. The difference between such temperature increase and stress increase is clearly visible.

- Obtained results clearly show that as the albedo value of the coatings increases, the layer temperature distribution, the maximum amount of displacement, the layer temperature distribution and the thermal stresses decrease, especially the surface temperature. Thus, due to the daily temperature difference, the curling-warping effect of the concrete coatings can be removed and the cracks in the coating can be removed.

Abstract—In the present study, the effects of styrene-butadiene-styrene (SBS) and American gilsonite (AG) on the stiffness and thermal sensitivity of bituminous binders were investigated in bitumen modification. Şanlıurfa province was chosen as the application field. It was determined that 18% AG and 5% SBS additives should be used separately to obtain the adequate binder for Şanlıurfa province. It was also determined that 13% AG with 2% SBS, 10% AG with 3% SBS and 6% AG with 4% SBS were required to obtain binders with the same performance level. Penetration, softening point and rotational viscometer tests were conducted on neat and modified bitumen to determine the consistency of binders. Furthermore, thermal sensitivities of binders were determined from penetration index and penetration viscosity number values. It was determined that all additives increased the consistency of the binders, the most effective additive type and ratio was 18% AG on penetration values, and all additives had similar effects on the softening point and viscosity values. In addition, it was determined that the temperature susceptibility was reduced with additive use and the most effective contribution came from 5% SBS.

Keywords—Bitumen; styrene-butadiene-styrene; American gilsonite; consistency; temperature susceptibility.

I. INTRODUCTION

Bitumen obtained by distillation from crude oil is produced from the residues of this process. Bituminous binders are a complex mixture of organic particles containing aliphatic, aromatic and naphthenic hydrocarbons and could be divided into two basic groups, namely maltenes and asphaltenes [1]. The asphaltenes are dispersed in the maltene phase with a continuous phase and the structure that forms the bitumen structure includes saturates (S), aromatics (A), resins (R) and asphaltenes (AS). The complexity, aromaticity and molecular weight of the fractions are ranked as follows: $S < A < R < AS$ [2, 3].

The bitumen exhibits binding properties that binds aggregates due to their cohesive properties in road applications. The bituminous binder also prevents the aggregate particles

from falling apart under traffic loads, improves the driving comfort with the smooth surfaces they create, increases mixture stability with its cohesion, and provides impermeability by filling the voids in the mixture. Bituminous binders have a great effect on mixture performance, even though they are used at a low rate of 5 to 7% by weight in hot mix asphalts [4].

Various additives (modifiers) have been used to improve the properties of binders for a long time, thereby increasing the service life of the pavement by preserving its performance for a longer period of time. The additives used for this purpose vary depending usage. To increase the resistance of bitumens and bituminous hot mixes to heat and traffic loads, generally additive materials of polymer origin are added. Mostly Styrene-Butadiene-Styrene (SBS) Block Copolymers are used in these additives. Several previous studies determined that SBS improves the fracture resistance at low temperatures, and the generation of rutting and fatigue resistance at high temperatures [5-9].

Gilsonite is a solid hydrocarbon mineral available in nature with a potential to improve physical and chemical properties of bitumen [10]. Gilsonite can rapidly dissolve in bitumen since it is a kind of natural asphalt binder [11]. Gilsonite offers different advantages over other modifiers such as easy mixing and compatibility with asphalt mixtures [12]. Economically significant Gilsonite mineral is found in the United States and Iran.

When Gilsonite is added to the bitumen, the penetration of the bitumen decreases, its viscosity increases and as a result, a harder modified bitumen is obtained. Mixtures prepared with Gilsonite modified bitumens have higher stability, lower permanent deformation and temperature susceptibility, as well as higher resistance to stripping caused by water when compared to mixtures prepared with unmodified bitumen [13-16].

Several previous studies reported that storage stability of SBS modified bitumen is low, even though the rheological properties of SBS modified bitumen are superior to that of the neat binder [17, 18]. Furthermore, SBS is also a more expensive additive compared to Gilsonite. Using SBS and Gilsonite together in bitumen mixture instead of using only SBS-modified bitumen, so that the resulting performance would be the same, provides economic benefits [19]. The combined use of the two additives has been common during recent years and aimed to remove the negative aspects of the additives and to increase the rheological properties of the bituminous binders, and thus, increasing the performance of the BHM in different aspects [20-23].

In the present study, the effect of the combined use of SBS and AG in bitumen modification on consistency and temperature susceptibility of the bituminous binders were examined. For this purpose, penetration, softening point and rotational viscometer experiments were conducted with neat and five different modified bitumen samples. Furthermore, using penetration and softening point values, penetration index value, which is the indicator of temperature susceptibility, is determined. Thus, the effect of two different additives on the consistency and thermal sensitivity of the bituminous binders was determined.

II. MATERIAL AND METHOD

The binder design was conducted with the Superpave method in the study. Şanlıurfa, the warmest province in Turkey, was selected as the application field. The information on the highest temperature values for 7 consecutive days and the coldest day during the last 21 years was obtained from Regional Meteorology Directorate and it was assumed that the design traffic estimate was 3-30 million standard axle load equivalent and there was low-speed traffic (<50 km / Hour). It was determined that the binder class that should be used in the design criteria determined for Şanlıurfa was PG 76-10.

In the present study, Styrene-Butadiene-Styrene (SBS) Block Copolymer produced by Shell Bitumen Company and American Gilsonite (AG) obtained from American Gilsonite Company were used as additives to B 160/220 grade bitumen that was procured from TÜPRAŞ refinery in Turkey. The mix was obtained by mixing the neat bitumen and additive material for 60 minutes with 1000 rpm. mixer at a temperature of 180 °C (Figure 1). In previous studies, it was determined that when 5% SBS (MB_{5S}), 18% American Gilsonite (MB_{18G}), 2% SBS + 13% AG (MB_{2S+13G}), 3% SBS + 10% AG (MB_{3S+10G}), and 4% SBS + 6% AG (MB_{4S+6G}) were used, the performance level (PG 76-16) was suitable for Şanlıurfa province and the test results for these mixtures were similar. For this reason, 5 different additive ratios determined in the previous study were used.

Fig. 1. Modified bitumen mixer and mixing apparatus

A. Penetration Test (EN 1426)

The penetration test was conducted to determine the stiffness or consistency of the bituminous binder. Penetration is the amount of vertical penetration by a standard needle at a given temperature under a given load, and over a period of time (Figure 2). The unit of penetration is 0.01 cm. In the penetration test, a load of 100 g was applied to the bituminous binder sample at 25°C for 5 seconds.

In the penetration test, the bituminous binder sample is taken according to EN 58 standard and transferred to the sample container after heating. The samples are allowed to cool for 60-90 minutes at a temperature of 5-30°C. The sample containers are then placed in a constant temperature water bath in the transfer chamber for 1-1.5 hours.

Fig. 2. Penetration test apparatus

The transfer container that contains the sample container is placed on the penetration device plate. The needle loaded with the desired weight is adjusted to have contact with the sample surface. At least 3 tests should be conducted using points that are not closer to each other and the side of the container for more than 1 cm. The arithmetic mean of accepted measurements is rounded to the nearest whole number, which is taken as the penetration value.

B. Softening Point Test (EN 1427)

The softening point test aims to measure the resistance of bituminous binders to high temperatures. Softening point is the temperature at the moment when the softened material touches the base as a result of heating the bituminous material in the standard ring at a certain speed, which was placed in a water bath, with a ball on it. The test setup is shown in Figure 3.

Before the experiment, the bitumen sample is heated and poured into the standard ring up to the top of the ring and cooled for 1 hour. The bitumen overflowing the ring is cut off using a heated spatula.

Fig. 3. Softening point test apparatus

Pure water at a temperature of 5°C is placed in the beaker and the ring that contains the sample is submerged into the water. Then the ball is placed in the beaker filled with water. The temperature of the water bath is kept constant at 5°C for 15 minutes. The ball is then placed in the middle of the sample in the ring using a pair of suitable tongs. The water is heated at a rate of 5°C per minute. The temperature read from the thermometer is recorded as the softening point when the softening material touches the base of the bath as a result of the increase in temperature.

C. Rotational Viscosimeter (RV) Test (ASTM D 4402)

The Rotational Viscosimeter (RV) test is conducted to determine the viscosity properties of the bituminous binders at high temperatures. The high temperature viscosity values of binders are identified to determine whether the binders are sufficiently fluid during pumping and mixing procedures. In the experiment, viscosity values are obtained by measuring the resistance of a shaft rotating at 20 rpm within the binder (Figure 4). In the RV test conducted with the original binders, it is best when the viscosity at 135°C does not exceed 3 Pa.s (3000 cP) [24, 25].

Approximately 30 gr. sample is taken and it is heated in a drying oven with a temperature of less than 150°C. Approximately 11 gr. of this material is placed in the sample compartment, and the sample compartment is placed in a temperature-controlled container with a constant temperature. After the sample is kept at a constant temperature for 15 minutes, the test is conducted. After almost equal viscosity values are obtained, three readings are conducted, and the viscosity of the binder is accepted as the average of these three measurements.

Viscosity values are used to determine the mixing and compaction temperatures of hot mix asphalts (HMAs). For this purpose, the RV test is carried out at 135°C and 165°C temperatures. A temperature-viscosity graph is plotted and the viscosity values are marked on the graph and these values are connected by a straight line. The viscosity values of the bituminous binder of 0.170 ± 0.20 Pa.s and a compaction value of 0.280 ± 0.30 Pa.s are desired when mixing HMAs [24]. The

temperature values corresponding to these viscosity values are accepted as the mixing and compaction temperatures.

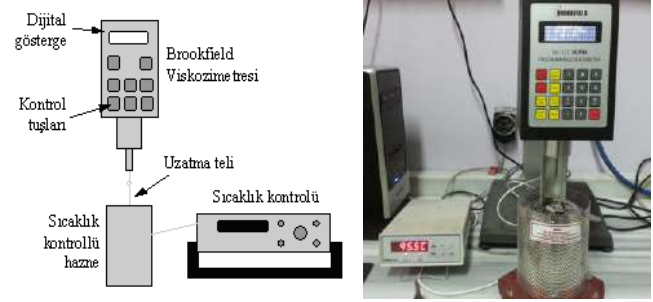

Fig. 4. Brookfield Viscosimeter

D. Temperature Susceptibility of Bituminous Binders

1) Penetration Index Method

Penetration Index (PI) is used to determine the temperature susceptibility of bituminous binders. The Penetration Index is determined with the standard penetration and softening point test results (Formulas 1, 2). P25 in the formula depicts the penetration value of the bitumen at 25°C and TYN indicates the softening point. The PI values decrease as the temperature susceptibility of bitumen binders increases. If the Penetration Index is less than -2, the bitumen is very sensitive to heat, whereas when it is greater than +2, it indicates that the bitumen is less sensitive to heat [26].

$$A = \frac{\log 800 - \log P_{25}}{T_{YN} - 25} \quad (1)$$

$$PI = \frac{20 - 500A}{1 + 50A} \quad (2)$$

2) Penetration Viscosity Number Method

Penetration-Viscosity Number (PVN), also called Pen-Vis Number, is an empirical correlation between asphalt cement factors and low temperature pavement cracking experiences. Asphalt cement factors considered in the original correlation are penetrations at 25°C, viscosity at 135°C and equation is proposed for selecting asphalt cements to prevent low temperature cracking of asphalt concrete pavements. The PVN method is used to quantify temperature susceptibility of an asphalt cement and estimate its ability to prevent low-temperature cracking. Lower values of PVN indicate higher temperature susceptibility, and asphalt mixtures containing binders with lower temperature susceptibility should be more resistant to cracking. The PVN number of a paving asphalt can be calculated precisely from the equations as follows [27];

$$PVN = -1.5 \frac{4.258 - 0.7967 \log P_{25} - \log V}{0.795 - 0.1858 \log P_{25}} \quad (3)$$

In the formula, P_{25} indicates the bitumen penetration at 25°C and V indicates the viscosity value at 135°C.

III. EXPERIMENTAL STUDY

In the present study, neat and modified binders were subjected to penetration, softening point and rotational viscometer tests to determine their consistency. Furthermore, the penetration index values, which indicate the temperature susceptibility of the bituminous binders, are determined using softening point and penetration values.

A. Penetration Test Results

The results obtained from the penetration tests applied to binders are presented in Figure 5.

Fig. 5. Penetration test results

Figure 5 demonstrates that penetration values decreased with the use of additives. It was determined that the use of 18% AG and 5% SBS were the least effective methods for decreasing the penetration value when compared to the neat bitumen. The penetration values increased as the SBS content increased when dual additives were used. The penetration values of the modified bitumen that contained 5% SBS, 18% AG, 2% SBS + 13% AG, 3% SBS + 10% AG and 4% SBS + 6% AG were 3.14, 7.50, 6.32, 5.34 and 4.56 times lower than neat binder, respectively.

B. Softening Point Test Results

The results obtained in the softening point tests applied to the binders are presented in Figure 6. Figure 6 demonstrates that the softening point values increased with the use of additives. This indicated that all utilized additives would increase the high temperature resistance of the bituminous binders. When the impact of the additives on the softening point values is considered, it was found that all the additives had similar effects on the softening point and increased the softening point values by about 45% when compared to the neat binder.

Fig. 6. Softening point test results

C. Specific Gravity of Bituminous Binders

Specific gravity values of neat and modified bitumen are determined based on the EN 15326 standard. The results obtained in specific gravity tests are presented in Figure 7.

Fig. 7. Specific gravity values of neat and modified binders

As can be seen in the figure above, the specific gravity values of bituminous binders were between the specification limits 1.0-1.1. When the changes in specific gravity with the use of additives were examined, it was observed that the specific gravity of binders increased with the use of American Gilsonite, whereas the specific gravity values decreased with the use of SBS. With the combined use of AG and SBS, specific gravity values increased regularly when compared to the use of 5% SBS, but decreased regularly when compared to 18% AG use.

D. Penetration Index Values

The Penetration Index values for neat and modified bituminous binders determined using formulas (1) and (2) are given in Figure 8.

Fig. 8. Variation in binder penetration index values with additive use

The Penetration Index results that demonstrate the temperature susceptibility of bituminous binders showed that the PI value increased as the SBS ratio in modified binders increased (Figure 8). Since the temperature susceptibility of bituminous binders decrease as the PI value increased, it could be argued that the use of SBS decreased the temperature susceptibility of bituminous binders. It was determined that as AG content in modified bitumen increases, the PI values decreases and thus, the temperature susceptibility increases. When SBS and AG are used together in the modified bitumen, it was determined that AG had a negative effect on the temperature susceptibility, and that this problem was eliminated by using SBS in conjunction with AG.

E. Penetration Viscosity Number Values

The Penetration Viscosity Index values for the neat and modified bituminous binders determined using the formula (3) are given in Figure 9.

Fig. 9. Variations in binder penetration viscosity number values with additive use

When the penetration viscosity number results that reflect the susceptibility of bituminous binders to low temperatures were evaluated, it was determined that the use of AG had a negative effect on temperature susceptibility in PVN values,

similar to the PI values, when compared to that of the SBS. It was also determined that SBS can be used to avoid the negative impact of AG on temperature susceptibility. It was determined that the temperature susceptibility decreased with the use of SBS instead of AG in dual modified bitumen (Figure 9).

F. Rotational Viscometer Test Results

Neat and modified binders were subjected to rotational viscometer tests at 135°C and 165°C temperatures. In the experiment, 20 rpm speed was used. Modification index values were obtained from the ratio of the viscosity value of the modified binder to the viscosity value of the neat binder ($\eta_{\text{modified}} / \eta_{\text{neat}}$). The viscosity results obtained from the tests are presented in Figure 10. The viscosity and modification index values obtained at high temperatures (135°C and 165°C) demonstrated that SBS increases the stiffness of the binders and reduces the workability at high temperatures.

Fig. 10. Variations in binder viscosity values with temperature and additive use

Figure 10 demonstrates that the viscosity values of all binders met the Superpave specification limit maximum value of 3000 cP at a temperature of 135°C. With additive use, the viscosity values increased at all temperatures. It was determined that the viscosity values of 5% SBS modified binders were the highest and the bituminous viscosity values with 18% AG were the lowest, despite their similar performance levels. It was determined that as the SBS content in the modified bitumen increased, the viscosity values increased at both temperatures.

The modification index ($\eta_{\text{modified}} / \eta_{\text{neat}}$) values determined by the ratio of the viscosity value of the modified bitumen to the viscosity value of the neat binder are given in Figure 11. When the modification index values were examined, it was determined that the additive that maximizes the viscosity value at all temperatures was SBS and the least contributing additive was AG. It was determined that the viscosity values of SBS and AG were higher than those of the sole use of AG and the viscosity values increased regularly as the SBS ratio in the mixture increased.

When the bituminous binders are mixed with the aggregates at the plant and the hot mix asphalts are compacted in the field, they must possess adequate workability. It is desirable that the bituminous binder has a viscosity value of

0.170 ± 0.20 Pa.s for compaction and 0.280 ± 0.30 Pa.s for the mixing [24]. In the plotted temperature-viscosity graphs, the viscosity values were marked and these values were joined with a straight line. The temperature values that correspond to these viscosity values are accepted as the mixing and compaction temperatures. As an example, the viscosity-temperature graph that shows the mixing and compaction temperature ranges for the modifier binder that contains 18% AG is presented in Figure 12.

Fig. 11. Variations in binder modification indexes with temperature and additive use

Fig. 12. Viscosity-temperature chart for the modified binder including 18% AG

The variation in the mixing and compaction temperatures with the type of additive is presented in Figure 13.

Fig. 13. Mixing and compaction temperatures of binders

As shown in Figure 13, higher mixing and compaction temperatures were required with the use of additives. This demonstrates that although higher binder performance is achieved with additive use, higher temperatures will be required during mixing it with the aggregate and compaction of the HMA, thus requiring more energy during the preparation at the plant. When the effects of the additive types and combined use of additives were evaluated, it was determined that the highest mixing and compaction temperatures were found with 5% SBS modified bitumen and the lowest values were found with 18% AG modified bitumen. As the SBS content in the modified bitumen increased, higher mixing and compaction temperatures were needed.

IV. RESULTS

In the study, consistency and specific gravities of neat and 5 different modified bitumen were determined and their temperature susceptibility was evaluated with two different methods. Initially, 18% AG and 5% SBS were used as additives separately, then 2% SBS and 13% AG, 3% SBS and 10% AG, and 6% AG and 4% SBS were used in conjunction to obtain bituminous binders with the same performance level.

- Penetration tests demonstrated that all additives increased the stiffness significantly. It was determined that the most effective additive was 18% AG and the least effective additive was 5% SBS.
- Softening point tests demonstrated that all additives increased the high temperature resistance of the bituminous binders significantly, and all modified bitumen had similar softening point values.
- It was determined that the specific gravity values of AG modified bitumen were higher since both the usage ratio and density of AG was higher than those of SBS as demonstrated in specific gravity tests.
- Penetration index values demonstrated that 5% SBS modified bitumen had the lowest thermal sensitivity and 18% AG modified had the highest. This negative aspect of AG modified binders was reduced with the addition of SBS.
- Penetration viscosity number values were consistent with PI values. With the use of AG additive, the low temperature susceptibility of bituminous binders have increased, and the use of SBS has reduced the low temperature susceptibility.
- It was determined that additive use increased binder stiffness values as observed in viscosity values. Consequently, the mixing and compaction temperatures increased with the modification values. The most effective additive on viscosity values was 5% SBS modification.

ACKNOWLEDGMENT

This study was conducted within the scope of the Scientific and Technological Research Council of Turkey (TUBITAK) project no. MAG-214M669. The authors would like to thank TUBITAK for their support.

Abstract-During the last few years, an increasing interest has been appeared for earth as a building material. Earth-based materials have been studied because of energy efficient and ecologically sustainable. The chromite deposits, 10% of the world reserves, are processed in Elazığ Ferrochrome Factory in Eastern of Turkey. Elazığ Ferrochrome slag (EFS) as a by-product of the factory is produced roughly 50.000 tons in a year. The disposal, removal and storage of this by-product is a serious problem. Therefore, the evaluation of this waste material in building applications is very important. The aim of this work is to investigate effects of gypsum and EFS additives on mechanical and physical properties of unfired earth brick (UEB) materials in order to assess their potential advantages in building applications. The earth material was characterized by laboratory tests. The four different UEB samples were produced by using different compositions of earth, gypsum, EFS and straw fibers. Compressive strength, water absorption coefficient, drying shrinkage and ultrasonic pulse velocity (UPV) of the prepared UEB samples were determined. The experimental findings have showed that the usage of gypsum and EFS in stabilizing process of UEBs was advantaged.

Keywords: *Elazığ ferrochrome slag, unfired earth brick, compressive strength, water absorption*

I. INTRODUCTION

The demand to reduce CO₂ emissions and to find more sustainable construction materials constitutes nowadays are a major economic and ecological challenge. Earthen construction can lead to reduce environmental problems. Actually, raw earth is one of the most widely used building materials in human history. It is estimated that nearly a third

of the world's population lives in some type of earthen houses. It is one of the oldest building materials used in many different ways around the world for centuries. Approximately 50% of the population of developing countries, the majority of rural populations, and at least 20% of urban populations live in earthen constructions [1]. During the last few years, an increasing attention has been appeared for earth as a sustainable material, therefore has been investigated in the engineering laboratories around the world in the purpose of the certification of earth building materials. The reason for this interest is that it presents several advantages that allow it to be a current response to energy and climate issues. In fact, raw earth is an abundant natural and recyclable resource. It is low embodied energy building material, compared to fired clay bricks and concrete. It reduces the amount of energy required for construction as well as transportation needs [2, 3].

Zami and Lee [4] summarized advantages of unfired earth brick (UEB) as follows: i) earth construction is economically beneficial, ii) it requires simple tools and less skilled labour, iii) it encourages self-help construction, iv) suitable for very strong and secured, v) it saves energy, vi) it balances and improves indoor air humidity and temperature which ensures thermal comfort, vii) earth is very good in fire resistance, viii) earth construction is regarded as a local job creation opportunity, ix) earth construction is environmentally sustainable, x) easy to design and high aesthetical value, xi) earth building provides noise control, xii) earth construction promotes local culture and heritage,

xiii) earth is readily available in large quantities in most regions.

The deterioration of porous building materials is mainly due to the interactions between their structures and water. Depending on the material characteristics, physical state of water (liquid or vapor) and environmental conditions, the quantity of water absorption and sorption mechanisms may be different [5]. In particular, the absorption of humidity from air, the capillary rise, the rain penetration, and water condensation phenomenon can lead to the formation of superficial moisture [6]. In brick production, there are two types of moisture content required for molding. The first one is the shrinkage water (initial water) which helps molding process. It exists in the brick body among the particles. The shrinkage water is also necessary for clay plasticity. The second one is the porosity water (or interstitial water) [7]. Drying shrinkage of the bricks was primarily governed by the plasticity index and cement content. Water-loss also contributes to the shrink of the clay fraction. For low clay mineral content (index plasticity below 20%), drying shrinkage showed steady increase with the increase of clay content, but for plasticity index beyond 25% – 30% drying shrinkage increased rapidly as the clay content also increased [8]. The compressive strength is a mechanical property used in brick specifications, which has assumed great importance for two reasons. Firstly, with a higher compressive strength, other properties like flexure, resistance to abrasion, etc., also improve. Secondly, while other properties are relatively difficult to evaluate, the compressive strength is easy to determine [9]. In some countries such as Papua New Guinea clayey soils are stabilized with native materials, e.g. volcanic ash, finely ground natural lime, cement and their combinations [10].

There is a need to improve the durability, production, and workability of earthen construction technology. Throughout its history as a building material, earth has been stabilized with different additives. Istanbul Technical University recovered gypsum used as a stabilizer from historical buildings in Eastern Turkey. Ongoing research since 1978 [11] proves that this combination of earth and gypsum called Alker (an abbreviated form of the Turkish words for gypsum and adobe, meaning gypsum-stabilized adobe) has improved physical properties. There are Alker buildings constructed and inhabited since 1983. Construction of Alker Building, 1995, can be seen in Fig. 1a and Urfa Pilot Building 1999 on Fig. 1b. [12]. Except for these pilot studies, there are also new buildings constructed with gypsum-stabilized earth bricks in Malatya (Fig. 1c).

Fig. 1. a) Construction of Alker Building, b) Urfa Pilot Building, c) Building constructed in Malatya

The chromite deposits, 10% of the world chromite reserves located within the boundaries of Maden town-Alacakaya village of Elazığ, are processed in Elazığ Ferrochrome Factory. Apart from the main product, many by-products are produced in this factory. One of these by-products is Elazığ Ferrochrome slag (EFS). The amount of slag generation is roughly 330 kg per ton of ferrochrome produced, and the annual production of EFS exceeds 50.000 tons. The disposal, removal and storage of by-products is a big problem. When considering accumulated amount of EFS so far and accumulate in the future, it is important to discover potential use of this by-product in UEB materials. The aim of this study is to examine effects of gypsum and EFS additives on mechanical and physical properties of UEB materials in order to assess their potential usage in building applications. Compressive strength, water absorption coefficient, drying shrinkage and ultrasonic pulse velocity (UPV) of UEB samples were tested.

II. MATERIALS AND METHODS

A. Materials

The four different materials were used, i.e. cohesive soil, gypsum, EFS and straw fibers. Cohesive soil used in this study was obtained from Malatya in Eastern of Turkey. EFS was obtained from Elazığ Ferrochrome Factory in Eastern of Turkey. EFS was ground to less than 45 μm particle size in order to increase the reactivity. Locally available gypsum and straw fibers were used. The average straw length was approximately 2 cm. The fibers were selected because of their positive impact on drying shrinkage of earth building materials. The drinking water at a temperature of 20 ± 2 °C was used. The composition of the cohesive soil texture was as 18% clay, 23% silt, 54% sand and 5% gravel.

B. Sample preparation

Initially, oversized gravel were removed from the natural soil. The cohesive soil was put in an oven to obtain dry weight at 105°C for 24h. Presence of organic matters in a raw material is inconvenient and undesirable, because organic compounds significantly reduce the strength and binding properties of building materials. The content of organic matter in the soil was determined in accordance with TS EN 1744-1 [13] and at the end of experiment, resulting color demonstrated that no organic matter was found.

Particle size distribution was determined using a wet sieving and a sedimentation test, according to standard [14]. The grain size distribution of soil used in this study is given in Fig. 2. The chemical composition of the soil was determined by X-Ray Fluorescence (XRF) technique. The chemical composition of soil and EFS are presented in Table 1. The Atterberg limits were determined as WL = 54.7% (liquid limit), WP = 34.3% (plastic limit) and IP = 20.4% (plasticity index).

Fig. 2. Grain size distribution of soil

Table 1. The chemical composition of the materials, (% wt)

Component, (%)	Soil	EFS
SiO ₂	58.56	33.80
Al ₂ O ₃	15.12	25.48
Fe ₂ O ₃	4.72	0.61
CaO	3.10	1.10
MgO	2.50	35.88
Cr ₂ O ₃	0.02	2.12
TiO ₂	0.78	-
Na ₂ O	1.30	-
K ₂ O	3.10	-
LOI	10.65	1.01

Fig. 3. a) Mixing process, b) Compressive strength test, c) UPV test

The four different UEB samples were produced by using different compositions of earth, gypsum, EFS and straw fibers. Mixture proportion of UEB samples is given in Table 2. Water content is one of the most important factors affecting mechanical and physical properties of UEB materials. Optimum water/solid ratio was determined as 0.30, experimentally. The amounts of materials were calculated as dry weights. Then, the specified amounts of raw materials of cohesive soil, gypsum, EFS, straw fibers and water were poured into mechanical mixer (Fig. 3a). The mixture was stirred until a homogeneous mixture was obtained. Finally, the freshly mixed brick mortar was taken from the mixer, fed into specimen moulds and vibrated until to obtain full compaction.

Table 2. Mixture proportion of UEB samples

Sample code	Description of UEB samples
R (Reference)	Soil with 1 mass per cent straw fibers
G10*	Soil with 10 mass per cent gypsum and 1 mass per cent straw fibers
S10	Soil with 10 mass per cent EFS and 1 mass per cent straw fibers
G5S5*	Soil with 5 mass per cent gypsum, 5 mass per cent EFS and 1 mass per cent straw fibers

*Due to the early setting time of gypsum, deformation and crack risk to the structure during the drying period was prevented by adding 1-2% lime.

C. Testing apparatus and procedure

Sample production and testing of compression strength of mortars are stated in EN 1015-11 standard [15]. 7 and 28-day compressive strengths of UEB samples were determined in accordance with this standard (Fig. 3b). Compressive strength specimens are prisms with the dimensions of 160 x 40 x 40 mm. The UPV tests were conducted in accordance with ASTM C 597-97 [16] (Fig. 3c). 2004-Relationship between ultrasonic velocity. Shrinkage is the physical phenomenon, which occurs during drying process, due to the evaporation of moisture content in the brick. The drying shrinkage (S_d) was calculated according to testing method ASTM C326-09 [17] and defined in Eq. (1). Drying length (L) and initial length (L_0) were used in the calculation.

$$S_d = \frac{L_0 - L}{L_0} \times 100 \quad (1)$$

The determining method for the water absorption characteristics were conducted in accordance with BS EN 772-11 [18]. After drying to constant mass, a face of UEB samples was immersed in water for a specific

period of time and the increase in mass was determined. The minimum immersion period is usually one hour, as specified in BS EN 771-4 [19]. The coefficient of water absorption of masonry materials is normally stated at 10, 30, 60 and 90 minutes [20]. Water absorption coefficient of UEB samples was calculated by using the following Eq. (2) [18].

$$C_w = \frac{M_w - M_d}{A \sqrt{t}} \quad (2)$$

Where,

C_w: Water absorption coefficient (kg/m²min^{0.5}),

M_w: Wet mass (kg), M_d: Dry mass (kg),

A: Surface area (cm²) and t: Time (min)

III. RESULT AND DISCUSSION

A. Compressive strength

The 7 and 28-day compressive strengths of UEB samples are given in Fig. 4 and Table 3. As can be easily seen in Fig. 4, maximum compressive strength was obtained from G10 samples containing 10 mass per cent gypsum. Although the highest compressive strength was obtained in samples containing only gypsum, a dramatic difference was not observed between samples with or without EFS. Addition of 10 mass per cent EFS brought about slightly reduce in compressive strength, but the usage of gypsum and EFS together increased compressive strength. The overall results showed that the gypsum stabiliser led to higher compressive strength values compared to EFS stabiliser. The results also showed that the compressive strength increased progressively from 7 days to 28 days curing period. When compared to other samples, increase in compressive strength from 7 to 28 days of S10 is higher. The reason of this behaviour may be due to the puzzolanic effect of EFS.

The influence of stabilizers was studied by Hossain et al. [21]. The compressive strength in this case varies between 0.39 and 3.10 MPa. Isik and Tulbentci [12] stated that compressive strength of gypsum-stabilized earth brick ranges from 2 to 4 MPa. In this study, compressive strength of gypsum-stabilized UEB samples is higher than mentioned these values. Furthermore, compressive strength of reference samples in this study is higher than values obtained from previous studies [10, 22, 23].

Table 3. Compressive Strength and UPV values of UEB samples

Sample Code	Compressive Strength, (MPa)		UPV, (m/s)	
	7 day	28 day	7 day	28 day
R (Reference)	4.14	4.24	1086	1116
G10	4.51	4.58	1228	1251
S10	3.39	3.84	987	1051
G5S5	3.86	4.1	1167	1193

Fig. 4. Compressive strength of UEB samples

B. Capillary Water Absorption Coefficient

The presence of water is one of the main decay factors in buildings. Capillary water absorption curve of UEB samples was obtained as a function of the root of time. Fig 5 shows the results of the average mass variation per contact area in the capillary absorption process for UEB. The capillary water absorption coefficients were calculated according to BS EN 772-11 [18], and obtained coefficient values are shown in Fig. 6 and Table 4. The maximum water absorption coefficient value was obtained from S10 sample which has minimum compressive strength. The minimum capillary water absorption coefficient value was obtained from G10 sample which exhibits the best behaviour in compressive strength. Likewise, Isik and Tulbentci [12] stated that gypsum addition improves the water resistance, workability, and mechanical properties of UEBs. It is also

stated that basic principle of the stabilization is to prevent water attacks to obtain a durable material [24].

From the experimental data, it was observed that there was an inverse relationship between the compressive strength and the capillary water absorption coefficient. Also, this observation was supported by the coefficient values of the R and G5S5 samples. Oti et al. [25] stated that the amount of water absorption of unfired clay masonry bricks depends on compressive strength. The overall capillary water absorption coefficient values for all stabilised mixtures were within the acceptable limits for stabilized UEB. The curve of water absorption, by capillary action, as a first step of absorption (short-time faster) is directly proportional to the square root of time just as it would be expected [26].

Fig. 5. Capillary water absorption curve of samples, as a function of the root of time

Table 4. Capillary Water Absorption Coefficient of samples, ($\text{kg}/\text{m}^2\text{min}^{0.5}$)

Time, (min)	R (Reference)	G10	S10	G5S5
10	2.25	1.96	2.13	1.96
30	2.03	1.9	2.08	1.87
60	1.9	1.81	2.03	1.82
90	1.85	1.69	1.92	1.81

Fig. 6. Capillary Water Absorption Coefficient of samples

C. Drying shrinkage

In the drying experiments, drying shrinkage behavior of UEB samples produced with different additives was investigated. For all UEB samples, shrinkage measurements were performed up to 30 days. Drying shrinkage values of UEB samples are shown in Fig. 7. At the end of 30th day, while minimum drying shrinkage value was obtained from G10 sample with 4.12%, maximum drying shrinkage value was obtained from reference sample with 7.57%. As can be observed in Fig. 7, drying shrinkage values of G10 samples are approximately half of reference ones. The reason of this significant decrease in drying shrinkage can be explained by addition of gypsum and lime. Similarly, Pekmezci et al. [27] stated that the low shrinkage values and crack free adobe can be attributed to a rigid skeleton formed by a hardening of gypsum and lime in the structure. Calcite crystals and binding gels formed as a result of the pozzolanic reaction also result in lower shrinkage of gypsum and lime adobe samples. Finally, the secondary structure, which prevents deformations from stresses caused by shrinkage, may be an effective parameter in reducing shrinkage values [27].

Fig. 7. Drying shrinkage of UEB samples

When compared to reference samples, the addition of EFS contributed to decrease in shrinkage values of UEB samples. Moreover, the addition of both gypsum and EFS led to further decrease in drying shrinkage of UEB samples. It is stated that the drying shrinkage depends on the characteristics of clay such as the mineralogical nature and the particle size. If the material shrinks more than 8%, drying process may cause problems in the bricks such as cracking and internal fractures [7, 28, 29]. In the light of this information, overall drying shrinkage values obtained in this experimental study are within acceptable limits.

D. Ultrasonic Pulse Velocity (UPV)

UPV values of UEB samples are displayed in Fig. 8 and Table 3. As can be seen in Fig. 8, UPV values are ranging from 1086 to 1428 m/s and 1123 to 1451 m/s for 7 and 28-days samples, respectively. Maximum UPV values were obtained from G10 samples which have highest compressive strength. On the other hand, minimum UPV values were obtained from reference samples. It was observed that there was a slight increase in UPV values 7 to 28 days. When the increases are evaluated, the highest increase in UPV was obtained from S10 samples 7 to 28 days. This increase may be due to pozzolanic reactions of EFS. Likewise, Galan-Marín et al. [30] investigated influence of utilising natural polymers as a form of soil stabilization. UPV and mechanical strength tests were conducted. Obtained UPV results ranged from 1075 to 1818 m/s in accordance with compressive strength.

Fig. 8. UPV values of UEB samples

IV. CONCLUSION

In this article, it was investigated the effect of gypsum and EFS additives on mechanical and physical properties of UEB materials for a potential usage in building applications. The results of the obtained experimental findings are as follows:

1. Gypsum stabiliser indicated the higher compressive strength values compared to EFS stabiliser. However, there was not a significant decrease in compressive strength by using EFS additives.
2. Compressive strength increased progressively from 7 days to 28 days curing period. When compared to other samples, increase in compressive strength from 7 to 28 days of S10 is higher. The reason of this difference may be associated with the pozzolanic effect of EFS.
3. It was determined that there is an inverse relationship between the compressive strength and the capillary water absorption coefficient.
4. From the capillary water absorption experiments, it was seen that there was an obvious decrease in water absorption coefficient with increasing time.
5. The use of gypsum and lime together led to a significant decrease in shrinkage values compared to other samples. Similarly, the addition of EFS contributed to decrease in shrinkage values.
6. Maximum UPV values were obtained from G10 samples which has highest compressive strength.

As a result of this experimental study, it was shown that EFS (a by-product) can be used in stabilising of UEBs because usage of EFS in stabilising of UEBs improved overall properties except for compressive strength. Additionally, it will be beneficial to investigate effect of different mineral additives and mixture proportions on mechanical and physical properties of UEBs.

Abstract—Although the cracked beams have been widely utilized in fracture mechanics of concrete, there have been some advantages of the cubical/cylindrical specimens such as compactness and lightness. In the present work, the wedge-split-tension tests on cubical specimens with different cement contents and water/cement ratios were initially performed for the effective crack model. Finally, some relationships based on regression between the fracture parameters and the strength properties of concrete were derived. The results of the split-tension cube tests look viable and very promising.

Keywords—concrete; effective crack model; wedge-splitting test

I. INTRODUCTION

Fracture mechanics applications of cement-based materials were initiated by Kaplan [1]. However, in 1970s, experimental investigations on concrete fracture revealed that Linear Elastic Fracture Mechanics (LEFM) has been no longer valid for cementitious materials such as rock and concrete [2]. Because of the existence of a relatively large process zone in front of and around the tip of the main notches and this inelastic zone is ignored by LEFM, it is inapplicable for concrete. Therefore, several deterministic fracture-mechanics approaches have been developed to describe fracture-dominated failure of concrete structures [3-8].

These models can be categorized as cohesive crack models [3, 4] and effective crack models [5-8]. LEFM uses a single fracture parameter such as the critical strain energy release rate, but these models need at least two experimentally determined fracture parameters to estimate failure of concrete/reinforced concrete structures.

The cracked beam tests have been widely utilized, because they were used in the first LEFM standard test for metals in order to estimate fracture parameters of quasi-brittle materials. Nevertheless, there are some important advantages of cubical/cylindrical specimens as follows [9-13]:

- 1) They are compact and lighter than notched beams. Therefore they are useful for investigating the size effect.
- 2) They can be easily cast at the construction site by using the same molds as for strength tests.
- 3) The self-weight of the specimens can be neglected in the computing of fracture parameters, contrary to cracked beams.

The tests on the cylinder and cube samples in fracture mechanics of concrete can be classified as split-tension tests and wedge-splitting tests. The wedge-splitting tests have been performed on the cylinder/cube specimens with an edge crack. The wedge-splitting tests are also useful for the effective crack models although they were initially developed for the cohesive crack fracture models [9].

In the present work, the wedge-splitting tests (WST) on cube specimens with different cement contents and water/cement ratios were initially performed for the effective crack fracture model (ECM). Finally, some relationships based on regression between the strength properties and the fracture parameters of concrete were determined.

II. EFFECTIVE CRACK MODEL (ECM)

The effective notch length a_e in the effective crack model for the fracture of cementitious materials recommended by Nallathambi and Karihaloo [6] is computed from the secant stiffness of the real concrete body at the maximum load. The main idea behind this approach may be emphasized with Figure 1, in which the load and deflection curve of the cracked three-point beam up to maximum load is indicated. When the secant stiffness of the real body is equal to tangent stiffness of the body, of which the notch length is a_e , the fracture toughness achieves its critical value K_{Ic}^e . Consequently, according to the effective crack model, the fracture of cement-based materials is defined by two-parameter: the critical fracture toughness K_{Ic}^e and the effective notch length a_e .

Though the effective notch length is computed from the load and displacement curves by trial and error approach in practice, it can also be calculated by the following regression formula:

$$\frac{a_e}{d} = \gamma_1 \left(\frac{\sigma_u}{E_c} \right)^{\gamma_2} \left(\frac{a_0}{d} \right)^{\gamma_3} \left(1 + \frac{d_{max}}{d} \right)^{\gamma_4} \quad (1)$$

in which a_0 is the initial notch length, d is the specimen depth, d_{max} is the maximum aggregate size, the nominal strength $\sigma_u = 6M_u / (bd^2)$, M_u is the maximum moment and $\gamma_1 = 0.088$, $\gamma_2 = -0.208$, $\gamma_3 = 0.451$ and $\gamma_4 = 1.653$. When elasticity modulus

of cement-based materials E_c is estimated from the separate experiments, these constants are $\gamma_1 = 0.198$, $\gamma_2 = -0.131$, $\gamma_3 = 0.394$ and $\gamma_4 = 0.600$ [14]. Nevertheless, elasticity modulus of cementitious materials in Eq. (1) may be determined according to the following expression [15]:

$$E_c = 4730 \sqrt{f'_c} \quad (2)$$

where f'_c is the cylindrical strength for concrete. E_c and f'_c in Eq. (2) are in [MPa]. The critical fracture toughness K_{Ic}^e according to the effective crack model may be determined from Eq. (3):

$$K_{Ic}^e = \sigma_u \sqrt{a_e} Y(\alpha_e = a_e/d) \quad (3)$$

in which α is the relative notch length (a/d) and $Y(\alpha)$ is the function of geometry for computing the fracture toughness of the notched three-point beam and may be obtained from any fracture mechanics handbook [16].

Fig. 1. Determination of fracture parameters of concrete according to ECM

III. WEDGE-SPLITTING TEST

Although notched-beam specimens have been widely used in concrete fracture mechanics, compact tension (CT) and wedge-splitting (WS) specimens have some advantages over beams, such as compactness and lightness (Fig. 2). CT specimens were initially used by Wittmann et al. [10] to determine the fracture energy and evaluate the strain-softening behavior of cement-based materials. Brühwiler and Wittmann [9] proposed a popular wedge-splitting test, which has been used in recent years in concrete fracture testing with test specimens.

A WS specimen can be considered a compact form of the three-point bending beam, as shown in Fig. 2b. WS specimens with grooves were developed for use as CT specimens, as shown in Fig. 2c. WS and CT testing can be conducted on both cylindrical and cubical specimens. The use of cylindrical test specimens, which may be obtained from existing concrete/reinforced concrete structures by coring, offers the great advantage of estimating the fracture properties of existing structures based on fracture mechanics. In WS testing, the load is applied to the specimen by means of a wedge and a loading device with roller bearings, as illustrated in Fig. 2d. The horizontal load P_H acts on the rollers because of the vertical load (P_V) on the wedge, as shown in Fig. 2e. Friction forces also occur between the rollers and the wedge. However, the friction forces can be ignored when the wedge angle $\theta=15^\circ$. The horizontal load can be calculated as follows:

$$P_H = \frac{P_V}{2 \tan \theta} \quad (4)$$

For CT and WS test samples, the fracture toughness can be computed as follows:

$$K_I = \frac{P_H}{bd} \sqrt{d} Y(\alpha) \quad (5)$$

where the dimensionless function $Y(\alpha)$ is given by the following equation [16]:

$$Y(\alpha) = \frac{(2 + \alpha)(0.886 + 4.64\alpha - 13.32\alpha^2 + 14.72\alpha^3 - 5.6\alpha^4)}{(1 - \alpha)^{3/2}} \quad (6)$$

The accuracy of Eq. (6) is $\pm 0.5\%$ for $\alpha > 0.2$.

IV. EXPERIMENTAL STUDIES

Cubical wedge-splitting (WS) specimens with 150 mm were used in this study (Figure 2). The maximum aggregate diameter of 16mm was used. The cement contents varied from 250 kg/m³ to 490 kg/m³ whereas the water-cement ratios (w/c) varied from 0.44 to 0.81. The batches were designed for two slump values=6±1 and 12±2 cm. Eight series specimens (48 cube specimens), namely A, B, C, D, E, F, G and H, were tested concerning the above variables in different combinations. The test specimens in each batches were cast from the same mix of concrete. The cracks were precast in all test samples. The test specimens in all series were of the same size, but they had different notch lengths for each specimen geometry. Table 1 summarizes the cement content, the initial crack length, a_0 , the concrete compressive strength, f'_c , and the ultimate vertical load, P_V , of the test specimens.

Three identical cube specimens with 150 mm were also cast from each mix of concrete in order to estimate the compressive strength of concrete. All test specimens and identical test cubes were removed from the mold after 1 day and then were cured at 20 °C in water until testing at 28-day. The compression tests and the split-tension tests were made by using a digital compression machine with a capacity of 100 kN. Typically, approximately 3 min (± 30 sec) elapsed before the peak load capacity for each test specimen was reached. Identical cubes were tested at an age similar to the other specimens.

V. ANALYSIS OF TEST RESULTS

In this study, WS specimens were analyzed according to ECM. For this, equations 1-6 were utilized. The nominal strength in Eq. (1) may be computed for WS specimens according to the principles of the classical strength of materials as follows:

$$\sigma_u = \frac{P_H}{bd} + \frac{6P_H d/2}{bd^2} = \frac{4P_H}{bd} \quad (7)$$

The computed fracture parameters of concrete based on ECM: the effective fracture toughness and the relative effective notch length values were also given in the last two columns in table 2. It is well known that there is a very strong correlation between f'_c and water-cement ratio. f'_c decreases with increasing w/c. The following formula by Abrams may utilized to stabilize the effects of the factors related to curing conditions, concrete age and cement properties, which directly influence the internal structure of cement-based materials:

$$f_c = \frac{K_1}{K_2^{w/c}} \quad (8)$$

where K_1 and K_2 are the empirical constant and the constants which depends on the cement properties, respectively [17]. These constants may be computed as $K_1=A$ and $K_2=e^{-C}$ from the regression based on exponential function performed on $Y=AX+C$ with $Y=f'_c$, $X=w/c$. Fig. 3 shows the two relationships $K_{Ic}^e - f'_c$ and $K_{Ic}^e - w/c$. The two empirical formulas were derived in this figure. The results indicate that K_{Ic}^e increases with increasing f'_c while K_{Ic}^e decreases with increasing w/c.

Tests have revealed that fracture parameters of cement-based materials are generally influenced by the four material parameters; namely compressive strength, aggregate type, maximum aggregate diameter and water/cement ratio (w/c) [11-13, 18-20]. It is noted that fracture parameters of concrete can also be affected by other material parameters such as cement type, aggregate/sand ratio, curing conditions and porosity etc. Therefore, these empirical formulas are approximate and they should only be utilized for preliminary design and for the bodies of low fracture sensitivity although their correlation coefficients are very high $r>0.900$.

VI. CONCLUSIONS

In recent years, splitting specimens such as compact-tension, wedge-splitting and cylindrical/cubical splitting tension test specimens have been commonly preferred over beams for use in concrete fracture testing. Wedge-splitting test results were used for the first time in this study to determine the fracture parameters of cement-based materials via the effective crack model. The following conclusions should be drawn from the results of this study:

- 1) Notched compact tension specimens and beams have been used with the effective crack model. The results of this study indicate that the effective crack model can be successfully applied to wedge-splitting specimens.
- 2) Many structural laboratories do not have sophisticated testing equipment such as closed-loop testing systems and displacement-controlled testing machines. The effective crack model offers the great advantage of requiring measurement of only the maximum load applied to specimens to determine the values of the fracture parameters of concrete.
- 3) The fracture parameters of cementitious materials required for the effective crack model were investigated in this study. Nevertheless, the results obtained may easily be transformed to other fracture models, such as the size effect fracture model, the two-parameter model and the double-K model by the related LEFM formulas.

Abstract—In this study, the lightweight concrete masonry units with pumice aggregates were analyzed to determine the compressive strengths and porosities at elevated temperatures ranging from 20 to 350°C. In order to produce the lightweight concrete mixtures for production of masonry wall units, the pumice aggregates were supplied from Nevşehir region in Turkey and they were crushed and screened into two grain sizes of 0-4mm (as fine pumice aggregate) and 4-8mm (as coarse pumice aggregate). To analyse the effects of elevated temperature on the strength properties of lightweight concrete masonry units, the range of different pumice aggregate/cement (A/C) ratios of 3.11, 3.17, 3.22 and 3.28 by weight and constant cement content of 210 kg/m³ were used to make up the pumice aggregate lightweight concrete (PALWC) mixture testing samples with the slump of 3 mm. To accomplish this purpose, cubic concrete specimens of 150x150x150mm were prepared. Also PALWC masonry units with 4 different mixture batches were cast into a mould with vibro-compacting, de-moulded immediately and transferred to a storage area for curing up to 360 days in normal air condition. PALWC masonry units were produced suitable according to BS 1881 and EN 771-3 specifications. The web and shell thickness of the unit were designed as 20 mm. Totally 21 cellular space with 14 mm in width were placed in the block design and the block dimensions are 190 mm in height, 390 mm in length and 190 in width as mostly used block dimensions in Turkey. After their production the block specimens were analysed at different elevated temperatures for 28 and 90 days. All measurements have been carried out after cooling of the material.

The experimental research findings showed that PALWC masonry units have the strength change comparable to normal weight concrete masonry units at different elevated temperatures. The experimental analyses showed that initial strength of the masonry samples reduced up to 100°C at 28 days of curing, whereas the reduction was continued up to 150°C at 90 days of curing. Beyond these temperatures, strength of the masonry samples all gradually increased. Although the initial strength value at 20°C for 90 days of curing was higher compared to the value of 28 days curing, strength of the masonry samples at 350°C for 28 days of curing was higher than that of 90 days curing. Porosity of the masonry samples were also affected by the temperature changes. Consequently, it seems to be that for

the high temperatures, age of the concrete influence the initial strength reduction.

Keywords—pumice; lightweight masonry; temperature dependency; compressive strength; porosity

I. INTRODUCTION

The success of designing lightweight aggregated building elements for a required fire endurance depends on how accurately certain properties of the component materials are known in the 0 to 1200°C temperature range. Lightweight concrete masonry unit is among the most commonly used building materials and deserves priority in a program intended to develop the knowledge of the behavior of building materials at elevated temperatures. Some research results and discussions are available in literature on some thermal and mechanical properties of hydrated Portland cement and lightweight concretes. However, there is very limited information for lightweight concrete masonry units at elevated temperatures. When considering building in fire occurrence and processes, the behavior of the lightweight concrete units at elevated temperatures is an issue that should be examined in detail. In addition, the role of porous aggregate type and its production utilization rate by the temperature effect are another important issue to understand the structural and mechanical changes in concrete masonry units.

Pumice displays as an ideal aggregate for its light and insulate character caused by the porous structure. It is used in lightweight building elements, prefabricate building components, roofing, lightweight mortar and plaster production, as roof and floor isolation filler and in lightweight concrete production in building trade. Accept all of these; its usage in these areas is well known as wide spread. The lightweight concrete; derived from appropriate pumice aggregate that is produced with appropriate granulometric components can be used in different production forms according to their strength values in industrial areas. The lightweight concrete can be produced in bearing, semi-load bearing and non-load bearing forms.

Temperature is a key variable affecting the curing of cement-based materials because it influences both the early hydration kinetics and the properties of the hardened cement paste or concrete. Although concrete initially gains strength more rapidly when cured at elevated temperatures, the final strength is lower and the permeability is higher. Elevated temperatures also reduce the tendency for irreversible creep and shrinkage [1]. Most of these effects have been related to the increased rate of silicate polymerization at elevated temperatures [2, 3, 4], which densifies and stiffens the C-S-H as it forms.

The behavior of concrete subjected to high temperatures is a result of many factors [5, 6]; such as heating rate, peak temperatures, dehydration of C-S-H gel, phase transformations, and thermal incompatibility between aggregates and cement paste. On the other hand, quality control of concrete, by means of non-destructive methods, in structures subjected to fire or not so high temperature exposure conditions, is not particularly easy to be carried out. The correlation already exists usually refers to the hydration age of 28 days [7]. Many investigations have been carried out on the residual mechanical properties of normal weight concrete with using lightweight aggregates subjected to elevated temperatures, but limited data on the deterioration of durability of masonry units produced by pumice lightweight aggregate concrete are available in the past researches. Limited conclusions only, therefore, have been drawn for lightweight concrete masonry units, where damage is not only due to a combination of chemical and mechanical changes to the constituents of concrete, but is greatly influenced by factors such as the properties of lightweight concrete itself, fines aggregate ratio of the mixture, and the curing conditions.

Neville [8] has reported that after exposure to 600°C heat affects much more less strength loss in lightweight concrete compared to normal weight concrete. No more experimental study has been experienced in literature related to strength properties of pumice derived lightweight concrete after heat exposure. Usually, there is literature data about high strength concretes derived from different aggregate species. In these studies, the mechanical properties of concrete exposed to 200 °C and higher have been evaluated. Altun [9] has performed a study which evaluates the mechanical changes under heat effect of the low cement ratio aggregate derived concrete. Xu et. all. [10] has examined the effects of the concrete under high heat derived from fly ash. Mahdy et. all. [11] evaluated the effect of high temperatures on the weight and strength of high strength concrete. Cülfik and Özturan [12] have also evaluated the effect of high temperatures on the mechanical properties of high strength mortar. In all of these experimental studies, the heat effect on concrete and mortar which is derived from different aggregate and addition agent species was evaluated and different results have been achieved. For example; Cülfik and Özturan [12], pointed out that the graphite dust addition to concrete mixture has increased the high temperature resistance. Xu et. all. [10] observed that generally strength is declined as the temperature inclines. But controversially they reported strength incremental at 250°C derives. This strength increase is

probably related to strengthening of cement paste caused by drying.

The scope of this work is to provide experimental data on the residual compressive strength properties of lightweight concrete masonry units subject to curing conditions at different elevated temperatures. These properties are very important for the safe design of lightweight aggregate concrete masonry units and in the repair of masonry structures.

II. EXPERIMENTAL STUDY

A. Purpose of Assessment

The purpose of this research is to examine the influence of elevated temperatures on the strength properties of new generation design lightweight concrete masonry units prepared with special reference to Nevşehir pumice aggregates. The research basically was focused to evaluate the effects of elevated temperatures on strength – porosity relationship for the masonry units for non-load bearing conditions. No admixtures or additions apart from pumice fine and coarse aggregates, powder calcite, cement and water were used in the mixtures.

B. Materials Used in the Research

In order to analyse the lightweight concrete masonry units, general block dimensions mostly used in Turkey was used as a model block with 190 mm in height, 390 mm in length and 190 mm in width throughout the experimental work. The web and shell thickness of the unit were designed as 20 mm. Totally 21 cellular space with 14 mm in width were placed in the block design. The model of masonry unit is represented in Fig. 1.

Fig. 1. The model of masonry unit.

The pumice aggregate samples were taken from the quarry in Nevşehir region, Turkey. The pumice aggregate samples were first crushed by a primer crusher and then they were screened into two different sizes of 0-4 mm as fine pumice aggregate (FPA) and 4-8 mm as coarse pumice aggregate (CPA) to produce pumice aggregate lightweight concrete (PALWC) with different mixture proportions. These size fractions are commercially used in pumice aggregate masonry block productions in Turkey [13]. The physical properties of pumice aggregate are given in Table 1. Pumice is not a trade name but a type of glassy volcanic rock originating from lava of strictly determined chemical composition. The chemical contents of the pumice aggregates are given in Table 2. Pumice is a well known lightweight concrete aggregate, although its use has mainly been restricted to dry mixes such as for block making and masonry use. There are both advantages and drawbacks connected with the material as an aggregate [14, 15, 16]. Dry bulk density and water absorption of the pumice aggregate samples, as received from the quarry, were determined as 920 ± 30 kg/m³ and $28 \pm 5\%$, respectively. The compressive strength of the pumice aggregate is about to 15.7 ± 1.5 MPa in accordance with DIN 1604.

Ordinary Portland Cement (OPC) conforming to ASTM C 150 Type 1 (42.5 N/mm²) was used for this study. The chemical composition of the cement is given in Table 2. The Bogue compound composition of the cement was calculated according to ASTM C 150 [17] and is also given Table 2. The cement was tested for its mineral content and the loss on ignition using the X-ray Fluorescence (XRF) analysis. The average particle size distribution was determined by laser particle analyzer. The specific gravity of cement was determined according to the British Standard (BS 1377:Part 2) using the small pycnometer method. The fineness of the cement was determined by conducting the Blaine surface area test according to ASTM C 204-94a and given in Table 3. The mechanical and physical properties of the cement used in this research are given in Table 3.

TABLE III. MECHANICAL AND PHYSICAL PROPERTIES OF THE CEMENT

Specific gravity (g/cm ³)	3.12

Initial setting time (min)	146
Final setting time (min)	198
Volume expansion (mm/m)	2.87
Compressive strength (MPa)	
2 days	14.8
7 days	27.4
14 days	35.3
28 days	43.4

The calcite used in the composition of mixture combinations was also a commercial product in Turkey. The calcite used in this experimental program was a white powder form obtained by grinding from calcite minerals. The calcite material was as a powder calcite filler (PCF) material in mixture combinations. Its maximum particle size was 750 µm and its bulk dry density value was also 1240 kg/m³. The chemical composition of PCF is given in Table 2.

Mixing water was general drinking water liquid.

C. Mixture and Manufacturing of Samples

The test specimens for the whole experimental program made from the lightweight concrete mixture compositions are given in Table 4.

TABLE IV. MIX DESIGN OF LIGHTWEIGHT CONCRETES

Mixture	OPC (kg/m ³)	FPA (kg/m ³)	CPA (kg/m ³)	PCF (kg/m ³)	Water (kg/m ³)	Aggregate/Cement Ratio	Fines Ratio by weight (%)	W/C
M1	210	147	343	164	147	3.11	30	0.70
M2	210	200	300	164	147	3.17	40	0.70
M3	210	256	256	164	147	3.22	50	0.70
M4	210	315	210	164	147	3.28	60	0.70

In order to analyze the effects of low elevated temperatures on the compressive strength of pumice aggregate lightweight concrete masonry units, four mixture batches (M1, M2, M3 and M4) were cast in different fine and coarse pumice aggregate ratios as 30%, 40%, 50% and 60% by weight of the total pumice aggregate amount, respectively. Each mixture batch consists of the constant cement content of 210 kg/m³. The water/cement (W/C) ratio of all mixture batches was used as constant in value of 0.70, too. The pumice aggregates were soaked in water for 30 minutes prior to mixing so as to allow them to absorb the water which they would have absorbed in the mixing phase. Therefore the water used during mixing was only the reaction water. It has shown that to give the best results as to resistance and workability characteristics.

BS 1881: Part 125 [18] was used for mixing and sampling the fresh concrete in laboratory and BS 1881: Part 114 [19] was used for measuring the density of hardened concrete. According to the preliminary trial batch results, the fines content for optimum plastic properties in the concrete was determined. After completing the trial experiments, the final mixture compositions for the concrete work were determined. Cube samples of 150x150x150 mm were used for the preliminary trials in testing the mixture strengths and the effectiveness of fines content. For each mixture, twelve samples were cast. After casting the samples, they were cured in a special condition as illustrated in [20]. The concrete specimens were first covered with polyethylene foil which restrained the leakage of excessive water from the surface bed of the test bodies. Then, approximately 10 h after the manufacturing ended, the samples, including the forms, were covered the polyethylene foil.

A cellular hollow block form suitable with the specifications of BS 6073: Part 1 [21] standard was used for preparation of PALWC masonry samples. The ratio of solid area and solid volume of the block form are the same values of 68.7% due to being open sub-section of the block. The web and shell thickness of the block are 20 mm and the block dimensions are 190 mm in height, 390 mm in length and 190 mm in width. For each mixture, 24 block samples were cast and compacted on a vibration machine. Block samples were then air cured in laboratory conditions up to 28 days and there after until the time of testing. After curing, the samples were analyzed in air dry condition for compressive strength testing in accordance with BS 6073: Part 1 [21].

D. Heat Treatment of Specimens and Test of Strength and Porosity Properties

Heat treatment of the concrete samples was carried out as similar testing schedule stated in [20]. The cube and the masonry samples of PALWC were analyzed at the age of 7, 14, 28, 90, 120, 150, 200 and 360 days with 20°C curing condition, respectively. However, the masonry samples were only tested at elevated temperatures at the age of 28 and 90 days, respectively. They were exposed to stabilize the heating 1oC per minute. The specimens then remain at the chosen elevated temperatures approximately 180 minute and after that they were cooled down in a controlled way to the room temperature during 24 h. Actually this duration of exposure at elevated temperatures was determined with the experiments of specific heat capacity of PALWC samples in laboratory trials during this research. It was observed that the concrete samples are heated uniformly and the required stable temperature is reached within the whole testing sample volume with sufficient accuracy. A similar characteristic phenomenon was also stated by [20]. Testing activities have been followed on unsealed concrete samples which were continuously heated up to temperatures 20, 80, 100, 150, 180, 200, 250, 300 and 350°C.

After curing at elevated temperatures, the samples as fully cooled condition were tested for compressive strength in accordance with BS 1881: P116. Determination of porosity is, in fact a quite complex problem. Pore structure of concrete consists of several types of pores: gel micropores (of characteristic sizes 0.5-10 nm), capillary mesopores (10-5000 nm) and macropores [20]. Although the influence of the gel pore distribution (via overall porosity of concrete) may be neglected in S(P) relationship, to measure the remaining pore system through mercury porosimetry means that the maximal pressure has to be sufficient to cause intrusion of Hg into the smallest capillary pores; otherwise rather apparent porosity is determined [22]. In our case, porosity of hardened cement paste of lightweight concrete was determined using the Vacuum Saturation Apparatus. Basic measurement aspects of the apparatus were defined by Cabrera and Lynsdale [23, 24]. Porosity measurements were conducted on slices of 68 mm diameter cores that were drilled out of the centre of a 150 mm cube samples. The slices were dried at 105± 5°C until constant weight had been achieved and were then placed in a desiccator under vacuum for at least 4 h, where after the desiccator was filled with de-aired, distilled water. This is the reason why it was impossible to determine porosity exactly at room

temperature. This means that corresponding to the case without heat pretreatment of the sample [20]. The porosity of the tested samples is the sum of the entrained air voids and the voids within the paste.

III. RESULTS AND DISCUSSION

As a first trial work, the change of strength for PALWC masonry unit samples at 20°C curing condition (representing the room temperature) was examined depending on the curing age. The tests for this trial were conducted up to 360 days after casting the masonry unit samples. Fresh and hardened average densities of PALWC mixture and the compressive strength of the masonry samples at 28 days and 90 days curing are given in Table 5. The strength characteristics of PALWC masonry samples in relation to the curing time at 20°C room temperature were presented in Fig. 2.

Fig. 2. Effect of curing time on compressive strength of PALWC cube samples.

It was experienced from the trial results as expected that the strength of all the mixtures increased with curing time. The effects of fines ratio of the mixture on the strength development were further studied in beginning of this research. In generally, it is assumed that fines ratio of the concrete increases the compressive strength.

According to compressive strength results of the trial mixtures, the last hydration duration was estimated as 90 days of curing for the concretes because strength of the concrete remained acceptably stable over 90 days of curing time. Therefore, it was decided that the research work to analyze the effects of elevated temperatures on the compressive strength of the concretes was followed at 28 days and 90 days curing time. Dependence of compressive strength on heating temperature is presented in Figs. 3 to 6 for 30%, 40%, 50% and 60% fines ratios for PALWC masonry unit samples, respectively.

TABLE V. TEST RESULTS OF PALWC MASONRY UNIT SAMPLES.

	Fresh Density of Concrete (kg/m ³)	Dry Density of Hardened Concrete (kg/m ³)	Compressive strength of masonry samples after 28 days (MPa)	Compressive strength of masonry samples after 90 days (MPa)	Oven Dry unit weight of masonry samples (kg)
M1	1212	1049	2.84	2.92	10.15
M2	1226	1062	2.98	3.01	10.28

Fig. 6. Effect of temperature on compressive strength of PALWC masonry unit (60% fines ratio).

Fig. 4. Effect of temperature on compressive strength of PALWC masonry unit (40% fines ratio).

Fig. 5. Effect of temperature on compressive strength of PALWC masonry unit (50% fines ratio).

The research showed that there is a reduction in the tendency to strength up to 100°C and an increase in the tendency to strength after 100°C elevated temperatures at 28 days of curing. However, this strength tendency was different at 90 days of curing. The strength tends to decrease up to 150°C and tends to increase after 150°C elevated temperatures at 90 days of curing for PALWC masonry units. These temperature values were accepted in this study as “turning point of strength for elevated temperature” depending on the cure time. The strength value of 28 days curing time at 20°C temperature for PALWC masonry units was evaluated as initial strength of the tested masonry units throughout the research. Effect of elevated temperature on the strength was also variable with the fines ratio of masonry mixture combinations. Increase of fines ratio relatively defers the strength change based on progressive elevated temperatures.

Furthermore, the ratio of strength value after cooling of the masonry sample and its original value before heat pretreatment is generally referred to be “residual strength ratio” [20]. In this research, the residual compressive strength after heating at different temperatures T was expressed as a ratio f_T/f_{20} , where f_T is the strength after heating at $T^\circ\text{C}$ and f_{20} is the initial strength of concrete at 20°C [7, 25]. The strength ratio f_T/f_{20} as a function of PALWC masonry samples versus temperature T is represented in Figs. 7 and 8 for the mixtures.

Fig. 7. Residual compressive strength of PALWC masonry unit (at 28 days).

Fig. 8. Residual compressive strength of PALWC masonry unit (at 90 days).

The initial strength was acutely varied depending on the fines ratio and curing time. PALWC masonry samples with 30% fines ratio had a reduction in strength of 7.40% at 28 days curing up to 100°C and of 3.42% at 90 days curing up to 150°C, while the respective reduction for the masonry samples with 40% fines ratio was 6.71% and 3.65% at 28 days and 90 days curing times, respectively. The change of initial strength of the masonry samples for 50% and 60% fines ratio was a convergent value comparing both these two concrete mixtures: 3.43% and 15.7% at 28 days and 2.78% and 15.6% at 90 days curing times, respectively. It can be stated that another important factor influencing the initial strength loss up to turning points of strength for elevated temperature was the curing time. As evaluating the above mentioned strength values; the change of initial strength was lower at 90 days of curing than at 28 days of curing. These results are very similar to those published by Vodak et. al. [20].

Several physical phenomena occurred in the temperature range between 100°C and 350°C. At these temperatures interval, it was observed that all masonry samples begin again to gain the strength beyond the turning point of strength for elevated temperature. These strength gains were ranged from 11.8%, 10.10%, 5.48% and 23.60% with 30% to 60% fines ratio at 28 days curing, respectively. Similar strength increasing trend was also depicted at 90 days curing. Therefore, it was observed that increasing the fines ratio of the concrete mixture become evident the strength changes. Upper limit of the strength change in the masonries was ranged from 23.6% to 14.5% at 28 and 90 days curing for 60% fines ratio mixtures, respectively. However, increasing age of the concrete showed not the same condition as dictated with 28 days of curing. The initial strength was only slightly altered depending on low fines ratio. The research showed that the change of initial strength of the concrete increased at 28 days of curing time with the increase of fine pumice aggregate and it decreased at 90 days of curing. Therefore, up to 350°C, the best performance was accepted by 40% fines ratio to concrete at 28 days of curing.

Changes of porosity with temperature of heating are depicted in Figs. 9 and 12 for 30%, 40%, 50% and 60% fines ratios for PALWC masonry unit samples, respectively. Every point of all these curves corresponds to the statistically averaged value obtained from 5 to 8 measurements.

Fig. 11. Effect of temperature on porosity of PALWC masonry unit (50% fines ratio).

Fig. 12. Effect of temperature on porosity of PALWC masonry unit (60% fines ratio).

The lightweight aggregate concrete includes capillary water, physically absorbed water and interlayer and chemically bound water in C-S-H and Ca(OH)_2 . During heating the cement paste dried and water was free to be driven out. The strength reduction was evaluated as due to the stresses generated at the interface between the aggregate and hardened cement paste on heating. Mahdy et. al. [26] also stated the similar conclusions that the difference between the thermal expansion for the cement paste and aggregate can result in microcracking and disruption of the cement-aggregate bond with consequent reduction strength. Kaplan et. al. [27] investigated the changes of concrete structural properties at elevated temperatures. They demonstrated that changes in physical properties of unsealed specimens exposed to low temperatures of 70, 100 and 150°C were greater than those sealed specimens exposed to higher temperatures of 250 and 400°C. They also found that changes in concrete properties were mainly related to loss of water from the cement gel and the capillary pores in cement paste.

The water in the form of steam is eliminated most intensively and affects the surrounding phases of cement paste. Mainly due to the flow resistance and high temperature, steam creates a high pressure in the paste [7]. An increase of hydration products in concrete leads to the increase of its strength [28]. This effect originates probably from by larger mobility of water molecules in gaseous phase (as compared with their mobility in liquids) for temperatures ranging from 100 to 300°C [20]. In consequence, so-called steam curing or internal autoclaving causes similar behavior of concrete as certain curing treatments and it appears in the cement paste. This process results an additional hydration of anhydrous cement grains.

During hydration, a system of capillary pores is formed in the cement paste. The radii of these pores are smaller than the pores of pumice aggregates. Due to hydration and drying, a humidity gradient develops as soon as relative humidity decreases [29]. The capillary forces of the cement paste are high enough to absorb the water from the lightweight aggregate grain and transport it to the dryer cement paste where a reaction with the anhydrous cement takes place, forming Ca(OH)_2 .

After reaction of Ca(OH)_2 new hydration products of types calcium silicate hydrate (C-S-H) are built [30]. They grow in the pores of the cement paste, in available space and into the microcracks thus causing them to get smaller. The capillary suction, which is the inverse to the square of the pore radius, increases as the radius becomes smaller and thus enabling the pores to continue to absorb water from the lightweight aggregate. This continues until all the water from the lightweight aggregate has been transported to the cement paste [29]. This is actually a time dependent transport of at the begin water and in the end vapour with higher rate in the early age of concrete and lower at later age. The research showed that hydration process for PALWC mixtures dominantly increased especially at the age of 28 days curing due to intensifying hydration with elevated temperatures between 100 and 350°C. This process was continued with relatively large volume of unhydrated cement. Due to water evaporation beyond 100°C the gradient increased and the higher strength values were obtained at 28 days of curing. However, although the initial strength values were higher at 90 days of curing than at 28 days curing time, strength values of the masonry units beyond 100°C elevated temperatures were all lower at 90 days of curing due to practically terminating the hydration process. In this respect as a hypothesis stated by [20], the major role is played by microcracking. This effect is illustrated by experimental study in Fig. 13 as the changes of pores size distribution. Additional very low hydration is caused mostly by water molecules of relatively high kinetic energies released at temperatures above 250°C. Similar act was also declared by [20]. This event leads to increasing of the strength and decreasing of porosity.

Fig. 13. Effect of temperature on pore size distribution of PALWC concrete at 90 days curing.

In experiments on the compressive strength evaluation, it was also observed that pumice aggregate lightweight concretes with improved strength, enhanced degree of hydration, and reduced autogenous shrinkage could be obtained by addition of fine saturated pumice aggregates up to 40% fines ratio in the mixture.

Actually, it should be emphasized that this research work was carried out for one particular concrete mixture with using constant w/c ratio of 0.7 and cement dosage of 210 kg/m³. This

study is still an ongoing work with the different w/c ratios and cement dosages. Furthermore, the type of lightweight aggregate and the characteristic of pumice aggregates are also investigated in these experimental studies to determine their effects on the compressive strength of masonry concrete mixtures at elevated temperature curing.

Abstract—The aim of this study is to investigate the mechanical properties and durability of self-compacting mortars (SCMs) produced from high-calcium fly ash (HCFA) and silica fume (SF) as mineral additives. In this scope, 12 series of SCMs including control mixture were prepared that consist of binary mixes of silica fume (SF) by the ratios of %6, %10 and %14, and HCFA with the ratios of %10, %20 and %30. In ternary mixes, provided that mineral additive ratio doesn't exceed %30 of cement, %10 of HCFA with 6% , %10, % 14 of SF and %20 of HCFA with %6 , %10 of SF were produced by weight of cement. A total of 48 specimens of 40x40x160 mm were produced and cured at the age 28 day for compressive and tensile strength tests and 36 specimens of 50 mm cube specimens were prepared and cured at 28 days for water absorption, sorptivity, porosity and density tests. Flexural tensile strength and compressive strength of 40x40x160 mm specimens were measured at the curing age of 28 days. All of the SCMs mixes examined provide satisfactory fresh self-compacting properties, In addition, the FA series performed better with workability properties when compared to the SF series. Ternary mixes of FA10SF10 and FA10SF14 have the lowest relative slump values as compared to control and other binary and ternary mixes of SCMs. In both binary and ternary mixes of SCMs, as FA content increases, relative slump values also increases. In other words, less amount of SP was needed to ensure the same slump diameter while increasing the amount of FA. This can be explained as existing lower internal friction of FA which has relatively smooth surface and spherical shape replacing cement which has angular particles. the relative funnel speed values that are between 0.9-1.4 as suggested by EFNARC (2002) The relative funnel speed of binary mixes of FA10 and FA20 is higher than all binary and ternary mixes and almost the same as the control mix. It can be concluded that the workability of binary mixes of FA is better than the other mixes of SCMs except FA30. The compressive strength of binary mixes of FA reduces as the content of FA increases up to 30% which has the lowest value in all SCMs. FA10 and SF6 performed well in the binary mixes of SCMs. The slow pozzolanic reaction and the dilution effect of FA caused the decrease in compressive strength of the FA blended of SCMs. Binary mixes of SF and ternary mixes of SCMS containing 10% of FA generally have higher compressive strength than binary mixes of FA and ternary mixes of high replacement content of FA. When FA and SF content increased, the sorptivity coefficient values of SCMs with FA increased while the sorptivity coefficient of SCMs with SF decreased. It is well known that the compressive strength of mortar/concrete is affected by porosity. The sorptivity coefficient values of the mortars with SF were lower than that of all mortars except for SF5 while the mixtures with SF10 had lowest sorptivity coefficient in all SCMs due to filler effect of SF as well as pozzolanic activity. The results also indicated that binary and ternary mixes of SCMs having high sorptivity values generally exhibits low compressive strength as the sorptivity results are compared to compressive strength of samples cured in water at the age of 28 d.

Abstract— The aim of this study is to investigate the mechanical properties and durability of self-compacting mortars (SCMs) produced from ground pumice powder (GPP) as a mineral additive. In this scope, 8 series of SCMs including control mixture were prepared that consist of 5%, 10%, 15%, 20%, 25%, 30% and 35% of ground pumice powder by weight of cement. A total of 72 specimens of 40x40x160 mm were produced and cured at the age of 3, 28 and 90-day for compressive and tensile strength tests and 24 specimens of 50 mm cube specimens were prepared and cured in water at 28 days for water absorption, sorptivity, porosity and density tests. Flexural tensile strength and compressive strength of 40x40x160 mm specimens were measured at the curing age of 7, 28 and 90-day. Mini V-funnel flow time and mini slump flow diameter tests were also conducted to assess rheological properties. The results indicated that SCMs containing 20% of GPP have the highest slump value as 5.1 which are in the range of limits recommended by EFNARC committee. This slump value is slightly higher than control mixtures. SCMs incorporating 5, 10 and 35% of GPP have relative slump of 4.8. It can be concluded that slump values increases up to 20% of GPP the decreases as the content of GPP goes to 35%. The results of relative funnel speed showed that 20% of GPP had the lowest relative funnel speed time as 1.17 (1/s) in all SCMs mixes including control mixtures. Relative funnel speed time of all SCMs mixtures including control mix is in the range of EFNARC limits which is 0.9-1.4.10%. SCMs with 10% of GPP have the highest relative funnel speed value. The value of relative funnel speed reduced to 20% of GPP and then increased to 35% of GPP. The strength properties of GPP revealed better results. The compressive and flexural tensile strength of GPP increased up to 15% of GPP replacement and then decreased to the lowest strength value for 35% of GPP for all SCMs and control specimens. The compressive strength values are in the range of 34.84-84.87 MPa. The highest value belongs to 15% of GPP at the curing age of 90 days. The lowest value belongs to 35%GPP at the curing age of 3 days. The flexural tensile strength behaves similar to the compressive strength. The range of tensile strength varies between 5.04-10.54 MPa, mortars having 15% of GPP 15 gained the highest strength at the age of 90 days, mortars having 35% of GPP gained the lowest strength. Both total water absorption and porosity decreases parabolically up to about 15% of GPP replacement then total water absorption and porosity increases as GPP replacement increases up to 35%. Sorptivity coefficients decrease as the GPP replacement changes from 5% to %10. When GPP content ratios are between 15% and 25 %, the sorptivity coefficient values of SCMs have the highest as compared to other mixes. This sorptivity coefficient nearly the same as the control mix with the value of $3.5 \times 10^{-3} \text{ cm/s}^{0.5}$. GPP30 mixture possesses the lowest value as $2.81 \times 10^{-3} \text{ cm/s}^{0.5}$.

Abstract— In this study, it is aimed to determine the camber of prestressed concrete girder after detensioning. At the time of strand release, detensioning, prestressed concrete girders are under the dead and prestressing loads effect. At this stage, camber of prestressed girder is summation of the upward deflection due to the prestressing force and the downward deflection due to dead loads. For the calculation of these deflections, it is generally considered that prestressed concrete girder behaves linear-elastic. In this paper, differences between camber calculations with the linear-elastic beam and elastic-stability theories are presented. Two prestressed concrete girders with the same number of prestressing cable but different configuration are chosen as examples. Girders have 100 cm height and 24.8 m effective span length. 3D finite element models (FEM) of the girders are developed by SAP2000 software, and the deflections of girder are obtained from linear and nonlinear-static analyses. Only geometric nonlinearity is taken into account for nonlinear-static analyses. The results of the linear-elastic beam and elastic-stability theories are compared with FEM results and each other. It is seen that the camber calculation by elastic-stability theory gives acceptable results than the linear-elastic beam theory while strand releasing.

Keywords— *camber, deflection, detensioning, finite element model, linear and non-linear static analyses, elastic-stability, prestressed concrete.*

I. INTRODUCTION

Prestressed concrete girder bridge construction consists of some stages. At these stages, girders are under the effect of different material properties, prestress losses, and load conditions. For all these reasons, deflection behavior of girder at any stage is different from each other. Generally the deflection of prestressed concrete is classified into two groups: short-term and long-term. Short-term deflection refers to the immediate deflection after detensioning, while the long-term deflection occurs over a long period of time largely due to losses of prestress, shrinkage and creep of the materials. In order to better predict long-term camber of girder, it is important to be able to better predict the camber at release [1]. The uncertainty of the predicted camber in precast, prestressed girders can lead to problems during construction. Predicting of camber accurately is difficult because the camber depends on

many random variables, some of which are interdependent and change over time. Some of the most important variables are the compressive strength and Young's modulus of concrete, amounts of creep and shrinkage, thermal gradients within the girder, and the time-dependent variations in prestressing force [2].

Numerous theoretical as well as experimental investigations on structural behavior and load-deflection behavior of prestressed concrete structures have been carried out over the last decades. [3] found considerable variations between the predicted and actual cambers of eight identical American Association of State Highway and Transportation Officials Type IV girders. [4] presented a model for the calculation of both short and long-term deformations in reinforced, prestressed, and composite concrete beams with generalized end conditions subjected to bending about any transverse axis. [5] conducted to develop improved methods of predicting camber in prestressed concrete girders. They used adjustment factor for Young's modulus to minimize the predicted error on the camber immediately after release. [6] presented several factors related to girder production that have a significant impact on the prediction of camber and examined the accuracy of the current NCDOT method for predicting the prestress losses and camber for prestressed concrete girders as compared to field measurements. [1] carried out an experimental research to determine both short-term and long-term deflections of prestressed girders. [2] investigated factors related to prestressed concrete girder production that could affect the camber, and recommended the camber prediction methods. [7] presented the development of a finite element model for the geometric and material nonlinear analysis of bonded prestressed concrete continuous beams.

The main objective of this research is to investigate the differences between calculation of camber after detensioning with linear-elastic beam and elastic-stability theories and effect of cable configuration on camber. For this purpose two prestressed concrete girders with 100 cm height, 24.8 m effective span length and different cable configuration are selected as an application. The 3D FEM of the girders are developed by SAP2000 software [8]. Nonlinear and linear-static analyses are performed under dead and prestressing loads to obtain deflection of the selected girders. Only geometric

nonlinearity is taken into account. The results of the linear-elastic beam and elastic-stability theories are compared with FEM results and each other.

II. CAMBER CALCULATIONS

During the manufacturing process of prestressed concrete girders, prestressing force is transferred from strands to concrete by bond at their interface. Due to existence of the eccentrically located tendons, the girders tend to deflect upwards also called camber. Camber of prestressed girder at detensioning is a summation of the upward deflection due to the prestressing force and the downward deflection due to the dead loads. The magnitude of camber depends on the self-weight of the girder, the amount of strand and prestressing force. The schematic form of deflection of prestressed girder after detensioning is shown Fig. 1.

Fig. 1. Deflection of prestressed girder after detensioning

In this study, deflection of girder is calculated with the linear-elastic beam and elastic-stability theories. According to the linear-elastic beam theory, the equilibrium equation is formulated for undeformed state of girder, in which secondary moment is neglected. However the elastic-stability beam theory is formulated the equilibrium equation for deformed state of girder. According to the linear-elastic beam theory, mid-span downward deflection of prestressed concrete girder under the effect of self-weight is determined by:

$$\delta_{sw} = \left(\frac{5 \times q_{beam} \times L^4}{384 E_{ci} I_{girder}} \right) \quad (1)$$

where L is the length of girder, q_{beam} is the linearly distributed dead load over the length of girder, E_{ci} is the Young's modulus of concrete and I_{girder} is the moment of inertia.

The upward deflection of prestressed concrete girders at mid-span due to prestressing force is determined by:

$$\delta_{ps} = - \frac{P_{re} \times e \times L^2}{8 E_{ci} I_{girder}} \quad (2)$$

where e and P_{re} are the eccentricity of strand and the total prestress force at release, respectively.

The downward deflection due to dead loads can be calculated with linear-elastic beam theory because the secondary moment does not occur with deformation of girder. However, under the effect of prestressing force the direction of force and displacement are perpendicular to each other, so the

effects of secondary moment due to prestressing force must be taken into consideration. In this case, the elastic-stability theory formulated the equations of equilibrium in the deformed state should be used. According to the elastic-stability theory it is assumed that the girder is initially straight and materials obey Hooke's law [9].

Fig. 2 Eccentrically loaded girder

A simple supported girder exposed eccentricity load cut at a distance x from the pinned support is shown in Fig. 2. This partial section of the girder must be equilibrium. Thus we have

$$EIy'' + P_{re}(e + y) = 0 \quad (3)$$

where EIy'' is the internal resisting moment. By solving Eq. (3), the upward deflection due to prestressing force at the mid-span according to the elastic-stability theory can be obtained as

$$\delta_{ps} = e \left(\frac{1}{\cos \left(\frac{L}{2} \sqrt{\frac{P_{re}}{E_{ci} I_{girder}}} \right)} - 1 \right) \quad (4)$$

III. PRESTRESSED CONCRETE GIRDER MODELS

In this paper, simply supported prestressed I-girder with 100 cm height and 24.8 m effective span length is selected as an application. A typical appearance and the dimensions of cross section are seen in Fig. 3. The ultimate strength of concrete (f_c) is taken as 45 MPa. The low-relaxation Grade 270 prestressing strand (characteristic tensile strength f_u of 1860 MPa) 15 mm (0.6 in.) in diameter is selected as a strand type. Strands layout along the girder length is assumed as linear. The distance between strands (5 cm) given by the American Association of State Highway and Transportation Officials' AASHTO LRFD Bridge Design Specifications [10] is used. To determine the Young's modulus of concrete, there are many models and expressions. These models and expressions predict the Young's modulus of concrete based on the concrete strength and, possibly, other parameters ([11], [12], [13] etc). [1] determined that the Pauw equation most closely predicted the Young's modulus in comparison with the other models at detensioning. The expression for the Young's modulus of concrete according to Pauw equation is given as:

$$E_{ci} = 0.043 K_1 \gamma_c^{1.5} \sqrt{f'_c} \quad (5)$$

where γ_c is the unit weight of concrete at time of test, in kg/m^3 , f_c is the concrete compressive strength at time of test, in MPa and K_I is the correction factor for source of aggregate to be taken as 1.0 unless determined by physical test. The other material properties considered in the numerical analysis are given in Table 2.

Fig. 3. Cross-section of the investigated girders

Table 2. Material properties.

Material	Young's Modulus (MPa)	Poisson's Ratio	Density (kg/m^3)
Concrete	33914	0.2	2400
Strand	197000	0.3	0

Efficient design of prestress concrete bridges demands an accurate prediction of prestress losses. The prestress losses are defined as the loss of tensile stress in the prestress steel due elastic shortening, creep, shrinkage and relaxation. During the transfer operation of prestress, the girder tends to reduce in length, which is called elastic shortening. The prestress loss due to elastic shortening is

$$\Delta f_{pES} = \frac{E_p}{E_{ci}} f_{cgp} \quad (6)$$

where, E_p is the Young's modulus of prestressing steel, f_{cgp} is the sum of concrete stresses at the center of gravity of prestressing tendons due to the prestressing force at transfer.

Strand relaxation that occurs between the time of strand pull and release is another effect that leads to prestress loss. However, this effect is rather small (i.e., prestress losses on the order of approximately 1%) and is neglected by MnDOT and by the precasters [1].

IV. FINITE ELEMENT MODELING

Nonlinear-static and linear-static analyses of the girders are performed with SAP2000 in order to obtain the deflections of the girders. In nonlinear-static analysis, only geometric nonlinearity is taken into account. Three-dimensional FEM of girder is given in Fig. 4. The girder model consists of 10 frame elements and 14 tendons. The girder and strands are represented by frame and tendon, respectively. As a boundary condition, the left and right hand supports are selected as pinned and roller, respectively.

Self-weight of girder is calculated from the finite element software directly. Prestressing force is calculated as 181 kN when the prestressing losses are taken into account. This force is simultaneously applied to all strands at both sides. During the strand release time-dependent factors such as creep and shrinkage are not taken into consideration.

Fig. 5. Finite element model of the girder

V. NUMERICAL RESULTS

The maximum deflections occur due to the self-weight, prestressing force and total of these forces obtained from analytical methods and FEM are shown in Table 2. The downward deflection obtained from FEM and beam theories are equal each other. It is clearly seen that calculation of downward deflection due to the self-weight of girder is not affected from the geometric nonlinearity.

According to the linear-static and nonlinear-static analyses, the maximum upward deflection is obtained from Girder-I and Girder-II 6.24cm - 6.99cm and 5.82cm - 6.52cm, respectively. The upward deflection of girder obtained from the nonlinear-static analysis, in which P-Delta displacement is considered is greater than that of the linear-static analysis. Total net upward deflection of prestressed girder is a summation of the upward deflection due to the prestressing force and the downward deflection due to the self-weight of girder. According to the linear-static and nonlinear-static analyses, the maximum camber is obtained from Girder-I and Girder-II 3.54cm - 4.23 cm and 3.06cm - 3.76 cm respectively.

Method	Deflection		
	Self-weight of girder (cm)	Prestressing force (cm)	Total net camber (cm)
GIRDER-I	Linear-elastic beam theory	-2.73	6.24
	Elastic-stability theory	-2.73	6.99
	SAP2000(Linear-static)	-2.76	6.24
	SAP2000(Nonlinear-static)	-2.76	6.99
GIRDER-II	Linear-elastic beam theory	-2.73	5.82
	Elastic-stability theory	-2.73	6.52
	SAP2000(Linear-static)	-2.76	5.82
	SAP2000(Nonlinear-static)	-2.76	6.52

VI. CONCLUSION

The aim of this paper is to investigate the calculation differences of short-term deflection of prestressed concrete girder after detensioning with the linear-elastic beam and elastic-stability theories. According to the linear-elastic beam theory, the equilibrium equation is formulated for undeformed state of girder, but in elastic-stability theory, the equilibrium equation is formulated for deformed state of girder so secondary moment is taken account. Simply supported prestressed I-girder with 1.0 m height and 24.8 m effective span length is selected as an application. FEM of girders are developed by SAP2000 software, and the nonlinear and linear-static analyses are performed under dead and prestressing load. In nonlinear-static analysis, only geometric nonlinearity is taken into account. The prediction of girders' short-term deflection with linear-elastic beam and elastic-stability theories is compared with each other and the result of FEM. The main conclusions drawn from this analytical study are:

- The downward deflection of the girders obtained from the linear and nonlinear analyses of FEM and beam theories are equal to each other. It is clearly seen that the calculation of downward deflection due to dead load is not affected from geometric nonlinearity because the deflection of girder is in the same direction with the load, thus secondary moment does not occur.
- The downward deflection due to the self-weight of girder can be accurately calculated with the linear-elastic beam theory.
- The upward deflection of girders obtained from the nonlinear-static analysis, in which P-Delta displacement criterion is taken into account is greater than the linear-static analysis of FEM. Also, the result of elastic-stability theory is greater than the linear-elastic beam theory. It is seen that, as the strands are released and the girder begins to camber up, the secondary moment occurs due to prestressing force.
- The maximum upward deflection obtained from the linear-elastic beam theory and linear-static analysis of FEM is pretty close to each other. Also, the nonlinear-static analysis of FEM has almost same results with the elastic-stability theory.

Papercrete, lightweight environmental friendly building material utilizing paper waste as ingredient

Zahid Ali

Consultant, Structures, Building Materials & Green Buildings

zee9_786@yahoo.com

Abstract: According to a recent study of resource consumption and waste generation of the financial sector, sixty percent (60%) of the waste produced in company head offices was paper waste, including printing and writing paper, newspapers and magazines and cardboard. Statistics say most GCC countries rank in the top ten (10) worldwide in terms of waste production, Saudi Arabia producing 60% of the waste in the region, followed by the UAE (20%) and the others Kuwait, Qatar, Oman and Bahrain. Recycling is of immense importance in today's world as it reduces the amount of garbage thrown in landfills thereby reducing the negative impact on the environment. Papercrete was originated way back in 1928 but could not find its way in the market, until recently rediscovered in 1983. A name for it is yet to be settled, as some call it fibrous cement and others call it papercrete, the later used by the author in this paper. Papercrete is composed of soaked paper waste, old magazines, newspaper, etc and cement or soaked paper waste, sand and cement. Generally, 60% soaked paper waste, 30% sand and 10% cement. Blocks can be made for low cost housing or for lightweight insulation tiles / blocks for roof insulation or it can be poured into wall forms as well. Papercrete is an environmental friendly material as it utilizes paper waste, lessen the burden on resources, resource efficient and has good insulating value thereby can be used for energy efficiency. The paper deliberates about its properties, utility and benefits.

INTRODUCTION

Recently tremendous interest has been developed in the development of sustainable building materials ranging from bamboo, mud straw to cob. Relatively newcomer to the green materials arena is papercrete or fibrous concrete. Papercrete can be used as a building material being lighter in weight and having high insulating properties. Papercrete was originally patented back in 1928, but it was too cheap and simple to be profitably marketed at that time. It has been independently rediscovered by several experimenters, beginning in 1983. It's so new that people haven't even settled on a name for it yet. Some calls it fibrous cement while others call it Papercrete, the name used by the author. The unlikely marriage of re-pulped paper and portland cement has produced a material with some intriguing characteristics.

Papercrete can be used in many of the same applications as concrete, but is lighter in weight and has a high insulating value, as with many new green materials, papercrete is being researched and tested, (Michael Cockram, 2002) [1].

An important aspect in case of resource efficiency, in sustainable development, is to look for products with identifiable recycle content and papercrete can fulfill this very effectively by recycling paper waste.

PAPER WASTE

In the period from 1983 to 1996, consumption of paper and cardboard had increased by 46 per cent, corresponding to 3.5 per cent per year in EU countries. In absolute figures the increase is from 41 million to 64 million tonnes. It is reasonable to assume that consumption is equivalent to waste generation (Christian Fischer, 1998) [2].

According to Regional Report / Saudi Arabia published in Clean Middle East Issue 2011, the municipal waste landfill in Riyadh received more than 3.5 million tons of different kinds of waste during the first six months this year. Disposed commercial and domestic waste reached 1.4 million tons while other waste including construction debris reached 2.1 million tons. It is a given fact that a rise in GDP registers a rise in consumer spending which gives rise to more waste. It is the same with industrialization and urban growth which increases levels of pollution and waste. Saudi Arabia's annual garbage production has reached 12 million tons, with each citizen producing an average of 1.4 kilograms of waste per day, making the kingdom look for more effective and advanced recycling and waste management solutions, (Clean Middle East, Issue# 6, Vol:2, 2011) [3].

In UAE, "The general trend shows an increase in the amount of waste generated annually," says Naji Alradhi, Head of Waste Treatment Section,

Environment Department of Dubai Municipality. Dubai generates about 31,000 tons of waste every day. The total waste collected in 2005 was 11.3 million tons, an increase of 71.2 per cent over the 6.6 million tons of waste generated in 2003 (Libini Joy, 2006) [4].

According to a recent report by the Arab Foundation for Environment and Development (AFED), the Arab world produces approximately 250,000 tons of solid waste every day, most of it dumped untreated in make shift landfills, if it is collected at all. Skyrocketing income levels in areas such as UAE has resulted in increased consumer spending which has had a direct effect on waste levels. The per capita production of solid waste in Arab cities such as Kuwait, Riyadh and Abu Dhabi is over 1.5 Kg per day, placing them among the highest waste producers in the world, (Jane Meikle, Gulf Times Qatar, 2009) [5].

The mounting levels of waste produced in Dubai are sounding alarm bells for officials. Hussain Lootah highlighted that in year 2000, up to 3000 tons of waste was heading straight to landfills daily, and by year 2008 this had grown to 11000 ton every day making the yearly growth rate of waste 20 per cent, Gulf News, 2009 [6].

In 2010, about 6.5 million tons of waste was generated in Singapore, and each person generated around 1,280 kg of waste in a year. The recycling rate in Singapore for 2010 is 58% and has been increasing steadily over the years. The government has set a target of 60% recycling rate by 2012 in the Singapore Green Plan 2012, and 70% recycling rate by 2030 in the Sustainable Singapore Blueprint.

42% of Singapore's waste is still disposed of, with 40% going to the waste-to-energy plants for incineration and energy recovery, and 2% of non-incinerable waste such as construction and demolition waste, used slag and treated sludge, going to the Semakau Landfill for land filling.

According to % Composition of Waste Generated, the top 5 waste types make up 74% of the total waste generated in Singapore, which are either disposed of at the waste-to-energy plants and landfill, or recycled locally and exported: Paper/Cardboard (21%), Ferrous Metal (18%), Construction Debris (14%), Plastics (11%), Food Waste (10%). According to % Composition of Waste Disposed, the top 3 waste types make up 66% of the total waste disposed in Singapore: Paper/Cardboard (23%), Plastics (24%) and Food Waste (19%). According to % Composition of Waste Recycled, the top 3 waste types make up 74% of the total waste recycled in Singapore: Paper /Cardboard (20%), Ferrous Metal (30%), Construction Debris (24%).

More efforts are needed to reduce the amount of paper, plastics and food waste disposed and to increase their recycling rates. Half of the paper and cardboard waste generated still ends up being burned at the waste-to-energy plants, (Zero waste Singapore, Singapore 2010 Waste Statistics, May 3, 2011 by Eugene) [7].

Major constituents of the municipal solid waste (MSW) are organic, whereas recyclable materials constitute almost 1/3 of total MSW in big cities. Paper/board constitutes 12% and 14.2% of solid waste in Izmir Greater Municipality and Istanbul Greater Municipality [8].

EYES ON SUSTAINABLE DEVELOPMENT

The widely used definition of sustainable development, coined by Brundtland in its report, is "Sustainable development is development which meets the needs of the present without compromising the ability of future generation to meet their own needs." (World Commission on Environment and Development, Harlem Brundtland, 1987) [9]. This report was quite significant as it helped in triggering a wide range of actions such as UN Earth Summits (Rio de Janeiro 1992 and Johannesburg 2002), International Climate Change Convention and World "Agenda 21" programs. Sustainable Construction is the application of sustainable development to the construction industry. Resource Efficiency is one of the important factors of sustainable development. Besides various other means, resource efficiency can be accomplished by using Products with identifiable recycled content. Buildings can play a key role in combating climate change, the U.N. Environment Program said in a report issued in Oslo during a conference on ways to promote economic growth without damaging the environment (Alister Doyle, 2007) [10].

In Turkey, more than half of the waste generated could be reused and recycled, and transformed from a problem into an asset. However, it is a well known fact that the rates of recycling are very low, although there are no hard data in this area. Since a sound waste management infrastructure is not established in Turkey, each and every year, millions of tons of natural resources, the employment opportunity for thousands of people, a wealth of millions of dollars are wasted and the revival capacity of environment is rapidly exhausted [11].

Thus, we need to keep our eyes open in order to keep in mind sustainable and resource efficiency for reusing and recycling our waste product into materials beneficial for building industry and energy conservation.

PAPERCRETE

Papercrete is the product having a distinct identifiable recycled content. Papercrete is composed of water soaked paper waste, old magazines, newspaper, etc and cement or water soaked paper waste, sand and cement. Blocks can be made for low cost housing or for lightweight building partitions or it can be poured into wall forms as well. Papercrete is an environmental friendly material as it utilizes paper waste, lessen the burden on resources thereby providing resource efficiency. A small amount of lime can also be added for getting the benefits of lime like smoother finish and for avoiding damage by wet/dry cycles, incase any.

Some have combined sand and fly ash as well and termed the recipe for the material, as "papercrete" or "fibercrete," with a combination of wastepaper, water, Portland cement, sand and fly ash, which is captured through giant smoke stack filters and reported that the material is environmentally friendly and can cut heating and cooling costs by as much as 70 percent and construction costs by one-third, Chris Casacchia, 2006 [12].

Presently, Blocks of sizes 75 mm x 150 mm x 300 mm some solid and some with a 25 mm hole at the center were made as per the first category of soaked paper waste and cement. The two ratios of 90% soaked paper waste: 10% cement and 80% soaked paper waste: 20% cement were tried. Samples of 100 x 100 x 100 mm size were also made. Block and samples sizes are shown in Figure-1 and Figure-2 respectively.

Fig.1 - FIRST CATEGORY SAMPLE SIZE

Fig.2 - SECOND CATEGORY SAMPLE SIZE

Density

The density of the first category of ratio 90% soaked paper waste and 10% cement recorded as 299 Kg / cubic meter (18.68 lbs / cubic foot) or 300 Kg / cubic meter (19 lbs / cubic foot). The density or weight of

the second category of ratio 80% soaked paper waste and 20% cement recorded as 580 Kg / cubic meter (36.2 lbs / cubic foot) or 581 Kg / cubic meter (36.3 lbs / cubic foot) as shown in Table-1.

TABLE 1 – DENSITY RANGE OF SAMPLES

Type	Size (mm)	Volume (cu m)	Weight (kg)	Density
1st	75x125x300	0.002812	843	300 kg / cu m
	80x125x270	0.002808	840	299 kg / cu m
2nd	100x100x100	0.001000	580	580 kg / cu m
	80x95x95	0.000722	419	581 kg / cu m

R-Value

R-Value is a measure of a material's resistance to heat flow. The R-Value of papercrete is reported to be between 2.0 and 3.0 per inch and mostly ranges between 2.5 and 3.0 per inch. Papercrete is lightweight and has a high insulation value estimated around R 2.8 per inch. (Gordon Solberg, 2002) [13]. Thus, it qualifies to be a very good insulation wise building materials in very hot climatic regions. Thus, the papercrete roofing tiles can greatly help in reducing the energy cost consumed in air conditioning.

Compressive Strength

Several sample of 100mm cubes of the two categories of ratios that is soaked paper waste : cement that is 90% : 10% and 80% : 20% were tested under compression. It was observed that Papercrete has very low compressive strength (160-320 psi), but fails by slow compression rather than in a brittle manner (quite different from cement concrete cube compression failure). The failure under compression is not in a brittle fashion like in case of cement concrete but it rather converges to pressed form. The samples under compression test are shown in Figures 3 & 4.

Fig.4 – PAPERCRETE CUBE AFTER COMPRESSION FAILURE

Fire Resistance

The papercrete 100x100x100 mm block was held in an open flame for three minutes but it did not catch fire as shown in Figure-5. The only visible change was that it got blackened which can be seen in Figure-6. This is not to say that papercrete will never burn. Any material will burn or melt or disintegrate if enough heat is applied but the test was carried out to dispel the impression that because of the higher content of paper it might catch fire.

LIGHTWEIGHT CONCRETE COMPARISON

"We believe that ultra-lightweight concrete is one of the most fundamental bulk materials of the future." From the book "A Pattern Language" by Christopher Alexander & Associates, Oxford Press, 1977, page 958 [14].

The majority of regular concrete produced is in the density range of 150 pounds per cubic foot (pcf). The last decade has seen great strides in the realm of dense concrete and fantastic compressive strengths (up to 20,000 psi) which mix designers have achieved. Yet regular concrete has some drawbacks. It is heavy, hard to work with, and after it sets, one cannot cut or nail into it without some difficulty or use of special tools. Some complaints about it include the perception that it is cold and damp. Still, it is a remarkable building material - fluid, strong, relatively cheap, and it is available in almost every part of the world.

Lightweight concrete begins in the density range of less than 120 pound per cubic foot. It has traditionally been made using such aggregates as expanded shale, clay, vermiculite, pumice among others. Each has their peculiarities in handling, especially the volcanic aggregates which need careful moisture monitoring and are difficult to pump. Decreasing the weight and density produces significant changes which improves many properties of concrete, both in placement and application. Although this has been accomplished primarily through the use of lightweight aggregates, since 1928 various preformed foams have been added to mixes, further reducing weight. Lightweight concrete mostly ranges between 300-1600 Kg / cubic meter (19-100 lbs / cubic foot). Comparing papercrete densities of 300 Kg / cubic meter (19 lbs / cubic foot) to 582 Kg / cubic meter (36 lbs / cubic foot) with above mentioned lightweight concrete ranges of 300 to 1600 Kg / cubic meter (19 to 100 lbs / cubic foot), we can easily say that papercrete falls in a reasonable good category of lightweight concrete as shown in Figure-7.

Fig. 7 – Papercrete Comparison with Lightweight Concrete

DISCUSSION

Waste paper is defined as used newspapers, magazines, journals, books and cartons. In general, such waste represents up to 33% of total waste in countries which could negatively impact the environment, if not properly handled. The potential harm of waste paper briefly listed as:

- Waste paper normally ends up in garbage disposal dumping sites in quantities that exceed the capacity of the landfill site for such waste.
- Waste paper would be dumped along with the other types of waste materials. As a result of the excessive humidity conditions, mosquitoes and other insects multiply at very high rates.
- Burning the waste materials causes pollution to the atmosphere, environment and nearby localities.

Utilizing and recycling waste paper serves to eliminate above harmful effects and results in the following benefits:

- Disposing of waste materials in an economical, scientific way.
- Preservation of the environment
- Raising environmental awareness and healthy practices of the public.

As a reference the Author would like to quote an example from Brazil. Due to environmental, social and economic reasons, the recycling of solid waste is an expanding activity in Brazil. According to the Business Commitment to Recycling (CEMPRE), compared to other countries, the Country presents high levels of recycling, and has potential to develop even more in this area, (Recycling, Bracelpa) [15].

Besides being its renewable source, paper is among the products that have the largest recycling rates in Brazil. In total, 43.7% of all papers used in the country in 2008 were sent to recycling post-consumption, according to Ciclossoft Research from

the Business Commitment to Recycling (CEMPRE). Besides, a large quantity of wastepaper is used in the manufacture of other products – such as roofing tiles – whose volume is not included in statistics. Additionally, the recovery of material after its consumption helps decrease the volume of debris dumped in the already filled-to-capacity sanitary landfills, (Paper Recycling) [16].

Thus, instead of overburdening landfill site with waste paper, it seems to be a better and efficient way of utilizing paper waste in making papercrete which in turn will result in resource efficiency and will be a step towards sustainable development. Papercrete with its good insulating quality can be utilized in energy efficiency there by saving our precious energy resources and further having an additional effect / achievement towards sustainable development. We need to develop a thought process in order to save our precious resources and use the material and energy resources efficiently.

CONCLUSIONS

- Instead of burning and dumping in landfills, Papercrete is an effective and environmental friendly way of taking care of the paper waste material.
- Papercrete can become an important means of resource efficiency as it recycles paper waste into a useful building material. Resource efficiency in turn leads to sustainable development.
- Papercrete can effectively be used in low cost houses in masonry walls in the form of blocks or by pouring into wall formwork.
- In multistoried buildings structural weights could also be reduced by having papercrete partition walls.
- Papercrete can be used in roof insulation resulting in reducing energy cost that is contributing to energy efficiency and in turn the environment.

Abstract— Most of the countries are placed in a seismic zone which has high activity and has extremely experienced large-scale losses due to several destructive earthquakes such as Turkey. Therefore, governments are seriously trying to produce the projects that will significantly reduce the earthquake effects in order not to experience this kind of potential disasters. The most important part of these projects is urban regeneration. Within the context of urban regeneration activities, renewal of the buildings which have low earthquake-resistant is targeted. While the earthquake resistance level of a building is decided, one of the important steps is the determination of the strength of the building materials. There are many standard NDT methods that will be able to be used to determine the compressive strength. However, it is necessary to choose the appropriate methods in order to quickly and reliably estimate the strength properties of the materials. The purpose of this study is to determine the optimum NDT method for the urban regeneration. So, feasibility analysis was carried out for the standard NDT methods, and the performance of these methods was evaluated based on the cost and the accuracy. The result is the requirement new NDT method which is the practical and efficient for the large-scale projects such as urban regeneration.

Keywords—*NDT; compressive strength; urban regeneration; in-place test; earthquake*

I. INTRODUCTION

The most popular performance measure which is used by design engineers to estimate the actual strength of concrete is the compressive strength, which is usually measured by breaking cylindrical or cubic specimens in a compression-testing machine. The compressive strength results can be used for the quality control, the formwork stripping times, the curing times, the fault diagnosis on the existing reinforced concrete/masonry structures, the research works, and the in-place strength of concrete/mortar. Specifically, it is critical to estimate the in-place compressive strength of concrete, mortar

and rock to establish the safety of the concrete and the masonry buildings. Because most of the countries in the world are frequently exposed to the destructive earthquakes. After these earthquakes and tragedies, millions of buildings were severely damaged or collapsed [1-7]. To figure out this problem, the governments have been trying to renew the buildings using urban regeneration/transformation policy or post-earthquake rehabilitation and reconstruction before the earthquakes [8, 9] and, for instance, Turkey is one of these countries. Urban regeneration was regulated with the Law: “The Regeneration of the Areas under Disaster Risk (Law No: 6306)” in Turkey in May 2012. Decreasing the risk before the disasters, which are especially earthquakes, is aimed at this law [10]. Minimizing the risk before the earthquakes mean that hundreds of thousands of existing buildings, which have low earthquake resistance or insufficient resistance, should be renewed. First of all, earthquake resistance of these buildings, namely safety, must be determined. The in-situ strength of concrete, mortar and rock is an important part to establish the safety of the buildings [11].

Urban regeneration projects where the buildings have been rebuilt, include not only a building, but also at least dozens of buildings. Although the earthquake resistance of these buildings which are usually reinforced concrete or masonry buildings are estimated to be weak or inadequate, this problem still legally needs to be proven. For this reason, it is necessary to estimate the in-place compressive strength of the concrete in the buildings. Standard NDT methods and drilling core method are usually used together to estimate the strength properties of the concrete. However, since the number of buildings is very high, the cost of determining the strength of the concrete is greatly increasing. In addition, a considerable amount of time is lost. It is critical to determine the concrete strength quick and reliable so that urban regeneration projects continue economically and rapidly.

Many standard NDT methods, such as UPV, rebound hammer, and penetration tests, are presently used to estimate the strength of the concrete. In this paper, the most preferred standard NDT methods are evaluated in terms of cost, reliability and practicality, and a feasibility analysis is carried out considering carefully requirements and expectations. The purpose of this study by the feasibility analysis is to provide the possibility of comparing the NDT methods for the researchers and engineers. So, they will be able to determine the most effective method for their projects at the earliest convenience. Consequently, a practical graphic-based method is proposed to choose the NDT methods to be used in urban regeneration projects.

II. NDT METHODS

There are many NDT techniques used to determine the concrete strength. The most known of these can be listed as follows:

- Rebound Number (Schmidt Hammer Test) [12, 13]
- Ultrasonic Pulse Velocity [12, 14]
- Penetration Resistance (Probe and Pin Tests) [12, 15]
- Pullout Test [12, 16]
- Break-off Number [12, 17]
- Maturity Method [12, 18]
- Cast-in-place Cylinders [12, 19]
- PNT-G Test [20]
- Drilling Resistance [21]
- Nail Penetration [22]
- Twist-off Test [23]

For the feasibility analysis, the NDT methods just used in the standard, current, and for existing buildings have been taken into consideration, and their characteristics have been clearly presented.

A. Rebound Number Test

The rebound number test is technically a test for surface hardness, and it approximately provides for establishing relationship between the rebound hammer number and the compressive strength of concrete. The Rebound Hammer has been around since the late 1940s and today is a commonly utilized method for estimating the in-place compressive strength of the concrete. Basic operation of the rebound hammer test is illustrated in Fig. 1. Schmidt Hammer is usually used for this test [24].

The tests can be carried out in horizontal, vertically upward, downward or any intermediate angled positions. The rebound hammer is simple to use, and a large number of readings may be obtained in a relatively minimum amount of time. This method is non-destructive and characteristically more economical than other NDT methods. However, with

these advantages come disadvantages related to technical limitations on accuracy, and the need for exact calibration and correlation with cores for assessment of an existing structure [25]. The surface texture, moisture content, and carbonation significantly affect the rebound (R) number of the tests.

Fig. 1. Operation of the rebound hammer as schematic [12].

The advantages and limitations of the RH test should be recognized and figured on if the rebound hammer will be used for a large-scale project about existing buildings.

B. Ultrasonic Pulse Velocity (UPV) Test

Pulses of the waves are produced by an acoustical transducer that is kept in contact with one surface of the concrete under evaluation. After traversing through the concrete, the pulses are gotten and altered into electrical energy by a second transducer placed a distance L from the transmitting transducer. The transit time T is directly measured electronically. The pulse velocity V is calculated by dividing L by T . The operational principle of modern testing equipment is illustrated in Fig. 2 [14].

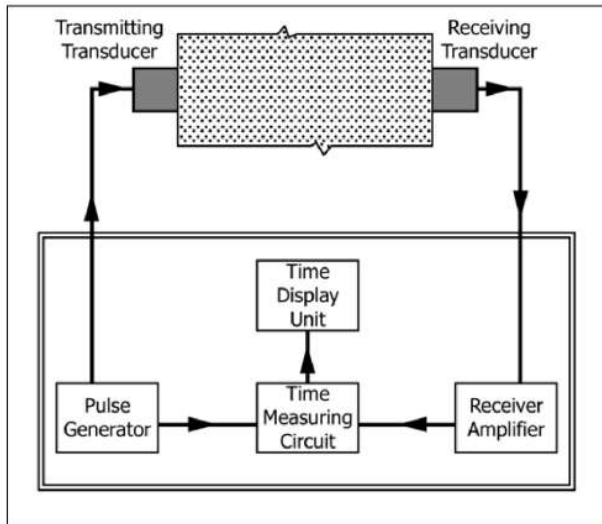

Fig. 2. Schematic diagram of the pulse velocity test [14].

UPV can be utilized for the following properties [26]:

- Estimation of the relationship between the strength and the pulse velocity.
- Estimation of uniformity of the concrete.
- Assessment of alters obtaining with time in the common properties of the concrete.

There are three possible configurations where the transducers can be settled as illustrated in Fig. 3. These are direct transmission (Fig. 3a), semidirect transmission (Fig. 3b), and indirect (surface) transmission (Fig. 3c). Indirect transmission should be used when only one face of the concrete is available. These configurations provide significant advantages for estimation of the in-place strength of the concrete [25].

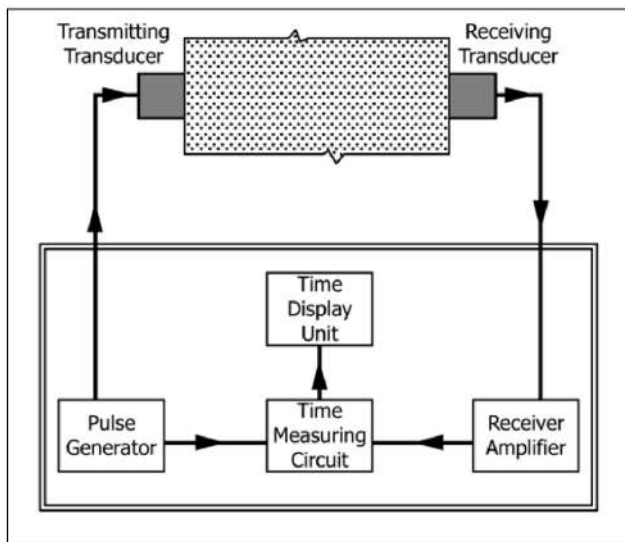

Fig. 3. Configuration of the UPV test application [25].

UPV method adequately provides the examination of relationship between the compressive strength and the pulse velocity of the sample, but the test results of UPV are affected by moisture content, properties of aggregates, cracks, voids. The usability of UPV test is much more limited to predict the compressive strength of concrete, mainly owing to steel reinforcement bars in concrete because the pulse velocity through steel is about 40% greater than through concrete. These limitations should be considered before preferred the UPV method [27, 28].

C. Pin Penetration Test

Nasser and Al-Manaseer described an NDT in which a new production hammer that forces a steel pin into the concrete is used to estimate the when it is safe to remove the concrete forms [29]. The apparatus occurs a spring-loaded hammer which may follow a pin of 3.56mm diameter and 30.5mm length with the tip machined [15].

Fig. 4. Configuration of the UPV test application [29].

The spring is forced by pressing the hammer against the surface of the concrete, and is released by a trigger causing the pin and the attached shaft and hammer to strike the surface of the concrete with an energy of about 108 Nm. After cleaning, the hole depth generated is measured with a dial gauge device [28]. There is an acceptable correlation between the pin penetration and the compressive strength of the concrete. Pin penetration (depth of the blind hole in the concrete element) test which requires less energy than the Windsor probe test. The pin test, although easy in concept, has technical disadvantages. The pin penetrates only a small depth into the concrete, and thus, the results can be seriously infected by the properties of the concrete at the surface.

D. Windsor Probe Test

The probe-penetration technique requires the use of a specially designed gun to run the steel probe into the concrete [15]. (This test system is commonly known as the Windsor Probe Test, as seen in Fig. 5).

Fig. 5. Windsor Probe Test equipments.

The Windsor probe test, like the rebound hammer test, is a hardness tester, and its inventors maintain that the penetration of the probe shows the exact compressive strength in a localized area is not certainly true [30]. Nevertheless, the probe penetration does refer to the some property of the concrete, so it has been possible to improve empirical correlations between the compressive strength and the probe penetration [25]. Schematically, failure of the concrete during Windsor probe penetration test is illustrated in Fig 6.

Fig. 6. Failure of the concrete during Windsor test schematically [28].

The advantages of the Windsor probe test are [25, 28, 31]:

- The test is adequately fast, and the result is obtained immediately provided an appropriate curve with good correlation is ready for use.
- The correlation with the concrete compressive strength is changed by a relatively small number of variables.
- Application is only required to one surface.

The limitations of the Windsor probe test are [25, 28, 31]:

- The test damages an about 8 mm blind hole in the sample in which the probe penetrated and, in elder concrete, this zone around the point of the penetration is usually broken.
- The least distance from a test location to any edges of the concrete sample or between two tests location is of the order of 150 mm to 200 mm.
- The distance from reinforcement can also be affected the depth of the penetration, especially if the distance is less than about 100 mm.
- The least thickness of the sample, that can be tested, is about three times the estimated depth of steel probe penetration.
- The costs of the operations are really high.

Although the PR method has some advantages, it is particularly sensitive to characteristics of aggregate and minimum member thickness, which can be tested. The advantages and limitations of the Windsor probe test should be recognized and taken into account if this test will be utilized for the existing buildings.

III. URBAN REGENERATION AND THE IN-PLACE TEST

Turkey connects the tectonic plates that are including the Eurasian, Arabian, and African and the Anatolian plates [32] and Turkey has a high seismic activity because of its location. Many destructive earthquake occurred in the past two decades in Turkey and the social and economic damages were really

huge [33]. So, Turkey is really important model to evaluate for the urban regeneration.

The Turkish earthquake knowledge and data regarding urban projects are seriously little and limited. In urban areas, risks related not only community services and infrastructure but also housing [34]. Erzincan earthquake which occurred in 1992 supplied valuable data to understand the dangerous of the building stock which has not been enough earthquake resistance. However, unfortunately, this experience was not enough to protect from the disasters which were occurred in Kocaeli (1999), Bingol (2003), Van (2011) et al [7].

Critical amount of Turkey's building stock does not comply with either the design codes, standards, and specifications that were efficient at the time of their built, or the ever more stringent modern design code applied today. It is not practicable to perform reliable estimates of seismic losses due to aforementioned complexities. However, researches based on the scenario earthquakes possible to Istanbul harshly predict 30.000 – 40.000 heavily damaged structures and eleven billion in direct losses due to damage to buildings [33]. The building stock which has low earthquake resistance is a very serious problem threatening many countries like Turkey. To solve this problem, governments are trying to produce efficient urban generation projects.

Urban regeneration is a first step in the rebuilding of a part of the cities, and that it has been designed as a governments-assisted urban regeneration strategy. The origin of the conversation of urban regeneration within the Turkish planning literature was an extension of government programs that were formed by efforts to secure a place in the 1980s world order [35]. Disaster risk resulted from the destructive earthquakes has become the main theme of the urban regeneration in Turkey, especially, in the last decade, and has soon become the primary reason for the application of urban regeneration projects with the Law on the 6306, "Regeneration of Areas under the Risk of Disasters", which was accepted on 16.05.12. This has added to the "legality" of urban regeneration projects that will be implemented all over the country with a quick and public model of rebuilding [36].

One of the most important parts of the existing urban regeneration projects is to determine earthquake risk levels of the buildings. When the risk levels of the buildings are determined, one of the basic steps is estimation of the compressive strength of the concrete. Determination of the strength of the concrete by just using the core drilling method is expensive, difficult and time-consuming. Therefore, as far as possible, the destructive methods should be used as minimum and NDT methods usually should be used. Even so, it is not easy to select the most suitable one/more from many NDT methods. Accordingly, in this study, a feasibility analysis was carried out for NDT methods in line with the urban regeneration requirements.

For the urban regeneration projects, estimation of the in-place strength of the concrete is the topic of discussion. Because, as all NDT is unsuitable for determination of the in-

place concrete strength, and also any NDT may not be suitable for urban generation projects.

Since the 1900s, there has been an ongoing investigation of the in-place strength of the concrete [37]. Although there are many in-place test methods, very few of them are standard [38, 39]. The standard methods have many advantages such as comparability with the previous works, experience, and easy reachability to the test equipment.

IV. FEASIBILITY ANALYSIS OF THE NDT METHODS

Feasibility analyses are originally formed by social scientist. In this study, the feasibility studies made is one of the first examples of its kind, and these methods will hopefully be more commonly performed in the future researches. A feasibility analysis estimates and observes an economic opportunity based on certain theory and estimations that have been put forward in the process of starting a new project [40]. Feasibility analyses aim to decide whether a business opportunity is possible, practical, and workable [41]. A number of the factors are considered and assessed in a feasibility analysis to calculate the most effective results.

Within the framework of urban regeneration projects, to determine the in-place strength of the concrete, priority expectations from the NDT methods are listed below:

- Economy (cost of the operation)
- Time (minimum labor and test time)
- Accuracy (more than 90%, if possible)

The critical issue for the project is that the cost of the operation should be more economical than the cost of the test equipment. The approximate cost of the operations and test equipment are presented in Table 1.

TABLE I. COST INFORMATION FOR THE NDTs

NDT Methods	Operation Cost (\$)	Equipment Cost (\$)
Rebound Hammer	Only labor	\$300.00
UPV	Only labor	\$4000.00
Pin Penetration	\$10/each	\$5000.00
Windsor Probe	\$18/each	\$5500.00

In order to be able to apply the tests in Table 1, there must be no plaster or coating on the surfaces of the concrete elements. If it is present, it has to be removed from the concrete surface. So, it is assumed that the labor that is for removing the coating will be in equal amounts, \$100, for all the tests.

At least three tests should be performed to determine the compressive strength of the concrete. These three tests are accepted as a set. In order to compare NDT methods, a certain number of test must be taken into account in feasibility analysis. Windsor probe test is taken as reference to determine this numerical value. This value is the test number that makes

the cost of the operation equal to the cost of the equipment. The number of the tests = $5500 / 18 \cong 305$.

Two parameters were used for feasibility analysis. The first is based on cost; the second is based on the benefit. The parameters of the analysis are explained in Table II.

TABLE II. PARAMETERS OF THE FEASIBILITY ANALYSIS

NDT Methods	CO/CE ^a	T ^b	A ^c	T/A ^d
Rebound Hammer	0.3	3	3	1
UPV	> 0.1	2	2	1
Pin Penetration	0.63	3	2	1
Windsor Probe	1	3	1	3

^a. CO/CE=(Cost of operation + labor) / cost of the equipment

^b. T: Application Time (0–15 min: 3, 16–60 min: 2, more than 60 min: 3)

^c. A: Accuracy (Excellent: 1, Good: 2, Approximate: 3)

^d. T/A: Time/Accuracy

The rate of CO/CE is developed to consider the cost effect on the choosing of the NDT. The rate of T/A is developed to consider the technical benefit on the selecting of the NDT.

Graphic based feasibility analysis is illustrated in Fig. 7. If it is desired to determine as fast, practical and approximate whether an NDT method is suitable for an urban regeneration project, first, the numerical values of the parameters of this method, CO/CE and T/A, are calculated. And then, these parameters are marked on the graphics, finally; the feasibility region is determined by Fig 7. The RED, YELLOW and GREEN Zones mean the unfeasible, acceptable and feasible NDT methods, respectively.

Fig. 7. Graphic of the feasibility analysis.

V. DISCUSSION AND RESULTS

Graphic based feasibility analysis is performed for the standard NDT methods, and result of the feasibility analysis are given in Table III.

TABLE III. FEASIBILITY RESULT OF THE NDT METHOD

NDT Methods	Feasibility Zone
Rebound Hammer	YELLOW
UPV	YELLOW
Pin Penetration	YELLOW
Windsor Probe	RED

Rebound hammer, UPV, pin penetration, and Windsor probe tests are in the yellow and red zones, respectively. Existing methods are not feasible but acceptable methods to utilize for the urban regeneration projects. Because these methods, which are in the yellow zone are neither economical nor sufficiently useful. The Windsor probe test is unfeasible because of the cost of the operation. This method is reliable and practical. However, cost of the operation of Windsor Probe test is so high. It is evident how large the economic loss will be, if it is assumed that the test will be used for tens of thousands of buildings in urban regeneration projects.

The proposed method in the current paper is a preliminary and practical method. This feasibility analysis can be used in non-standard NDT methods. However, accuracy must be carefully determined. The most important thing is that these analysis are done by experienced engineers. Because, if every numerical result passes from the engineer's filter, it gains significant value.

VI. CONCLUSION

Urban regeneration has become a strategy to avoid the earthquake damages in many countries like Turkey. Because the target is building stock, the strength of the concrete, which is the most-used material to produce the buildings needs to be determined. A feasibility analysis was carried out for the methods of determining the in-place concrete strength in this study. Following are some of the important conclusions.

- The number of drilled core specimens should be reduced as much as possible while the concrete strength is determined as the number of buildings in urban regeneration projects is too high. Even if it is possible, reliable results should be tried to be obtained without using destructive methods. It can be economically and quickly carried out.
- The efficiency of an NDT method by the help of the graphic based feasibility method can be evaluated with cost, time and accuracy limiters.
- None of the existing methods are in the green zone when the feasibility analysis performed. This

conclusion implies that a new feasible NDT method is required.

- Windsor probe test has high accuracy but not economic. So, it can be used for the specific works.
- None of the existing NDT methods can be applied to surface that has coating. Before the NDT is applied, the coating/plaster must be removed. Therefore, a new NDT is required to test the concrete elements without removing the coating, especially for the urban regeneration projects.

Abstract— Turkey is one of the countries, which is on the risky earthquake zone. Turkey has been exposed to destructive earthquakes many times and has experienced significant losses. The reason of these huge losses is the building stock which has not earthquake-resistant. Although a significant part of the existing building stock constitutes masonry structures, the number of masonry structures in newly constructed structures is steadily decreasing. In this study, the seismic codes and the performances of the masonry structures after the earthquakes have been widely examined. The reason for this review is to be able to decide the future strategy of masonry structures. As a result, the importance of necessary has not been given to the design of the masonry structures in Turkey. If the masonry building technology were supported enough, it would be realized that to construct the masonry buildings is easier and more economical than reinforced concrete buildings, which have earthquake-resistant. It is greatly desired that this study will create a new perception of the design of the masonry buildings in Turkey.

Keywords—masonry buildings; earthquake; performance; seismic codes; Turkey

I. INTRODUCTION

Masonry means a well-proven building material owning superior properties in terms of appearance, durability and cost in comparison with options [1]. Even so, the characteristic of the masonry in a building depends on the materials used, and therefore, all the masonry materials must adjust to certain minimum rules and standards. The fundamental elements of the masonry are brick, blocked stone, and mortar [2].

In Turkey, the existing building stock is usually consisted of the masonry and the reinforced concrete buildings [3]. However, considering the new buildings, the rate of the masonry buildings is decreasing gradually. New-generation buildings are being constructed as reinforced concrete both in the cities and in the rural areas. Even if new structures build as

masonry buildings, many of these buildings have so little engineering experience [4]. This situation may lead to prolonged problems in the future. The degree of these problems often arises after destructive earthquakes.

Turkey, after many destructive earthquakes, has experienced significant losses. In particular, the earthquakes of Erzincan [5], Marmara [6], Bingol [7], Elazig [8], and Van [9] have not been erased from the memories. After these earthquakes, and the damages some strategies are developed to reduce the losses. Unfortunately, the strategies commonly are based on the reinforced concrete structures. Although the masonry buildings are so important, but they are sometimes overlooked, and this overlooked detail causes significant problems.

If the new-generation structure strategy is planned by considering with masonry buildings, great economic advantages will be achieved [10]. The main reason for economic losses is due to the buildings in the rural areas. Required construction quality cannot be achieved for the structures built in the rural areas due to many reasons. Some of these reasons can be described as follows:

- Ready-mixed concrete plants are far from the rural areas
- Difficulties in finding the masters for the construction
- Difficulty of on-site concrete producing

For these reasons, the performance of the buildings can be low under seismic loading, so, the service life of these buildings is under the expectations. In addition, the structures are more suitable to be built in-place. The masonry buildings are more economical and the safe when considering their service life, since they have the less number of the floor and the floor area.

The purpose of this study is to draw attention to the importance of the masonry buildings. The increase in the

number of high-quality buildings will contribute to the economy of the country and the safety of its citizens in natural disasters like earthquakes. The strategy of this paper certainly does not mean that the earthquake resistance of reinforced concrete structures is weak. Every structure that is planned and built according to the seismic codes and the standards is robust. However, the main topic to be emphasized in this study is that the structure system must be selected by taking into account the conditions. In Turkey, the masonry buildings seem more suitable for rural areas, which are far from the cities and counties. As a result, it is very important, first, to develop a design code only for the masonry buildings, then to use masonry structural system in rural areas, for the life safety and the national economy.

II. MASONRY MATERIALS AND CONSTRUCTION SYSTEMS

Masonry building is one of the oldest forms of structure known to humanity. The name masonry refers comprehensively to brick, tile, stone, and concrete-block. In this section, masonry materials, units, types and design of the masonry construction systems are presented.

A. Masonry Units

The most popular buildings materials are brick and stone. Using brick has major advantages like has serial production, easy operation, economic, etc. Several popular uses of units in the masonry buildings are given as follows [11]:

- Valve vaults and manholes
- Backing for stones and bricks
- Curtain walls, party walls and firewalls
- Plasters and coatings
- Load-bearing walls (exterior and interior)

B. Masonry Materials

Bricks are made of calcium silicate or fired clay. Every country almost has its own standards for bricks. The compressive strength, frost resistance, absorption, dimensional changes, sulfate attack, and fire resistance tests are performed for the bricks. More than 90% of the masonry structures in Turkey are built with bricks [12].

Mortar is the mixture of the lime and/or cement, aggregates and water. Occasionally, mineral or chemical admixture are added to mortar to improve its fresh/hardened properties [13].

C. Mortar Joints

Mortar joints have a significant role in the bond designs and quality of a wall [14]. Thickness of the mortar joints are greater than the 3 mm for traditional mortar. Mortar joints can be finished as specified, when the surfaces of the masonry walls are not to be coated. Several types of the masonry joints are illustrated in Fig. 1.

D. Masonry Construction System

Masonry buildings, which mainly occur structural elements,

walls and floors, are box-type constructional systems [15]. The steel ties or reinforced-concrete floor levels to connect the walls. During earthquakes, floors should behave as a rigid horizontal diaphragm.

Fig. 1. Masonry joints of uncoated walls [16].

Although there are many different masonries, these can be collected in three general groups.

- Unreinforced/plain masonry (Fig. 2)
- Confined masonry (Fig. 3)
- Reinforced masonry (Fig. 4)

Plain masonry is obtained by just using the brick/stone/block and the mortar. It has basic design and is non-ductile structural materials.

Fig. 2. Plain masonry walls [17].

If masonry structural walls are confined with reinforced concrete on all four sides, this constructional system called as confined masonry. The confined masonry is not design to resist

seismic and the vertical loads. Their purpose of the construction mainly supports the floors.

The steel rebar or mesh is inserted in the mortar or placed in the holes and filled with grout is a construction system that

named as reinforced masonry. The resistance and the energy absorption capacity of the masonry buildings under seismic loads can be improved by using reinforced masonry system.

Fig. 3. Confined masonry walls [17].

Fig. 4. Reinforced masonry walls [17].

III. SEISMIC CODES AND STANDARDS IN TURKEY

When the natural disasters are mentioned in Turkey, the first earthquakes come to mind [18]. Since the earthquakes greatly affect the structures, the design codes have been constantly renewed so that robust structures can be built [19]. Seismic design codes [20], which were established from past to today are listed as follows:

- 1940 - Temporary building regulation in earthquake zones [21].
- 1944 - Temporary building regulation in earthquake zones [22].
- 1949 - Turkish building regulation in earthquake zones [23].
- 1953 - Regulation for structures in disaster areas [24].
- 1962 - Regulation for structures in disaster areas [25].
- 1968 - Regulation for structures in disaster areas [26].
- 1975 - Regulation for structures in disaster areas [27].
- 1998 - Regulation for structures in disaster areas [28].

- 2007 - Regulation for structures in earthquake areas [29].

In the first regulation published in 1940, a design method for the masonry buildings was not contained. In this regulation, constructive rules were given for the masonry buildings according to seismic zones (Zone I and II). Minimum limits for the structural elements such as height and number of the floors, wall lengths and thickness were determined.

There were no significant updates in the regulations established in 1944. However, in the regulation published in 1949, the number of rules related to masonry structures is increasing, and the content becomes more comprehensive. In particular, there were important explanations about the beams which were placed on the structural walls.

In the 1953 disaster regulation, significant developments were noteworthy. The structures were classified, and the rules are effectively separated for each structure. The rules of the masonry structures were given for different sections such as foundation, walls and flooring.

In the 1962 disaster regulation, dynamic analysis was applied the first time to the structure design. In the disaster regulations of 1968, 1975, 1998 and 2007, important developments were made in the sections related to reinforced concrete structures; however, the masonry buildings did not have the same development.

In the current regulation, there are only rules about the plain masonry structure. The design rules of confined and reinforced masonry buildings should be in the earthquake regulation. For this reason, efficient strategies have not been able to develop for the masonry buildings which are earthquake-resistant [30].

IV. SEISMIC PERFORMANCE OF THE MASONRY BUILDINGS

Seismic performance of the plain, confined, and reinforced masonry buildings are evaluated in many research, especially, after the destructive earthquakes [31, 32]. The seismic performance of the masonry buildings can be clearly explained by macro-seismic scales, also named intensity scales, as seen in Fig. 5. The macro-seismic scale has five damage grade to determine the damage class of the plain masonry buildings. These grades are explained as follows [33, 34]:

- Grade 1: There is no structural damage for the walls. It can be seen hair-line cracks in few walls and small damages for plasters.
- Grade 2: The buildings have slight structural damage. There are bigger cracks in the wall and moderate damage for plasters/
- Grade 3: There are substantial heavy damages. The cracks are large and extensive and placed in most walls. The roof and non-structural elements has significant damage.

- Grade 4: The building has very heavy damage. All the elements, structural and non-structural have very heavy damage. There are serious failure of floors, roof and the walls. It is no longer possible for the building to be restored and reused.
- Grade 5: The building is partially or completely collapsed. Destruction and very heavy structural damage.

Fig. 5. Damage classification of the masonry buildings [33].

While the damage levels of the buildings are determined after the earthquakes, the important consequences relevant to the masonry buildings are noteworthy. There are many types of masonry structures, in addition, the most commonly used types of these structures have stone and brick walls. Today, all of the masonry buildings are almost built by using bricks.

If the investigations on the buildings after the destructive earthquakes in Turkey and elsewhere are considered, there is general satisfaction from the seismic behavior of the masonry buildings. Many researchers have stated that in their papers. However, the seismic behaviors of unreinforced, and reinforced masonry buildings are different from each other.

The weakest point of the masonry structures is the non-ductile behavior. The reinforced masonry structures have the high ductility. Especially, old-adobe, field-stone and simple-stone masonry structures do not have the earthquake resistant (Fig. 6 and 7).

Fig. 6. Adobe masonry structure.

Fig. 7. Regular stone masonry structures.

The reasons of the damages of the heavy damaged structures are very critical [35]. With the analyzing of these data, urban and rural structural strategy can be determine. The

reasons of the destructions of the heavy damaged structures are very critical. With the analyzing of these data, urban and rural structure strategies can be obviously determined.

V. DISCUSSION AND THE FUTURE STRATEGIES

When the current seismic zone map of Turkey checks carefully, more than 90% of the Turkish population lives in the high risky zone (Fig. 8). Turkey needs a comprehensive strategic plan for housing. If these strategic plans cannot be made or are not made sufficiently sensitive, unfortunately, Turkey will continue to loss own citizens and physical resources [36].

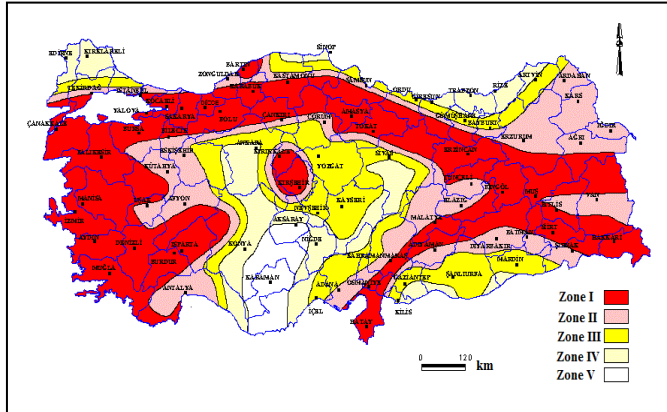

Fig. 8. Current seismic zone map of Turkey.

Planning the housing strategy in Turkey separately for the city and rural areas will provide many benefits. There are two important objectives for the housing process. The first one is life safety during the earthquakes, and the second one is economy. The budget spent for the elimination of losses after the earthquakes in Turkey brings a great burden to the nation's economy. For this reason, the housing strategy is critical [37].

After 1970's there have been huge increases for the building stock. An important part of the building stock is reinforced concrete structures. The majority of the buildings especially in the cities are reinforced concrete. It is interesting to note that the majority of the structures built in rural areas during recent years are reinforced concrete structures.

Unfortunately, after the Marmara earthquakes of 1999, authorities started to work on construction control system. The implementation of the construction control system throughout Turkey is quite new. The problems with the building audit already are continuing [38].

Project, manufacturing, inspection, regulations, rules are inseparable parts of construction. The combining of all of them reveals the strategy of construction. When the 2007 earthquake regulations are examined, the dominance of reinforced concrete structures attracts attention. The reinforced concrete structures absolutely have many advantages. However, it should not be forgotten that they have many disadvantages.

To build earthquake-resistant reinforced concrete structures in rural areas is really difficult due to problems related to

placing of the steel rebar, insufficiency of the building audit, and workers faults. Building earthquake-resistant reinforced concrete structures in rural areas is really difficult due to problems related to placing of the steel rebar, insufficiency of the building audit, and workers faults. Structures have been damaged even during small-scale earthquakes in the past and even if lives were not lost, there were big economic damages.

In the current seismic design code of Turkey, the section related to the masonry buildings is very short. However, today, the masonry structures built as confined, and reinforced masonry buildings. So, it is possible to obtain the earthquake-resistant structures. Economic losses can be reduced by these structures.

Technological masonry structures can be constructed faster and more securely. The potential of the brick production in Turkey supports this advantage [39].

For the development of the new generation of masonry structures in rural areas, firstly, only a regulation of the masonry structure should be published as it is in many countries. This regulation must be prepared by considering the conditions of Turkey. With the new regulation, the sector will gain momentum.

In addition, in the civil engineering departments, and architecture faculties, the masonry structure system should be taught in more detail. In the meantime, the next generation will provide a well development of the building stock.

VI. CONCLUSION

The aim of this study is to summarize the steps of the strategy plan that to take in order to benefit from the advantages of confined and reinforced masonry building technology and to draw attention to its importance. Following are some of the important conclusions.

- For the safe building stock in Turkey, the strategy of the masonry structure needs to be updated. It is the first step of this innovation to publish a new seismic regulation only for masonry structures. Regulation for masonry buildings is a necessity.
- The rules for unreinforced, confined, and the reinforced masonry buildings must be included in the new regulation.
- Economic and robust structures in rural areas will provide significant contributions to the nation's economy.
- The designing and building of both confined masonry and reinforced masonry structures should be encouraged. Seminars and conferences can be organized for importance of the masonry structures.
- In the civil engineering departments, the masonry structures should be introduced in a comprehensive manner. The syllabuses should be updated about the masonry structures which are earthquake-resistant.

Abstract— Hollow block slab is a floor slab system that consists of a thin slab and joists. There are nonstructural materials between joists. Because of advantages of ribbed slabs in architectural areas, the using of this type slabs have become more common. Hollow block slab usually consists of wide and shallow beams. Because of low beam height in this system, its lateral stiffness is less than beam floor systems. Because hollow block slab has low lateral stiffness, there is a risk under lateral loads in buildings that tend to be soft-story. Therefore, in building with hollow block slab should be detailed investigated regarding soft story. For this reason, in this study buildings with stores of 5, 8 and 11, which constructed with hollow block slab were numerically investigated for different ground story height. According to analysis, lateral drift ratios was acquired for each story. As ground story height increased, the lateral drift ratios of buildings with hollow block slab were increased nearly between 33% and 50%. The high values of drift ratios in ground story increase soft-story risk. This situation has a negative effect on building performance under lateral loads. For improving this negative effect shear walls that restrict lateral drift ratios under lateral loads added to the system and analysis was repeated. Because shear walls have decreased drift ratios of buildings nearly between 40% and 60%, the performance of the building is improved under lateral loads. According to results of analysis, in the high seismic zone, it is agreed on that building with hollow block slab should be designed as a wall-frame system.

Keywords— *hollow block slab; soft story; lateral drift ratio; reinforced concrete building*

I. INTRODUCTION

Hollow block slab is a floor slab system that consists of a thin slab and joists. There are nonstructural materials between joists. Hollow block slab provides important advantages such as effective using of story height and interior design in buildings for architects. Furthermore, hollow block slab that has a flat

slab ceiling reduce formwork and construction time. Because of these advantages, the using of this type slabs have become more common.

Hollow block slab usually consists of wide and shallow beams for providing a flat slab ceiling. The height of hollow block slab is determined compatible with nonstructural materials (styrofoam, briquette, tile) that use between joists. In Turkey, the thickness of the hollow block slab is usually 300 mm or 320 mm [1]. Because of low beam height in this system, its lateral stiffness is less than beam floor systems. Because hollow block slab has low lateral stiffness and more clear height of columns, lateral drift ratio in this system may be more under lateral loads, and this system may show weak performance under earthquake load.

In Turkey, the ground story of buildings that is existed two sides of main streets is used as commercial areas. For this reason, the height of this story is more than other stories and infill walls that are existed in upper stories between frames partly or completely remove in ground story. Recent years, in this building, hollow block slab have become more common for using story height effectively and for providing a flat slab ceiling [2]. This situation reduces the drift stiffness of buildings especially ground story and increase the risk of soft-story effect. This situation has a risk for buildings in Turkey where has earthquake zones. In Turkey, the soft-story effect is one of the main reason of damage sustained by reinforced concrete buildings during earthquakes [3, 4].

In this study, soft-story in building with hollow block slab was numerically investigated for different ground story height. For numerically study, 5, 8, 11 stories buildings that are used commonly in Turkey were investigated. Structure analysis software SAP2000 and IdeCAD was used for analysis [5, 6].

According to analysis, lateral drift ratios was obtained for each story. It is shown that as ground story height increased, the lateral drift ratios of buildings have reached limits that have negative effects on building performance under earthquake load. For restricting lateral drift ratios and improving building performance under earthquake load, shear walls added to the system and analysis was repeated. It is shown that because shear walls restrict lateral drift ratios of ground story, the earthquake performance of the building is improved.

II. THE EARTHQUAKE PERFORMANCE OF BUILDING WITH HOLLOW BLOCK SLAB

Over three decades, because of advantages of hollow block slab have been commonly used in Middle East countries including Turkey [7]. Because there is not enough experimental and numerical study that investigate the performance of hollow block slab under lateral loads, the performance of this system under earthquake loads doesn't know as much as beam floor systems. Because there is not enough experimental study that investigates the performance of hollow block slab under earthquake loads, most country's earthquake codes prevent using this system in seismic regions or allow with some requirement about dimensions or spacing of reinforcement using this system in seismic regions [8, 9].

Fig 1. A building with hollow block slab

Hollow block slab (Fig.1.) usually consists of wide and shallow beams. Because of low beam height in this system, its lateral stiffness is low. Because hollow block slab has low drift stiffness, this system may have more lateral drift ratio under lateral loads. In the building, more lateral drift ratios may cause more second order theory. This situation has a negative effect on building performance under earthquake loads. For example, in 23 October 2011 Van-Erciş earthquake, it is shown that damage to infill walls in building with hollow block slab are

more than beam floor system. The reason for this is that hollow block slab that has shallow beam can't restrict the rotation at the end of the column at enough level under lateral loads, and big lateral drift ratios happen in building [13].

Fig 2. A damaged building with hollow block slab after Van earthquake (2011)

In hollow block slab, weak performance because of low lateral stiffness has been considered and restricted by Turkey Earthquake Code (TEC). TEC-1997 and TEC-2007 allow using of hollow block slab in high seismic zones only if structural elements (column, beam and beam-column joints) are designed ductile. If the structural elements are not ductile, shear walls have to be used in the system [11, 12]. TEC-1975 allows using this system in a seismic zone with a requirement which shear walls must be used in this system [10]. But, in existing buildings with hollow block slab, TEC requirements are neglected, and buildings with largely weak performance under earthquake loads have been built. The most important proof of this situation is that these type buildings were heavily damaged in Bingöl Earthquake (2003) and Van Earthquake (2011) [3, 2]. Fig 2. shows a damaged building with hollow block slab after Van earthquake (2011).

III. SOFT-STORY EFFECT

In Turkey, the ground story of buildings that exist two sides of main streets is used as commercial areas. For this reason, the height of this story is more than other stories. Furthermore, infill walls that exist in the upper story between frames partly or completely remove in ground story. In this situation, in the ground story that has big earthquake loads, lateral stiffness of building is decreased, and because of lateral drift ratio, the building experiences degradation of strength. Furthermore, recent years, in these buildings, hollow block slab have become more common for using story height effectively and for providing a flat slab ceiling [2]. Authors think that in these type buildings, the using of hollow block slab reduces the performance of building under earthquake loads. After Van-Earthquake (2011), observations in field influence this opinion. Designing of the ground story with more height than upper story and removing of infill walls of the ground story have

negative effects on reinforced concrete (RC) building performance under earthquake load. Because infill walls restrict lateral drift ratios of the building, infill walls increase the load carrying capacity of the building. For example, a research analyzes performance, under Lorca earthquake, of RC buildings with one-way slabs with wide beams. For buildings, three wall densities are considered: no walls, low wall density, and high wall density. Results show that infill walls increase the lateral stiffness of buildings and decrease lateral drift ratios of buildings under earthquake loads [14]. Especially, because infill walls that exist in the upper story between frames partly or completely remove in ground story, ground story have more lateral drift ratio than the upper story. Past studies show that if infill walls of the ground story are removed, the lateral load carrying capacities of building reduce 30% and the lateral drift ratios of building increase 10% [15]. Although TEC-2007 in the design of reinforced concrete building considers the weight of infill walls, it neglects the effect of infill walls on frame system [12]. The real performances of the buildings cannot be calculated due to this negligence. For this reason, they think that design of these type buildings should be detailedly investigated. Authors are planning a long-term study that considers the effect of infill walls on the building.

IV. NUMERICAL STUDY

In this study, soft-story in buildings with hollow block slab was numerically investigated for different ground story height. For numerical analysis 5, 8 and 11 stories square plan of buildings was investigated. Fig 3. show the typical square plan of buildings. According to common using heights of the first floor was determined for 3.0 m, 3.5 m, 4.0 m, 4.5 m. Except for height of ground story, all heights of stories are 3.0m.

In hollow block slab, the dimension of joists was chosen as 15/32 cm and the dimension of the slab as 7 cm. The nonstructural material was chosen as styrofoam. For providing a flat slab ceiling, heights of all beams of frames was chosen as 32 cm, and for providing enough stiffness, wide of all beams was chosen as 60 cm. Material properties were chosen 25 MPa for concrete compressive strength and 420 MPa yield strength for steel.

Buildings were designed minimum requirement accordance with TEC-2007 and TS-500 (*Turkish Building Code*) [12, 16]. Buildings were designed for first earthquake zone and Z3 soil class. Dimensions of the column in a building stayed unchanged so that only effect of changing of ground story height is investigated. Table 1. presents the dimension of columns and beams.

For linear analysis of design buildings, structure analysis software SAP2000 and IdeCAD was used for analysis. According to analysis, lateral drift ratios was obtained for each story. Two different software, in these sensitive systems, were considered for investigating accuracy rating of software. According to analysis, lateral drift ratios were acquired for each story. For the different height of the ground floor, changing of obtained lateral drift ratios have been presented in tables and graphics. The lateral drift ratios that were obtained from

structure analysis software IdeCAD have been presented in graphics (Fig 4-9). The lateral drift ratios that were obtained from structure analysis software SAP2000 have been presented in tables (show in Table II). The limited number of paper influences this presentation.

According to analyses result in a frame system, as ground story height increased, the lateral drift ratios became more. For designing safety building against to earthquake, TEC-2007 state that the lateral drift ratios can't exceed 2% [12]. But it is shown that as the number of stories increased, the lateral drift ratios have approached limits and the lateral drift ratios of 11 stories building have reached 2%. This increment increases the risk of soft-story.

TABLE I. DIMENSIONS OF COLUMNS AND BEAMS			
	Dimensions of Columns		Dimensions of Beams
	Inside	Outside	
5 stories	45/45	45/45	60/32
8 stories	50/50	45/45	60/32
11 stories	55/55	50/50	60/32

For reducing the lateral drift ratios, in the horizontal and vertical direction in systems, as much as 1% of the area plan, shear walls added to system and analysis was repeated. At both direction, four shear walls that have 30/210 dimension symmetrically added to the system. It is shown that shear walls have considerably reduced the lateral drift ratios and have reduced negative effects from the increment of ground story height. It is shown that in the frame-wall system, lateral drift ratios have reached maximum 1.4%.

V. CONCLUSION

In this study, the performance of hollow block slabs under earthquake loads was investigated regarding lateral drift ratios. The effect of the height of ground story that is designed with more height than an upper story on lateral drift ratios was numerically investigated.

In Turkey, the height of ground story is more than upper story, the effect of this situation on lateral drift ratios was numerically investigated. For numerically study, lateral drift ratios of 5, 8, 11 story RC buildings was obtained for different ground story height. According to analyses;

- For frame structures, it is shown that when the height of ground story reached from 3.0 m to 4.5 m, lateral drift ratios of ground story increased nearly 50%.
- As the number of stories increased, the lateral drift ratios approach upper limit 2% which is recommended by TEC-2007. For 11 stories buildings, drift ratios that are obtained from using structure software SAP2000 reached this limit.

The effect of infill walls was not considered for this study. In case infill walls which are usually used for design are removed

in ground story, it is thought that the increasing in lateral drift ratios will exceed the limit 2% value. Because TEC-2007 don't consider the effect of infill walls on the frame in design, the risk of soft-story is high in these type buildings. For preventing the risk of soft-story, shear walls should be added the systems. It is shown that shear walls reduce the lateral drift ratios of 5 stories buildings on average 65%, 8 stories buildings on average 55%, 11 stories buildings on average 45%. In the wall-frame system, lateral drift ratios reached maximum 1.4%.

Because hollow block slab has low lateral stiffness, it shows weak performance under earthquake loads. This type slabs in the high seismic zone should be carefully designed as a wall-frame system. Furthermore, lateral drift ratios in hollow block slab should be investigated with the effect of infill walls on the building.

Wind-Catchers in Iranian Traditional Architecture as a Sustainable Solutions for Building Ventilation

Saeideh Farnian

Department of Architecture
Karadeniz Technical
University Trabzon, Turkey
s.farnian@gmail.com

Abstract— Sustainability which is one of the most crucial issues in many scientific field has gained a particular significance within recent decades due to the increasing awareness on restriction of irreplaceable energies and risk of energy crisis. A considerable number of studies also are done in field of architecture on designing more energy-efficient and sustainable buildings.

Taking a look at traditional architecture also opens up new windows and gives new perspectives towards sustainability. Environmental and natural conditions have significant role in construction of the region's interrelated cultural, economic, and social infrastructures. Studying the valuable achievements of traditional architecture, not only provides us with precious information about our ancestor's genius on coping with their environmental difficulties and facilitating comfortable living places but also can be inspiring for contemporary architects to design more sustainable works.

In this research, values of sustainable design is handled regarding Iranian traditional and vernacular architecture focusing on one of the most significant elements of Iranian traditional architecture which is called Badgir in Persian.

Wind catcher (Badgir) is a significant element of Iranian traditional architecture which has been used as a natural ventilation element in the buildings throughout centuries and valuable examples of them still exist in diverse Iranian cities located in desert plateau. This architectural element plays a great role in cooling and moderating interior spaces of the buildings located in the central and southern parts of Iran with hot and arid climate.

This study aims to introduce the wind catchers and how their system works since conventional and the modern versions of wind-catchers can be incorporated appropriately into the designs of modern buildings in the hot-arid regions of Iran and other areas of the world with similar climate, to provide summer thermal convenience with less use of non-renewable energy.

Keywords— *Wind-catcher; Sustainability.*

I. INTRODUCTION

A wide range of studies have demonstrated that the issues related to sustainability can influence all aspects of human life. Sustainability principles which encompass a great number of fields aim to improve quality of life for human parallel to

preserving natural and environmental resources and guarantee their durability for coming generations [1].

Hřebík et al. [2] define sustainable development as a better quality of life for everybody, now and for the next generations and it is type of development which meets the requirements of the present without compromising the ability of future generations to satisfy their own needs.

Various tasks are defined in order to achieve a sustainable development some of which comprise attaining a balance between preserving the existing cultural heritage, attracting new investments and supporting existing living and working communities and conserving and improving the natural built environment [3].

These studies raise questions among the policy makers and scholars as well as designers about the effectiveness of sustainable approaches to human activities including architecture. Most studies tend to focus on the issue from view of energy consumption both in terms of energy-efficient modern designs and investigating the roots of sustainability ideology through past but there is still lack of conclusive studies on how the sustainable architecture methods and techniques particularly those employed in traditional architecture can be appropriately used in order to achieve the desired level of sustainability.

Iran is a rather vast country extended from Caspian Sea to Persian Gulf. Therefore, it owns different sorts of climatic conditions in each part of the country. Since central and southern part of Iran is located in hot and arid climate with vast desert regions, Iranian traditional architecture has developed rich vernacular solutions for human comfort in response to difficult climatic conditions of the region. Studying valuable elements and technics of traditional architecture not only provides us with valuable information about our ancestors genius on handling their environmental difficulties and facilitating convenient living places but also can be inspiring for contemporary architects to design more sustainable works. Moreover, gaining such a knowledge on traditional architecture can be guiding in deciding for appropriate usage of technology in a sustainable way [4].

The buildings in Iranian desert regions are constructed according to experiences and knowledge being accumulated by paying attention to climatic and geographic features of the region throughout long centuries and this factor has made them

valuable and worth-studying. Due to lack of any modern heating and cooling equipment in ancient times the architects were obliged to rely on usage of natural energies and utilizing local and climatic potentials of the region to provide interior space with ideal condition and convenience [5].

Wind-catchers (Badgir) can be dealt from diverse perspectives and there are a vast range of subjects about them which worth to be investigated but this study is confined to handle the subject by abstractly expressing what wind-catchers are and how their mechanism work in shade of their relation with sustainability principles. The results taken by studies of this research can enlighten architects to design more sustainable and energy efficient buildings by employing natural potentials.

II. THE STRUCTURAL AND FUNCTIONAL SYSTEM OF WIND - CATCHERS

As a ventilation structure wind catchers were very crucial in cooling interior of the buildings in Iranian traditional architecture. The wind-catcher operates according to the condition of the wind and sun radiation in the region. In ancient times this part of building functioned like the present modern air conditioning system. Wind-catcher is like a chimney whose end is in the underground and the top is set over a specific height on roof and they were majorly built at entrance of the house over underground water reservoirs or ponds built inside house. Dry and warm wind passes over a cool pond which in some cases is equipped with a fountain and gets cooler and gains moisture through evaporation. The system of a wind catcher is schematically demonstrated in Fig. 1.

Fig. 1. Schematic model for the function of wind-catchers

The material of wind catchers is very crucial because of high fluctuation of temperature between day and night in hot and arid climate. They are majorly made by mud-bricks.

Two different types of wind-catchers can be seen in two different parts of Iran. The first type is in the hot and humid area in south (such as Lenghe Port) and the second type in hot and dry area of central plateau (such as Yazd city).

The function of both type is the same while some details of their physical form may vary according to climatic conditions and wind orientation of the region (Fig. 2). Since the function of wind-catcher is to get desired wind and transfer it to internal

space, its dimensions acts as a canal through which the air passes and the ratio of length to height and width to length has particular importance in functionality of it [6].

Fig. 2. Comparing location of wind catchers according to wind direction in Yazd city and Bandar Lenghe [6].

The height of wind catchers are different in each city since the speed and orientation of wind is different in each city. The top of wind-catchers are open and the interior of the shaft is majorly divided to one, two, four, six or eight diagonal partitions in a way that from whichever direction wind blows down, in the opposite direction wind is sucked out. This process ventilates the air within the building [7].

III. FUNCTION OF WIND CATCHERS DURING DAY AND NIGHT

During the day, since the sun rays hit on the southern elevation of the wind catcher, the air in the southern part gets hot. Accordingly its density decreases and the hot air goes up. This air taken above through the inner air of the porch is compensated and in fact it makes a kind of proportional vacuum inside the porch and takes the cool air of the inner court into itself. Therefore, the existing air in the northern opening of wind catcher is pulled down as well (Fig. 3).

Fig. 3. Comparing the function of wind-catcher during the day and night [6].

During the night due to excessive temperature difference between day and night in desert regions, there is a sudden decrease in outside temperature and the cold air which is more dense moves down from wind catcher shaft. This cool air absorbs the heat being trapped within building materials and becomes warm and then goes up. This circle continues until the temperature of the walls and outside become equal.

This is how the system of a wind-catcher is similar to a modern water cooler. When wind enters a wind-catcher, it is channeled to pass above a water pool. After being exposed to water and evaporation process due to absorbing the heat

brought by hot winds of desert, the cool breeze is directed to the summer rooms through small windows [8].

IV. SORTS OF WIND-CATCHERS

Wind-catchers are classified according to their number of partitions which affect their external form. The simplest of them are one-sided wind catchers (Fig. 4). In this type in order to be protected from storms and heavy winds, wind-catchers are built in the direction of the most agreeable wind and are closed off in all other directions [9].

Fig. 4. One-sided wind catchers in Yazd whose entrances are built toward agreeable wind.

As the number of division partitions increases the system of wind-catchers get more complicated (Fig. 5).

Fig. 5. The plans of different sorts of wind-catchers [9].

In those with more than one partition the interior part of wind-catchers shaft usually is divided by brick, wood or plaster partitions to direct the wind to a particular direction.

In Yazd and some other central regions of Iran, multi-directional (eight and sometimes even circular) wind-catchers can be observed. The reason of designing such a sort is that due to extremely hot days in most months of year, these multi-sided wind-catchers can draw agreeable and pleasant winds from almost any direction and channel it into the building to ventilate hot air inside.

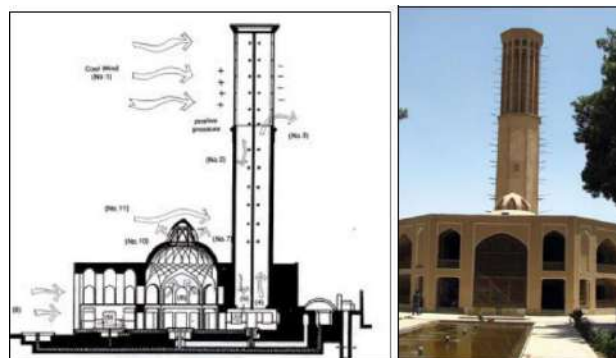

Fig. 6. A section and a picture from Dolatabad Garden, Yazd City [5].

As it can be observed in Fig. 6, this sort of multi-sided wind-catcher performs as the wind hits an obstacle. Since the density of the cool air is more than warm air, on the side of the wind direction where the cool wind is caught by the top of the shaft, a positive pressure becomes generated in this direction while a negative pressure caused by warm air from interior space with less density exist on the other side. Therefore the cool wind is drawn into interior of building and the warm air circulating inside is piped out simultaneously. As mentioned above the wind coming from outside gets moisturized by superficial evaporation of water within a pool and provides building interior with a pleasing air condition [10].

V. CONCLUSION

The wind-catcher which can be counted as one of the masterpieces of Iranian traditional architecture has been used since early times. The results information given in this investigation and other similar studies can have many advantages for us and future generations. Firstly, elaborately studying the application system and construction technics of such a valuable architectural element can help us to better preserve them. Secondly, despite of existing technological facilities of today due to economic and environmental outcomes of using non-renewable energy in ventilation of buildings, wind catchers with their original form and function still can get used particularly as an option particularly in rural areas and the places which has access problem to technological products. Lastly, studying wind-catchers as well as other traditional architecture element can be inspiring for contemporary architects to design more sustainable works.

Abstract—This paper reports an experimental study results on the design of Self-Compacting Lightweight Smart Concrete (SCLWSC) and investigation of some properties produced with acidic pumice. In this study, CEM I 42.5 type N cement and fly ash were used as a binder and powder materials obtaining from Elazığ and Sivas respectively. 6 type SCLWSCs were designed together with carbon based micro steel fibre and micro carbon fibre in different percentages. Acidic volcanic pumice and river sand were used as aggregates. Slump-flow, L-box and V-funnel tests were conducted out to obtain self-compacting concrete properties. Compressive strength, flexural tensile strength and ultrasonic pulse velocity (UPV) tests were applied after 7, 14 and 28 days water curing. Moreover, electrical conductivity tests were performed to identify smart properties on designed concretes for the situations under the flexural tensile load and without any load at 28 day.

Keywords— *Fibre reinforcement; lightweight concrete; self-compacting concrete; smart concrete.*

I. INTRODUCTION

Conventional concrete is composed of aggregate, water and cement and is widely used because of its strength, durability and economy. Because the concrete produced with the advancing technology is produced according to the characteristics of the building elements, it is called special concrete [1]. Heavy concrete, lightweight concrete, self-compacting concrete and fibre reinforced concrete can be given as examples of novel concrete. Every single special or novel concrete is produced for a special purpose. In this study, lightweight, self-compacting and smart concretes have been described firstly because these concretes are constitute the main frame of this work idea.

A. Lightweight Concrete

It is possible to produce concrete by reducing dead-load, earthquake and vertical loads to minimum level by using lightweight aggregate such as pumice, tuff, expanded perlite etc. Lightweight concrete or construction material similar with lightweight concrete was used primarily in a temples in Rome in the year 100 BC with pumice aggregates. In our country, it is seen first in the Hagia Sophia. It was also used in the British Museum in England (1950) as a non-load bearing block. It was used in England after World War II. The first foamed

lightweight concrete was produced in 1950 as a Swedish block. Because natural aggregate source are not sufficient, lightweight concrete is more preferred in Europe [2].

B. Self-Compacting Concrete

Self-compacting concrete (SCC) is invented by the development of effective chemical materials which are influenced by the progressive concrete technology [3]. This special type of construction material is a concrete that does not require any vibration and it can be placed with its own weight without any segregation its constituents [4]. Most commonly it is used that the vibrator-machine can not apply in to the construction elements for concrete pouring. Self-compacting concrete was first developed in 1988 to form a permanent reinforced concrete structure in Japan. The first paper on SCC was presented in 1989 by Ozawa in the East Asian and Pacific Structural Engineering Conference. This declaration by Ozawa was presented at the Canmet & Aci International Conference in Istanbul in 1992, accelerating the announcement of the SCC to the world. This statement has become widespread development of SCC. [3]. Standard test methods for self-compacting concrete design have been developed. The main fresh concrete design tests are slump-flow, L-box and V-funnel test. In the slump-flow test, the spread diameter of the fresh concrete with its own weight gives information about the filling and spreading ability in the moulds. The V-funnel test describes flow-ability of concrete by recording the elapsed time with concrete's own weight. In the L-box test, it is possible to see the concrete's ability to pass between from the re-bars, as well as the ability to fill and flow into the moulds.

C. Smart Concrete

Concrete is simply described as a composite material but has a weak resistance against flexural tensile stresses. Because of these stresses, smart concrete has emerged to prevent all damages that may occur in the concrete [1]. Smart concrete is divided into two classes, externally and internally smart concrete. Such concrete is called externally smart concrete if it is provided in the concrete or on its surface by intelligence by embedding or mounting detectors, exciters and chemicals. It is not necessary to bury the probes in concrete in order to be smart concrete from the outside. By applying silver paint to the

probes, the concrete can be intelligent and traceable [5]. The inner concrete is obtained by adding a very small amount of conductive carbon fiber to the mixture. The carbon concrete, known as the intelligent concrete, was developed and tested by Chung, a professor at SUNY (State University of New York)-Buffalo [1].

The carbon fiber added to the concrete increases the electrical conductivity and gives the ability to follow the concrete. The method of electrical resistance is a method that can determine the damages that may occur in the concrete without damaging it [6]. The electrical conductivity in the carbon fiber-reinforced concrete shows a direct correlation with the volume of the fiber [7]. This fiber increases the bending strength of the concrete and increases the resistivity when exposed to the draw [8]. In this study, the electrical current permeability of concrete designed with pumice stone aggregate and fiber reinforcement, which is prevalent in Bitlis province, was investigated and intelligent lightweight concrete design that settled spontaneously was realized. The technical advantages of the intelligent concrete have been determined by examining the changes in the electrical current permeability of the specimens subjected to tensile stress with this designed concrete.

II. MATERIALS AND METHODS

A. Materials

Portland cement described from the TS EN 197-1 [9] and known as CEM I 42.5 N type was used as a binder material. The cement was provided from Elazığ Çimento Plant in the amount to be used in the experiments and kept under the laboratory conditions that would not deteriorate its chemical structure. The fly ash used in the concrete mix was provided in Sivas-Kangal. Some features of cement and fly ash were given in Table 2.1.

Table 2.1 Chemical properties of fly ash and cement

Content	Fly Ash	Cement
SiO ₂	38.35	21.15
Al ₂ O ₃	16.68	5.65
Fe ₂ O ₃	5.11	3.32
CaO	27.62	62.98
MgO	1.61	2.76
SO ₃	4.43	1.8
Na ₂ O	0.62	-
Other	5.55	-
Spec.Grav. (gr/cm ³)	2.26	3.1
Loss in ign.	0.79	1.79
f _{ce} (MPa)	18.2 (with Cem.)	51.7
Blane (cm ² /gr)	1345	3749

For the purpose of designing lightweight concrete, volcanic pumice aggregate belonging to Bitlis region was used. The aggregate diameter was 16 mm maximum and some physical properties of volcanic pumice aggregates were given in Table 2.2. The sand used as fine aggregate in the mixtures was obtained from Bitlis-Ahlat region. Physical properties related to sand were given in Table 2.3.

Table 2.2 Physical properties of pumice aggregate

Coarse Aggregate Group	Water Absorption Rate (%)	Dry Unit Weight (kg/m ³)	Specific Gravity (kg/m ³)
4-8 mm	38.9	381.7	0.88
8-16 mm	51.8	295.5	0.69

Table 2.3 Physical Properties of Sand

Water Absorption Rate	3.72
Specific Gravity (kg/m ³)	2.22

Sika Hi-Tech Viscocrete-28, a third-generation hyperplasticizer supplied by Sika Construction Chemicals Inc., was used as a chemical additive. The properties of this material is given in Table 2.4.

Table 2.4 Properties of chemical additives

Appearance	Color: Light brown liquid
Ph value	5-9
Chemical structure	Modified polycarboxylate based polymer
Density (kg/l, in 20°C)	1.045-1.085
Freezing point (°C)	-6
Water soluble chlorine (%)	Not more than 0.1%, chloride free

The fibres were added to 0.5% of the cement volume. Carbon fibre taken as a fabric was cut into 6 mm and used in concrete mix. The reason for using this size is that the carbon-based metal fibre and the carbon fibre should be of equal length. The length of the carbon-based metal fibre was 6 mm length. The properties of the fibres were given in Table 2.5.

Table 2.5 Properties of fibers used

	Carbon Fibre	Carbon Based Steel Fibre
Specific Grav. (gr/cm ³)	1.82	7.17
Length (mm)	6	6
Equivalent dia. (mm)	15±3µm	0.15
Length / Diameter	-	40
Tensile Str. (MPa)	4950	2000
Geometry	fibrillated	Straight

B. Method

In this study, the design and properties of SCLWSC with acidic volcanic pumice belonging to Bitlis region were investigated. In particular, the relevant literature, information and documents and resources have been examined. Materials to be used in the study were then investigated. Main materials to be used in the laboratory work; Cement, aggregate, chemical and mineralogical additives had been provided for optimum supply and shortest time. After all these preliminary studies were made, necessary systems and devices were created and experimental studies were done in laboratory conditions according to the standards. Firstly, mixture calculations were made in accordance with the experimental purpose and trial mixtures were prepared based on EFNARC and Turkish Standards [10-14].

In the slump-flow test, the prepared mixture is filled into the funnel. Then the funnel is raised upright in 30 seconds. Fresh concrete is expected to fully spread. The widest span is measured and recorded. This recorded spread was assessed according to the standards. According to EFNARC, the standard limitations of the slump-flow test is given in Table 2.6

Table 2.6 Slump-flow limitation [14]

Class	Propagation Diameter (mm)
SF1	550-650
SF2	660-750
SF3	760-850

The prepared fresh mixture is filled in the V-Funnel and the lid is opened after 10 seconds from the time the top of V-Funnel is cleaned. This elapsed time is recorded by the chronometer. This recorded time is evaluated again according to the standards. According to EFNARC, the limitations of the V-Funnel test is given in Table 2.7.

Table 2.7 V-Funnel test limitations [14]

CLASS	T ₅₀₀ , s	V-Funnel Flow Time
VS1/ VF1	≤ 2	≤ 8
VS1/ VF2	> 2	9-25

In the L-box test, the concrete is poured from the container into the filling hopper of the L-box and allowed to stand for (60 ± 10) sn. Then, the gate is raised so that the concrete flows into the horizontal section of the L-box. When fresh concrete movement has ceased, the vertical distance is measured, at the end of the horizontal section of the L-box, between the top of the fresh concrete and the top of the horizontal section of the L-box at three positions equally spaced across the width of the L-box. The standards limitations on L-box according to EFNARC are given in Table 2.8.

Table 2.8 L-Box Standards according to EFNARC [14]

CLASS	PASSING ABILITY
PA1	≥ 0.80 with 2 rebars
PA2	≥ 0.80 with 3 rebars

After the design process on fresh concrete mixtures, hardened concrete samples were prepared and tested at the ages of 7, 14 and 28-days. Firstly, ultrasonic pulse velocity test was made with the device called Pundit at the same curing ages. The device is calibrated before starting the experiment. The two probes on the device are fixed with jell so that they can come into full contact with the sample. The probes stuck to the samples must be in the same line. In the experiment, three different measurements are made in one sample to minimize the error rate.

In the electrical current permeability test, an alternating current is applied to the samples completing the curing time using the signal generator and multi-meter. Inside the beam sample, two 4x6 cm plate probes are fixed and current is applied. Electrical current permeability test was applied two different way in this study after 28 curing day. Firstly, this alternating current is given at different frequencies (5-1000000 Hz.). Reading the current value in the sample takes 15 seconds and the read value is recorded. In the second application, alternating current is given at constant frequency (25000 Hz.) but increasing the flexural tensile load.

In the flexural tensile strength test, the beam samples (75x75x300 mm) were placed in the device according to the procedures specified in TS EN 12390-5 [15] after completing the curing time mentioned above. For the samples completing 28 curing day, the probes for the plate alternating current in the sample are connected. Once the device is installed, in the same frequency, electrical current and flexural tensile load are recorded. As for the compressive strength test, it was conducted out according to TS EN 12390-3 standard [16].

III. MIXTURE DESIGN AND FRESH PROPERTIES

In the concrete mixtures design, firstly cement, sand as fine aggregate, acidic volcanic pumice as coarse aggregate and mineral admixture were added, then water and chemical additives were added. As for the concrete mixtures including fibres, the same mixture was prepared and the fibres were added by taking care to homogeneously disperse with different percentages and combinations. The reason for paying attention to homogeneity was that the fibres exhibit different electrical behaviour according to the amorphous or crystalline structure [17]. The mix proportions of designed concretes were given in Table 3.1.

Table 3.1 Concrete mix proportions for 1000 dm³

Concrete Type	CTRL	S	S1C1	S2C2	S3C3	C
Water (kg)	160	160	160	160	160	160
Cement (kg)	400	400	400	400	400	400
Fly Ash (kg)	150	150	150	150	150	150
Sand (kg)	989.37	989.37	989.37	989.37	989.37	989.37
4-8 mm Pumice (kg)	46.5	46.5	46.5	46.5	46.5	46.5
8-16 mm Pumice (kg)	55.75	55.75	55.75	55.75	55.75	55.75
Chemical Add. (%)	2.25	2.25	2.25	2.25	2.25	2.25
Carbon Based Metal Fibre (gr)	-	110	82.5	55	27.5	-
Carbon Fibre (gr)	-	-	7.5	15	22.5	30

Fresh properties of designed concrete mixes were determined by applying the SCC fresh state test methods mentioned above (ps. in section II) and obtained results were presented in Table 3.2. Obtained fresh concrete test results are very similar because the only variable is fibre inclusion. The fibre inclusion in concrete design takes so small place (0.5% of cement) in the concrete matrix. For this reason, fresh properties of all designed concretes gave the similar results. This results are suitable for SCC requirements and it can be said that all designed concretes could be called self-compacting-lightweight-concretes.

Table 3.2 Fresh Concrete Test Results

Concrete Mix.	Slump-Flow Diameter (mm)	Slump-Flow Time, T ₅₀₀ (sn)	V-Funnel (sn)	L-box (H2/H1)
CTRL	800	1.97	11.25	0.93
S	790	2.05	7.70	0.95
S1C1	790	2.01	8.25	0.96
S2C2	795	1.95	7.55	0.92
S3C3	795	2.10	10.25	0.95
C	805	2.05	9.05	0.95

After the determining mixture design and fresh properties, SCLWSCs were prepared for hardened state test based on Table 3.1. Prepared SCLWSC samples were removed after waiting for a day in the mould. Then, the samples were allowed to stand for 3-4 hours in laboratory conditions and then left in the pool for water curing at the ages of 7, 14, 28 days in accordance with TS EN 12390-2 [18]. The samples that completed the curing period were removed from the curing-pool and was dried for two days in 50°C so that electrical current measurement stability. The dried samples were stored for 3-4 hours under laboratory conditions. For each sample,

ultrasonic sound permeability test and electrical measurements were performed for varying frequencies. Based on the strength properties of the samples and the differences of changing electric resistance, the electric resistance was monolithically decreased after 14 and 28 days while increased after 7 days tests [19]. Thus, the effect of curing time of concrete was examined.

IV. RESULT AND DISCUSSION

The flexural tensile strength, compressive strength and UPV test results of the prepared concrete samples are presented in Figure 1-3. The electric current values in the different frequency values of these samples are shown in Fig. 4. The current values of each sample under flexural tensile load are also shown in Figure 5-10. When the strength characteristics are presented in Fig. 1-2 and the UPV test results are presented in Fig. 3, it is understood that each concrete gives close results. The main reason why these results are close to each other is that only the fibre inclusion differs in the concrete mix. The fiber materials used do not make a great difference in strength due to the use of a very low percentage of the concrete volume. The flexural tensile strength results of designed SCLWSCs changed between 5.7 MPa and 7.4 MPa after 28 curing day while compressive strength test results varied from 42.1 MPa to 48.6 MPa after 28-day. Figure 1-2 show that concrete specimens using steel carbon based micro-fibres relatively exhibit higher strength properties when examined more carefully. UPV test results also confirm the strength test results (ps Figure 3). When Figure 4, in which the current values are presented under different frequencies, it is seen that the current value increases with increasing frequency value and with increasing amount of carbon fiber. In this figure, it is seen that the worst results are obtained from the control series and interestingly from the carbon based steel fibre including dense percentage in the mix. When Figure 5-10 in which the current values were presented under the flexural tensile loads, if the applied load increased, then the current values increased. The specimens subjected to the test show a sudden decrease in the current value at the time of cracking and breakage. However, in the control concrete where no fibre is used in the mixture, the current value decreases with the increase of the load. This general result suggests that the fracture can be detected by adding carbon based steel and carbon fibres to the concrete structure at certain ratios. The uncommon and interesting result between the Figure 5-10 is presented in Figure 8 and 10. These two figures include the very similar electric current values under the similar flexural tensile loads. S2C2 concrete presented in Figure 8 has 50% of carbon based steel fibre and 50% of carbon fibre while C concrete include 100% carbon fibre. This result is remarkable in terms of economy and smart properties.

V CONCLUDING REMARKS

The SCLWSCs were designed successfully in the frame of SCC criteria. There was no significant change in compressive strength and UPV test results with addition of carbon and steel carbon fibre to concrete. In the flexural tensile strengths, higher strength values were obtained in concrete using carbon based steel fibre. Produced SCLWSCs gave 48.6 MPa (S2C2) compressive strength while flexural tensile strength value obtained 7.4 MPa in the highest range. The current values were increased with increasing frequency without loading on the samples. It has been observed that there is a steady decrease in the current value at the moment when the fracture occurs, while the constant frequency under flexural load has an increase in the current in the fibre-concretes with the increase of the load. On the other hand, the current value of the control concrete under the increasing load was observed to decrease. These results show that carbon based steel fibre and carbon fibre can be used to provide concrete sensing capability. This capability could be called smartness or intelligence property of concrete.

Abstract--In this study, the analysis and design of composite steel I beamed straight bridges were performed by Line-Girder method in SAP2000 package program. Bridge analysis with Line-Girder is done with influence lines classically. The classic Line-Girder bridge analysis is quite complex. Here, based on AASHTO HL-93 truck for bridge analysis, a practical and precise solution method based on Line-Girder is given in SAP2000 program. In practice, a two-span composite I-girder steel bridge is solved. Composite steel I-Girder bridge analysis results are compared for Line-Girder and influence line solutions.

Keywords—Bridge; AASHTO; Steel beams: Line-Girder; Bridge design

I. INTRODUCTION

Steel Girder Bridges are structurally the simplest and the most commonly used on short and medium span bridges. Steel I-section is the simplest and most effective solid section for resisting bending and shear [1], [2].

In this study straight composite steel-concrete plate girder bridges are investigated by the Line-girder method and influence lines. A design example of the two span continuous composite plate girder bridge is given to illustrate the design procedure. ASTM A 709 (Grade 50) structural steel is used for this bridge structure [3].

Concrete with 28-day compressive strength $f_c' = 4.5$ ksi is used in concrete deck slab construction.

The line girder analysis method uses load distribution factors to isolate a single girder from the rest of the superstructure system and evaluates that girder individually. The load distribution factors can be simply determined by some approximate formulae for both straight bridges [4].

II. DESIGN EXAMPLE – TWO-SPAN CONTINUOUS COMPOSITE PLATE GIRDER BRIDGE

A two-span continuous composite I-girder bridge has two equal spans of 165 ft and a 42 ft deck width. The concrete slab is 9.5 inch thick. A typical 2.75 inch haunch was used in the section properties. The elevation and Bridge Cross Section are shown in Figure 1 [4].

Concrete barriers weighing 640 plf and an asphalt wearing surface weighing 60 psf have also been applied as a composite dead load. HL-93 loading was used per AASHTO, including dynamic load allowance [2], [4], [5].

Steel girder I section dimensions for positive and negative flexure regions are given in Figure 2. Steel girder bridges are modeled as beam elements (See Figure 3). Flexural stiffness of composite section is assumed over the entire bridge length even though the negative moment regions may be designed as non-composite for the section capacity. Moment zero points (contraflexure points) of girder bridges are taken as 0.8 times of beam space (i.e. 0.8×165 ft = 132 ft).

A. Bridge Load Calculations

1) Dead Load Calculations

DC dead loads (structural components) include; Steel girder self weight (DC1), Concrete deck self weight (DC1), Haunch self weight (DC1), Barrier walls (DC2).

DW dead loads (structural attachments) include; Wearing surface (DW).

Dead Load Calculations for SECTION1, SECTION 2, DECK, HAUNCH and BARRIER walls are given as follows [4], [5]:

Steel girder self-weight DC1:

$$W_{\text{SECTION},1} = 278.1 \text{ lb/ft}$$

$$W_{\text{SECTION},2} = 439.5 \text{ lb/ft}$$

Deck self-weight DC1:

$$W_{\text{DECK}} = 1425 \text{ lb/ft}$$

Haunch self-weight DC1:

$$W_{\text{HAUNCH}} = 52.5 \text{ lb/ft}$$

Barrier walls DC2:

$$W_{\text{Barrier}} = 320 \text{ lb/ft}$$

Wearing surface DW:

$$W_{\text{Wsr}} = 585 \text{ lb/ft}$$

This calculations are carried out for a per girder.

The following Dead Load results were obtained from the FE analysis (shown Table 1): The maximum positive live-load moments occur at stations 58.7' and 271.3', The maximum negative live-load moments occur over the center support at station 165.0'

TABLE 1. DEAD LOAD RESULTS

	Max (+) Moment [k-ft]			Max (-) Moment [k-ft]	
	Ref(4)	This study		Ref(4)	This study
DC1-Steel	475	476,79		-1189	-1186,18
DC1-Deck	2415	2421,18		-5708	-5689,36
DC1-Haunch	89	89,2		-210	-209,61
DC1-Total	2979	2987,17		-7107	-7085,16
DC2	553	543,7		-1251	-1277,61
DW	1011	994		-2286	-2335,65

The DC1-Total moments calculated as M3-3 in SAP2000 [6] are shown in Figure 4. In this

study, almost 100% results were obtained with SAP2000 Line-girder method.

Fig. 4. DC1-Total moments

2) Live Load Calculations

The following design vehicular live load cases described in AASHTO-LRFD are considered [4], [5]:

- TANDEM+LANE load:** The design tandem consists of two 25^{kip} axles spaced 4.0ft apart. The lane loading consists of a 0.64^{kif} uniform load on all spans of the bridge. (HL-93M in SAP2000)
- TRUCK+LANE load:** The effect of one design truck with variable axle spacing combined with the effect of the 0.64^{kif} lane loading. (HL-93K in SAP)
- TRUCK-TRAIN Negative Moment Loading:** 90% of the effect of a truck-train combined with 90% of the effect of the lane loading. The truck train consists of two design

trucks spaced a minimum of 50ft between the lead axle of one truck and the rear axle of the other truck. The distance between the two 32^{kip} axles should be taken as 14ft for each truck. The points of contraflexure were taken as the field splices at 132ft and 198ft from the left end of the bridge. (HL-93S in SAP)

All live load calculations were performed in SAP 2000 using a Line-Girder analysis. The nominal moment data from SAP2000 was then input into Table 2. An Impact Factor of 1.33 was applied to the truck and tandem loads within SAP2000.

The maximum positive live-load moments occur at stations 73.3ft and 256.7ft, The maximum negative live-load moments occur over the center support at station 165.0ft.

TABLE 2. LIVE LOAD RESULTS

	Max (+) Moment [k-ft]		Max (-) Moment [k-ft]	
	Ref(4)	This study	Ref(4)	This study
HL-93M	3725	3716.79	-3737	-3797.71
HL-93K	4396	4395.55	-4261	-4323.09
HL-93S	N/A		-5317	-4789.14

The Live load (HL-93 vehicle) moments calculated as M3-3 in SAP2000 are shown in Figure 5. In this study, under the load of HL-93M and HL-93-K, almost 100% results were obtained

with SAP2000 Line-girder method. For TRUCK-TRAIN Negative Moment loading (i.e. HL-93S), the approach is 90% as shown in Table 2.

a) HL-93M Vehicle

b) HL-93K Vehicle

c) HL-93S Vehicle

Fig. 5. HL-93 Vehicle Moments

B. Influence Line Analysis

This two-span bridge is also analyzed by the influence lines and the moments of the moving load (HL-93 vehicle) are calculated. The influence lines are obtained by defining a general vehicle in SAP2000 and applying unit loading.

HL-93M, HL-93K and HL-93S moving loads were also taken as vehicle loading in the

analysis with influence lines. Moving load moments are determined by multiplying the influence line ordinates by vehicle loads and impact factor. The results are given in Table 3.

Using the influence lines, the moment value of 5343.60 k-ft was calculated, especially for the negative moment on the internal support (HL-93S Vehicle). This value is exactly the same as that calculated in Reference [4].

TABLE 3. LINE-GIRDER AND INFLUENCE LINE MOMENTS

	Max (+) Moment [k-ft]			Max (-) Moment [k-ft]		
	Ref(4)	This Study		Ref(4)	This Study	
		Line-Girder	Influence Line		Line-Girder	Influence Line
HL-93M	3725	3716.78	3613.83	-3737	-3797.71	3716
HL-93K	4396	4395.55	4266.10	-4261	4323.09	4229.60
HL-93S	N/A			-5317	4789.13	5343.60

III. RESULTS

In this study, it was shown that Straight Composite Steel I-Girder bridges can be solved by Line-Girder method. The finite element method is used for the solution in SAP2000 by Line-girder method. The results obtained here are acceptable. Again, more precise results were obtained with the influence line in the SAP2000 program.

From all these calculations, the following result has been achieved: By deriving from the influence line analysis, the moments obtained with the SAP2000 program can be reliably used for bridge analysis and design.

Abstract— Seismic risk determination of precast buildings is a key subject in mitigation of economic losses in the future seismic events as these buildings play important role on the economic growth and one of the primary sources of workmanship in Turkey. For this reason, seismic risk of precast industrial buildings under potential destructive earthquakes should be determined. From this perspective, one story hinge connected buildings which constitutes a great part of industrial building stock of Turkey were selected and seismic capacity of these buildings were determined by the current Turkish Earthquake Code. Seismic demand of buildings were obtained by performing nonlinear time history analyses using more than 300 real ground motion records. Earthquake records were selected to represent low, moderate and high intensity levels in terms of their peak ground velocity (PGV) and selected earthquake records were then divided into numerous groups according to their intensity levels. Then, damage probability of precast buildings was calculated by different probabilistic methods based on comparison of performance levels and seismic demands for each earthquake intensity group and performance levels. Three different methods were used to calculate damage probability of buildings and each method has different aspects in calculating the probabilities of structural damages. By this way, damage probabilities and consequently the Damage Probability Matrices (DPM) were derived for each earthquake and performance levels. Results obtained from DPM of precast buildings have indicated that damage probabilities can highly be affected from the calculation method used.

Keywords—Precast Buildings; damage probability matrices; nonlinear time history analysis

I. INTRODUCTION

In last decade, various moderate to large scale earthquakes occurred in Turkey. Important part of precast industrial buildings suffered from excessive damages in Adana-Ceyhan and Marmara earthquakes [1-2] occurred in 1999. Although some studies were performed on the reasons and causalities of damages in precast buildings [3-5], damage-earthquake intensity relations and collection of damage evaluation data of these buildings were not conducted at effected sites or regions. However, destructive earthquakes occurred in the past caused

adverse effects on economic growth of the country. Occurrence of damage probabilities and their relation with ground motion indices might be very helpful to make risk assessment of precast buildings in the future seismic events. For this reason, derivation of damage probability matrices for precast industrial buildings will be important step in understanding of damage-earthquake relations and may be helpful in reducing economic losses of seismic events in the future.

Determination of knowledge between ground motion indices and structural damages very appropriate to the probabilistic methods and they are commonly used to determine such relations. Although fragility or vulnerability curves are available to describe damages of building with earthquake damage indices [6-8] the other probabilistic method is damage probability matrices (DPMs). Damage probability matrices are actually determined by collecting damage data [9] from the region affected by earthquakes. Compared to fragility curves, damage probability matrices define the discrete probabilities of reaching damage state at specified or various ground motion levels and DPMs are empirical as they are mainly based on expert-opinions. This method is also the basis of ATC-13 [10]. DPMs can also be used for the estimation of earthquake insurance rates [11-13]. In this regard, it can be said that derivation of DPMs has a critical importance in determining seismic risk of precast buildings and mitigation of economic losses.

For this purpose, 98 real hinge connected precast industrial buildings located in Denizli Organized Industrial Zone (DOIZ) were used and damage probability matrices (DPM) of considered precast buildings were derived by using three different methods which have different aspects in calculating the damage probabilities. Results obtained from DPM of precast buildings have indicated that damage probabilities can considerably be affected from the calculation method used.

II. CAPACITY DETERMINATION IN HINGE CONNECTED PRECAST BUILDINGS

Precast industrial buildings, constitutes majority of lightweight industrial facilities [14] in Turkey and most of

them are constructed as one story [15]. For this reason, one story hinge jointed precast building are considered in this study. As a consequence this connection type, precast columns behave like cantilever components, so strength and displacement response of members can directly be used for the determination of capacity curve. For this purpose, moment-curvature analyses of precast columns were performed. During the analyses, ultimate displacement capacity of columns was described in terms of strain limits of confined concrete and tensile longitudinal reinforcement considering the TEC-2007 [16] (see (1)). In the equation, ε_{ccu} and ε_{su} define the strain value of confined concrete and tensile reinforcement. Minimum curvature value is attained that corresponds to these strain limits.

$$\phi_u = \phi_{\min}[(\varepsilon_{ccu} = 0.04 + 0.014(\rho_s/\rho_{sm}) \leq 0.018); (\varepsilon_{su} = 0.06)] \quad (1)$$

The intermediate damage levels, on the other hand, were determined by using 10% and 75% of plastic deformation capacity of the RC sections. Finally, base shear capacity (V_i) of the buildings were calculated by summing of individual strength capacity of precast columns (v_{ui}). Furthermore, performance limits of were determined by taking minimum of individual columns deformation responses for considered damage limit as shown in Fig. 1.

III. ESTIMATION OF SEISMIC DEMAND

In order to determine relation with damage and ground motion parameters, seismic demand should also be calculated for considered buildings. For this aim, nonlinear time history analysis was performed and real earthquake records were used for seismic demand estimation. During the selection of ground motion records Peak Ground Velocity (PGV) was selected as reference seismic damage quantity and records were chosen to represent low, medium and high intensity earthquake sizes. More than three hundred ground motion records were used and some of these records (72 of 364 records) were scaled to fulfill the need of high intensity earthquake sizes, but maximum scale was not taken higher than 1.54. Selected records were divided into twelve PGV groups with increments of 5cm/s. Some salient attributes of PGV groups are given in Table I. It can be seen from the table that number records of individual groups are almost identical as it was aimed to reduce bias between the

TABLE I. FEATURES OF EARTHQUAKE RECORDS USED IN TIME HISTORY ANALYSIS

Intensity Level	PGV Group No	Number of Records	Average PGV of the group (cm/s)	Standard Deviation (cm/s)
I	1	29	21.69	1.21
	2	31	27.31	1.5
	3	34	32.05	1.48
	4	30	37.35	1.49
II	5	30	41.77	1.28
	6	30	47.15	1.54
	7	30	52.16	1.47
	8	30	57.18	1.32
III	9	30	62.07	1.14
	10	30	67.52	0.97
	11	30	72.55	0.75
	12	30	77.31	1.09

results. Minimum and maximum value of PGV was 20cm/s and 80cm/s respectively. These PGV intensity levels were proposed to make rapid assessment in reinforced concrete structures in Turkey by Sucuoglu and Yazgan [17]. Sucuoglu and Yazgan used three intensity zones having PGV increments of 20 cm/s.

IV. DERIVATION OF DAMAGE PROBABILITY MATRICES

Whitman [9] was first time used to determine damage probability of prototype buildings by using damage observations from site investigation reports. Even though, DPM are based on empirical damage observations of experts, three different damage probability matrix calculation methods based on the analytical nonlinear dynamic analysis of precast buildings is presented in this study,. Before the description of calculation methods, some information about typical DPM is given. In Table II, damage states (DS), central damage ratios (CDR) of each damage state and damage probabilities $Pr_k(DS, I)$ for each ground motion size for k type of buildings can be seen as common components of DPM.

TABLE II. TYPICAL TABULAR FORM OF DPM

Damage State	Central Damage Ratio (CDR)	Seismic Damage Quantity (e.g. MMI)			
		V	VI	VII	VIII
No Damage	0	$Pr_k(DS, I)$			
Slight Damage	5				
Moderate Damage	30				
Extensive Damage	70				
Collapse	100				

Fig. 1. Typical representation of capacity curve construction

It should be stated that CDR values have important contribution on calculation of MDR curves. In this study, CDR values given in Table II, proposed by Gurpinar et al. [18], is used for calculation of MDR curves.

Although table gives detailed information about the probabilities of each damage state (DS), yet does not indicate the probability of damage to structure at specific earthquake size. In order to determine such quantity, Mean Damage ratio (MDR), sum of product of damage state probabilities and central damage ratios (CDR), should be calculated (see (2)). By this way, DPMs of different buildings or calculation methods can be compared easily by using MDR curves as also used in this study. In further sections, DPM calculation methods are expressed.

$$MDR(I) = \sum_{DS} Pr(DS, I) \times CDR(DS) \quad (2)$$

A. Method-1

This method is based on the empirical calculation method as shown in equation (3). In the equation, $N(DS, I)$ and $N(I)$ express the number of k -type buildings in damage state DS and total number of k type buildings under earthquake intensity I .

$$Pr_k(DS, I) = N(DS, I)/N(I) \quad (3)$$

This equation can also be used for analytical dynamic time history analysis results as the total number of buildings and damage state of buildings for each earthquake size after dynamic analysis can be determined. However, each earthquake size has more than one record, for instance 30 ground motion records, so selection of appropriate DS becomes essential. In this case, it can be assumed that the worst damage state can be the crucial on seismic behavior.

TABLE III. APPLICATION OF METHOD-1 TO SAMPLE BUILDING

PGV Group No		1	2	3	...	10	11	12
Cumulative number of damage occurrence numbers								
DS	NoDamage	25	15	13	...	2	1	0
	$> \Delta_y$	4	16	21	...	28	29	30
	$> \Delta_{MN}$	0	4	13	...	28	28	28
	$> \Delta_{GV}$	0	0	0	...	5	7	12
	$> \Delta_{G\check{C}}$	0	0	0	...	0	0	4
Damage Occurances according to Method-1								
DS	NoDamage	0	0	0	...	0	0	0
	Slight	1	0	0	...	0	0	0
	Moderate	0	1	1	...	0	0	0
	Extensive	0	0	0	...	1	1	0

PGV Group No	1	2	3	...	10	11	12
Collapse	0	0	0	...	0	0	1

By this way, the most unfavorable condition can be considered by using two digits system like 0 and 1. As the cumulative damage states of building can be determined for each building and PGV group, then undesired damage state can apparently be seen and digit of 1 can be marked to related DS and PGV groups and rest of other DS can be marked as "0" in the table. Aforementioned process is clearly shown in Table III for sample building which exists in the inventory. If such calculation is applied to rest of building in the inventory then empirical DPM based on analytical calculation results can be obtained for considered building type.

B. Method-2

In Method-1, the worst damage states are considered, but in this method all possible damage states are considered. By this way, possibility of any damage case on the damage probabilities of buildings is taken into account.

In this method, firstly cumulative damage state occurrence numbers are found by comparison of performance limits. These values are shown in Table III for sample building in the inventory. Later, damage state occurrence numbers are determined by extracting the adjacent damage levels and this step is illustrated in Table IV for same building. If the pre-described methodology is applied to the rest of precast buildings in the inventory, occurrence numbers of each damage state for each earthquake size can be calculated. As in method-1, damage probabilities can be calculated for each PGV bin by proportion of occurrence number of damage state and sum of all possible damages.

C. Method-3

Damage probability matrices are used to specify the discrete probabilities of reaching damage state at specified or various ground motion levels. Fragility curves, on the other hand, describe the reaching or exceeding of damage state probabilities, for various ground motion sizes. In this case, occurrence damage probabilities can be obtained by subtracting the adjacent curves. It should be reminded that, fragility curves are continues functions, but DPMs are discrete, so damage probabilities should be calculated for considered earthquake size. This procedure is also illustrated in Fig. 2. In this study, each earthquake size is described in Table I in terms of average PGV value of each PGV bin.

TABLE IV. APPLICATION OF METHOD-2 TO SAMPLE BUILDING

PGV Group No		1	2	3	...	10	11	12
Occurrence number of damage states								
DS	NoDamage	25	15	13	...	2	1	0
	Slight	4	12	7	...	0	1	2
	Moderate	0	4	13	...	13	15	14
	Extensive	0	0	0	...	5	7	8
	Collapse	0	0	0	...	0	0	4

and hence the MDR curves of the buildings. For this reason, selection of ground motion records has also important effect on damage probabilities of buildings. In this study, effect of ground motion selection on the damage probabilities is not taken into consideration. So, sensitivity of MDR curve determined from Method-1 is not investigated. Nevertheless, independent from the ground motion records used, it is possible to admit that Method-1 can be used represent the worst condition for the building type considered.

In fig. 3, MDR curves of Method-2 and Method-3 is also

Fig. 2. Transformation of probabilities from fragility curves to Damage Probability Matrices for Method-3

In order to determine DPMs of inventory buildings in this study, average fragility curves provided by Palanci [11] for inventory buildings are used. Considering the similar circumstances, Palanci and Senel [19] also determined the DPMs of one-story inventory buildings.

V. COMPARISON OF DAMAGE PROBABILITY MATRICES

It can be said that all presented methods is established on different probabilistic views. For this reason, it is possible to determine different damage probabilities for precast industrial buildings. As mentioned earlier, DPMs are used to represent discrete probabilities of damage states in terms of different earthquake intensity levels. To represent the damage probability of related building type to distinct earthquake levels MDR values are used. By this way, damage curves can be drawn and compared.

In fig 3, MDR curves of all presented methods are drawn according to PGV level. Ordinate values of the graph are determined by using (2). It can be seen from the figure that MDR curve of Method-1 is very different from the Method-2 and Method-3. It can be understood from the MDR curve of Method-1 that this method may be used to represent for upper level of damage probabilities. Since Method-1 uses the worst damage case for buildings, it probable to determine higher damage probabilities compared to other methods. As empirical DPM curves are determined from the damage observations after destructive earthquakes, these curves or damage probabilities maybe also be determined higher for non-code conformed buildings. Except from the quality of the buildings, the use of ground motion records may also affect the DPMs

drawn. From the figure, it can be implied that both methods gives almost similar damage probabilities. Note that Method-2 uses the all possible damage cases in calculation of damage probabilities for this reason each damage case have contribution on damage probabilities of buildings. In method-3 damage probabilities are calculated by subtracting the damage probabilities of adjacent damage probabilities. This situation indicates that both methods may likely be similar in estimating the damage probabilities as they almost use identical probabilistic view. The difference is that Method-2 directly uses the damage occurrence numbers and then calculates the probabilities by taking the ratio of occurrence number for each damage case and all occurrence numbers for considered earthquake size.

Finally, it can be said that all obtained damage probabilities are the consequences of use of probabilistic view. The difference between the results also is the indicator of uncertainties caused by lack of knowledge, use of different probabilistic view, in selection of ground motion records and etc. In this case, if the obtained results were combined with

Fig. 3. Comparison of MDR curves of all presented methods

appropriate approach, an important finding could be drawn about the damage probabilities of the precast buildings.

In the scope of this study, all presented methods are combined by summing of all damage probabilities multiplied by constant coefficients. Mathematical expression of this statement is given in (4). According to (4), 50% of Method-1 and 25% of Method-1 and Method-2 is used. This situation shows that weight of Method-2 and Method-3 is taken equal. Coefficients were taken equal owing to damage probability similarities of these methods. Actually, equation can be considered as the weight of Method-1 and weight of Method-2 and Method-3 are equal since the damage probabilities of Method-2 and Method-3 is very similar.

$$\sum_{DS} \Pr(DS, I) = \sum_{DS} [0.5\Pr(DS, I)_{M-1} + 0.25(\Pr(DS, I)_{M-2} + \Pr(DS, I)_{M-3})] \quad (4)$$

In fig. 4, MDR curves of individual methods and their combination determined according equation (4) is plotted. In the figure, MDR curve determined from (4) is described as "Combination". It can be seen from the figure that, MDR curve of combined curve is range between the presented methods. It is expected that all methods presented herein can be used to represent the upper and lower damage probabilities limits of buildings and they naturally involves uncertainties. Combined MDR curve of presented methods, on the other hand, clearly emphasizes the importance of evaluating the different approaches together. In addition, this situation stresses that with appropriate approach, combination of different views of probabilistic calculations may be beneficial for risk assessment not only for precast industrial building but also any of interested building type.

VI. SUMMARY AND CONCLUSIONS

In this study, 98 existing one-story precast industrial buildings are used for determination of Damage Probability Matrices (DPMs). Determination of damage probabilities were performed by using nonlinear time history analysis of precast buildings. Dynamic analyses were performed by real ground motion records selected according to ground motion parameter of PGV. Selected records were divided to several groups to represent low, medium and high intensity earthquake levels.

Three different probabilistic calculation methods, called Method-1, Method-2 and Method-3, are presented in the scope of this study. Each method is based on the distinct probabilistic view so different damage probabilities were calculated from the presented methods. Observations have shown that Method-1 represents the highest damage probabilities for considered building type as the method uses the worst damage state for each earthquake intensity level. It was determined that outcomes of Method-2 and Method-3 are almost similar. Investigations on the reasons of this situation have implied that both methods uses almost similar views, but not completely identical. Method-2 is based on the damage state occurrence

numbers and occurrence numbers are determined from the subscription of adjacent damage levels. Different from the method-2, Method-3 concerns about the direct use of damage probabilities determined from fragility curves of precast buildings. However, it is worth to remind that fragility curves are continuous functions and they are mostly constructed by using probability distributions like lognormal distribution. As fragility functions are derived by fitting the best curve for probabilities of damage states, it may be difficult to construct best fitting curve to real damage probabilities of damage states in every circumstances. As the Method-2 is based on direct use of damage probabilities, the difference between these methods can also be observed. Furthermore, similarities in damage probabilities of method-2 and method-3 also highlights that constructed fragility curves for existing buildings are quite well as there is a good relation between the damage probabilities of these methods.

Fig. 4. Comparison of MDR curves of all presented methods and their combination

Consequently, it is noted that presented methods can be used to represent the upper and lower damage probabilities for precast industrial buildings. Considering the uncertainties involved in calculation methods, in selection of records, outcomes of all presented methods are combined. Results clearly stress the importance of using different probabilistic calculation methods to make risk assessment for structures.

ACKNOWLEDGMENT

The authors acknowledge support provided by Scientific and Technical Research Council of Turkey (TUBITAK) under Project No: 110M255. The authors wish to express their gratitude to directorate of DOIZ) for providing design projects of precast buildings. Ground motion records used in this study are downloaded from the PEER web site. The authors also acknowledge the PEER for providing the processed data..

Abstract—This paper presents hardened state properties of concrete produced with demolish waste as control concrete and concrete produced with steel and plastic fiber chips. Two sets concrete production were implemented and results were compared in terms of compressive strength, split tensile strength, ultrasonic pulse velocity and Schmidt hammer test.

Keywords—concrete; demolish waste; steel fiber; plastic fiber; mechanical properties

I. INTRODUCTION

Concrete is known as artificial rock. This artificial material composed of many ingredients. Last two decades' waste or any other natural or artificial materials are started to be added to concrete to evaluate fresh and hardened state properties. For this purpose, many researchers implemented experimental campaign. Liu et al. [1] investigate that the effect of the recycled aggregate on concrete failure mechanism. In this study, Elasticity modulus and strength parameters of recycled concrete under both compressive force and tensile loading were experimentally studied to present failure mechanism. Results show that the old mortar has more predominant influence on both the strength and the Elasticity modulus of recycled concrete. Padmini [2], Xiao and Du [3] produce concrete and tested the Young's modulus and strength of the concrete as a former step by using it to make recycled concrete. Presented experiments demonstrated that for a known w/c ratio, the recycled concrete containing basic concrete with superior properties has a higher compressive strength and a higher Elasticity modulus. A similar experimental study was made by Etxeberria et al. [4]. In their experimental program they used recycled coarse aggregates obtained by crushed concrete. Concrete mix were designed and produced with 0%, 25%, 50%

and 100% of recycled coarse aggregates, respectively. The mix design calculations were made to reach the similar compressive strength class for the all usage level of recycled coarse aggregate. The level of the standard deviation of the compressive strength achieved up to 50% for concrete made with 100% of recycled concrete aggregate. The standard deviation change is derived from the recycled aggregate qualification distribution in the mix. The water absorption capacity is another important parameter. Recycled aggregate has a great amount of absorption capacity. For this reason, water content of recycled aggregate must be known prior to the utilization in concrete production to control properties of fresh and hardened concrete. Some of the investigators propose to limit recycled aggregate ratio at 30% level to maintain the ordinary requirements of 5% of absorption capacity of aggregates for structural concrete [5,6]. Compressive strength of the concrete made with 100% recycled coarse aggregate is smaller when the usage of lower level w/c ratio respect to the conventional aggregate produced with the same w/c content. Furthermore, the w/c ratio is utilized at the same level to produce the conventional and recycled concrete, the conventional concrete has the biggest compressive strength [7]. Cement produced 100% of recycled aggregate in concrete to achieve the same workability and compression strength as ordinary concrete is higher amount against the cement content of traditional concrete [8]. Sagoe-Crentsil et al. [9] made an investigation for the fresh and hardened properties of concrete made with commercially produced coarse recycled concrete aggregate and natural fine sand. The test results of these samples compared with the characteristics of fresh and hardened recycled aggregate concrete and natural aggregate concrete mixtures. The abrasion loss of recycled aggregate concrete made with ordinary portland cement is about 12%

higher than compared to normal concrete, while the corresponding drying shrinkage was about 25% higher at 1 year. Lotfi et al. [9] investigated that the compressive strength and related mathematical curvature like the stress-strain curve (SSC) of recycled aggregate concrete (RAC) made with changing replacement ratio of recycled coarse aggregate (RCA). For the testing of concrete samples uniaxial compression loading is applied. Recycled concrete made with fully recycled aggregate has a reduction in modulus of elasticity about 45% while the peak strain is 20% higher than the normal concrete. Previous studies shown that [10] the stress-strain relationship for recycled aggregate concrete is very close to the shape of normal concrete. When a structures made of recycled aggregate desired to design, theory of plasticity can be use like structures made of normal concrete. Stress-strain curves of concretes with different RCA replacement percentages shows similar inclination. When the level of the replacement is increased, the curvature of the curve is developed gradually. While the replacement level is increased with the coarse aggregate, the values of compressive strength, toughness, plastic energy capacity and elastic energy, and the elastic modulus decrease. Some of the experimental investigation offers some empirical model that can be used directly in design [11,12,13]. Rahal [14] made an experimental study for the difference of the tension and compressive strength with the changes of age. The mixes of concrete with target compressive cube strength ranging from 20 to 50MPa were cast using normal or recycled coarse aggregates. The indirect shear strength of recycled aggregate concrete was nearly the 90% of those of natural aggregate concrete with the same mix proportions. The modulus of elasticity of RAC was very closely that of normal aggregate concrete (NAC). With 100% replacement of coarse aggregates with recycled aggregates decrease the compressive strength between 9% to 45%. The change of the modulus of elasticity is reduced 15% for the lower water-cement ratio but with the higher water-cement ratio this level come to 45% [15-17]. Koper [18] produce RCA was obtained by crushing laboratory concrete having a wide range of water/cement (w/c) ratio (from 0.35 to 0.7); it allowed to obtain the concrete having compressive strength from 30 to 60 MPa. According to the experimental results, the water absorption of the best quality RCA approaches 5% and the mineral dust content in aggregates, obtained from concrete debris crushing, must be in the range of 0.3 – 1%. The quality of the RAC is directly related with the aggregate obtained from the primary concrete recycling. The replacement level of coarse and fine natural aggregates by RCA higher than 50% or above significantly reduced the compressive strength while 50% of air-dried RCA contamination of was optimal for producing the RAC up to 60 MPa [19-21]. Nováková and Mikulica [22] used precast demolished member as a RCA in concrete mix. Investigation based on the replacement of natural aggregates with the RCA produced from precast production defected elements which are carted off and recycled with other demolition waste. Results from testing of RAC proved that the replacement of raw aggregates by RCA up to 20% has no negative influence on physico-mechanical properties of concrete. The main reason of the strength loss is the weak interfacial transition zone (ITZ). It can be improved this connection face between old mortar and new mortar with the

usage of fly ash, nano-silica or other fine materials. The positive changes of carbonation depth in case of RC with 20% of replacement of (natural aggregate) NA by RCA [23-26]. ITZ mechanical strength is strongly influenced by the coarse aggregate types and their surface and shape. Concrete made with crushed aggregates provides higher values of the fracture energy than for concrete made with spherical ones. Due to their smoother surface and therefore weaker anchorage, pebble aggregates present areas dislodged from the matrix, leading to concretes with them have lower fracture energy than those with crushed rock [37-29]. Guo et al. [30] produced rubber crumb and steel fiber reinforced recycled aggregate concrete (RSRAC). A series of concrete mixes were prepared with Ordinary Portland Cement (OPC), recycled concrete coarse aggregates (RCA) or natural coarse aggregates (NCA), 1% steel fibre (by volume) and rubber particles with different fine aggregate (sand) replacement ratios. The investigators examine the compressive properties, including compressive strength, Young's modulus (stiffness), stress-strain curves and energy absorption capacity (toughness) of the different concrete mixes subjected to elevated temperatures. The results showed that both the compressive strength and stiffness of concrete mixes decreased after exposure to elevated temperature, with higher replacement of fine aggregate by rubber leading to lower compressive strength and stiffness magnitude. Nevertheless, rubber crumbs significantly enhanced the energy absorption capacity and explosive spalling resistance. Evangelista and Brito [31] experimentally investigated that the use of fine recycled concrete aggregates to partially or partially replace natural fine aggregates (sand) in the production of structural concrete. Compressive strength, split tensile strength, modulus of elasticity and abrasion resistance test were made on the produced RAC. From these results, the use of fine recycled concrete aggregates does not much more influential on the mechanical properties of concrete, for replacement ratios up to 30%. All these research also have clearly promoted the promising use of RCA in construction. To date, RAC has been successfully applied in pavements and building structures in China, as shown by Li et al. [32].

In this study, two sets of concrete production were implemented. These two sets composed of concrete with waste demolish as control concrete and concrete with steel and plastic fiber. Hardened state properties were studied in terms of compressive strength, split tensile strength, ultrasonic pulse velocity test and Schmidt Hammer test.

II. EXPERIMENTAL DESCRIPTION

A. Design of Experiments

This experimental campaign was carried out with two sets of experiments. Control concrete specimens were produced as conventional concrete. Target strength is determined 25 MPa for control concrete. Modified set of concrete composed of ternary ingredient like demolish waste, steel fiber and polypropylene fiber. Dimensions of the waste demolish aggregate used in concrete is between 8 mm and 16 mm diameter. These demolish waste is used 40 % of total aggregate. Maximum aggregate diameter is determined 16 mm for this study. Steel and polypropylene fibers were used in the

concrete mix for second set of production. Control concrete properties and amounts were tabulated in Table 1. Used steel fiber chips can be seen in Figure 1 and Polypropylene fiber can be seen in Figure 2.

TABLE I. AMONTH OF MATERIAL FOR 1000 DM³ CONTROL CONCRETE

Water (lt)	Cement (kg)	0 – 4 mm	4 – 8 mm	8 – 16 mm
195	367.92	881.85	348.53	487.96

Figure 1. 12 mm length steel fiber chips

Figure 2. Polyproplene fiber

Waste demolish was replaced with aggregate to produce second set of specimen 40% of 8 – 16 mm aggregate. Amount and dimensions of steel fiber and polypropylene fiber were tabulated in Table 2.

TABLE II. AMONTH AND PROPERTIES OF STEEL AND POLYPROPYLENE FIBER

Fiber	L/D Ratio	Length	Amount
Steel	0.55	NA	55 kg/m ³
Polypropylene	NA	12 mm	90 gr/m ³

III. RESULTS AND DISCUSSION

Results of these experimental study divided into three sub title in terms of axial compressive and split tensile test results, Ultrasonic pulse velocity and Schmidt hammer test results.

A. Axial Compressive and Split Tensile Test Results

Axial compressive test results of produced concrete specimens were evaluated and reported in this section. Compressive strength and split tensile strength test results were tabulated in Table 3 and Table 4.

TABLE III. 7 DAYS COMPRESSIVE AND SPLIT TENSILE STRENGTH TEST RESULTS FOR CONTROL CONCRETE

Number	Unit Weight (Kg/m ³)	Compressive Strength (MPa)	Unit Weight (Kg/m ³)	Split Tensile Strength (MPa)
1	2319	15.66	2310	3.43
2	2316	16.02	2319	3.12
3	2224	15.52	2303	3.11
Avg.	2286	15.73	2311	3.22

TABLE IV. 28 DAYS COMPRESSIVE AND SPLIT TENSILE STRENGTH TEST RESULTS FOR CONTROL CONCRETE

Number	Unit Weight (Kg/m ³)	Compressive Strength (MPa)	Unit Weight (Kg/m ³)	Split Tensile Strength (MPa)
1	2291	48.06	2278	9.62
2	2342	45.23	2325	9.49
3	2360	46.63	2355	10.06
Avg.	2331	46.64	2319	9.72

After substituting demolish waste with aggregate, adding steel and polypropylene fiber results of compressive strength and split tensile strength test results were obtained as indicated in Table 5 and Table 6 below.

TABLE V. 7 DAYS COMPRESSIVE AND SPLIT TENSILE STRENGTH TEST RESULTS FOR MODIFIED CONCRETE

Number	Unit Weight (Kg/m ³)	Compressive Strength (MPa)	Unit Weight (Kg/m ³)	Split Tensile Strength (MPa)
1	2366	21.28	2376	5.85
2	2359	22.65	2371	5.78
3	2372	22.18	2364	6.04
Avg.	2366	22.04	2370	5.89

TABLE VI. 28 DAYS COMPRESSIVE AND SPLIT TENSILE STRENGTH TEST RESULTS FOR MODIFIED CONCRETE

Number	Unit Weight (Kg/m ³)	Compressive Strength (MPa)	Unit Weight (Kg/m ³)	Split Tensile Strength (MPa)
1	2389	30.42	2380	8.81
2	2388	30.92	2351	9.92
3	2396	31.57	2364	9.47
Avg.	2391	30.97	2365	9.4

TABLE IX. 7 DAYS ULTRASONIC VELOCITY TEST RESULTS FOR MODIFIED CONCRETE

Number	Unit Weight (Kg/m ³)	Pulse Velocity (m/s)	Pulse Duration (μ)
1	2291	3978	27.9
2	2342	3978	27.9
3	2360	4051	27.3
Avg.	2331	4002	27.7

As indicated from test results externally added ternary group of materials developed early age compressive and split tensile strength of conventional concrete. 7 days compressive strength test results increased from 15.73 MPa to 22.04 MPa. However, 28 days test results decreased from 46.64 MPa to 30.97 MPa. Split tensile strength test results increased with adding ternary compounds to concrete from 3.22 MPa to 5.89 MPa for 7 days. Moreover, these ternary material additions resulted very slight decrease for 28 days split tensile strength. These slight decreases occurred from 9.72 MPa to 9.4 MPa.

TABLE X. 28 DAYS ULTRASONIC VELOCITY TEST RESULTS FOR MODIFIED CONCRETE

Number	Unit Weight (Kg/m ³)	Pulse Velocity (m/s)	Pulse Duration (μ)
1	2389	3908	28.04
2	2388	3864	28.50
3	2396	3964	28.00
Avg.	2391	3922	28.20

B. Ultrasonic Pulse Velocity Test Results

Ultrasonic pulse velocity test results of concrete specimens were tabulated in Table 7 and Table 8 for control concrete, Table 9 and Table 10 for modified concrete.

TABLE VII. 7 DAYS ULTRASONIC VELOCITY TEST RESULTS FOR CONTROL CONCRETE

Number	Unit Weight (Kg/m ³)	Pulse Velocity (m/s)	Pulse Duration (μ)
1	2319	3908	28.4
2	2316	3922	28.3
3	2224	3978	27.7
Avg.	2286	3936	28.1

Ultrasonic pulse velocity test results proved that added ternary materials filled porous volumes. There is only 5.7% increase in pulse velocity time and there is a 4.8% decrease in ultrasonic pulse velocity at 7-day age while compared with control and modified concrete specimens. There is a 2% decrease in ultrasonic pulse velocity and naturally 1.7% increase in pulse velocity time while compared control and modified concrete specimens.

C. Schmidt Hammer Test Results

Schmidt hammer test results obtained from all specimen with ten reading. These results were tabulated in Table 11 below. Table 11 shows average of ten readings.

TABLE VIII. 28 DAYS ULTRASONIC VELOCITY TEST RESULTS FOR CONTROL CONCRETE

Number	Unit Weight (Kg/m ³)	Pulse Velocity (m/s)	Pulse Duration (μ)
1	2366	3675	30.5
2	2359	3788	29.4
3	2372	3775	29.3
Avg.	2366	3746	29.7

TABLE XI. SCHMIDT HAMMER TEST RESULTS

Avg. Reading of Specimens	Control 7 Days (MPa)	Control 28 Days (MPa)	Modified 7 Days (MPa)	Modified 28 Days (MPa)
1	24.1	30.7	24.2	28.2
2	23.4	32.1	21.5	29.2
3	21.4	32.7	23.1	28.2
Avg.	22.97	31.83	22.93	28.53

As seen from Table 11, test results show that there is no change of 7 days Schmidt hammer test results with control and modified concrete test results. However, there is a certain decrease in 28 days' hammer test results of modified concrete while compared with control concrete.

IV. CONCLUSION

In this study, hardened properties of two different set of concrete specimens were evaluated in terms of compressive strength, split tensile strength, ultrasonic pulse velocity and Schmidt hammer. First set of concrete was produced with conventional concrete without external additive material usable in concrete. Second set of concrete was produced with demolish waste, steel and plastic fiber. Demolish waste substituted with 40% of 8 – 16 mm aggregate. Compressive strength results proved that mentioned external materials developed early age mechanical properties of modified concrete. However, these materials decreased long term mechanical properties of concrete. Split tensile strength property was increased with adding demolish waste, steel and polypropylene fiber. There is a 40% increase in compressive strength test results for 7-day age, but 34% decrease in compressive strength test results for 28-day age. Ternary materials for modified concrete developed 83% split tensile strength for 7-day age. However, the same materials resulted in 3.4% decrease in split tensile strength test results for 28-day age. Ultrasonic pulse velocity decreased with adding ternary materials and velocity time was increased for 7-day age and 28-day age specimens. Schmidt hammer test results are nearly the same for both set of specimens at early age. There is only 10% decrease in 28-day age specimens.

Abstract— Housing right is one of the basic rights that is guaranteed by the constitution and accorded to individuals by the executive power of the state. Executive branch tries to realize this according to the principles of equality and justice.

Housing is one of the major problems for university students in our country. They cope with this problem by staying at private and state dormitories, apart-hotels, and rented flats or by staying with relatives. Socio-economic status of the student, housing and building capacity of the city a student lives in play a role in choosing the form of housing. The authority to plan and build the housing buildings and facilities to meet the students' need of sheltering belongs to the Ministry of Youth and Sport. To this end, the Ministry developed standards and launch projects to meet the need for dormitory buildings throughout the country fast and economically. These standards that are established by taking into consideration building cost, management, function, aesthetic and efficiency levels of housing are very important in terms of spatial comfort of the users.

In this study, the availability level is evaluated by comparing the Ministry regulations for preparing projects and the typical project for building dormitories for 500 people that is currently applied by the Ministry.

Abstract— In the buildings, the conventional building systems offer limited opportunities in order to provide the requirements of user demands. The new construction technologies along with the development in technology occur producing flexible and adaptable solutions have tried to provide the requirements. Modular constructions include more flexible opportunities than the conventional building systems.

After industrialization experienced the population growth, intensive urbanization, intensive housing demand and developments in technologies have led to emergence the construction with low cost and craftsmanship, little time and produce higher quality building. In a rapidly developing and changing society, different space requirements occur depending on the building owners and users. The flexible and adaptable spaces gain important to respond the requirements.

Today, the developments in technology offer flexible spaces created with easy disassembled, assembled, maintained and repaired construction systems and components. The construction provide the flexibility to remove or renovation whole building.

In this context, modular construction systems are highly effective system to build flexible structure in order to respond the requirements with mobile building construction and building components. In this study, modular construction systems are examined in terms of flexibility and adaptability with case studies.

Abstract—We present a Metasurface (MS) polarization converter to transform linearly polarized signals into circularly polarized signals. The unit cell of the proposed structure consists of two metallic patches placed in the cross corners of a rectangular loop. Polarization conversion quality referred to axial ratio is kept below 3 dB. The axial ratio is obtained numerically and experimentally by the division of cross-polar and co-polar responses of the antennas. Quite good axial ratio bandwidth, 260 MHz, is achieved experimentally which supports the simulation results. The proposed MS structure can be fabricated and configured easily for any desired frequency range due to its simple design. It can be used efficiently in many applications such as weather radar, airport surveillance radar and satellite communications.

Keywords—axial ratio; axial ratio bandwidth; metasurface; polarization conversion

I. INTRODUCTION

Metamaterials (MTMs) are artificial materials having unusual electromagnetic properties which cannot be found in nature. First theoretical study about double negative material (DNG) was carried out by Veselago in 1968 [1]. In the late 20th century, Pendry et al. produced materials which have negative value of dielectric permittivity [2] in 1996 and magnetic permeability [3] in 1999. In 2000, Smith et al. realized the first DNG material which consists of a split ring and wires providing negative permittivity and negative permeability, simultaneously [4]. In recent years, many researchers study MTMs and its application areas and this attention gradually increases [5]-[7].

Metasurfaces (MSs) are the two dimensional equivalent of MTMs. MSs take up less volume and they can be less

lossy structures comparing to the three dimensional MTMs [9]. There are many potential application areas concerning MS structures such as controllable smart surfaces [10], wave guide structures [11] and absorbers [12]. In addition to these topics, MSs are also configured as polarization converter structures. Many radar and satellite systems need circularly polarized signals rather than linearly polarized ones, because circular polarization keeps signal constant at bad weather conditions.

In this study, we present a polarization converter MS structure to transform linearly polarized signal into circularly polarized one, numerically and experimentally. In order to show the conversion feature, the axial ratio (AR) of the proposed MS is calculated by dividing cross and co-pol responses. In the design, metallic patches placed in cross corners of rectangular loops are provide phase difference to obtain circular polarization. The proposed MS has two dip points which provide perfect polarization conversion activity at 2.85 GHz and 3.10 GHz. It has also 260 MHz of axial ratio bandwidth (ARBW) at two separate frequency ranges. The polarization converter can be efficiently used in S-band applications such as weather radar, airport surveillance radar, and satellite communications and so on.

Furthermore, in antenna industry, you must design two separate antennas if you need both linear and circular polarization. It is not only costly and time consuming but it also requires more physical space which is extremely important in the sector. Physical space for the antenna integration is generally limited meaning that the engineers mostly faced up the problem shrinking the antenna to fit the limited space on the radio transmitter or receiver structures. Therefore, there are many studies and researches concerning about the miniaturization of antennas. This problem can be overcome by

using the proposed structure, having an antenna which is capable of radiating both linearly and circularly polarized waves will be possible. In other words, designing a linear polarized antenna will be enough to work with in any application requiring both linearly and circularly polarized signals. In addition, the structure only contains a single layer which makes it possible for us to integrate the structure on any traditional radomes of antennas. Thus, no extra space will be used and radiation in a desired polarization can be achieved by a simple radome change which can be considered another advantage of the proposed model. Using multilayer structures may give good results in polarization conversion but it will most probably ruin the radiation pattern as well as the gain and directivity.

II. DESIGNING OF THE METASURFACE POLARIZATION CONVERTER

The unit cell of the proposed MS polarization converter consists of two metallic patches placed in crossed corners of a rectangular loop. The construction of MS structure is arranged by 16 unit cell in 4X4 layout. Rogers RT 5870 is used in the structure substrate with a thickness, loss tangent and relative permittivity of 1.575 mm, 0.012 and 2.33, respectively as shown in Fig. 1(a). The unit cell of the periodic structure is shown in Fig. 1(b) with a strip line whose thickness is $w = 0.48$ mm while the width and length are $x = 14.68$ mm $y = 14.90$ mm, respectively connecting the metallic patches. Dimensions of each metallic patches are $R_x = 4.90$ mm, $R_y = 4.64$ mm.

The goal of the study is to obtain circularly polarized signals from linearly polarized signals that can be investigated by the axial ratio (AR) which can be simply written in dB as;

$$AR(dB) = Mag(20 \log(AR(\omega))) \quad (1)$$

Figure 1.(a) Linear to circular polarization converter MS (b) unit cell dimensions of MS

AR is;

$$AR(\omega) = \frac{T(\omega)_{cross-polar}}{T(\omega)_{co-polar}} \quad (2)$$

III. NUMERICAL AND EXPERIMENTAL STUDY

Numerical study of the proposed MS structure is realized by CST Microwave Studio which is a commercial simulation software and 3D full wave electromagnetic solver based on finite integration technique. Periodic boundary conditions and floquet port mode are chosen for this study. To obtain efficient circular polarization, AR is kept below 3 dB. The proposed MS has two dip points at 2.95 GHz and 3.15 GHz which give perfect polarization activity in the simulation results of AR as shown in Fig. 2(b). About 300 MHz of ARBW is also obtained between the frequencies of 2.92 GHz and 3.22 GHz.

Figure 2.(a) Fabricated MS sample (b) simulated and measured AR results of proposed structure

Experimental study is achieved by Rohde & Schwarz ZVL6 vector network analyzer (VNA) with two linearly polarized microwave horn antennas. Fabrication of MS is realized by using LPKF E33 Protomat as shown in Fig. 2(a).

To obtain transmission values ($T(\omega)$), VNA is calibrated by using free space measurement. Both co-pol and cr-pol responses should be measured in order to obtain AR for the working frequencies. To measure co-polar response, the MS is placed between two horn antennas whose E-fields are in the same direction and for cross-polar response measurement, one of the horn antennas is simply rotated by 90° and the scattering parameters for the transmission (S_{21}) is measured and recorded. Finally, AR is calculated by the division of these two responses as in Eq. (2). There are two frequency bands below 3 dB which is optional to choose operating frequency range of MS as shown in Fig. 2(b). First band is between 2.82 GHz and 2.88 GHz with a ARBW of 60 MHz. The second one is occurred between at 2.98 GHz and 3.16 GHz with a ARBW of 200 MHz. Since we have dual working frequency band, the proposed MS polarization rotator can be used with dual band antennas, either. Another dip points are also obtained at 2.85 GHz and 3.10 GHz for the proposed structure.

Although there is a small mismatch between numerical and experimental results as shown in Fig. 2(b), AR dip points and ARBW of these results are almost at the same level and agree well with each other. The deficiencies are originated by not having ideal measurement conditions in the laboratory and the manufacturing defects of MS sample.

IV. CONCLUSION

A metasurface polarization converter which transforms linearly polarized signals into circularly polarized one is realized in this study. Simulated and measured results are compared to each other and it shows that the results are in a good agreement. AR is kept below 3 dB for polarization conversion quality. The perfect polarization conversion activities are obtained at frequencies of 2.83 GHz and 3.10 GHz and the ARBW of 260 MHz is also obtained at two frequency bands when the measured results are considered. Since circularly polarized signals are not affected by the weather conditions, the proposed MS can be used effectively in S-band radar and satellite systems. In addition, this design can be used on the existing linearly polarized antennas without using any extra space on the enclosures on which antennas are mounted. Furthermore, the proposed MS structure can be easily fabricated, integrated and reconfigured for any desired frequency range.

Abstract—A metamaterial based sensor is designed and demonstrated numerically and experimentally for the detection of microfluids. The structure consisting of a single circular split ring resonator (CSRR) has a simple geometry and can be adjusted to any desired frequency depending on the material to be characterized. In this study, two different chemical liquid sensor applications have been investigated. First, a liquid sensor application which can successfully achieve the alcohol content of the ethanol water mixture. Second, application of chemical liquid sensor to distinguish branded and unbranded diesel samples from each other are designed. The results show that the proposed structure is especially applicable to liquid sensor applications in biochemistry.

Keywords—metamaterial; biochemical sensor; liquid sensor; microwave

I. INTRODUCTION

Sensor applications have always attracted the attention of many scientists. In this work, a novel sensor technology recently interested by many scientists is being investigated. This technology is based on metamaterials (MTM) exhibiting unusual electromagnetic behaviors. Using these extraordinary materials, it is possible to achieve negative permeability and permittivity at the same time. MTMs [1]-[3] have great potential and wide application prospects in perfect absorber [4], perfect lenses [5], invisible cloaks [6], chirality [7], and super definition [8] and so on.

Recently, many MTM-based sensor structures have been investigated in microwave frequencies. Characterization and applications of various sensing devices such as liquid sensing based on a discrete ring resonator was performed by Withayachumnankul et al [9]-[10]. The operating principle of such microfluidic sensing devices depends on the interaction

between the samples placed in the sensing layer and the electric field provided by the microstrip lines. A chiral MTM sensor structure has been designed by Karaaslan et al [11] to determine the properties of samples with chiral properties. Various MTM-based strain sensor applications have been implemented by Melik et al [12] to detect mechanical deformation in microwave frequencies.

In this work, we proposed a metamaterial sensor with the ability to detect ethanol-alcohol mixed liquid detection and branded-unbranded diesel fuels in microwave frequency regime theoretically and experimentally. The proposed structure has a simple circular split ring resonator (CSRR) topology coupled with a microstrip transmission line to investigate the transmitted signal. First, the operating frequency of the structure was investigated numerically and experimentally, assuming that the sensor layer was empty. To perform the liquid sensing application, the dielectric constant and dielectric loss values of the ethanol-water mixture and the diesel samples were measured using the dielectric probe kit at the operating frequency band. The sensing ability of the proposed structure according to the obtained dielectric properties of the fluids was analyzed numerically and experimentally with a simulation program and a vector network analyzer.

II. NUMERICAL AND EXPERIMENTAL DESIGN

The proposed sensor structure is designed and fabricated as a circular split ring resonator (CSRR). A microstrip transmission line, which forms the magnetic coupling effect with the CSRR, is integrated on the structure to observe the shifts in resonance frequency as shown in Fig. 1 (d). The back side of the structure is covered with a metallic plate, which is set as the ground plane. A radial gap was created in the CSRR

to measure the sensitivity of the samples by monitoring the shifts in resonance frequency, which is an important parameter for the sensor applications. Typical dimensions of the CSRR and microstrip line obtained from parametric studies are given in Table 1.

Table 1. Typical dimensions of the proposed structure

r1	r2	sr1	sr2	rg	rd
7.0 mm	5.0 mm	4.35 mm	3.85 mm	2.0 mm	7.30 mm

Numerical studies were carried out with electromagnetic simulator software based on finite integration technique. As shown in Fig. 1 (c), two separate connection points are integrated at both ends of the microstrip transmission line to monitor the transmission coefficient S_{12} . Electromagnetic properties of the ethanol water mixtures and diesel samples were measured with the Agilent 85070E dielectric probe kit and these mixtures and diesel samples are defined as new materials according to the values measured in the simulation program.

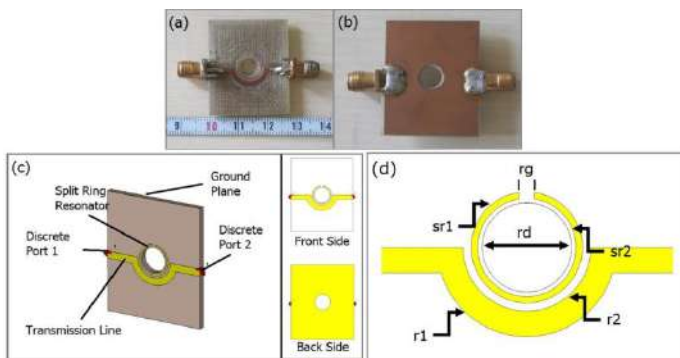

Figure 1. (a) The front side of the proposed structure, (b) the back side of the proposed structure, (c) The simulation model of the sensor structure, and (d) the geometrical dimensions of the proposed structure.

The metamaterial-based sensor structure was fabricated by the LPKF E33 Protomat PCB prototyping machine as shown in Fig. 1 (a) and (b). The dielectric substrate used in simulation and production is FR4 with a thickness of 1.6 mm, relative permittivity of $\epsilon_r = 4.3$ and loss tangent of $\tan \delta = 0.02$. The metal plates on the dielectric substrate is copper with a thickness of 35 μm and an electrical conductivity of $\sigma = 5.80001 \times 10^7 \text{ S/m}$. In addition, 50 Ω connectors are soldered on both sides of the transmission lines.

Experimental study of the sensor was performed with the PNA-L Agilent vector network analyzer (VNA) with operating frequency up to 43.5 GHz. The experimental setup is shown in Fig. 2. Before connecting the sensor structure for measurement, the VNA was calibrated using the appropriate calibration kit.

Figure 2. The experimental setup

The structure was then connected to the VNA and measured without the sample to be measured in the sensing layer. The corresponding simulation and test results for the sensor structure without any sample placed in the sensing layer are shown in Fig. 3. It is observed that the proposed sensor structure has a resonance frequency of about 4 GHz. There was a slight difference between the measurement and simulation results, due to calibration errors and manufacturing errors.

Figure 3. Simulation and experimental results of the transmission coefficient

III. ETHANOL-WATER MIXTURE SENSING APPLICATION

An ethanol water mixture was used for liquid detection application. The dielectric constant and dielectric loss factor values of the mixtures were determined with Agilent 85070E dielectric probe kit based on the percentage of ethanol in the mixture. After the dielectric probe kit was calibrated, the ethanol ratio of the mixture was increased by 20% each time, and the measurements are carried out at the operating frequency of 4.1 GHz. Table 2 shows the dielectric properties of the alcohol content in purified water measured at 4.1 GHz by means of a dielectric probe connected to the network analyzer. The dielectric properties given in Table 2 are those obtained at 4.1 GHz.

Table 2. Dielectric and loss tangent values of the ethanol-water mixture at 4.1 GHz

Ethanol Content (%)	ϵ'	ϵ''	Loss Tan.	Sim. Res. Freq. (GHz)
0	78,64	11,34	0,144	3,897
20	69,42	11,03	0,159	3,911
40	52,85	10,03	0,190	3,924
50	45,03	9,27	0,206	3,930
60	37,66	8,16	0,217	3,943
80	25,35	6,99	0,276	3,987
100	8,96	5,22	0,583	4,057

In this section, the application of liquid sensor for specific ethanol and water mixture ratios of the CSSR sensor structure has been investigated. The observed transmission coefficient values are obtained numerically and experimentally as shown in Fig. 4. Examining the simulation results given in Fig. 4 (a), the resonance frequency is found to be at about 3.897 GHz for pure water content. When the percentage of ethanol in the mixture increases by 20%, the resonance frequency shifts to the right to new value of 3.911 GHz. As the amount of ethanol content in the mixture increases, the shift in the resonance frequency of the proposed sensor appears to be approximately linear as shown in the simulation results in Fig. 4(a). Such linear variation is also observed in the experimental results as seen in Fig. 4 (b). The experimental results have the resonance frequencies obtained for 0%, 20%, 40%, 50%, 60%, 80% and 100% of the ethanol content of the mixture at 4.024 GHz, 4.029 GHz, 4.033 GHz, 4.035 GHz, 4.038 GHz, 4.043 GHz, and 4.0, respectively. Numerical and experimental results demonstrate that the proposed CSSR based sensor structure has the potential to be used as a liquid sensor.

Figure 4.(a) simulation and (b) test results for the liquid sensor with respect to ethanol content

IV. BRANDED AND UNBRANDED DIESEL SENSING APPLICATION

In this section, an experimental study was conducted to distinguish branded and unbranded diesel fuels. First, the dielectric properties of the diesel samples were determined with the Agilent 85070E dielectric probe kit as shown in Table 3. Although the values are close to each other, the sensor structure of the proposed sensor has different capacitive effects on the sensor layer.

Table 3. Dielectric and loss tangent values of branded and unbranded diesel samples at 4.1 GHz

	ϵ'	ϵ''	Loss Tan.	Meas. Res. Freq. (GHz)
Branded Diesel	2.642	0.584	0.221	4.082
Unbranded Diesel	2.689	0.614	0.228	4.091

The experimentally obtained resonance frequencies for branded and unbranded diesel samples are shown in Fig. 5. It has been observed that the branded and unbranded diesel samples placed in the sensor layer shift the resonance frequency of the CSRR. The resonance frequency was obtained at 4.082 GHz for the branded diesel sample and 4.091 GHz for the unbranded diesel sample. A difference of about 9 MHz has occurred between the resonance frequencies of the two samples. When the results are examined, it is understood that the proposed sensor structure has the ability to separate two samples from each other.

Figure 5. Experimental results for branded and unbranded diesel samples

V. CONCLUSION

A CSRR type sensor structure with a metamaterial base exhibiting chemical liquid sensor characteristics has been analyzed both numerically and experimentally at microwave frequencies. In the study, first, the dielectric properties of the ethanol water mixture and diesel samples were determined. The samples are then tested both experimentally and numerically. When the findings are examined, it is understood that the proposed sensor structure works well as a chemical liquid sensor.

Abstract— As information security is one of the economic and national security problems, its importance has increased tremendously. It is very important in the military and intelligence fields of the countries. The components threat information security have entered the agenda not only in national governments but also in international communities. With evolving technology, all national and international community systems have searched new ways for security.

Keywords— Information Security, Cyber Attack, Information Security Awareness

I. INTRODUCTION

In recent years, with the use of the internet and developing technology, the importance given to information security, which has become one of the most important economic and national security problems of the countries, has increased greatly. Information security is of great importance especially in the military and intelligence fields of countries. Day by day, the intractable and complicated cyber threats have entered the agenda of not only national states but also international communities.

The unlimited progress of cyber attacks threatens many areas from international trade to personal banking. Our electronic devices, which become indispensable parts of our everyday life, are vulnerable to the Internet at any moment and can lead to serious problems against cyber attacks by computer hackers or even worse terrorist organizations. For example, a rogue hacker could penetrate into the operating system of a vehicle that is in the intelligent transport system and steer the flow in traffic, leading to huge problems that can not be predicted. Smart cities, energy stations, reliable sub-structures, etc. Increasing the usage areas and remote control of the oven, fridge computer and other devices in our house which can be connected by means of remote connection is a very serious security risk. Recently, the threats of artificial intelligence in

the world of science have been discussed, and many writers and screenwriters believe that intelligent robots and people produced by humans will fight in the future [1]. Cambridge University scientist Stephen Hawking, famous physicist, "artificial intelligence can bring the end of humanity" was found in the description [2]. Scientific and technological studies towards an autonomous system, which can be defined as the Cyber-Physical System (SFS) of today, are continuing rapidly [3]. Again, some systems used in our government institutions are also important for cyber security. It is also possible that an aggressor who seizes the remote controlled Mobile Electronic System Integration (MOBESE) system used in our security units will prevent detection of the offense leading to the incident and misguide it. Nowadays, the Internet, which has become one of the most used communication tools by people, has become a means of communication in many social events. This is an indication of how quickly information spreads on the Internet. For example, if you have 50 friends, this problem is solved in a few seconds by a social media group that is created together with each other.

Many people no longer wait in bank tails and do all banking work in the office or at the place where they live at home. Nowadays, many criminals are infiltrated into the computer system by finding exploits on the internet. Imagine that when a hacker who has leaked into your system runs an action defined as a crime in the world and your country's law from your computer, you may now be exposed to situations you do not want to be suspected or arrested. This is only a question that you can live individually and it is inevitable that everybody who uses the computer system absolutely must secure the information. Now, when an international crisis arises between countries, it is possible to start a cyber war immediately. The existence of this cause has also made it a requirement for countries to take themselves to the next level in combating cyber warfare.

Given that cyber attacks are taking place very quickly on the Internet, the prospect of designing very strong cyber security systems against attack will emerge. Various work has been done in this area. In the work done by Akyildiz [4], it is

determined how to infiltrate systems that have not been tested for safety by applying a network application. Afterwards, the importance of leakage tests has been emphasized, contributing to the awareness of the cyber security. Risk analysis methods have been determined by Aktaş [5] and four selected risk analysis methods have been tested and applied on a model. The proposed approach aims to increase confidence in risk analysis and management. In the work done by Mongol [6], it is emphasized why information security is important for companies, information about the company exposed to cyber attack and how important information protection is. A study by Durmuş [7] conducted a web-based survey on information security and examined the awareness of five different groups and highlighted the shortcomings of security measures in the

network structures of government employees and raised awareness among participants.

Today, these types of attacks, which are transformed into cyber warfare, have to make their own cyber security and have organizations that will respond quickly to this attack [8]. Countries have also been emphasized to work in coordination with institutions in this sector in order to ensure information security and to increase various penal sanctions within the country [9]. We need to identify the security level and risks in each system we use for information security and develop various security methods by analyzing these risks.

II. CONCLUSION

If information security is not emphasized, people or corporations can cause very important assets to be handed over to malicious people. Therefore, everyone should act sensitively to protect their knowledge and increase the continuity of their awareness.

- In the future, the following measures may be taken to enhance information security in the future:

- Institutions should provide information security training.

- Public institutions should conduct awareness raising activities.

- Countries should make more precise and clear laws by increasing the security of information security. .

- Security counseling and technical assistance units should be established in each unit.

- The awareness of individuals and institutions should be increased by conducting lectures on information security in universities.

- Ensure that basic information security training is as free as possible.

- Trainings on information security standards and policies should be given and the use of both institutions and employees should be ensured.

Abstract— In this study, the effect of using carbon fiber and carbon powder to the characteristic of wear and friction in automotive brake pads was investigated. Five different mixtures of brake pads were produced. The produced samples were tested in Friction Assessment and Screening Test (FAST) machine in order to determine the characteristic of wear and friction. Also, the microstructure of the friction surface of the samples were scrutinized by Scanning Electron Microscope (SEM). The sample in which %15 of carbon fiber is used showed more stable tribologic and mechanical properties than the other samples. So, it can be advised to use in automotive friction materials.

Keywords— Carbon fiber, wear, friction, brake pad

I. INTRODUCTION

In vehicle brake systems, kinetic energy in wheels is converted into heat energy via friction. The heat energy which occurs during severe braking conditions and cannot be got rid of the system, causes an overheating in the system. This is an undesired situation. Disc brake systems which are more advantageous than the drum brake systems in terms of cooling, are used commonly at present (Handa and Kato, 1996; Hee and Filip, 2005; Bijwe, 1997).

Braking system consist of a lot of parts such as master cylinders, wheels cylinders, tandem cylinders and a control system that is pneumatic or hydraulic system. Brake pads are of importance in each wheel for braking systems (Abhik et. al, 2014). In order that braking will have highly efficient, the wear level between disc and pad surface should be minimum and, a high and stable friction coefficient should be formed (Ertan and Yavuz, 2006). It should be known that there are many parameters which should be considered such as lower wear rate, stable coefficient of friction at different working speed, temperature, pressure and environmental condition in

order to develop a brake pad having better properties (Abhik et. al, 2014). The most important parameter is the composition and microstructure of the brake pad material. In the studies made on the brake materials, generally it is aimed to get the desired specifications by changing the composition. At the same time production method and production parameters should be evaluated together with composition. Because the pads which were produced with the same composition and different production method may show different performances (Ertan and Yavuz, 2006). There are several expectations from brake pads; they always should show constant friction coefficient, have a high friction coefficient and not be broken at high temperature (Ikpambese et. al, 2016). The production practices continue for friction materials which are not harmful for human health and show high tribological performance with low cost. In the production process of the pads materials which are high wear resistant and stable friction coefficient at high temperatures are used as basic bulk material. These materials are ceramic, metallic, polimeric and non-asbestos organic materials (Bijwe, 1997; Pauntenbach et. al, 2003).

Carbon fibers are materials which have micro graphite structure and are not used alone. They are generally used as reinforcing materials in the production of resin, ceramic and metal matrix composite materials. Due to high tensile and compressive strength, high hardness, low coefficient of expansion and self-lubricating properties, carbon fibers can be used for break pads. In the experiments, It was seen that which the carbon fiber ratios in the lining composition increased, the friction coefficient and wear values between the lining and the disc increased (Guan et. al, 2004).

In this study, In order to examine wear and friction characteristics of brake pads produced with carbon fiber having 30 mm of lenght and carbon powder, five samples were prepared different ratios and, wear and friction tests were conducted. As the mass ratio of the carbon fiber in the

composition increases, the mass ratio of the powder carbon is reduced. Using FAST test device, Tribological properties of brake pads samples were obtained. Frictional surfaces were investigated by SEM for microstructure characterization of brake pads samples. As a result of experiments, it was found that % 15 ratio of carbon fiber had positive effects on wear and friction characteristics (Malak, 2014).

II. MATERIAL and METHOD

The mass ratio was used to determine the composition of the brake pads samples. In order to examine the friction and wear behaviors of carbon fiber in the five selected composites, The total ratio of carbon fiber and powder carbon mixture was kept constant at 45%. The ratio of other materials was also kept constant at 55%, thus ensuring a clearer interpretation of the results. Three samples were produced from each sample and averages of the test results was taken into account by testing each samples by FAST.

Table 1. The Ingredients (Formulation) of Samples (WT.%)

Sample Code	3005	3010	3015	3020	3025
Carbon Fiber (30mm)	5	10	15	20	25
Carbon Powder	40	35	30	25	20
Steel Fiber	10	10	10	10	10
Cu Particles	5	5	5	5	5
Al ₂ O ₃	3	3	3	3	3
Rice Husk Dust	2,5	2,5	2,5	2,5	2,5
Graphite	7	7	7	7	7
Cashew	7,5	7,5	7,5	7,5	7,5
Phenolic Resin	20	20	20	20	20
TOTAL	100	100	100	100	100

The materials shown in Table 1 were prepared at the specified ratios and mixed for 20 minutes in a high-speed mixer to ensure homogeneity of the mixture. The homogenized mixture was cold pressed for 1 minute at pressure of 9.81 MPa for preforming. Hot pressing at 180 °C with a pressure of 14.71 MPa was then carried out for one minute per mm. The produced samples were tested by FAST test device in Figure 1.

Fig. 1. FAST test setup (Timur, 2007)

Before and after the test, the thickness measurements and weights of the samples were measured. Before the experiments, conditioning process was applied for overlap of %95 of friction surface at 0,7 MPa for 15 minutes.. After the conditioning process, the samples whose surfaces were cleaned and cooled were tested at pressure of 0,551 MPa for 90 minutes in order for friction performance tests. Datas obtained at each second were recorded on the computer.

In order for friction performance, friction coefficient-temperature-time graphs were generated with the datas obtained from experiments for every samples.

III. RESULTS

CHARACTER OF FRICTION SURFACE

SEM images were taken from the wearing surfaces to make microstructure studies on the friction surfaces. All samples showed both of abrasive and adhesive wearing. Abrasive wearing was detected at dark areas, and adhesive wearing was detected at light gray and white areas in the following pictures. When the image of five different samples is generally examined, it can be said that the components in the pads are homogeneous. Also it can be said that carbon fiber has an active role in friction and increases the amount of wearing by breaking off the surface in the friction surface areas.

Fig. 2. SEM image of sample with number 3005

Fig. 4. SEM image of sample with number 3015

Fig. 3. SEM image of sample with number 3010

Fig. 5. SEM image of sample with number 3020

When Figure 2 is examined, it can be seen that splits on the surface accumulates on the friction surface and continues to rub on the surface due to wear. In Figure 3, it can be said that the carbon fibers play an active role in friction and so increase the friction coefficient as well as the wearing amount.

The microstructure of the wear surface of the sample with number 3015 was given in Figure 4. It is seen that both the adhesive and the abrasive wear are carried out in the picture and all the components in the pads homogeneously affect to friction. This homogeneity plays an important role for reducing the specific wearing with increasing of the friction coefficient. In the Figure 5 and 6, It is estimated that specific wearing increases as carbon fibers can not be as homogenous as other samples and so the carbon fibers on the pad surface can be separated more easily in the pad.

Fig. 6. SEM image of sample with number 3025

FRICTION PERFORMANCE

The temperature-friction coefficient-time graph generated by the datas from experiments is shown in Figure 7. The graph was generated by taking the 5 minute averages of the values recorded for each second. Interface temperature increases with friction between the brake pad and the brake disk. With effect of this temperature, tribological properties of pad changes. In the Ostermeyer's study, it is defined that friction coefficient decreases with interface temperature (Ostermeyer, 2003).

When Figure 7 is examined, there is a steady decreasing change which is bumpy. The roughnesses on the surfaces of pad and disk combine, adhere and then separate. When this process continues as a continuous loop, there is a steady increase and decrease tendency in the friction coefficient (Boz and Kurt, 2005; Stachowiak and Batchelor, 2006). It is seen that the friction coefficient and temperature are different according to the brake pad composition.

Fig. 7. Temperature-Friction Coefficient-Time graph

The mean friction coefficient of $\mu = 0.65$ of the 3015 code sample is the highest coefficient of friction value. $\mu = 0.65$ which is average friction coefficient of sample with number 3015 was the highest friction coefficient. The lowest average friction coefficient was $\mu=0.49$ which belongs sample with number 3005. The average friction coefficient of sample with number 3010 was obtained as $\mu=0.52$. The average friction coefficient of sample with number 3020 and 3025 were lower than sample with number 3015, but higher than the others. The average friction coefficient of sample with number 3020 and 3025 were $\mu=0.58$ and $\mu=0.61$, respectively.

It is expected from pad materials that friction coefficient is high and stable. The sample with number 3005 and 3010 have the most stable structure with respect to friction coefficient. However, the frictional coefficient of these two samples is lower than the others. The sample with number 3020 and 3025 have unstable friction coefficient having high standart deviation. The friction coefficient of sample with number 3015 is high as well as generally stable. In this case, it can be recommended as the most suitable material.

Since the change in the friction coefficient directly affects the temperature, it is seen that the temperature graph is also parallel to the friction coefficient graph. The temperature in the samples which have high friction coefficient is higher. In addition, While the temperature increases, the friction coefficient decreases in general as phenolic resin deteriorated, that is, it lost its binding property (Anderson et. al, 1992). As a result of the friction test, the maximum temperature was measured as 218 °C for sample with 3015. The maximum average temperature is 180 °C which belongs sample with number 3015. The lowest average temperature is 122 °C which belongs sample with number 3005 having the lowest carbon fiber ratio.

The density of the samples was determined with Archimedes method. As the carbon fiber ratio in the composition increased, it was determined that the sample density generally decreased. After the friction test, the hardness values of the friction surfaces of the samples were determined with Brinell hardness measurement method. The surface roughness of the samples was also measured. As the carbon fiber ratio in the composition increased, the hardness and surface roughness of sample increased. Since 3 samples are produced from each sample, the values obtained from experiments are the average of the values of these three samples. The average values obtained are given in Table 2.

Table 2. Average density-hardness-roughness

Sample Code	Average Density (g/cm ³)	Average Surface Roughness (μm)	Average Brinell Hardness Number (HB)
3005	1,939	2,62	11,9
3010	1,874	3,04	16,1
3015	1,783	3,99	16,7
3020	1,783	4,53	13,8
3025	1,795	4,79	17,3

Average specific wear values were calculated using average friction coefficients, mean densities and average mass loss. As the friction coefficient increased, the specific wear value increased in general. Although the friction coefficient of sample with number 3015 was higher than the others, the specific wear value of sample with number 3015 was lower.

Table 3. Mean specific wear-friction coefficient-mass loss

Sample Code	Average Specific Wear (g/mm ²)*10 ⁻⁶	Average Mass Lose (g)	Average Temperature (°C)	Average Coefficient of Friction	Standart Deviation of Coefficient of Friction
3005	1,578	0,336	122,47	0,49	0,0600
3010	1,859	0,406	135,98	0,52	0,0574
3015	1,374	0,357	179,73	0,65	0,0989
3020	1,913	0,451	145,83	0,58	0,0695
3025	1,919	0,471	149,45	0,61	0,0778

IV. CONCLUSION

The friction coefficient value increased up to the additive ratio of 15%, but the friction coefficient value decreased above this ratio for 30 mm of the carbon fiber lenght. The highest friction coefficient was obtained as $\mu=0,65$ from sample with number 3015 reinforced %15 carbon fiber. The lowest friction coefficient was obtained as $\mu=0,49$ from sample with number 3005 reinforced %5 carbon fiber. Also, since the high friction coefficient will increase the temperature at friction areas, the samples having high friction coefficient have high interface temperature. While the maximum average temperature is 180 °C which belongs sample with number 3015, the lowest average temperature is 122 °C which belongs sample with number 3005.

It was found that while the carbon fiber ratio of samples increased, the density of samples decreased; the hardness and surface roughness increased. The minimum average density was 1,795 g/cm³ which belongs sample with number 3025, the maximum average density was 1,939 which

belongs sample with number 3005. Also, the maximum average hardness and surface roughness were 4,79 μm and 17,3 HB; the minimum average hardness and surface roughness were 2,62 μm and 11,9 HB, respectively.

The specific wear is a parameter which depends on density, friction coefficient and mass loss. As a disadvantage, with increasing of the friction coefficient, the specific wear increased. The minimum average specific wear was 1,578 g/mm²*10⁻⁶ which belongs sample with number 3005; the maximum average specific wear was 1,919 g/mm²*10⁻⁶ which belongs sample with number 3025.

Due to mentioned effects of carbon fiber on the brake pads, it can be used as a reinforcing material to brake pads in the automotive sector and the sample with number 3015 was the most suitable sample in all samples.

e-mail:ztugbaabaci@hotmail.com

Abstract—*Prunus* genus have over 400-430 species but only 98 species are of commercially importance. All the stone fruits are included in this group. Many important *Prunus* species have homomorphic gametophytic self-incompatibility (SI) mechanism, controlled by a simple multi-allelic *S* locus, which denies its own pollen. The incompatibility status is unknown in *Prunus* species causes significant economic losses in breeding programs. Identification of the incompatibility status can be detected by conventional and modern breeding methods. The modern breeding methods are fast, safe and saving on time. In this study, we analyzed so far makes SI studies by modern techniques in *Prunus* species. SI have been identified in 20 different *Prunus* species. It was determined 66 alleles in *P.armeniaca*, 54 alleles in *P. dulcis*, 51 alleles in *P.speciosa*, 41 alleles in *P.salicina*, 38 alleles in *P.avium*, 36 alleles in *P.cerasus*, 36 alleles in *P.mume*, 24 alleles in *P.spinosa*, 22 alleles in *P.virgiana*, 20 alleles in *P.africana*, 15 alleles in *P.cerasifera*, 14 alleles in *P. pseudocerasus*, 9 alleles in *P.humulis*, 9 alleles in *P.domestica*, 8 alleles in *P.davidiana*, 4 alleles in *P.japonica*, 2 alleles in *P.webbi*, 2 alleles in *P.yedoensis*, 1 alleles in *P.subhirtella* and 1 alleles in *P.tangutica*.

Ardahan/Turkey
e-mail:ztugbaabaci@hotmail.com

Abstract— *Moringaceae family has 14 species and Moringa oleifera is one of the species of this family. The plant has wide climatical adaptability and it can be grown many tropic and sub-tropic regions of the world. In this study, the benefits of Moringa were described. Moringa oleifera is one of the World's most useful trees, as almost every part of the tree can be used for food, medication and industrial purposes. Moringa is uses biomass, human food, animal food, , blue dye, foliar nutrient, antimicrobial agent, gum, honey and sugar cane juice-clarifier, medicine, tannin for tanning hides. Moringa has been used as a traditional medicine around the world, for anemia, skin infections, blackheads, anxiety, bronchitis, catarrh, chest congestion, asthma, blood impurities, cholera, glandular, swelling, headaches, conjunctivitis, cough, diarrhea, eye and ear infections, fever, abnormal blood pressure, hysteria, pain in joints, pimples, psoriasis, respiratory disorders, scurvy, semen deficiency, sore throat, sprain, tuberculosis, for intestinal worms, lactation ,diabetes and pregnancy. It is also an environmentally friendly due to the use of plants as a fertilizer, biogas, biopesticide, domestic cleaning agent, erosion preventive effect. The seeds of Moringa oleifera contains some coagulant matters and it is used in water purification.*

Abstract—This study focuses on moving object removal from video sequence. Firstly, all frames are extracted from video sequence. Then, an object is determined in the first frame and the determined object is detected and removed from all frames one by one. Empty region which is occurred after removing process, is restored by utilizing an inpainting algorithm. A software and an interface are designed for these processes. Synthetic and real video sequences are used to test and evaluate the developed method.

Keywords—*inpainting; object removal*

I. INTRODUCTION

In recent years, image and video processing have become more important because of developing technology and increasing usage of social media. Sometimes users are obliged to edit their photo or video due to undesired object, damaged region, noise etc. and these problems can be solved by image and video processing methods such as object removal, inpainting and texture synthesis.

When the relevant literature is taken into consideration, it is seen that many academic studies are made on object removal from video sequence and video completion. Zarif et al. [1] propose an approach to remove static object from video scene by utilizing local similarity and 3D hole filling. They state that proposed method has a faster processing and high quality. Bhatewara et al. [2] propose an inpainting system to remove undesired object from a video. They compare their method with other methods and show results visually. A video text removal method is presented by Mosleh and Bouguila [3] which uses stroke width transform and unsupervised clustering. They evaluate their method utilizing by different algorithms and they compare their method with other methods by computing mean square error. Herling and Broll [4] present a pixel based image and video inpainting study. They show visual results of comparisons with other methods and time performances. Yoo et al. [5] propose an approach to complete video using mosaicking, local motion computation and block matching. They show experimental results visually. A fast video completion study is presented by Afifi et al. [6]. Developed method which is based on patch synthesis and image registration is evaluated by human visual observation. Ebdelli et al. [7] present a novel video inpainting method which has a few steps such as spatial inpainting and global energy minimization. They state that proposed approach provides high quality inpainting results.

Zarif et al. [8] propose a video completion method based on gray level co-occurrence matrix. They show results visually and comparison of the execution time between the proposed method and other methods. A method is presented by Yang et al. [9] which detects and removes caption from video. They use colour edge detector and a method based on Criminisi algorithm. They show experimental results as correct rate, false detecting rate and missing rate. Jia [10] proposes a video inpainting algorithm based on texture synthesis. They show peak signal to noise ratio value of test results. Almatrafi and Sasi [11] present an object addition and removal study. The method can be used for image and video. Results are shown visually.

This paper presents a moving object removal method. After all frames are extracted from video sequence, an object is determined in the first frame. The determined object is detected and removed from all frames one by one. Empty region which is occurred after removing process is restored by utilizing an inpainting algorithm. We use the same shape of neighbourhood and searching method described in [12] for this process. Since we do not have an example texture patch, we searched appropriate pixel colour value within the empty region's surrounding.

II. MOVING OBJECT REMOVAL

Process of moving object removal consists of some sub-processes. Firstly, all frames are extracted from video sequence and they are registered as an image. Then an object is determined in the first frame manually. Determined object is removed from first frame and an inpainting algorithm is applied to fill occurred empty region. After processes related to first frame are finished, object is searched around previous location of object in the second frame so that if the object is moving, it is detected easily. After detection, removing and inpainting are carried out again. These processes are applied for all frames one by one.

Search and detection processes are shown in Fig. 1. Red square denotes search region (100x100 pixels). Sum of Absolute Difference (SAD) is used to find best matched region. Computing SAD is realized by summing absolute differences of R-G-B values. The region which has the lowest SAD, is accepted as detected moving object which is determined in first frame.

Fig. 1. Search and detection processes

Used inpainting algorithm is shown in Fig. 2. Shape of neighbourhood and searching method described in [12] are used. Red square denotes search region. Yellow squares denote pixels which are compared. White squares denote empty pixels which are occurred after removing object.

Fig. 2. Inpainting algorithm

The value of each empty pixel is determined by comparing its neighbours with all pixels in the search region. Its neighbours are shifted on searching region like a block. SAD is used to compare the difference of colour values. Computing SAD is realized by summing absolute differences of R-G-B values. The pixel which has the lowest SAD, is determined as best matched pixel. SAD which is applied in this algorithm, is given in (1).

$$SAD = \sum_{i=1}^{12} \alpha_i + \theta_i + \beta_i \quad (1)$$

α , θ and β denote absolute differences of R-G-B values between empty pixel's neighbours and pixels of search region. Algorithm is applied from left to right and top to bottom. Search region's height and width are accepted as 100x100 pixels.

III. EXPERIMENTAL RESULTS

We evaluate proposed method by using two real and three synthetic videos. Sample results of real videos are shown in Fig. 3 and Fig.4. Videos are obtained from [13]. They are explained and used in [14]. A person crossing the road is marked to remove in the first video. A static object is marked to remove in the second video but camera moves.

(d)

Fig.4. Results of the second real video a) marked object b) result of the first frame c) result of the second frame d) result of the third frame.

We use three texture images from Described Texture Dataset [15] which is explained and used in [16] to make synthetic videos. These textures are used for video's background and a synthetic moving ball whose diameter is 20 pixels is added on these textures so that synthetic videos are created. Moving ball is marked to be removed in these videos. Mean absolute errors (MAE) are calculated for each red, green and blue colour values to evaluate synthetic videos. First four frames of each video are used for this process. Tables I and II report two kind of evaluations. In the first one, one pixel shifting is applied in inpainting process. In the second one, two pixels shifting is applied. In Tables, v1-f1 means first video's first frame and v1-f2 means first video's second frame.

TABLE I. EVALUATION OF SYNTHETIC VIDEOS

(One pixel shifting)			
Frame	MAE (Red)	MAE (Green)	MAE (Blue)
v1-f1	24.27	23.07	25.73
v1-f2	7.53	6.43	5.95
v1-f3	27.18	27.39	29.75
v1-f4	6.80	6.31	5.57
v2-f1	28.03	30.76	33.53
v2-f2	30.92	37.77	44.52
v2-f3	33.98	47.66	63.78
v2-f4	31.13	34.58	39.22
v3-f1	37.63	42.12	40.45
v3-f2	33.43	31.64	34.22
v3-f3	25.93	33.97	33.60
v3-f4	20.66	21.01	19.63

TABLE II. EVALUATION OF SYNTHETIC VIDEOS

(Two pixels shifting)			
Frame	MAE (Red)	MAE (Green)	MAE (Blue)
v1-f1	40.86	58.60	51.17
v1-f2	7.95	7.01	6.36
v1-f3	29.06	27.74	30.87
v1-f4	6.16	5.57	5.28
v2-f1	31.16	34.59	37.97
v2-f2	33.11	39.54	45.47
v2-f3	35.41	48.47	66.21
v2-f4	30.33	35.20	41.87
v3-f1	33.43	40.02	40.28
v3-f2	29.42	28.51	29.85
v3-f3	24.63	29.98	30.02
v3-f4	20.27	19.85	20.16

Average errors of red, green and blue values are computed as 25.62, 28.56 and 31.33 respectively for the first evaluation. Average errors of red, green and blue values are computed as 26.82, 31.26 and 33.79 respectively for the second evaluation. Otherwise algorithm which uses two pixels shifting is three times faster than the one pixel shifting.

According to experimental results, assessments occur as follows;

- If the object which is determined to be removed is big or video's background is complicated, worse results are obtained for real videos.

- Computed averages errors of evaluations are not very different from each other but algorithm which uses two pixels shifting is three times faster than the one pixel shifting.

IV. CONCLUSION

Moving object removal is achieved by using a moving object detection algorithm and an inpainting algorithm. Proposed method is evaluated by utilizing real and synthetic videos. Results of real videos are shown visually. Otherwise, results of synthetic videos are evaluated by computing mean absolute errors. Occurred assessments according to results are explained. In the future we will add some processes to improve our method in terms of process duration and performance.

Abstract—Genetic Algorithms are widely used in many different optimization problems including layout design. The layout of the shelves play an important role in the total sales metrics for superstores since this affects the customers' shopping behaviour. This paper employed a genetic algorithm based approach to design shelf layout of superstores. The layout design problem was tackled by using a novel chromosome representation which takes many different parameters to prevent dead-ends and improve shelf visibility into consideration. Results show that the approach can produce reasonably good layout designs in very short amounts of time.

Keywords—market shelves layout, genetic algorithm, DEAP (evolutionary algorithm framework), python,

I. INTRODUCTION

Genetic Algorithm (GA) is one type of evolutionary algorithms which uses the evolutionary principles found in nature to find the optimal solution of problems [1-2]. Genetic Algorithms work according to probability rules and aim to find an answer for the existing problem and this answer is optimised over generations.

Although the design process for market shelves (Figure 1) seems to be easy, it is an important factor in the revenue and cost. For example, in a market design, a customer should be able to see all products on the shelves. The market shelves should not occlude each other. Another important factor includes the placement of entrance and exit doors. Customers should be able to navigate easily between shelves until they reach the exit door after entering through the entrance door.

Figure 1. A market shelf layout example

This paper describes the implementation of GA to the Floor Planning System. We describe our approach to designing a chromosome structure and fitness function to yield the optimal layout of the shelves. The result is a 2D map describing the shelf organization.

The rest of the paper is structured as follows: Section II describes the previous studies found in the literature which is followed by a brief explanation of the library used for the evolutionary system, namely Evolutionary Algorithm Framework (DEAP), in Section III. Section IV is dedicated to the description of the chromosome design and other implementation issues. Experimental results are described in Section V. Finally, the paper is concluded and future directions are outlined in Section VI.

II. BACKGROUND

Arrangement problems have a very important place when real life problems are considered. Since these problems are difficult to solve, heuristic algorithms such as genetic algorithm are used to produce near optimal results instead of traditional optimization algorithms.

In 2010, facility's layout plan was generated on Two Dimensional Shape Allocation with Genetic Algorithm [3]. Therein, the important point was shapes allocation with minimum space requirement on a 2D surface. Their results showed that the genetic algorithm gives optimal results in two dimensional shape fitting problems [3-4]. Our approach differs from this study in that we mainly focus on navigable corridors for customer walk instead of obtain the minimum space between shapes.

As a similar study, Rojas and Torres [5] designed a system using genetic algorithm to solving bank offices' layouts problem. They represented their problem solution in a chromosome that has five parts. First four parts of the chromosome represent the flanks of the office and fifth part contains the numbers of the departments located in the back part of office.

Maze generation problems are also quite related to floor planning problems [6-7], especially for computer games. Such

as automated maze generation for Ms. Pac-Man using Genetic Algorithms. In that study, a genetic algorithm was designed optimal mazes by specifying fitness function to create different mazes which can allow the game to be finished by the player [8]. The navigable corridor issue tackled here is very similar to the one in [8].

III. DEAP (EVOLUTIONARY ALGORITHM FRAMEWORK)

DEAP is an evolutionary computation algorithm developed by François-Michel De Rainville, Félix-Antoine Fortin and Marc-André Gardner in 2009 with the help of the Python program language [9]. Rapid prototyping allows users to quickly apply their own algorithms instead of limiting them [10]. Therefore, it is fairly easy to implement. The DEAP core consists of two basic structures; creator and toolbox. The Creator module allows generation of genes and populations from data structures such as list, set, dictionary. Toolbox is a structure that contains evolutionary algorithm operators.

IV. GENETIC ALGORITHM

Genetic Algorithms provide heuristic solutions to complex and difficult problems. GA based on natural biological evolution rules [11-13]. The fundamental principle of the GA is the survival of the fittest as it is in nature. Through the evolutionary process, each generation comes out to have superior features than their parents. To produce a fitter generation in time, the chances of reproduction of failed individuals are reduced. This is provided by several genetic algorithm operators. The most commonly used and important one is crossover operation in which an exchange of sections of the parents' chromosomes is performed.

Yet another GA operation is mutation. Only crossover on chromosomes can be insufficient for variation. Mutation operation ensures that a random modification of the chromosome. Selection of new individuals are made by a fitness function which constitutes the basis of an individual's quality. This function is defined in a problem specific fashion. It assigns a value to all individuals in a population. Selection operation is performed according to these fitness values assigned by fitness function. Outline of a GA can be described with the steps below:

- Creating initial random population.
- Calculating fitness of the each individuals in the population.
- Selection best fit from current population and generate offspring.
- Crossover and mutation operations to provide variety.
- Evaluating fitness of each offspring.
- Replacing failed individuals with newly generated ones.
- Repeating from step two until termination condition reached.

A. Chromosomal Representation

A solution to our market layout problem is created using blocks to represent market shelves. These blocks are represented in a chromosome which are divided four parts. The first part of the chromosome represents a block's direction; true for vertical blocks and false for horizontal blocks. The second and third parts of the chromosome represents position of block. The last one represents length of the block.

Figure 2. Block representation

```
isVertical = block[0]
xValue = block[1]
yValue = block[2]
blockLength = block[3]
```

An example chromosome may have the values (1,6,7,3) for a block with the following properties: This block was created vertical and 3 units lengths at (6,7) coordinates. This notation made it easier to implement the genetic algorithm and reach the solution.

B. Initial Population

Initial population is created with certain number of blocks that formed randomly. Each individual is represented by a 10x10 2-dimensional array with 10 blocks. For subsequent graphical display made easy, blocks were represented by 1 and corridors were represented by 0 in the array.

```
population [Individual([[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
                        [0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
                        [0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
                        [0, 0, 0, 0, 1, 1, 0, 0, 0, 0],
                        [0, 0, 0, 0, 1, 1, 0, 1, 0, 0],
                        [0, 0, 0, 0, 1, 1, 0, 1, 0, 0],
                        [0, 0, 1, 1, 0, 1, 0, 1, 0, 0],
                        [0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
                        [0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
                        [0, 0, 0, 0, 0, 0, 0, 0, 0, 0]])]
```

Figure 3. Map made out from blocks

C. Fitness Function

Fitness function is defined as a function which determined how good the individuals are as a solution. It assigns a value to each individual in the population considering their suitability for the solution. In GA Based Floor Planning System fitness values are assigned conforming to following purposes; floor design should let go around between all shelves and reaching all products to customers. That navigation control is provided by A* algorithm using a similar approach in [8]. Another criteria

for quality of the block is whether blocks are spread homogeneously on the floor and total number of blocks.

According to these constraints, we define the following,

$$r = \begin{cases} 0.05n, n \geq 5 \\ 0.05/n, otherwise \end{cases}$$

$$a = \begin{cases} +0.05, s \\ -0.5, otherwise \end{cases}$$

$$f = b/5.0$$

where

- b = total block count (1's in an individual)
- s = A* algorithm result that the map can complete process
- b = number of neighbours for a block
- r = neighbour count based fitness value
- a = A* algorithm based fitness value
- f = block count based fitness value

$$Fitness = f + a + r$$

D. Crossover

The crossover operator is used to create new solutions from existing solutions. This operator exchanges the genes information between individuals and puts together different parts of good solutions for create better solutions [14].

In this problem, crossover operator was applied to blocks instead of individuals. Selected blocks of population individuals were crossed to ensure variety as in Figure 4.

Figure 4. Two point crossover

DEAP's two point crossover method was used for floor planning system. In addition to this there are 2 more crossing methods including one point crossover and uniform crossover methods. In the first stage, a population of 100 individuals were generated. Then this number was increased and the effect of the number of population on the solutions was examined.

E. Selection

Selection process determines which individuals are chosen for reproduction. Main principle of the selection is gathering a group of high quality individuals have a higher chance of becoming parents in a mating pool. There are three major types of selection in Genetic Algorithm approach: tournament selection, rank-based selection and roulette wheel selection [15]. In this study, roulette wheel selection was employed.

The probability of selecting an individual in the roulette wheel method is the ratio of the fitness value of that individual to the total fitness values of all individuals as depicted in Figure 5.

Figure 5. Roulette selection for five candidates with different fitness values.

V. VISUAL INTERFACE GENERATION

Interface allows easy monitoring the improvements of generations. The python library graphics.py was used to create the interface. Graphics.py is a simple and easy object oriented graphics library written by John Zelle. The library is not a part of standard Python distribution so it must be imported. 500x500 pixels rectangle is created for the floor planning system using graphics.py.

10x10 empty grid is generated in this rectangle. In each individual which is result of crossover 1 values are replaced with a simple 2D box. A map can be directly visualised in this way as shown in Figures 6 and 7.

0	0	0	0	0	0	0	0	0	0
0	0	0	1	0	0	0	0	0	0
0	1	0	1	0	0	0	0	0	0

0	0	0	0	0	0	0	0	0	0

Figure 6. Blocks represented by 1s and 0s

Figure 7. Graphical representation of blocks in Figure 6

Figure 9. First generation resulting from GA

VI. EXPERIMENTAL RESULTS

The result of the study, individuals close to the expected solution are obtained. Low quality individuals are eliminated from the population. It is obtained that fitness values for next generations increased or remained stable in time.

Figure 8 shows how the fitness values change over time for 100 generations.

Figure 8. Fitness values alteration of individuals in time

Initial solutions are not ideal since they have many overlapping parts, see Figures 9. Note that these initial layouts are clustered together and hard to navigate.

The algorithm produces better layout designs over time. The evolutionary process eliminates the solutions where navigation is impossible and many overlapping parts exist. Further, the algorithm tries to make the best use of the whole floor by spreading the shelves across the whole surface as shown in the intermediate generation of Figure 11.

Figure 12 and 13 depict the final solutions, two best are shown here. These solutions definitely have navigable corridors where all shelves can be accessed. In addition, the use of the floor is more efficient than the initial solutions.

Figure 12. 100 th generation resulting from GA

Figure 13. 100 th generation resulting from GA

VII. CONCLUSION

The genetic Algorithm solution has become an effective algorithm that can be used to achieve fast and easy solution of many difficult and complex problems. This paper provided a solution to the design of market layouts. The ability of the genetic algorithm to obtain more than one optimum solution, possibilities to work with many parameters has also played a significant role in its acceptance. It is observed that the performance of the GA result changes according to given parameters and probability values. Results show that this approach was successful in generating good designs in an automated fashion.

In future work, fitness function will be improved to create better market layout. A way to achieve this is to integrate the shopping basket analysis along with this approach so that the market layout is in an agreement with users' shopping behaviour [16-17].

Abstract—The popularity of cyber-physical systems, which has a wide application area from military to medicine, is increasing day by day. It is practice and common to implement control algorithms such as fuzzy logic in the cyber layer in these systems where the cyber and physical layers are separate. Reliability and consistency are very important for cyber-physical systems, which is often used in large and critical jobs. Uncertainties, which is hard to be modelled, are the greatest threat to the consistency of a system. Type 2 fuzzy logic is a method developed to deal with uncertainties in fuzzy systems. However, computational complexity has prevented the widespread use of this method and has led to the emergence of non-stationary fuzzy logic. In this study, in order to see the appropriateness of using non-stationary fuzzy logic in cyber physical systems, where consistency and reliability are important, various effects on the system have been investigated. Different membership functions are represented by non-stationary fuzzy logic and comparative results are given.

Keywords—cyber-physical system; fuzzy systems; non-stationary fuzzy; uncertainty.

I. INTRODUCTION

Cyber-physical systems (CPS) are the systems whose physical elements -such as sensor, actuator, etc.- and cyber elements -such as algorithms- are not in the same place [1]. The integration and communication of these distinct layers are actualized thanks to communication technologies. Fig. 1 represents a basic diagram for CPS structure.

Fig. 1. Basic cyber-physical system structure.

In a cyber-physical system, data obtained by sensors are transported to cyber layer to be processed. As a result of the necessary operations which are actualized in cyber layer, it is calculated how the machines must move. The commands, which tell how the machines must behave, are transported to actuators in physical layer. At the end of the process, the machines know how to act and the systems work within this loop basically. As you can see from the basic principles of CPS working mechanism, the correctness of the system is directly related to the accuracy of the data obtained and transmitted. Uncertainty, which may have occurred unexpected times, is the major factor that affects the consistency of the system. In order to implement a robust CPS, uncertainties should be handled [2].

Fuzzy logic is used many times for solution of many different problems since it was introduced by Zadeh in 1965 [3]. In order to overcome the shortage of fuzzy sets in expressing uncertainties, the type 2 fuzzy logic was introduced by him after 10 years. Although the type 2 fuzzy sets make able to handle uncertainty, it is not common in real because of its complex computation requirements. The complexity of interval type 2 sets is reasonable for implementation in real problems, but such systems are not appropriate to represent variation in time [4]. Thus, non-stationary fuzzy sets are emerged to handle uncertainties with low computational efforts [5].

CPS has a wide application area from agriculture to medicine [6-8]. Lee et al. represented a CPS architecture for Industry 4.0 based manufacturing, which is new production trend of era [6]. Rad et al. established a system for monitoring potato crop with the help of CPS. The data obtained by sensors at field can be observed by user and farmer can make decisions based on other farmers' experiences according to that study [7]. Another study using CPS architecture is done in medicine by Pahlavan et al. They used micro cameras for taking pictures by endoscopy. The captured images sent to a computer by wireless technologies and the images are used to construct 3D map of human internal organs [8]. There are also studies about uncertainties and CPS under uncertainties in literature [9-11].

On the other hand, studies are done about fuzzy systems and handling uncertainties in fuzzy systems [12-16]. In this study, we investigated the effect of change in non-stationary fuzzy inputs to systems for being used in CPS. Different combines of non-stationary and type-1 inputs are given to system. Furthermore, randomly and uniformly created non-stationary sets are used and comparative results are given.

II. FUZZY SYSTEMS

A. Type-1 Fuzzy Systems

Fuzzy systems are emerged from the need of emulating human decision mechanism. Fuzzy sets, the sets used in fuzzy systems, is different from classical set theory. For further information about fuzzy sets, readers are advised to read fuzzy sets [A]. This paper will continue with the general steps of fuzzy systems. A type-1 fuzzy system consist of fuzzification, inference, and defuzzification steps. A block diagram of these steps are given by fig. 2.

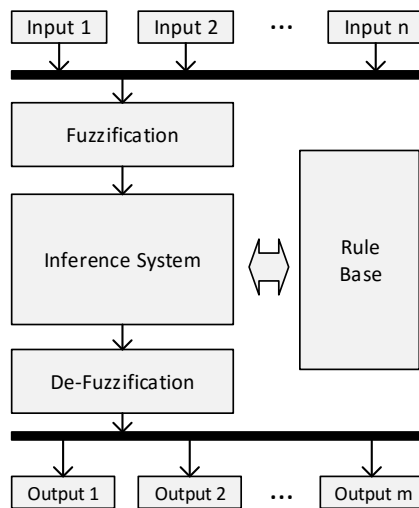

Fig. 2. Type-1 fuzzy system block diagram [17].

As seen in fig. 2, crisp inputs are given to fuzzy systems and crisp outputs are obtained. In fuzzification step, the crisp inputs are fuzzified by the help of membership functions. Most used membership functions in fuzzy systems are triangular, trapezoid, sigmoid, and gaussian functions [18].

After the fuzzification step, inference system come into work by the help of rule base. Rule base is the collection of if-else statements which are detected by experts. The result of cartesian product of the linguistic expressions in the separate entries which are obtained as the result of the fuzzification phase is determined according to this rule base. After that, the results are calculated according to inference mechanism. One of the most used inference mechanism in the literature is min-max method. Defuzzification is the step that makes crisp the variables again which are fuzzified. After output membership functions are limited by the inference results, a method, which

is called defuzzification method, is employed to obtain crisp output values. Center of area, center of gravity, first of maximum, last of maximum, indexed center of gravity, mean of maxima, and middle of maximum are some of the most used defuzzification methods [19].

B. Type-2 Fuzzy Systems

Type-2 fuzzy systems, which is introduced 10 years later from its first version by Zadeh, are developed to handle to uncertainties. Type-1 fuzzy sets are not able to represent uncertainties by single membership function. In order to handle them, in type-2 fuzzy systems there are two membership function which are upper and lower membership function. In type-2 systems, unlike type-1 systems, there is type reducer step before de-fuzzification step. A block diagram belongs to type-2 systems are given by fig. 3.

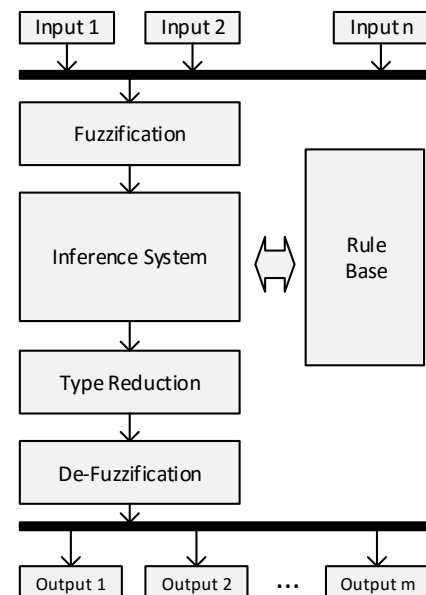

Fig. 3. Type-2 fuzzy system block diagram [17].

Because there are two membership function for each linguistic variable in type-2 fuzzy system, membership degrees cannot be specified by single value. Instead of this, a function which is called secondary membership function is used to express memberships.

The secondary is a constant function. Such systems which has constant secondary membership functions are called interval type-2 systems. Because of its complex computational requirements, interval type-2 systems are more preferable than general type-2 systems. But there still was a need for a new method due to the lack of representation of change over time.

C. Non-stationary Fuzzy Systems

Non-stationary fuzzy systems have emerged to eliminate the disadvantages of type-1 and type-2 systems. It represents

the change in time by low computational burden. In non-stationary systems, sub-type-1 systems are used to model type-2 fuzzy systems. A block diagram that shows the mechanism of non-stationary fuzzy system is shown by fig. 4.

As seen by fig. 4, type-2 system is represented by collection of sub-type-1 systems. Each sub-system is calculated and at the end of the processes, final de-fuzzification operation is applied to obtain single value for each output.

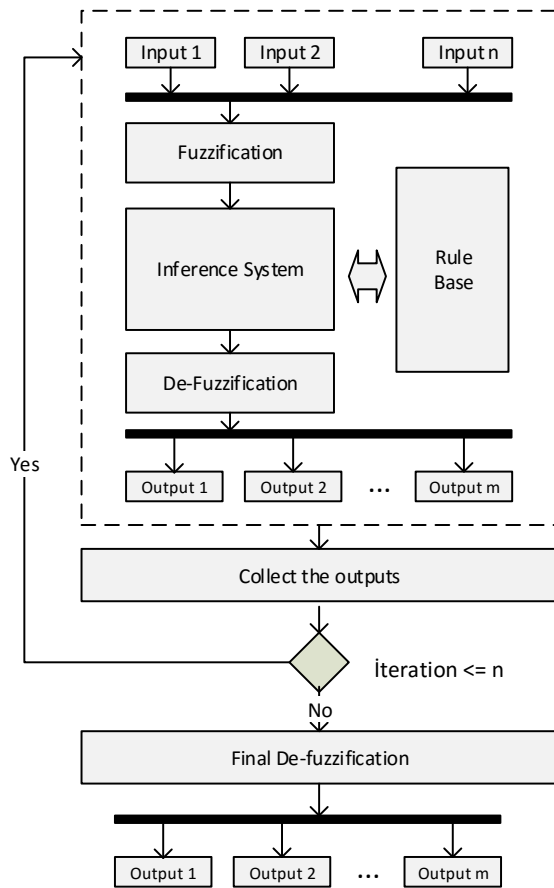

Fig. 4. Non-stationary fuzzy system block diagram [17].

III. COMPARATIVE RESULTS

In this study, in order to demonstrate the effect of non-stationary inputs a comparative study is done. A study that makes non-stationary the inputs for XOR operation done by Garibaldi before [4]. We aimed to take this one step further and see the consequences for different variations of entries in practice. XOR operation consist of two inputs and one output. The three functions have the same formula and there are two linguistic variables for each one. The linguistic variables and triangular type-1 membership function for the problem is given by fig. 5.

Fig. 5. Triangular membership functions for type-1 [4].

The general formula for triangular functions are given by (1). The a,b,c parameters are 0, 0.3, 0.6 respectively for linguistic variable 'low'; and 0.4, 0.7, 1 respectively for linguistic variable 'high'.

$$\max(\min\left(\frac{x-a}{b-a}, \frac{c-x}{c-b}\right), 0) \quad (1)$$

The truth table and fuzzy input values for this problem, which consist the rules, is given by table 1. While the values written in brackets in table 1 is fuzzy input values; 0 means low (L), 1 means high (H). A sample linguistic rule of the system is such that 'if input 1 is L and input 2 is L then output is L' for case 1.

TABLE I. XOR TRUTH TABLE AND INPUT VALUES

	Input 1	Input 2	Output
Case 1	0 (0.25)	0 (0.25)	0
Case 2	0 (0.25)	0 (0.75)	1
Case 3	1 (0.75)	0 (0.25)	1
Case 4	1 (0.75)	0 (0.75)	0

For comparison, 4 different scenarios have been implemented. The scenarios are given by table 2. The inputs for type-1 is like given in fig 5. Uniform and normal perturbation are employed to make the inputs non-stationary respectively. Non-stationary inputs are given by fig. 6 and fig. 7. While the amplitude remains constant, changes are made in the center within 0.1 (± 0.05) tolerance.

TABLE II. SCENARIOS TO BE USED IN COMPARATION

	Input 1	Input 2	Output

IV. CONCLUSIONS

Different combinations of type-1 and non-stationary fuzzy sets for XOR operation used to compare the results. The results with uniformly created non-stationary and randomly (normal) created non-stationary are given by table 3 and table 4. When we look the results, we can see that there is no difference or a few difference between scenarios when the inputs near to peak values (0.3 for low, 0.7 for high). But when the inputs near the middle value (0.5), the outputs for each case differs from each other. The results indicate that non-stationary makes the results softer. Thus, changes due to uncertainties don't affect the results too much as type-1 systems. And they can be used for CPS, when the effect of uncertainties must be declined.

Abstract—The determination of the needs of a city and the fulfillment of these needs in a short time are important for the development of the city. Many examples of smart cities have been created in the world in line with this purpose. The issues of how the city's residents can live more comfortably and how the city can develop are involved in countries' effort to transform their cities into smart cities. Many smart city models have been proposed so far. Water is the sub-heading of smart city wheel smart environment key of Boyd Cohen and people pillar in the smart city model proposed by IBM. This is due to the fact that water has had a crucial place for people's lives. The fact that water becomes poor quality while being distributed to people living in the city is one of the factors that threaten human health. It is possible to determine which pipes are unhealthy by comparing the water resources and the quality of running water in houses. In this article, it is aimed to help to take necessary precautions by continuously controlling water pipes. In the designed architecture, this process is performed by comparing the knowledge of the city's water source and the quality of the water received from the buildings.

Keywords—IoT, control of water pipes, city water quality check, mash-up, water quality sensor

I. INTRODUCTION

Nowadays, many scientists and entrepreneurs are developing various smart city applications for the solution of the problems faced by the people in city life and for people to live more comfortably. These applications are performed under many names such as smart city, digital city and intelligent city [1]. However, a precise definition has not yet been made in smart city studies carried out. Because there is not a model that will comply with every city [1]. The reason for this situation is the fact that each city has different problems and priorities. The

objectives to develop each city are different since they have different development levels, geographical structure, demographic structure and sources of income. However, some problems such as water are important for all cities. While the emerging problems are of top priority as the large cities of India have been continuously immigrated [2] one of these problems is clean water, the primary problems for Dubai are mobility, energy, water, open data, education and continuous learning, health, entrepreneurship, business incubation, and international exposure [3].

Problems need to be identified correctly for the solution of the problems. This situation causes Information and Communication Technology (ICT) to become an indispensable part of smart city. However, there has not been a precise definition of the role of ICT and technology type in the studies that have been carried out until today [4]. In [4], it was determined that ICTs such as web portal, NFC and RFID used in smart city studies that have been carried out until today have been used intensively.

Mash-up service means creating a new service by bringing together the services that are independent of each other [5]. While designing smart city, techniques such as mash-ups, widgets and portals are used to collect and access data from the real world [4].

The Internet of Things and Big Data systems have emerged in order for city to be more efficient and able to respond to problems more easily [6]. The Internet of Things provides data collection via software by connecting daily objects to the network [7].

There are various models developed in smart city design. In [8], the features of smart city are gathered under six headings. These are Smart Economy, Smart Environment, Smart Governance, Smart Living, Smart Mobility and Smart People. All of these features are defined by a series of factors. Each factor is defined by a series of indicators.

Figure 1.R. Giffinger Smart City Model Structure

Boyd Cohen defined a model that he called as smart cities wheel [9]. In the model, six key features were defined as smart people, smart economy, smart Environment, Smart Governance, Smart Living and Smart Mobility. Each feature has its own subcomponents. Since each city has different needs, the primary criteria of each city should be defined and the city should follow its own initial principles [10]. However, a series of indicators are assigned to each sub-component of each of the wheel in order to measure the sub-components of the wheel by considering that it does not have enough depth to add value to city planning [11].

Figure 2. Smart City Wheel Model Structure

Etzkowitz et al. defined the triple helix model, and this model has been used by many people in the smart city concept [12]. Triple helix model proposed the cooperation of academy, government and industry [13]. This cooperation positively affects the economic performance [13]. Effendi et al. developed the penta helix model based on the Triple helix model. In this model, media components were added to media support for the community and all stakeholders, for training

and interaction for ensuring digital adaptation to the triple helix model [12].

IBM defined three pillars in the model it defined [10]. They consist of the subheadings of people; education, health-care and social programs, infrastructure: energy, water and transportation and planning, planning and management: city governance, public safety, urban planning and managing natural resources and buildings [10].

The studies carried out should contribute to the development of environment, human, quality of life and so on and should be sustainable and secure for a city to be defined as a smart city [10][14]. Environment, people and quality of life are factors that affect each other. Water is one of the most important factors that will affect people's health. This shows us that the water source and the pipes used in the transmission of water should be quality.

In the article, the quality of the pipes can be consistently controlled by comparing the data of quality of water received from the water source with the quality of the water used by the residents of the city.

II. PROPOSED WORK

It is necessary to determine the problems of a city and to resolve these problems in a short time to make that city a smart city. But each city has its own dimension, social life, economy and demographic structure, therefore each city has its own priority problems. For instance, while the median age of people living in Vienna is 49.15 [14], it is 27 in Dubai [15]. The fact that the intensity of people that can be considered in the elderly group in Vienna is higher makes the precautions to be taken to make this group more comfortable even more important than the precautions to be taken by Dubai for themselves. However, the age alone does not show what the measures to be taken are. Because each person's needs are different. But there are also problems that will affect all people. One of these is water.

The fact that one of the most important sources in human life is water makes the problem of whether the cities' water supply networks are suitable for healthy water transmission a current issue. In this article, it is possible to determine whether the water in the regions is suitable for human life by using the data received from the sensors and controlling the water quality in order to solve this problem.

A. Receiving Data

The quality of the water resources of each city and the data obtained from the houses provide us information about the suitability of the method used for water transmission. Continuous control of a city's water pipes is almost impossible and difficult process. However, it is possible to reach the data on how healthy the pipes are by measuring the water quality of the city by means of the Internet of things. The Internet of things provides us with an access to information obtained from the objects through micro-

controllers and appropriate protocols [17]. The features of water such as conductivity, Ph value and TDS value can be obtained depending on the sensor used. Pipe systems consist of main and secondary pipes. As it is presented in Figure 3, all buildings are connected to each other by pipelines starting from the main source. This also allows us to control in order.

Figure 3. Water Network Sample

It is necessary to acquire the water quality data to be received from the whole buildings in the city and water sources for the assessment of water pipes in the city. The unhealthy conditions in water transmission reduce the water quality no matter how quality the water resource is. Therefore, data can be obtained by the sensors that measure the quality of water to be placed in each house and water resource. As it is shown in figure 3, Municipal office can reach the data obtained from the sensors by means of the Internet of things. It is possible to determine which water pipes are unhealthy by comparing these data obtained.

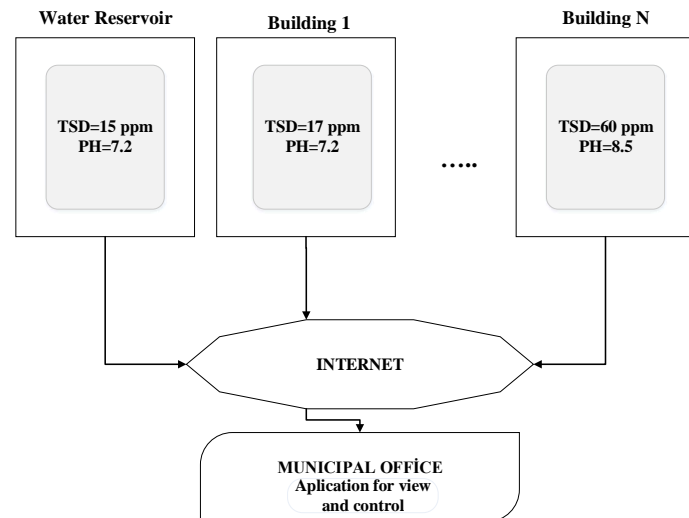

Figure 4. The architecture of the system that controls water quality with IoT

B. Evaluation of Data

When the data are obtained from the sensors with the information of the region where they are located, they will help us to obtain data about which regions provide higher quality transmission, in which regions the water delivery pipes are unhealthy and should be replaced. In addition, the changes in water quality information that are continuously received will help us to take precautions before the pipes reach at a level that will harm human health.

Table 1. SAMPLES OF INFORMATION FROM SENSORS

Adress	Information from Sensors		
	TSD	PH	...
Water reservoir	15	7.2	.
S1-B1	15	7.2	.
S1-B2	15	7.3	.
.	.	.	.
.	.	.	.
.	.	.	.
S99-B60	120	8.2	.

Only TSD and PH values are illustrated in the table above. However, all negative effects of the pipes on health can be controlled by the sensors. If the address process is performed in accordance with the mains supply, unhealthy pipes can be detected with the help of changing values.

While determining which pipe should be repaired, whether the pipes are healthy or not is firstly determined by comparing the data obtained from the buildings near the source. Then, the unhealthy pipe is determined by going away from the resource and continuing to control. The data about the location and water quality received from the whole buildings in the city and the water resource are compared, and the quality of the pipes providing the transmission between them can be measured.

There is no need to check the subsequent data if an unhealthy pipe is detected by controlling in a certain order. Because the water that passes over that pipe becomes poor quality. This will save us from performing unnecessary operations. If the data are obtained in order from water resource to the last point of the pipeline according to the city's own structure before receiving them collectively, it will be possible to prevent the system from slowing down with intensive data while determining the unhealthy pipe.

Mash-up further performs the merging of data and information obtained from more than one sources [18]. For the proposed study, it will be more convenient to determine which pipe is damaged according to the data obtained if the building locations and pipeline are shown on a city map.

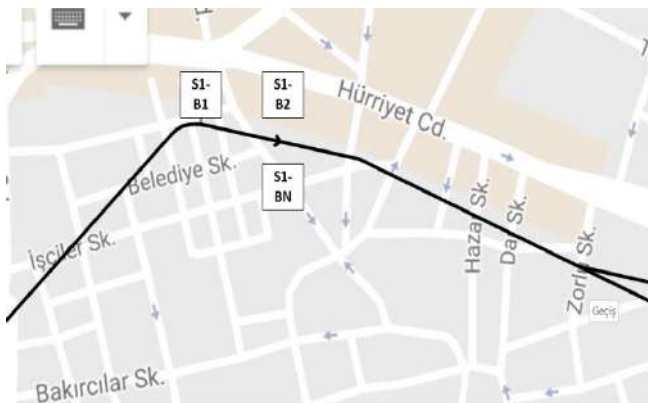

Figure 4. Mash-up Exemple for Recommended system

III. CONCLUSION

Water is one of the most important sources for human life. The fact that water is one of the subheadings of IBM smart city model and smart city wheel model from among smart city models, indicates how essential the water is for human life. Therefore, the health of the citizens should be protected by constantly controlling the quality of the water distributed to the city.

In the proposed study, it is determined whether the transmission pipes are suitable for human life by comparing the data of water source and water quality received from all houses of the city. These data reach the sensor data obtained by means of internet of things, and thus we have the opportunity to make comparisons. Thus, this smart city application is ensured to have both applicable and sustainable features. More than one water-related data can also be obtained depending on the sensor to be used.

It is possible to have a more convenient access to the data about which pipe is unhealthy by showing the locations of houses and pipes on a city map by Mash-up.

Abstract—with the vast increase in utilization of multimedia and communication technologies, the presence of digital records has increased tremendously. Every day people share something on the internet, in their e-mail boxes or in photo-video archives. It is evident that one needs to spend a lot of time searching this data to reach meaningful and necessary conclusions. Various methods are proposed to minimize this time necessity to be spent on. In recent days, image analysis has been performed by using different methods in combination with content based image retrieval which is a method that is mostly worked on. In this study, a portion of a public image database ‘imagenet’ has been used to classify images within it via convolutional neural networks which is one of the most popular deep learning methods.

Key Words: Content Based Image Retrival, Deep Learning, Convolution Neural Networks

I. INTRODUCTION

Image processing has become a very important topic nowadays because of rapid development in computer technologies. By employing image processing techniques, one can evaluate data at hand with lighting speeds and it would cost less time with lower error rates and simply easier. Machine learning technology facilitates our lives with a wide range of applications. Offering most relevant content with Internet searches, offering products according to our interests during online shopping, tagging images automatically on social media and speech recognition and voice control of mobile devices are just some examples of what machine learning offering to us. Moreover it is also employed in such areas like object detection and recognition, natural language processing, medical applications, autonomous cars and so on. Most of these said technologies are based on deep learning techniques and the number of never techs employing it is also growing [1].

Image processing is a field that manipulates, obtains inferences or defines patterns from still or moving images. It is utilized on many fields of science and its applications are increasing day by day.

It is desired to access and process data that are formed on digital platforms. As for today, these data are growing in such an exceptional way that handling, transmitting and accessing it demands some dedicated algorithms and workforce. Therefore,

content based image retrieving systems are assisting to solve this phenomenon in many areas [2].

II. CONTENT BASEING IMAGE RETRIVER

Accessing to images and classifying them have become important topics in today's access and retrieval systems. Therefore, need for Content Based Image Retrieval (CBIR) systems arose that will successfully match same or similar patterns on many problem domains [3]. Figure 1 depicts a usual subroutine to form a content based image retrieving system.

Fig 1. Block scheme for a content based image retrieving system

A system based on content based image access and classification mainly consists of the following three main elements.

A. Feature Extraction

In feature extraction stage, methods like pixel relation or post-conversion pixel relation are applied on both query images and the database. Feature extraction from textures that are found in nature is the most important step of the CBIR process [4]. The most important step for feature extraction is to create a model for every texture in feature space by using statistical data that distinguishes every texture from each other. When examined from a different point of view, textures that are found in nature rarely possess same scale, orientation, pose and contrast so therefore we can imply that it is crucial to find independent features for textures.

Many conversion methods have been developed to detect independent features such as scale, orientation and exposure.

SIFT [5], RIFT [6], GLOH [7] and SURF [8] provide successful performances in various fields. But a major deficit with overuse of these techniques is that vast increase in number of features and those yielding confusion. For instance in case of SIFT, when it yields successful results regarding independent features on scale and orientation, feature vector length could be in range of 1000's. Working with large feature vectors is accompanied by high memory and computational overhead requirements. With the help of feature extraction, color, texture and shape attributes of visual objects are transferred to the system and their visual contents are indexed [9].

B. Training

Feature training of a class is realized by using the common features of the images formed in the specified class. In this training phase, the acquired features of the images are trained on their own, and the common class inferences of the images are made according to the obtained values.

C. Testing

In the comparison phase, which is the last stage of image access, the resulting class features are compared to the database. As a result, it is determined which class does image belongs or similar images belonging to the specified class are acquired. All the images in the database are processed through the same way and the classification performance is obtained.

This process, which is applied to the query image and all the images in the database in the same way, is the most basic step to ensure a successful comparison. A number of features of the images in the database are extracted and saved into the system. Various transformations are made on this data. Although the number of selected features for image classification seems to be a success in image recognition, the increase in the number of features used during classification will lead to mixed and undesirable results in terms of both calculation complexity and similarity between classes. With respect to that, it is important to select the most appropriate and distinguishing basic attributes of the relevant class.

D. SIFT Algorithm

Scale Invariant Feature Transform (SIFT) is an algorithm that identifies and defines regional features that are unvarying for a picture like illumination, rotation and scaling. Image processing with the SIFT method consists of 3 steps [10]. These are:

Step 1: In this stage, the scale is used to determine the extreme value points in the space

$$L(x, y, \sigma) = G(x, y, \sigma) * I(x, y) \quad (1)$$

Here '*' symbol denotes convolution operator, $G(x, y, \sigma)$ denotes variable scaled Gaussian function, $I(x, y)$ denotes original image, (x, y) denotes processed images pixel coordinates and σ denotes scaling factor. Gaussian convolution equation is;

$$G(x, y, \sigma) = \frac{1}{2\pi\sigma^2} e^{-(x^2+y^2)/2\sigma^2} \quad (2)$$

Difference-of-Gaussian (DoG) defined as $D(x, y, \sigma)$ find scale-space endpoints with equations x.

$$\begin{aligned} D(x, y, \sigma) &= (G(x, y, k\sigma) - G(x, y, \sigma) * I(x, y)) \\ &= L(x, y, k\sigma) - L(x, y, \sigma) \end{aligned} \quad (3)$$

Here $k=1,2,3,\dots$ is used to present different scale space. The local minimum or local maximums of $D(x, y, \sigma)$ are calculated by matching each pixel with the neighborhood of the specified number in the upper and lower scales.

Step 2: Unwanted points that reside on the edges of the images that have weak description or low contrast are eliminated.

$$z = \frac{-\partial^2 D^{-1}}{\partial x^2} \frac{\partial D}{\partial x} \quad (4)$$

The 2×2 Hessian matrix is prepared by using spatial variants of 'z' belonging to a small area around the extremes. By looking at the relative proportions of the features at Hessian matrix, candidate edges and similar regions with low contrast are eliminated.

$$H = \begin{bmatrix} D_{xx} & D_{xy} \\ D_{yx} & D_{yy} \end{bmatrix} \quad (5)$$

The elimination criterion for a badly-defined long edge can be formed as follows:

$$\frac{Tr(H)^2}{Det(H)} < \frac{(r+1)^2}{r}, r = \frac{\alpha}{\beta} \quad (6)$$

Here α is big sized, β is small sized Eigen value. If this equation turns true than key points are eliminated.

Step 3: It aims to assign an orientation to the correct lock points according to local visual properties. In other words, it is desired that the lock points do not change according to their rotation movements. This orientation approach consists of four steps:

- Keypoint scaling is used to select the L-smoothed Gaussian method and the gradient size is calculated
-

$$m(x, y) = \sqrt{(L(x+1, y) - L(x-1, y))^2 + (L(x, y+1) - L(x, y-1))^2} \quad (7)$$

$$\theta(x, y) = \tan^{-1} \left[\frac{(L(x, y+1) - L(x, y-1))}{(L(x+1, y) - L(x-1, y))} \right] \quad (8)$$

- A trend histogram is formed from the gradient orientations of the sample points
- The highest peak value in the histogram is located.
- Corresponding orientations and local peaks up to 80% of this peak are assigned to the key points.

In the final step, descriptive vectors are calculated for the feature points. From a 16×16 region around the feature point,

for every 4×4 clusters 8 partitioned histograms are obtained. The value in each partition in the histogram is a component of the $4 \times 4 \times 8 = 128$ dimensional descriptor vector. The effect of the change on illumination is removed by resizing the 128 dimensional vector into unit length.

III. DEEP LEARNING

Deep learning is the training process of multi-layered feed-forward neural networks. This name is given because of having a hidden layer for learning. Deep learning is used by data scientists working in the academic and private sectors in a variety of applications, including image classification, image segmentation, video analysis and classification, voice recognition and processing and natural language processing. Deep learning occurs with the use of multi-level deep neural networks. It is often used to create systems that can extract information from large quantities of untagged training data by employing feature extraction techniques.

Deep learning architecture comes in many layers and hidden variables. The most commonly used algorithms are Deep Artificial Neural Networks, Automatic Encoders and Restricted Boltzmann Machines which is a derivative of Boltzmann Machines [11]. Convolution method is used together with this concept for separating data into classes or clusters. This method is also employed in this study.

A. Convolutional Neural Networks(CNN)

Convolutional Neural Networks (CNN), developed by YannLeCun in 1988, is a special type of multilayer neural networks. Although they have different architectures, like other neural networks, they are trained with a version of the feed forward algorithm [12]. CNN is designed to recognize direct visual patterns from pixel images with minimal preprocessing. They are very successful against over variable patterns and simple geometric transformations. It is also the most well-known and widely used network structure in all deep learning algorithms. CNN includes feature duplication and summarization layers thus offering different feature extraction approaches from other algorithms. CNN basically consists of 4 layers. These are convolution layer, Activation function layer (ReLU), Pooling and Normalization layers.

1) *Convolutional Layers*: The convolution layer performs a series of mathematical operations for each sub-region to produce a single value in the output feature map. The convolutional layers are then subjected to a ReLU activation function at the output to bring some non-linearity.

2) *Rectified Linear Unit Function(ReLU) Layers*: It is accomplished by following a linear filter with a non-linear activation function applied to each component of a feature map (i.e., pointwise). Such simple functions are called Rectified Linear Units (ReLU). There are many activation functions. List of activation functions and their mathematical interpretations are given below.

Maximum activation function;

$$y_{ijk} = \max\{0, x_{ijk}\}, \quad (9)$$

Sigmoid activation function;

$$y_{ijk} = 1/(1 + e^{-x}) \quad (10)$$

Tangential activation function;

$$y_{ijk} = 2\sigma(2x) - 1 \quad (11)$$

is shown as. In this study, the maximum activation function was selected for the ReLU layer.

3) *Pooling*: It combines the feature values near each pixel value by applying an appropriate operator. The most commonly used pooling methods are max-pooling and mean-pooling methods. Max-pooling takes the highest pixel value of a group of pixels while Mean-pooling calculates the average of them. Pooling layer, gradually reduces spatial size of representation, reduce the number of parameters and amount of computation in a network and thus controlling the over fitting. It is a common practice to place a pooling layer between convolutional layers in CNN architectures.

4) *Normalization*: Normalizes the vector of feature channels in each spatial location in the input map. It is calculated as shown in the following equation.

$$y_{ijk'} = \frac{x_{ijk}}{\left(k + \sum_{k \in G(k')} x_{ijk}^2\right)^{\beta}} \quad (12)$$

Here $G(k) = [k - [p/2], k + [p/2]] \cap 1, 2, \dots, k$ is a group of consecutive feature channels in the input map. In normalization, the adjustment of the image is performed with altering of 4 parameters. After the normalization phase, images are on their final forms and all features are obtained. By using these features, it is possible to perform many image processing operations such as classification, segmentation, edge extraction, object recognition, face recognition, background extraction and the so on.

IV. EXPERIMENTS

The system was tested on the network created with the images obtained from the Image-net project [13] and its performance was evaluated. We transferred learning for our selected dataset with respect to acquired network. Our database consists of actual images in the form of aircrafts and cars was presented as input to the prepared system and the classification achievements of these image classes were evaluated. A total of 350 car images and 1037 aircraft images were used in the study.

A. Convolution Neural Network Structure Used

The CNN model that occurs in the convolution, ReLU, Pooling, Normalization layers is shown in Fig 2.

Fig 2. CNN model used

As shown in Fig. 2, the network consists of 21 layers and consists of 8 layers of convolutions, 7 layers of ReLU, 3 layers of pooling, 2 layers of normalization and finally a layer of Softmax. When these layers come together, a CNN model is created and the test operation was performed on this model.

B. Method

Imagenet's [13] publicly accessible web - based images and dataset models were tested separately and their performance was examined. The obtained image database has been pre-processed before hand.

Images are forwarded through layers according to the proposed CNN. Input images that are fed into the first stage of the CNN were resized to 224x224x3 dimensions in order to conduct a proper evaluation. We tried to obtain the features for different image categories by passing them through the CNN model. Then we matched these features to previously prepared dataset in order to reveal a class information. As a result of these operations, correct classification rate of the image class information was tried to be determined.

C. Database

The actual images that contain images of aircraft and cars are transformed into a dataset. We need to point out that entire database is formed of different types of aircraft and car images. For cars, we can tell that there are sports cars, panel vans, racing cars, jeeps and etc. For airplanes, there are passenger aircraft, private aircraft and jets. Figure 3 shows images from both categories. These images are obtained from the web address of imagenet.

Fig 3. Real image in the car and airplane category.

D. Implementation Results

In this study, a total of 350 images for cars are passed through the CNN model, then the resulting pattern is tested on the image-net dataset and the category information of the image is obtained. Table 1 below shows the statistical values for each car type

TABLE 1. CLASSIFICATION RESULTS OF IMAGES IN CAR TYPE

Car Type	Number of vehicle	Average similarity	Maximum similarity
Sports car	227	0,6200	0,9786
Race car	75	0,5686	0,9781
Open car	33	0,4967	0,8461
Taxi	8	0,4052	0,4821
Others (wrong)	40	0,3653	0,3659

When Table 1 is examined, the images in the car type are tried to be classified under 5 categories. The examples in this class are categorized as sports cars, racing cars, open cars, taxis and other vehicles. When the achievements in this category are considered, the highest performance rate is found in the category of sports cars. The maximum similarity rate was 0.9786 for sports cars and 0.9781 for race cars. The number of vehicles determined according to the category are 227 sports cars, 75 race cars, 33 open cars, 8 taxis from 350 images. 40 of the images tested in this dataset were incorrectly classified. The average similarity of 0.3654 was found to be very unstable during the test phase. In Table 2, statistical information is shown when the cars are separated as automobiles and others.

TABLE 2. CLASSIFIED ACHIEVEMENTS OF THE CAR TYPE

Car Type	Number of vehicle	Average similarity	Maximum similarity	Achievement ratio
Automobile	310	0,6549	0,9786	0,8857
Others(False)	40	0,3653	0,3655	0,1142
Total	350	0,6218	0,9786	1,00

The classification performance is 0.8857, and the error rate is 0.1142, which can be considered as a high performance.

Fig. 4. Performance ratios of car-type images

Figure 4 shows the maximum and average performance ratios of the car types. It has been determined that the lowest values are the mean and maximum similarities of misclassified images. Figure 5 shows a sample image that is incorrectly classified.

Fig 5. Example of misclassified image

In the second phase of this study, the image containing 1037 real aircraft objects was passed through the CNN model, and then the obtained pattern was tested on the dataset that we used before and tried to reach the category information of the images. Table 3 shows the statistical values of real images in the aircraft type.

TABLE 3. AIRPLANE CLASSIFICATION PERFORMANCE

Plane Type	Number of vehicle	Average similarity	Maximum similarity	Achievement ratio
Airplane	892	0.7567	0.9996	0,8602
Others(False)	145	0.4513	0.935	0,1398
Total	1037	0.7570	0.9996	1,00

When Table 3 is examined, it is classified under 2 categories in images of aircraft type. They are categorized as airplanes and others as misclassified. When we look at the performances achieved in this category, we obtained a performance ratio of 0.8602 in the category of airplanes. This rate was found to be very high in some airplanes (which is often close to this value) is 0.9996. When looking at the number of airplanes detected, 892 of the 1037 airplanes were identified as passenger airplanes, while the 145 images seemed to be misclassified, including the different types of airplanes (54 of them were described as warplanes). The error rate was limited to 0.138.

V. CONCLUSION AND FUTURE WORK

In this study, randomly selected images that have RGB channels are classified with the help of Convolutional Neural Networks. This study is classified according to the CNN method on the commonly used images. The correct classification performance ratio of the data in the airplane group is 0.8602 and the classification performance ratio for the cars is 0.8857. In the next studies, different CNN methods will be developed to try to develop and implement success on different images and videos.

Abstract—Computational intelligence methods are algorithms that utilize a simple approach as a solution technique of search and optimization problems and are recently getting strong and becoming more popular due to their advantages. Computational intelligence optimization algorithms have been proposed and used to find well-enough solutions at a reasonable computation time when the classical algorithms are not applicable or do not provide good solutions to these problems due to the unmanageable search space in many different fields such as management science, engineering, computer, etc. Many existing algorithms are nature-inspired, which work by simulating or modeling different natural processes. Due to the philosophy of continually searching the best and absence of the most efficient computational intelligence algorithm for all types of problems, novel algorithms or new variants of current algorithms are being proposed. Stochastic Fractal Search Algorithm (SFSA) is the one of four mathematics inspired global optimization algorithm inspired by the natural phenomenon of growth using a mathematic concept called the fractal. This paper explains the operators of SFSA used in optimization and search problems and represents the comparative results obtained from other mathematics based computational intelligence algorithm, namely Sine-Cosine Algorithm for different benchmark functions for the first time. Although no optimization has been implemented for its parameters and no variants have been proposed, obtained results from the experiments are promising. SFSA seems a simple and efficient global optimization algorithm that may efficiently be used in many complex search and optimization problems. Its variants with optimized parameters may be proposed for more efficient solutions in future works.

Keywords—Computational Intelligence; Global Optimization; Stochastic Fractal Search Algorithm

I. INTRODUCTION

There are many challenging problems in industry and science which can be formulated as optimization problems. Nowadays, many companies have faced problems in need of optimization. Computational intelligence search and optimization algorithms

are the methods that utilize a simple approach as a solution technique of search and optimization problems and are recently getting strong and becoming more popular. They provide general solution strategies that can be applied to the problem in case of concurrent different decision variables, objective functions, and constraints and they do not depend on the solution space type, the number of decision variables, and the number of constraints [1, 2]. Furthermore, they do not require very well defined mathematical models that are hard to organize for system modeling and objective function. Their computation power is also good and they do not require excessive computation time. Their transformations and adaptations are easy. They give efficacious solutions to the high-scale combinatorial and non-linear problems. These algorithms do not require the assumptions that are hard to be approved to adapt a solution algorithm to a given problem as done in classical algorithm. They do not require the alteration on the interested problem as done in the classical algorithms. They are adaptable in order to solve different types of search and optimization problems. Due to these advantages, these algorithms are densely being used in many different fields such as management science, engineering, computer, etc. General purposed computational intelligence algorithms are generally classified in different groups like biological based, social based, music based, sports based, water based, plant based, chemistry based, physics based, and math based. There are also hybrid methods formed with these methods [1].

Although there are many effective and successful methods that have been introduced to the literature, it is an important task for the science that there should be always effort to improve and search for the best. Also, there have not been any algorithm that can solve all types of problems effectively, often new algorithms are introduced and also improved versions of the introduced ones are proposed in order to improve their effectiveness. Especially in recent years, researchers have introduced such new computational intelligence methods to the literature and

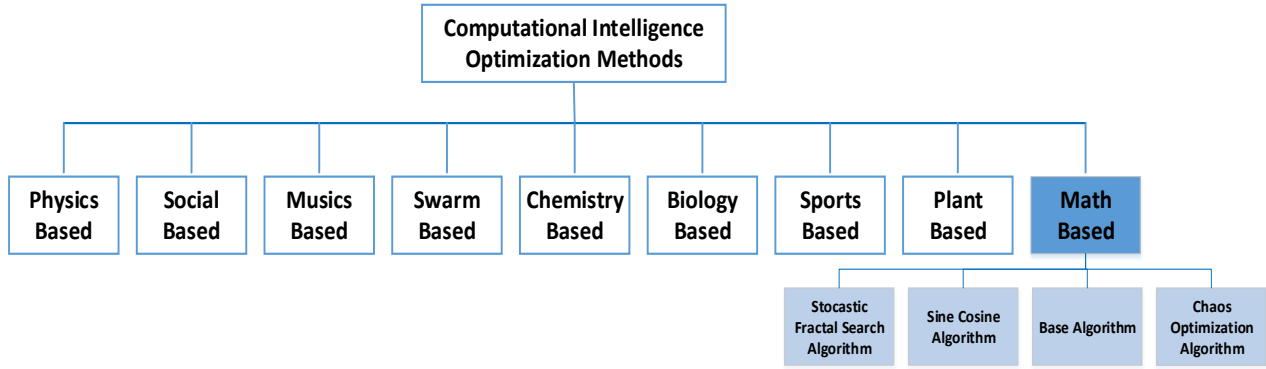

Figure 1. Classification of artificial intelligence optimization methods.

performed successful applications [3]. Due to the philosophy of continually searching the best and absence of the most efficient computational intelligence algorithm for all types of problems, novel algorithms or new variants of current algorithms are being proposed [1-4]. These algorithms can be classified in nine different main categories, as shown in Figure 1. There are also hybrid version of these methods. There are only four algorithms which are based on mathematics. They are, Sine Cosine Algorithm (SCA) [5], Base Algorithm (BA) [6], Chaos optimization algorithms [7], and Stochastic Fractal Search Algorithm (SFSA) [8]. The term Matheuristic is also used for optimization algorithms made by the interoperation of mathematical programming techniques and (meta) heuristics [9].

In this paper, the operators of SFSA has been introduced and the comparative results obtained from other mathematics based Sine Cosine algorithm for different benchmark functions have been presented. Section 2 SFSA has been explained. Section 3 describes the works about SFSA. Section 4 defines the benchmark functions used for comparisons. Section 5 presents the experimental results and finally Section 6 concludes the paper along with future research directions.

II. STOCHASTIC FRACTAL SEARCH ALGORITHM

A fractal is a mathematical set that exhibits a repeating self-similar pattern displayed at every scale. Random fractals can be generated by modifying the iteration process via stochastic rules such as Levy flight, Gaussian walks, percolation clusters, self-avoiding walks, fractal landscapes, trajectories of Brownian motion and the Brownian tree. SFSA is a new global search algorithm based on random fractals. This algorithm has been proposed overcome the shortcomings of basic fractal search. All procedures in SFSA can be divided into two processes called Diffusing and Updating processes. In the first process, each particle diffuses around its current position using Gaussian Walks and Levy Flight to increase the chance of finding the global minimum and it can be considered as exploitation phase of the SFSA. In the latter process, SFSA uses some random methods as updating

processes based on the positions of other selected candidates in the group to explore the problem space efficiently and this can be considered as exploration phase of SFSA [8]. After initializing a set of points uniformly distributed within the search range, the Diffusion process is started to generate new particles using one of the two Gaussian Walks as shown in (1) and (2).

$$GW_1 = \text{Gaussian}(\mu_{BP}, \sigma) + (\varepsilon \times BP - \varepsilon' \times P_i) \quad (1)$$

$$GW_2 = \text{Gaussian}(\mu_p, \sigma) \quad (2)$$

ε and ε' are two uniform random numbers within the [0, 1] interval, BP is the position of best point while P_i is the position of the i th candidate. The two means μ_{BP} and μ_p are equal to BP and P_i . Standard deviation σ is computed as shown in (3) t is the generation number.

$$\sigma = \left| \frac{\log t}{t} \times (P_i - BP) \right| \quad (3)$$

Update process consists of two procedures. The first one uses (4) to update the j th index of each point while second procedure uses (5) to update the point.

$$P'_i(j) = P_r(j) - \varepsilon \times (P_t(j) - P_i(j)) \quad (4)$$

$$P'_i = \begin{cases} P_i - \varepsilon \times (P_t - BP), & \varepsilon \leq 0,5 \\ P_i + \varepsilon \times (P_t - P_r), & \varepsilon > 0,5 \end{cases} \quad (5)$$

P'_i is the new point, P_r and P_t are two different random values selected from the candidates; BP is the best point and ε is a random number within the [0, 1] interval [8]. Flowchart of SFSA has been depicted in Figure 2.

III. WORKS ABOUT SFSA

After introducing the SFSA, it has been used in many different fields and new variants have been proposed. In [10] query optimization problem in large distributed databases has been solved with SFSA. SFSA has been proposed for optimization of planer frame to minimize its weight subjected to the

strength and displacement requirements and effective results have been reported against other methods [11]. Solution of multi objective economic and emission dispatch problem has been solved by SFSA in [12] and competitive results have been obtained. In [13], a penalty guided SFSA has been adapted for solving reliability allocation, redundancy allocation, and reliability–redundancy allocation problems and superiority of the method compared to others from literature has been reported. In [14], SFSA has been proposed for Power system tracking state estimation under sudden load changes and improved results compared to genetic algorithm and particle swarm optimization have been reported. Chaos has been embedded to SFSA in [15] to improve SFSA in terms of convergence speed and fitness accuracy.

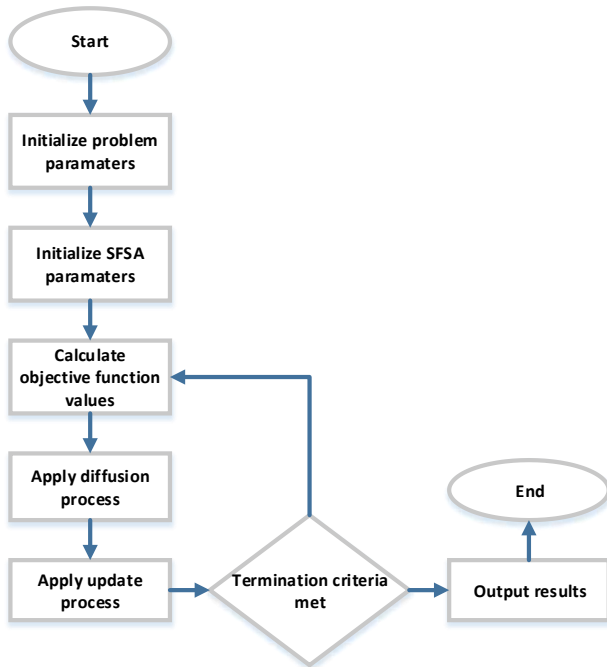

Figure 2. Flowchart of SFSA.

SFSA has been hybridized with differential algorithm in [16]. In [17], chaotic SFSA has been used parametric modelling of a twin rotor system and superior results have been obtained. In [18], authors have introduced a novel hybridization between differential evolution and update processes of the SFSA and statistically superior performance over most of the tested benchmarks, especially hybrid and composition test functions compared to the other contestant algorithms have been reported. In [19], a hybrid SFSA and pattern search based cascade PI-PD controller has been proposed for automatic generation control of thermal, hydro and gas power unit based power systems in presence of plug in electric vehicles and competitive result have been obtained.

IV. BENCHMARK FUNCTIONS

Benchmark test functions are used to evaluate and compare the characteristics of optimization algorithms in terms of

convergence, precision, robustness, and general performance as a rule. The nature, complexity and other properties of these benchmark functions can be easily obtained from their definitions. The difficulty levels of most benchmark functions are adjustable by setting their parameters [20].

A. Chung Reynolds Function

Chung Reynolds Function is a continuous, unimodal and scalable function with less complexity and it can be used to evaluate the converging behaviors of search and optimization algorithms [21]. It is represented by (6).

$$f_1(x) = (\sum_{i=1}^n x_i^2)^2 \quad (6)$$

subject to $-100 \leq x_i \leq 100$. The global minimum is located at $x^* = f_1(0, \dots, 0)$ and $f_1(x^*) = 0$. Graph of this function with two dimensions has been shown in Figure 3.

Figure 3. Chung Reynolds function with two dimensions intervals of which are $[-100, 100]$.

B. Griewank Function

Griewank function has many widespread local minima regularly distributed [22]. It is a continuous, multimodal, scalable, convex, and quadratic test function and it can be used to test the global search ability of algorithms in avoiding premature convergence. It is represented by (7).

$$f_2(x) = 1 + \frac{1}{4000} \sum_{i=1}^n x_i^2 - \prod_{i=1}^n \cos\left(\frac{x_i}{\sqrt{i}}\right) \quad (7)$$

where the bounds are $-600 \leq x_i \leq 600$. The global minimum is at $x^* = (0, 0, \dots, 0)$ and $f_2(x^*) = 0$. The terms of the summation produce a parabola, while the local optima are above parabola level. Figure 4 shows its graphs with two dimensions. The dimensions of the search range increase on the basis of the product, which results in the decrease of the local minimums. The more the search range increases, the flatter the function becomes [23].

Figure 4. Griewank function with two dimensions intervals of which are $[-60, 60]$.

C. Rastrigin Function

Rastrigin function is example of non-linear highly multimodal function. This function contains millions of local optima in the interval of consideration. It has several local minima [24]. It is represented by (8):

$$f_3(x) = \sum_{i=1}^p (x_i^2 - 10 \cos(2\pi x_i) + 10) \quad (8)$$

subject to $-5,12 \leq x_i \leq 5,12$. The global minimum is located at $x^* = f_3(0, \dots, 0)$ and $f_3(x^*) = 0$. Graph of this function with two dimensions has been shown in Figure 5.

Figure 5. Rastrigin function with two dimensions intervals of which are $[-5, 5]$.

V. EXPERIMENTAL RESULTS

In the first experiment, the performance of SFSA has been tested with one of the other math inspired computational intelligence optimization algorithms, namely Sine Cosine Algorithm (SCA) in Chung Reynolds function with 30 dimensions. Initial population size of all algorithms is selected as 50 and maximum iteration number for termination criteria is determined as 100.

Parameter values for SFSA such as maximum diffusion and walk and parameter values for SCA are listed in Table 1.

Table 1. Parameter values for SFSA

	SFSA		SCA
Parameter	Maximum Diffusion	Walk	a
Value	2	1	2

All of the algorithms have been run for 30 times and objective function values obtained from Chung Reynolds function have been demonstrated in Table 2.

Wilcoxon rank-sum tests have also been performed for these experiment results. Table 3 reports the obtained test results from Chung Reynolds function using two math inspired SFSA and SCA. This is used to test the null hypothesis that the means of two populations (obtained from SFSA and SCA) are equal with 95% confidence. With a two-tail test (inequality), if $t \text{ Stat} < -t \text{ Critical two-tail}$, $(-3,338449603 < -2,045229642)$ we reject the null hypothesis. It can be seen that the observed difference between the sample means is convincing enough to say that success of SFSA is significantly better than that of SCA in this unimodal function.

In the second experiment, the performance of SFSA has been tested with SCA in multimodal Griewank function with 30 dimensions. Initial population size of all algorithms is selected as 50 and maximum iteration number for termination criteria is determined as 100.

All of the algorithms have been run for 30 times and objective function values obtained from multimodal Griewank function have been demonstrated in Table 4. Wilcoxon rank-sum tests have also been performed for these experiment results. Table 5 reports the obtained test results from Griewank function using SFSA and SCA. $t \text{ Stat} < -t \text{ Critical two-tail}$ $(-16,76937873 < -2,045229642)$ and thus the sample means is convincing enough to say that success of SFSA is significantly better than that of SCA in this multimodal function.

In the third experiment, the performance of SFSA has been tested with SCA in multimodal Rastrigin function with 30 dimensions. Initial population size of all algorithms is selected as 50 and maximum iteration number for termination criteria is determined as 100.

All of the algorithms have been run for 30 times and objective function values obtained from multimodal Rastrigin function have been demonstrated in Table 6. Wilcoxon rank-sum tests have also been performed for these experiment results. Table 7 reports the obtained test results from Rastrigin function using SFSA and SCA. $t \text{ Stat} < -t \text{ Critical two-tail}$ ($-16,39482536 < -2,045229642$) and thus the sample means is convincing enough to say that success of SFSA is significantly better than that of SCA in this multimodal function.

VI. CONCLUSIONS

Due to the many advantages of natural phenomena inspired computational intelligence algorithms, they are efficiently used for solving different highly complex problems providing working solutions in time, especially with dynamic problem definitions, fluctuations in constraints, incomplete or imperfect information, and limited computation capacity. Some researchers study to incrementally improve the algorithm by proposing the new versions while others explore the application of these algorithms in a novel context. Due to the philosophy of continually searching the best and absence of the most efficient artificial intelligence algorithm for all types of problems, recently novel algorithms are also being proposed. SFSA is a relatively one of the most recent mathematics based computational intelligence algorithm and inspired by the natural phenomenon of growth using a mathematic concept called the fractal.

In this paper, the main steps of SFSA are introduced and its comparative performance within the unimodal and multimodal benchmark functions which are as complex as

engineering search and optimization problems has been presented. The performance of SFSA has been tested with other mathematics based computational intelligence optimization algorithm, Sine-Cosine Algorithm (SCA), within benchmark functions. From the experimental results, it can be concluded that SFSA has better performance than SCA in unimodal and multi-modal benchmark functions. More efficient multi-objective, distributed, and parallel versions of SFSA may be proposed for future works.

Abstract—In recent years, many nature-inspired metaheuristic optimization algorithms have been proposed and applied to solving constrained optimization and engineering design problems. The aim of developing metaheuristic methods are to provide robust and efficacious solution strategies for high-scale combinatorial and non-linear problems and to solve problems faster. Water Cycle Algorithm is a new optimization method which is inspired from nature and based on the observation of water cycle process and how rivers and streams flow to the sea in the real world. The Evaporation Rate based Water Cycle Algorithm is the new concept of Water Cycle Algorithm. Evaporation rate for different rivers and streams offer improvement in search. To verify the performance of the ER-WCA, two classical engineering design optimization problems are solved and results are compared with those available in the literature. It has been observed that the optimization method can effectively be used for solution of constrained engineering design optimization problems.

Keywords—Metaheuristics; Performance; Evaporation Rate based Water Cycle Algorithm

I. INTRODUCTION

Optimization plays an important role in many real-world problems such as engineering, economics, management, and medicine. Many real life and engineering problems are commonly quite difficult to solve and search space of these problem increases exponentially with problem size. In addition, real world problems contain complex objective function and different decision variables under constraints. Providing of suitable solution for these problems in rational time has been received considerable attention among engineers and researchers. Therefore, during the last decades, many new optimization methods have been proposed to solve various problems in real world.

Optimization methods are classified into two general categories: mathematical programming and metaheuristic methods. Different mathematical programming methods such as linear programming, homogeneous linear programming, integer programming, dynamic programming, and nonlinear

programming have been developed to solve various optimization problems. These methods use gradient information to generate the solution space that convergence to a global optimum solution. However, mathematical programming methods are insufficient to solve the complexity of real world structural design problems. Metaheuristic optimization methods have been proposed as an alternative to mathematical programming methods to obtain the global optimum solution of these problems. These methods have gained a lot of popularity in recent years because of their ability to solve complex, multimodal, high dimensional and nonlinear search and optimization problems. Most of these methods usually mimic some natural or social phenomenon, such as physic, social, music, swarm, chemistry, biology, sports, and math. Therefore, metaheuristic optimization methods can be evaluated in nine different main groups as shown in Figure 1.

Various physic based metaheuristic methods have been presented in literature. The most popular methods are Gravitational Search Algorithm, Electromagnetism-Like Algorithm, Big Bang-Big Crunch Algorithm, Ions Motion Optimization, Artificial Physics Algorithm, Magnetic Optimization Algorithm, Water Drops Algorithm, River Formation Dynamics Algorithm, Water Cycle Algorithm, Water Flow Algorithm, Water Flow-like Algorithm, Water Wave Optimization, Circular Water Wave Algorithm, Artificial Showering Algorithm [1, 2]. The last eight method is inspired by the natural behavior of water. Evaporation Rate based Water Cycle Algorithm (ER-WCA) is one of the physic based metaheuristic optimization method and modified version of Water Cycle Algorithm (WCA).

In this paper, ER-WCA has been introduced and the comparative performance results obtained by other metaheuristic methods for engineering design problems have been presented. Section 2 presents a brief overview of ER-WCA. In section 3, engineering design problems used for comparisons have been defined. Section 4 presents

Figure 1. Metaheuristic Methods

experimental results. Finally, conclusions are given in Section 5.

II. EVAPORATION RATE BASED WATER CYCLE ALGORITHM

Evaporation Rate based Water Cycle Algorithm (ER-WCA) is modified version of Water Cycle Algorithm (WCA) [3]. The basic idea of WCA is inspired from nature and based on water cycle process [4]. WCA observes the flow of rivers and streams to the sea. ER-WCA have been proposed by applying new modifications to the WCA [5]. These modifications are listed as:

(a) Evaporation process has been used for exploitation capability of WCA. Evaporation rate for rivers and streams is proposed in ER-WCA.

(b) In the ER-WCA, variable evaporation rate (ER) is used to set the evaporation of the water as shown in (1).

$$ER = \frac{Sum(NS_n)}{(N_{sr}-1)} \times rand, \quad n = 2, \dots, N_{sr} \quad (1)$$

NS_n is the number of streams and N_{sr} is the total of number of rivers.

(c) Streams are forced to be searched in sea coast by ER-WCA using the concepts of variance as shown in (2) if the evaporation condition is satisfied.

$$X_{Stream}^{New} = X_{Sea} + \sqrt{\mu} \times randn(1, N) \quad (2)$$

μ is used for area being searched around the sea.

(d) In the ER-WCA, the occurrence of evaporation considerably reduces during the repetition process.

The pseudo code of ER-WCA is given in Figure 2.

III. ENGINEERING DESIGN OPTIMIZATION PROBLEMS

The first stage of engineering design problem is to form a mathematical model. The mathematical model can be expressed as (3).

$$\begin{cases} \text{Minimize } f(X) \\ \text{Subject to } g_i(X) \leq 0 \quad i = 1, 2, \dots, m \\ h_j(X) \quad j = 1, 2, \dots, n \\ X_L \leq X \leq X_U \end{cases} \quad (3)$$

Where $f(X)$ is called objective function of engineering design problem, $g_i(X)$ inequality constraint and m is the number of inequality constraint. $h_j(X)$ is known as constraint function and n is number of function $h_j(X)$. $X = (x_1, x_2, \dots, x_k)$ is design variables and X_L, X_U are variable upper and lower boundary respectively.

A. Welded Beam Design Optimization Problem

The structure of welded beam shown in Figure 3, was introduced by Rao [6], is a standard constrained engineering problem that has been used as benchmark problem. The objective of the problem is to design a welded beam that has minimum cost subject to constraints on shear stress (τ), bending stress in the beam (σ), buckling load on the bar P_c , and deflection of the beam (δ), and side constraints. The design variables are the thickness of the weld $h(x_1)$, length of the welded joint $l(x_2)$, the width of the beam $t(x_3)$ and thickness of the beam $b(x_4)$. The decision vector is $X = (h, l, t, b) = (x_1, x_2, x_3, x_4)$. The mathematical formulation of the problem is defined in Table 1.

Step 1. Choose the initial parameters: N_{sr} , d_{max} , N_{pop} and maximum number of iteration.
Step 2. Generate random initial population and form the initial streams, rivers and sea.
Step 3. Calculate cost value for each stream.
Step 4. Determine the intensity of flow for rivers and sea.
Step 5. Streams flow to the rivers and sea.
Step 6. Exchange positions of rivers/sea with a stream which gives the best solution.
Step 7. Rivers flow to the sea.
Step 8. Exchange positions of river with the sea.
Step 9. Calculate the evaporation rate.
Step 10. Check the evaporation condition among rivers and streams and calculate the new positions of rivers and streams.
Step 11. Check the evaporation condition between sea and rivers /streams and calculate the new positions of rivers and streams.
Step 12. Reduce the d_{max} .
Step 13. Check the stopping condition. If the stopping criteria is satisfied, the algorithm will be stopped, otherwise return to Step 5.

Figure 2. Pseudo code of ER-WCA

B. Tension/Compression Spring Design Optimization Problem

Tension/compression spring design optimization problem was introduced by Arora [7]. The aim of this problem is to minimize the weight of a tension/compression spring subject to constraints on minimum deflection (g_1), shear stress (g_2), surge frequency (g_3) and limits on outside diameter (g_4). This problem has three continuous variables defined as: the wire diameter $d(x_1)$, the mean coil diameter $D(x_2)$ and the number of active coils $N(x_3)$. The problem is shown in Figure 4.

The mathematical formulation of the problem is defined in Table 2.

Figure 3. Welded beam design optimization problem

Figure 4. Tension/compression spring design optimization problem

Table 1. Welded Beam Optimization Problem

Problem: Welded beam design optimization problem	
Minimize:	$f(X) = 1.10471x_1^2x_2 + 0.04811x_3x_4(14 + x_2)$
Subject to:	$g_1(X) = \tau(X) - \tau_{max} \leq 0$
	$g_2(X) = \sigma(X) - \sigma_{max} \leq 0$
	$g_3(X) = x_1 - x_4 \leq 0$
	$g_4(X) = 0.125 - x_1 \leq 0$
	$g_5(X) = \delta(X) - 0.25 \leq 0$
	$g_6(X) = P - P_c(X) \leq 0$
	$g_7(X) = 0.10471x_1^2 + 0.04811x_3x_4(14 + x_2) - 5 \leq 0$
Where:	$\tau(X) = \sqrt{\tau_1^2 + 2\tau_1\tau_2(x_2/2R + \tau_2^2)}$
	$\tau_1 = P/\sqrt{2}x_1x_2$
	$\tau_2 = MR/J$
	$M = P(L + \frac{x_3}{2}); J(X) = 2\left\{\frac{x_1x_2}{\sqrt{2}}\left[\frac{x_2^2}{12} + (\frac{x_1+x_3}{2})^2\right]\right\}$
	$R = x_2^2/4 + ((x_1 + x_3)/2)^2$
	$\sigma(X) = 6PL/x_4x_3^2$
	$\delta(X) = 4PL^3/Ex_3^3x_4$
	$P_c(X) = (4.013\sqrt{EGx_3^2x_4^6/36/L^2})(1 - x_3/2L\sqrt{E/4G})$
	$G = 12 \times 10^6[psi], E = 30 \times 10^6[psi], P = 6000[lb]$
	$L = 14[in], \sigma_{max} = 30000[psi], \tau_{max} = 13600[psi]$
	$\delta_{max} = 0.25[in]$
	With boundary conditions: $0.1 \leq x_1 \leq 2; 0.1 \leq x_2 \leq 10; 0.1 \leq x_3 \leq 10; 0.1 \leq x_4 \leq 2$

Table 2. Tension/Compression Spring Design Optimization Problem

Problem: Tension/compression spring design optimization problem	
Minimize:	$f(X) = (x_3 + 2)x_2x_1^2$
Subject to:	$g_1(X) = 1 - \frac{x_2^3x_3}{71785x_1^4} \leq 0$
	$g_2(X) = -\frac{4x_2^2 - x_1x_2}{12466(x_2x_1^2 - x_1^4)} + \frac{1}{5108x_1^2} - 1 \leq 0$
	$g_3(X) = 1 - \frac{140.45x_1}{x_2^2x_3} \leq 0$
	$g_4(X) = \frac{x_1 + x_2}{1.5} - 1 \leq 0$
With boundary conditions: $0.05 \leq x_1 \leq 2; 0.25 \leq x_2 \leq 1.3; 2 \leq x_3 \leq 15$	

IV. EXPERIMENTAL RESULTS

In this section, the ER-WCA is evaluated against the previous robust methods by using two well-studied problems: welded beam design problem and tension/compression spring design problem. To evaluate the performance of ER-WCA for optimizing the two constrained problems, the same constraint handling have been used. For each problem, population size of all methods is selected as 50 and maximum iteration number for termination criteria is determined as 1000. The results of the compared methods for these two problems are taken from related studies in the literature.

Until now, a variety of optimization methods have been applied to solve the welded beam design problem by other researchers [7-18]. Table 3 summarizes the best results obtained by ER-WCA and other different methods. The convergence curve of ER-WCA for welded beam design optimization problem is given in Figure 5.

Figure 5. Convergence curve of ER-WCA for welded beam design optimization problem

From the Table 3, illustrates that ER_WCA is more optimal than that of references [8-18].

In the literature, different approaches proposed to tackle the tension/compression spring design optimization problem. The comparison of the best results obtained by ER-WCA and other methods are reported in Table 4. The convergence curve of ER-WCA for tension/compression spring design optimization problem is shown in Figure 6.

Present Study	0.051521	0.352691	11.528973	0.012665

From Table 4, it has been observed that the ER_WCA performs much better in comparison to the algorithms.

V. CONCLUSIONS

Due to the simplicity, flexibility and inexpensive computational cost of the metaheuristic optimization methods, they are efficiently used to solve constrained optimization and engineering design problems. Many metaheuristic optimization methods mimic natural phenomena. ER-WCA is physics based metaheuristic

optimization method inspired by nature. In this paper, ER-WCA has been briefly introduced and its performance has been tested with other available methods in the literature for welded beam and tension/compression spring design optimization problems. The comparison results with other optimization methods demonstrate that the ER-WCA proves to be effective and efficient for locating the global solution or finding a near-global solution to each problem tested. This powerful metaheuristic optimization method may be extended to study multi-objective optimization application.

Abstract—Development in technology and transition to information society brought a lot of innovations. Mass media keeps up with change most. By the help of widespread use of internet, provision of wide band internet services mass media take part in every aspect of life using a lot of internet based programs. These platforms are free from place and time owing to 20 million mobile phones used since 1994. These mobile devices have advanced features to execute many features as computers. Thanks to these features they are able to carry, send, receive and store data. Therefore mobile devices are spreading in individually and institutionally usage. Nowadays by the help of mobile devices easy access and variety of contents is possible. Users are choosing contents considering downloading time, mobile application template, user friendly design, security of sending and receiving data, code to text ratios and out of page redirect. Usage of internet is spreading in all over the world and Turkey. Owing to its young generation Turkey is becoming one of the leader countries in the world on behalf of internet usage.

This study aims to analyze mobile device, computer, internet and social media use and habits in Turkey. A survey was conducted by habitants living in İstanbul. In the study demographics such as age, gender and education of participants analyzed. Also frequency of internet using, reasons of internet using such as social media, entertainment, information gaining, news, travelling, shopping, communication, internet using device such as mobile device or computer were investigated. Relationships between computer, internet, mobile device, and social media use and demographics were analyzed. Additionally reasons of internet usage were predicted for participants. According to results of our study young and educated people uses internet more. Additionally most of responders use internet by mobile devices. They used internet for communication, information and social media most.

Keywords—Mobile device, computer, internet, social media, usage

I. INTRODUCTION

Development in technology and transition to information society brought a lot of innovations. Mass media keeps up with change most. By the help of widespread use of internet, provision of wide band internet services mass media take part in every aspect of life using a lot of internet based programs. These platforms are free from place and time owing to 20 million mobile phones used since 1994. These mobile devices have advanced features to execute many features as

computers. Thanks to these features they are able to carry, send, receive and store data[1]. Therefore mobile devices are spreading in individually and institutionally usage. Nowadays by the help of mobile devices easy access and variety of contents is possible. Users are choosing contents considering downloading time, mobile application template, user friendly design, security of sending and receiving data, code to text ratios and out of page redirect[2].

Internet use is recognized as an essential part of modern life. Owing to web-based technologies and increases of internet Access, internet use has increased dramatically across the world reaching the number of global users more than 3 billion in 2015[3].

However, online activities are extremely diverse, ranging from sending emails to gambling to selling products. The diversity of uses is related to the interactive nature of the internet as a medium where users – audiences – make active decisions about how to engage with the breadth of possible uses of the internet[4,5].

It is clear that the mobile internet will play a key role in bringing the next billion users online. Mobile internet has already leap-frogged fixed access in many countries because of limitations in the coverage of the fixed network, and the availability of mobile internet access significantly outpaces adoption today. The mobile internet is therefore central to realising the internet society vision that ‘The Internet is for everyone’.

Further benefits of the mobile internet are arising from new innovative services based on mobile access to the internet, using all the features embedded into the smart devices, and accessed through apps. These services enable social inclusion, interaction with government, and commerce, among other applications. These innovations are already driving a further evolution of the internet that has been in a state of constant change since its founding.

Laptop and tablet ownership also went up, and no doubt contributed to the increase in internet users. But smartphones are the most commonly owned internet access device as of last year.

We highlight a few key statistics and trends regarding internet users:

- 3 billion Internet users were likely by May 2015.

- Mobile Internet penetration is forecast to reach 71% by 2019.
- Usage per device is forecast to more than triple by 2019.
- 192 countries have active 3G mobile networks, which cover almost 50% of the global population.
- Smartphone sales are the majority of mobile handsets sold worldwide; tablet sales will soon exceed total PC sales.
- While there are at least five mobile platforms, Android has an 84% share of smartphones, and 72% of tablets.
- There are well over 1 million apps available, which have been downloaded more than 100 billion times.
- Time spent using apps exceeds time spent on mobile browsers, and in the US, at least, exceeds time spent on desktop and mobile browsers combined[3].

Usage of internet is spreading in all over the world and Turkey. Owing to its young generation Turkey is becoming one of the the leader countries in the world on behalf of internet usage.

The share of the population in Turkey ages 16 to 74 who use the internet has nearly doubled since 2008, from 32.2% to 58.3% in 2016, according to an August 2016 report by the Turkish Statistical Institute. While there are stil more male internet users than female, the growth from 2008 to this year is nearly identical across the genders.

While the percentage of the population that used the internet grown incrementally every year, the largest leap, for both genders and thus in total as well, came from 2015 to 2016.

In 2015, about 61% of the male population of Turkey were internet users; this year, that figure is nearly 68%. Women, meanwhile, jumped from 42% to 49% [6].

This study aims to analyze mobile device, computer, internet and social media use and habits in Turkey. A survey was conducted by habitants living in İstanbul. In the study demographics such as age, gender and education of participants analyzed. Also frequency of reasons of internet using such as social media, entertainment, information, news, travelling, shopping, communication and, internet using device such as mobile device or computer were analyzed.

II. METHOD

In this study, the results of the survey conducted by 442 participants living in İstanbul were analyzed. Questions about demographics, and internet usage habits were asked to responders. Data were analyzed by SPSS 21 package program.

III. RESULTS AND DISCUSSIONS

Demographics and internet usage habits of 442 participants were investigated and results were shown on Table 1.

Of 442 participants 55.7% were male and 44.3% were female. Most of the participants were between 20-30 (31.4%), 31-40 (27.6%) and 41-50 (24.7%). The majority of the participants had university degree (51.4%). A serious number of responders reported that they used internet everyday (44.1%) and more than three hours a day (40.9%). Most of the responders (67.6%) declared that they used mobile devices while using internet. Nearly 32% of participants reported that they used computers additionally. Most of participants were using internet for communication, information, social media and shopping.

Statistical analysis were conducted in order to find relationships between demographics and frequency of internet usage of participants. All results can be followed from Table 2.

It can be seen from Table 2 that there is a non significant relationship between gender and internet usage but it is obvious that young people utilizes internet more ($\chi^2=32,836$, $p<0,05$). Education plays an important role on internet usage, participants who are more educated utilize internet more ($\chi^2=49,356$, $p<0,01$).

Table1. Demographics and internet usage habits of participants

	N	(%)
Gender		
Female	196	44.3
Male	246	55.7
Age		
20-30	139	31.4
31-40	122	27.6
41-50	109	24.7
51-60	51	11.5
65+	21	4.8
Education		
High school	41	10.2
Vocational High School	71	16.1
University	227	51.4
Master	79	17.9
Phd	20	4.5
Frequency of Internet using		
Rarely	3	0.7
A few times a month	14	3.2
A few times a week	49	11.1
Every day	195	44.1
More than 3 hours a day	181	40.9
Internet using device		
Only mobile phone/tablet	299	67.6
Both mobile device and computer	143	32.4
Reason for internet usage		
Communication	121	27.37
Information	97	21.94
Social media	77	17.42
Shopping	66	14.93
News	34	7.69
Travelling	27	6.10
Other	20	4.52
Total	442	100

Table 2. Relations between demographic variables and internet usage frequency

	Internet usage frequency	
	χ^2	p
Gender	5,79	0,326
Age	32,836	0,035*
Education	49,356	0,003**

*p<0,05, **p<0,01

IV. CONCLUSION

In our study results of a survey conducted by 442 people living in İstanbul, Turkey and using internet actively are analyzed. We analyzed mobile device and internet usage habits in Turkey. It is found that young people and educated ones are using internet more frequently. This is in agreement with some studies [7,8,9] which found similar results as ours. In the study demographics such as age, gender and education of participants analyzed. As social media became a very important part of our lives most of the participants are using internet for social media. On the other hand internet is used for communication firstly for many responders. Most of our responders were young, so it is not surprising that accessing internet by mobile devices is more widespread among them.

Abstract—In this study technical quality of 100 hospitals in Istanbul, Turkey were analyzed by a tool developed by writers. SSL (Secure Sockets Layer), downloading time, google page score, browser compatibility of the websites were analyzed. Also having mobile application template is a very important issue for webpages. Broken links on the web page is also another factor that always downgrades the quality of the website. The code to text ratio of a page is used by search engines and spiders to calculate the relevancy of a web page. Having a higher code to text ratio than your competitors gives you a good start for on-site optimization (seo chat). Meta elements are tags used in HTML and XHTML documents to provide structured meta data about web page, which can be used by search engines to help categorize the page correctly. Well-written meta tags can help make the page rank higher in search results. These features were analyzed by scoring each website.

In order to analyze technical features of hospital web pages we used some different methods. We utilized a web tool named R10.net-Webmaster Tools (r10net, www). It is a website to test technical quality of websites. Among these tools SSL Checker was used to check SSL certificates. To assess the sites' broken links we used Broken Link Checker. We used Website Speed Test to measure the loading time and Google speed scores. To evaluate the code to text ratio we used Website Code to Text Ratio Checker. For browser compatibility we used Responsive Design Checker. To determine meta tags information we used Website meta tag Xtractor. The evaluation process was conducted between 2.2.2017 and 7.2.2017. The time of evaluation was between 11:46 Am and 13:46 Am.

Keywords—Website, hospital, quality, technical, Istanbul

I. INTRODUCTION

An electronic commerce marketing channel is fully mediated by information technology, stripping away much of a product's physical informational cues, and creating information asymmetries (i.e., limited information). These asymmetries may impede consumers' ability to effectively assess certain types of products, thus creating challenges for online sellers [1,2].

To succeed in the highly competitive e-commerce environment, it is vital to understand the impact of website quality in enhancing customer conversion and retention. Although numerous contingent website attributes have been identified in the extant website quality studies, there is no unified framework to classify these attributes and no

comparison done between customer conversion and retention according to the different website quality attributes and their varying impact [3,4].

The rapid growth in use of the Internet and World Wide Web for acquiring health information has received a great deal of attention in recent years. In that time, the Web has been variously described as a harbinger of empowerment and as a threat to the wellbeing of patients.

Website credibility is one factor that consumers use to make judgments about the quality and utility of information posted on a site. As such, website credibility has the potential to influence consumer [decision-making](#) and health behaviors [5,6]

Usability is all about the practical considerations of what goes into good website design, such as speed, user-friendliness, security, technical details like sitemaps, etc. A lot of these details aren't visually apparent; you don't see a website's security when you type in its URL. Nonetheless, usability is a make-or-break issue for websites that work. If a visitor can't find what he or she is looking for because of poor navigation, he or she will usually leave. If pages take too long to load, both search engines and visitors will notice. So to see how usable your site is, ask yourself the following:

- How long does it take my pages to load, and will visitors get bored waiting? How easy is it to find information?
- Is there a search button for visitors?
- Do all the links work?
- Does the site work in different browsers? (Internet Explorer, Safari, Firefox, Chrome, etc.)
- Does my site work on mobile devices?
- If I'm asking for personal details or use a commerce option, is customer information secure? Have I communicated this to my readers? [7]

In this study websites of 100 hospitals in Istanbul were investigated according to their technical features. As it is very important for patients to access information about hospitals, websites have a crucial role for individuals. Also a technically strong website serves better and leads more people to prefer the hospital.

II. METHOD

In our study a cross sectional study was conducted analysing 100 private hospitals' websites. In İstanbul, among 172 private hospitals 135 have active web sites. We gave scores to websites objectively, by measuring some features. All scores were scaled according to frequencies of criteria and evaluated by a computer engineer and professional in the area of health management. Data were analyzed using descriptive and analytical statistics. The study data were collected by using a checklist.

For technologic evaluation of websites 8 subcategories were defined. For Presence of SSL certificate, Browser Compability and Mobile Application two scores were defined (Presence=1, Absence=0). On the other hand for broken links criterion it was opposite (Presence=0, Absence=1). As downloading time was mesured in seconds, metric of seconds were turned into scores, 1 for slowest, 2 for normal and 3 for fastest website respectively. Alsolikert scale was used in order to evaluate scores for google page scores and code to text ratio and meta tags information. By

the help of the checklist we could therefore calculate a score for each website and % of response defined as the percentage of items found over the total number of items. We calculated a mean website evaluation score for each dimension and calculated a mean website evaluation score for each of the four dimensions of the checklist to identify the strengthness and weakness of hospitals' online services.

III. RESULTS AND DISCUSSIONS

Scores of 100 hospital websites were analyzed and results were shown in Table 1.

The average % of response for Technical features was moderate (58,5%). Among Technical features, % of response of downloading time scores were highest (89%) and the second was browser compatibility (65%). It was found that only 54,40 % of them provided high google page score, while near 44% of them had mobile application. Only 56% of webpages don't have broken links. Regarding meta tag information criteria scores seemed to be lowest (39%).

Table1. Scores of 100 Hospitals' websites according to Technical features

Technical features	Score	%	Total Score	% of response
SSL Certificate				
Presence	1	59	59/100	59,0
Absence	0	41		
Downloading Time(in seconds)				
1,33- 2 sec	1	9	9	3,00
0,67- 1,32 sec	2	3	6	2,00
0-0,66 sec	3	88	264	88,00
Total		100	279/300	93,00
Google page score				
0-20	1	9	9	1,80
21-40	2	40	80	16,00
41-60	3	21	63	12,60
61-80	4	30	120	24,00
81-100	5	0	0	0
Total	100	100	272/500	54,40
Browser compatibility				
Presence	1	65	65/100	65,0
Absence	0	35		

Mobile application template				
Presence	1	43	43/100	43,0
Absence	0	57		
Absence of Broken Links

4	12	12	48	9,60
5	12	12	60	12,00
Total			195/500	39,00
Average % of response				58,5

REFERENCES

IV. CONCLUSION

Many health systems' websites have begun to include tools and information for both patients and visitors designed to make navigating complex health encounters more "user-friendly"; provide information about conditions, treatment, and follow-up; and create a positive organizational image [8,9]. If hospital websites are going to play an important role in delivering care information, it is likely that these sites will play a role in forming patients' expectations against which they will form service satisfaction judgments. To the extent that discharge instructions and other postcare information are made available through hospitals' websites, they may play a direct role in the care experience and influence patients' satisfaction assessments. [10].

We evaluated total scores of websites of hospitals in İstanbul and found that average score of them was moderate. As it is very important for consumers to access technically strong websites, patients also demand qualified service while accessing websites of hospitals. Hospital websites in İstanbul should be strength more.

Abstract— Metaheuristic algorithms are very popular due to their many advantages and are used in many fields for search and optimization. Swarm intelligence is one of the most popular branch of metaheuristic algorithms and is developed by observing the movements of live swarms such as bird, fish, cat, and bee. In this paper, the performances of the newest swarm intelligence based search and optimization algorithms, namely; Chicken Swarm Optimization, Crow Search Algorithm, and Krill Herd Algorithm, have been compared in unimodal and multimodal unconstrained problems for the first time to the best of our knowledge. From the simulation results Chicken Swarm Optimization has shown better performances than other swarm based algorithm within both unimodal and multimodal test functions. Chicken Swarm Optimization is relatively new swarm intelligence based algorithm and it can be efficiently designed for different types of problems by proposing new versions and adjusting its parameters.

Keywords— Chicken Swarm Optimization, Metaheuristic Algorithms, Benchmark Functions

I. INTRODUCTION

Metaheuristic optimization algorithms are algorithms that produce solutions that are close to optimum in the acceptable time for large-scale optimization problems. They are recently getting strong and increasingly increasing its popularity. They are used extensively in various fields such as management, computer, engineering due to advantages such as not having difficult mathematical models to set up, good calculation powers, and requiring no change on the interested problems like classical algorithms and new versions are proposed. Recently, the herd-based optimization algorithms, developed inspired by the herd-like behavior of the living, have begun to become popular in the solution of many complex problems that can take a long time to solve, even if the mathematical model cannot be created or created [1].

General purposed metaheuristic optimization algorithms are evaluated in eight different groups including biology-based, physics-based, swarm-based, social-based, music-based, chemistry-based, sports based, and mathematics based. Genetic Algorithm, Differential Evolution Algorithm, and Ant Colony

Algorithm are biology based; Water Cycle Algorithm, Electromagnetism Algorithm, Artificial Physics Optimization Algorithm are physics based; Tabu Search Algorithm, Imperialist Competitive Algorithm, Social Emotional Optimization Algorithm, Teaching-Learning Based Optimization Algorithm, Brain Storm Optimization Algorithm, Social Based Algorithm, Parliamentary Optimization Algorithm are social based; Artificial Chemical Reaction Optimization Algorithm is chemistry based; Harmony Search Algorithm is musical based; League Championship Algorithm is sports based algorithms and models. Although there are many effective and successful methods that have been introduced to the literature, there have not been any algorithm that can solve all types of problems effectively. New algorithms are introduced and suggestions are given in order to improve the effectiveness of existing versions. Especially in recent years, researchers have introduced such new metaheuristic methods to the literature and performed successful applications [2].

There are many metaheuristic optimization methods that are based on swarm intelligence. Swarm intelligence based optimization algorithms have been developed by observing the movements of live swarms such as bird, fish, cat, and bee. Some of the search and optimization algorithms based on swarm intelligence can be listed as: Particle Swarm Optimization (PSO), Ant Colony Algorithm, Artificial Bee Colony, Bird Swarm Algorithm, Swallow Swarm Algorithm, Chicken Swarm Optimization (CSO), Crow Search Algorithm (CSA) [3], Krill Herd Algorithm (KHA) [4]. CSO, CSA, and KHA are some of the newest swarm based metaheuristic algorithm. CSO aims to simulate the intelligent behavior of the chickens to find the solution of search and optimization problems.

In this paper, the operators of CSO have been introduced and the comparative results obtained from other novel metaheuristic algorithms (CSA, KHA) for different benchmark functions have been presented. In Section 2, CSO has been explained. Section 3 defines the benchmark functions used for comparisons. Section 4 presents the experimental results and finally Section 5 concludes the paper along with future research directions.

II. CHICKEN SWARM OPTIMIZATION

Chicken Swarm Optimization (CSO), an optimization algorithm based on swarm intelligence, was proposed by Meng et al. in 2014 [5]. It mimics the hierarchal order in the chicken swarm and the behaviors of the chicken swarm. CSO can efficiently extract the chickens swarm intelligence to optimize problems. The chicken swarm can be divided into several groups, each of which consists of one rooster and many hens and chicks. CSO consists of 4 rules.

- (1) There are several groups of chickens. Each group comprises a dominant rooster, a couple of hens and chicks.
- (2) Chicken swarm are divided into various groups and suitability values are used to identify the identity of the chickens (rooster, hens, chicks). Each of the chickens with the best fitness value behaves like a head cock in a group. Chickens with the worst fitness values would be determined as chicks. The rest would be hens. The hens randomly choose which group to live in. Mother-child relationships are also randomly established between hens and chicks.
- (3) Hierarchical order, dominance relationship, and mother-child relationship in a group remain unchanged. These situations only update every several time steps.
- (4) Chickens are watching their group mate rooster to search for food, when they can prevent ones from eating their own food. It is assumed that chickens have stolen randomly the food previously found by others. The chicks search for food around their mother (hen) and the dominant individuals have considered advantage in competition for food [5].

Chicken Swarm Optimization. Framework of the CSO

```

Initialize a population of  $N$  chickens and define the related parameters;
Evaluate the  $N$  chickens' fitness values,  $t=0$ ;
While ( $t < \text{Max\_Generation}$ )
    If ( $t \% G = 0$ )
        Rank the chickens' fitness values and establish a hierarchal order in the swarm;
        Divide the swarm into different groups, and determine the relationship between the
        chicks and mother hens in a group; End If
    For  $i = 1 : N$

III. BENCHMARK FUNCTIONS

Well-defined benchmark functions based on mathematical functions can be used to measure and test the performance of optimization methods. The nature, complexity, and other characteristics of these benchmark functions can easily be derived from their definitions and have the nature and complexity of most engineering problems. The selected benchmark functions and its properties have been demonstrated in Table I. Sphere function and Chung Reynolds function are unimodal with less complexity and they can be used to evaluate the converging behaviors of algorithms [6, 7]. Ackley function and Griewank function are multi-modal functions with many

local optima and they can be used to test the global search ability of the algorithms in avoiding premature convergence [8, 9]. Their graphs with two dimensions have been shown in Figure 1, Figure2, Figure3, and Figure4.

TABLE V. BENCHMARK FUNCTIONS

Function No	Function Name	Definition	Interval	Dimension	Global Minimum
F ₁	Sphere	$f_1(x) = \sum_{i=1}^d x_i^2$	$-5.12 \leq x_i \leq 5.12$	30	0
F ₂	Ackley	$f_2(x) = a \exp \left(-b \sqrt{\frac{1}{d} \sum_{i=1}^d x_i^2} \right) - \exp \left(\frac{1}{d} \sum_{i=1}^d \cos(cx_i) \right) + a + \exp(1)$	$-50 \leq x_i \leq 50$	30	0
F ₃	Chung Reynolds	$f_3(x) = \left(\sum_{i=1}^d (x_i^2) \right)^2$	$-100 \leq x_i \leq 100$	30	0
F ₄	Griewank	$f_4(x) = \frac{1}{4000} \sum_{i=1}^d (x_i)^2 - \prod_{i=1}^d \cos \left(\frac{x_i}{\sqrt{i}} \right) + 1$	$-600 \leq x_i \leq 600$	30	0

IV. EXPERIMENTAL RESULTS

The obtained results from CSO for Sphere function have been compared with those obtained from other newest swarm based algorithms named CSA and KHA. Simulation has been run 30 times with different numbers of initial population size (10, 30, 50, and 100) for all of the algorithms. Dimension is 30 and the maximum iteration number is 1000 for all of the algorithms. The results have been shown in Table II. From these reported results, CSO has better performance than other used swarm based algorithm.

The obtained results from CSO for Ackley function have been compared with those obtained from other newest swarm inspired metaheuristic methods named, CSA and KHA. All of the algorithms have been run 30 times with different numbers of initial population size (10, 30, 50 and 100). Dimension is selected as 30 and the maximum iteration number is selected as 1000 for all of the algorithms. The results have been shown in Table III. According to the results of this experiment, CSO has better performance than other used swarm based algorithm.

The obtained results from CSO for Chung Reynolds function have been compared with those obtained from CSA

and KHA. Algorithms have been run 30 times with different numbers of initial population size (10, 30, 50, and 100). Dimension is 30 and the maximum iteration number is 1000 for all of the algorithms.

The results have been shown in Table IV. According to the results of this experiment, CSO has better performance than other selected swarm based algorithm.

The obtained results from CSO for Griewank function have been compared with those obtained from other newest swarm inspired metaheuristic methods named, CSA and KHA. All of the algorithms have been run 30 times with different numbers of initial population size (10, 30, 50, and 100). Dimension is selected as 30 and the maximum iteration number is selected as 1000 for all of the algorithms.

The results have been shown in Table V. According to the results of this experiment, CSO has better performance than other used swarm based algorithms.

V. CONCLUSIONS

Metaheuristic methods are very popular and efficiently used in many complex real world search and optimization problems. Due to the philosophy of continually searching the best and absence of the most efficient metaheuristic method for all types of problems, novel algorithms or new versions of current algorithms are being proposed. Chicken Swarm Optimization (CSO) is one of the newest swarm intelligence based metaheuristic algorithm and aims to simulate the intelligent behavior of the chickens to find the solution of search and optimization problems. In this paper, the performances of the newest swarm intelligence based search and optimization algorithms, namely; Chicken Swarm Optimization, Crow Search Algorithm, and Krill Herd Algorithm, have been compared in unimodal and multimodal unconstrained problems for the first time to the best of our knowledge. From the experimental results CSO has shown better performances than other swarm based algorithms within both unimodal and multimodal test functions. CSO is relatively new swarm intelligence based algorithm and it can be efficiently designed for different types of problems by proposing new versions and adjusting its parameters efficiently and dynamically.

In general, it is expected that the algorithm will be used effectively in many problems in the future because CSO provides good results in both unimodal and multimodal benchmark functions. Since CSO is still new, single and

multidimensional chaotic maps, orthogonal arrays and uniform population can be used for initializing the algorithm to improve the performance. In addition, multi-objective, distributed, and parallel versions of the algorithm can be proposed and effectively used in different search and optimization problems.

Abstract—Machine vision applications are low cost and high precision measurement systems which are frequently used in production lines. With these systems that provide contactless control and measurement, production facilities are able to reach high production numbers without errors. Machine vision operations such as product counting, error control, dimension measurement can be performed through a camera. In this paper, a machine vision application is proposed, which can perform object-independent product counting. The proposed approach is based on Otsu thresholding and Hough transformation and performs automatic counting independently of product type and color. Basically one camera is used in the system. Through this camera, an image of the products passing through a conveyor is taken and various image processing algorithms are applied to these images. In this approach using images obtained from a real experimental setup, a real-time machine vision application was installed. As a result of the experimental studies performed, it has been determined that the proposed approach gives fast, accurate and reliable results.

Keywords—otsu threshold; hough circle; object counting; image processing.

I. INTRODUCTION

Production lines have become very easily controllable and auditable with machine vision applications [1, 2]. With these systems measurement operations can be carried out without the need for an expert control. These measurements are made in a completely non-contact manner, and defective products are sorted out as they pass through the conveyor [3]. Very fast machine vision systems allow for many measurements in a short period of time. This increases the instantaneous production capacity of production facilities. It is critical that machine vision based applications are able to work with near perfect precision [4, 5]. The products to be delivered to the end user must be complete, exact and identical, and are the most important criteria in these applications [6].

A conveyor is basically a system in which products are passed over and faulty products are sorted out on this band. An image of the products through a camera integrated in this system is taken and the faulty products are determined [7]. The general structure of these systems is shown in Fig. 1.

Fig. 8. General structure of machine vision systems [7]

Object counting is a frequently encountered problem in many machine vision applications [8]. Especially in production systems operating at high speed, it is very difficult to perform measurement without using computer vision. Object counting is a frequently encountered problem in many machine vision applications. Especially in production systems operating at high speed, it is very difficult to perform measurement without using computer vision. As a result, the use of machine vision systems becomes essential. In one of these studies using high speed cameras, products passing through the conveyor were recorded via a camera capable of recording 60 fps. In this study, basement background extraction was performed and moving objects were detected. Then, it is checked whether the objects in a specified area pass or not, and the counting process is performed. A block diagram summarizing this proposed approach is as shown in Fig. 2 [9].

Image processing based computer vision applications use many different areas. In one of the works carried out for this purpose, image processing is used for diagnosing the fault. In the proposed method, pantograph catenary images taken from the railway are used. Images were thresholded using the otsu method. The obtained results were combined with the time series and particle swarm optimization to detect faults. The flow diagram of the proposed method is given in Fig. 3. [10].

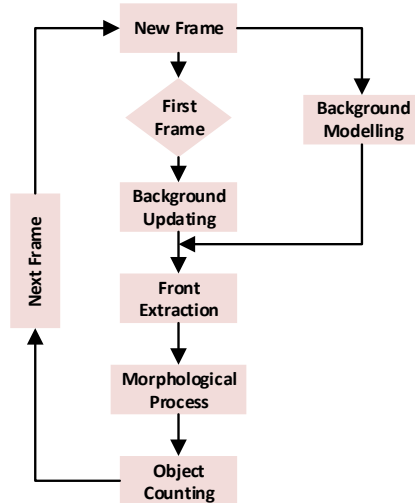

Fig. 9. A proposed approach in the literature [9]

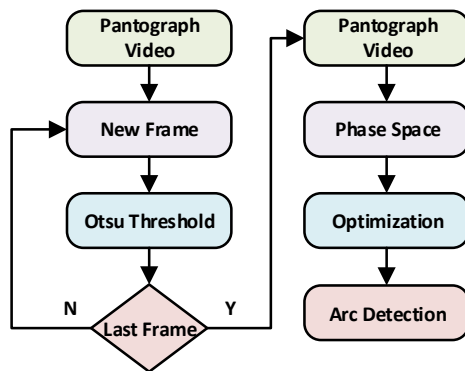

Fig. 10. A proposed approach in the literature [10]

In a study related to the subject, an application was developed to detect biscuit cracks for quality control. In the study, the characteristics of the cracks were determined using Hough transformation, Canny filter and Laplace edge extraction [11]. In another study, object counting was performed. In this application, which is performed for counting the objects which are overlaid, the boundaries of the objects are determined and the counting process is performed with classical geometric operations [12]. Khlule and dig. [13] performs the counting of the objects contained within the tablets. The proposed approach includes the steps of input image, preprocessing, segmentation and counting. The automatic counting method proposed in this study is tested on two applications and high performance is achieved.

In this study, an automatic object counting method based on grassy thresholding has been developed. Images of products passing through a moving conveyor were taken through a camera and pre-processed. Later, Otsu and Hough methods were applied to these images, and the detection and counting of the products was performed. Eggs and soda bottles were used in the tests and high precision counting process was performed.

II. PROPOSED METHOD

The object counting process that is frequently encountered in machine vision applications are used in many areas. Detection of objects on conveyors running at high speed and counting with high precision is a very important issue. The counting of the objects in the egg and soda bottle packets performed with the proposed approach in this study. The proposed approach works independently of the object type in real time. Sample images of the objects used in the study are shown in Fig. 4.

The study mainly involves the monitoring, detection and counting of the products passing through the conveyor by means of a camera. For this purpose, Otsu thresholding and Hough transformations were used. The images used in the study were obtained from a system that operates in real time. A camera that monitors the conveyor from above is integrated into the system and the images of the products are taken instantaneously. The steps of the machine vision based automated product counting approach proposed in this study are presented in Fig. 5.

Fig. 11. Sample images a) Soda bottle pack b) Egg packet

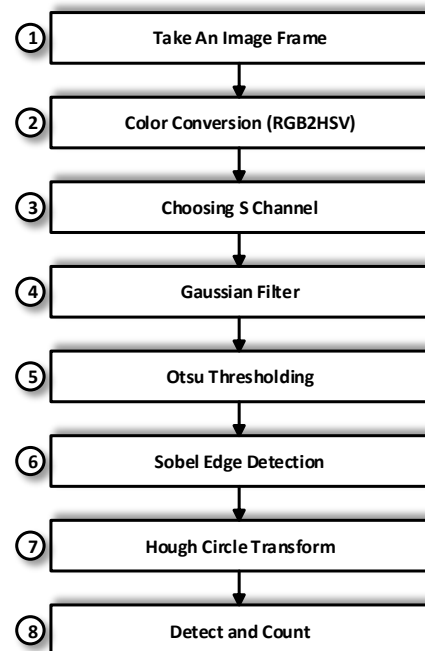

Fig. 12. A block diagram of proposed method

The proposed approach first takes an image of the object through the camera. The image in RGB color format is converted into HSV color space. The aim of this transformation is to be able to obtain the details of the image more clearly, independent of the light conditions [14]. Only the saturation (S) channel is used in the system after this conversion. The conversion from RGB color space to HSV color space and the calculation of S channel are given in Equation 1.

$$\begin{aligned} MAX &= \max\{R, G, B\} \\ MIN &= \min\{R, G, B\} \\ S &= \begin{cases} 0, & \text{if } MAX = 0 \\ 1 - \frac{MIN}{MAX}, & \text{else} \end{cases} \end{aligned} \quad (1)$$

After reducing the image to single channel, this image is subjected to a Gaussian filter. The general mathematical expression of this filter used to eliminate the noises on the image is presented in Equation 2.

$$G(r) = \frac{1}{(2\pi\sigma^2)^{w/2}} e^{-r^2/(2\sigma^2)} \quad (2)$$

The threshold values in the image can be determined adaptively by the Otsu threshold method. Techniques using this process in the literature generally work according to the two-level Otsu method [15]. Three-level Otsu method was developed and used in this study. With this approach, adaptive 3 different threshold levels are determined and the image applied by gauss filter is divided into 4 color ranges. In this process the aim is to reveal all the details in the image. In the other step of the proposed approach, edge detection of the thresholded image is performed. Sobel edge detection method is used in this process. The reason why this method is preferred is that it is very easy to apply. Basically, two convolution matrices, called G_x and G_y , are the process of navigating through the image data [16, 17]. These convolution matrices are given in Equation 3.

$$G_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}, \quad G_y = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix} \quad (3)$$

Hough transformation is used in the last step of the proposed method. This method basically works with the ratios of the geometric shapes of the edges [18, 19]. With this method applied to the image removed the edges, geometric objects in the image can be detected. A pseudo code fragment shows the flow of this method are given in Fig. 6.

The Hough transformation marks the geometric shapes identified as the working principle and finds the center of these shapes [20, 21]. In this sense, there is no need for a process such as determining the boundaries of objects again. In this case, the algorithm does not perform any extra processing and contributes to the algorithm in terms of time.

```

For each pixel (x,y)
  For each radius r=10 to r=60
    For each theta t=0 to 360
      a=x - r * cos(t * PI/180);
      b=y - r * sin(t * PI/180);
      A[a, b, r] + = 1;
    end
  end
end

III. EXPERIMENTAL RESULTS

The data obtained in this study was obtained from a real-time working system. For this purpose, a camera has been installed which continuously monitors the conveyor. This camera has a capacity of 60 frames per second. Imagery from the camera is instantly transferred to a computer via the Ethernet port. On the computer side of the system, an automatic object counting algorithm developed within the scope of the study is carried out. A block diagram summarizing the experimental setup presented is shown in Fig. 7. Detailed features such as resolution, frame rate of the camera used in the study are given in Table 1.

Fig. 14. A pseudo code for Hough circle transform

TABLE I. CAMERA FEATURES USED STUDY

Camera Features	
Feature	Values
Resolution	1280x720 px
Frame Rate	59 fps
Shutter Type	Global
Sensor Type	CCD
Interface	GigE
Pixel Bit Depth	12 bit
Mono/Color	Color

In this study, the test procedures were performed for two different product groups. These products are egg and soda bottles respectively. The same procedure was applied to both test groups and successful results were obtained. The sample image processing results obtained by applying the proposed approach on egg packages are given in Fig. 8.

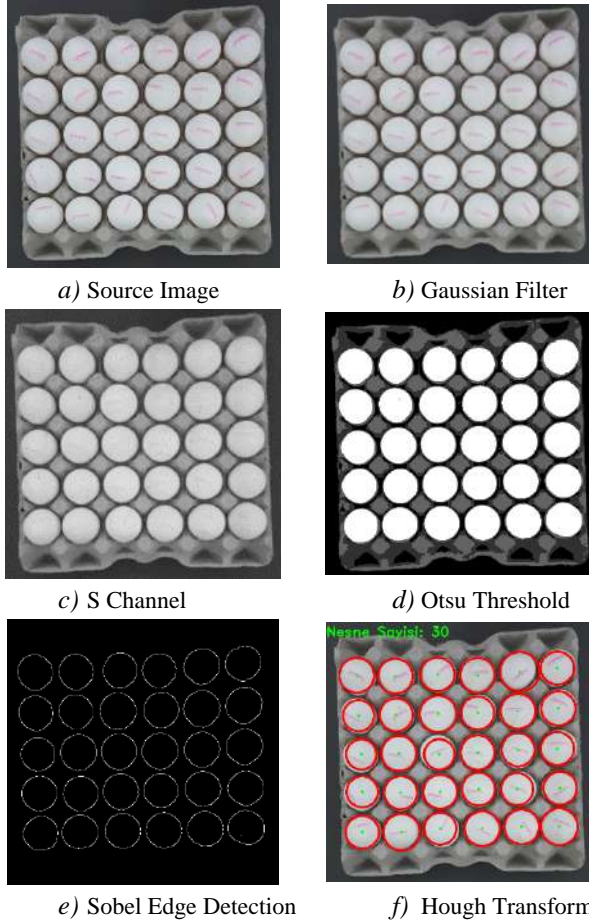

Fig. 15. The proposed automatic object counting method

As can be seen from Fig. 8, the method basically consists of 8 steps. In this frame, the egg packages were tested under different conditions. The sample results from these tests are shown in Fig. 9.

Fig. 16. The example test results for egg packets

As mentioned at the beginning of the section, the studies was carried out for two different product groups. One of these products is soda bottle packages. All of the steps of the image processing application are implemented in these images and good results are obtained. The results of the image processing algorithm performed for this product group are presented in Fig. 10.

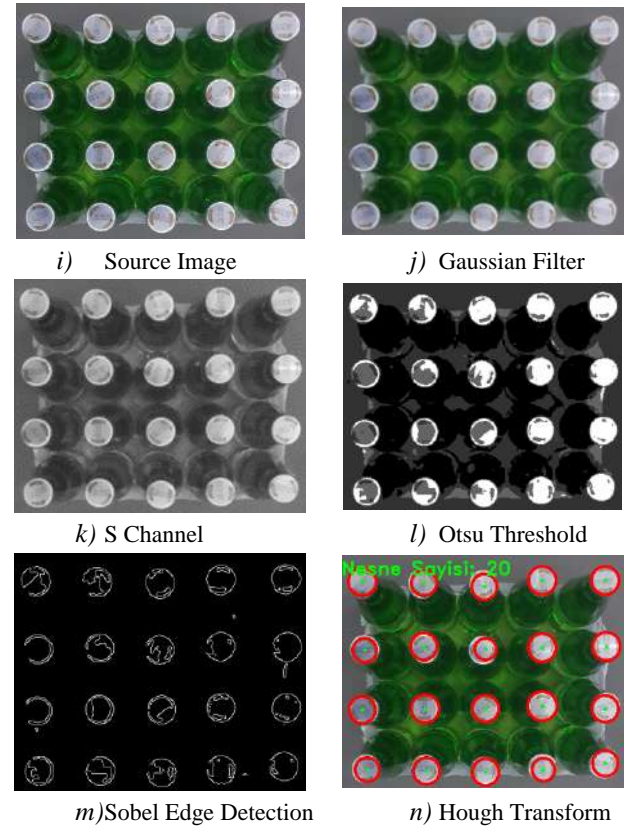

Fig. 17. Steps of the proposed approach

All the steps of the proposed approach are tested in this product group and very good results are obtained. As in the case of egg packages, test procedures were performed in different conditions within these products and the results of these tests are given in Fig. 11.

Fig. 18. The example test results for soda bottle packets

IV. CONCLUSIONS

Today, machine vision applications are actively used almost entirely in production systems. Especially contactless measurement is preferred because of its ability to provide high speed and precise measurement. Machine vision based systems have the some advantages such as low installation and maintenance costs as well as excellent production capacity of these systems.

In this paper, object counting, which is a frequently encountered problem in machine vision, has been performed. When the studies done in the literature are examined, it is seen that the applications carried out are directed to a specific product group. With the proposed approach, we have come from the top of this situation and have been able to count different product groups with a single algorithm. For this purpose, Otsu thresholding and Hough transformation methods are used. The images were taken in real time from a conveyor and tested with the machine vision application suggested in the study. When compared with the current studies in the literature, the proposed approach has shown that the method can measure accurately, quickly and with high accuracy.

Abstract— Swarm intelligence is a study area that investigates the behavior of insects or other animals herd with a collective manner of intelligence. In this study, the performance of an algorithm called Social Spider Optimization (SSO) proposed for herd intelligence has been investigated. The SSO algorithm is based on the simulation of the behavior of spiders in collaboration. The SSO algorithm performance, stability, and sensitivity are compared with Ant Lion Optimization (ALO) and Moth Flame Optimization (MFO). The success of the algorithm is examined using Uni-Modal (UM) and Multi-Modal (MM) benchmark functions. The results are presented in tables and graphs. It is predicted that the SSO algorithm will make a lot of attention in the literature.

Keywords—Optimization, Heuristic Algorithms, Swarm Intelligence, Benchmark Test Functions, Social Spider Algorithm (SSO), Ant Lion Optimization (ALO), Moth Flame Optimization (MFO)

I. INTRODUCTION

The intelligent behavior of many animal or insect groups such as ant colonies, fish flocks, bees, and termite flocks, has shown to be of interest to researchers. The collective behavior of insects or animals is known as herd behavior. This artificial intelligence is called the herd of swarms, dealing with the collective behavior of the elderly through complex and interactional interactions among them. Bonabeau described herd intelligence as "inspired by the collective behavior of other animal communities and social insect colonies when attempting to design any algorithms or to design a common problem solving device." [1]. Herd intelligence has many advantages such as scalability, fault tolerance, adaptation, speed, modularity, autonomy and parallelism [2].

The key components of herd intelligence are self-organization and the workforce. In a self-organizing system, each of the closed units responds to local stimuli individually and acts together to perform the global task by separating the workforce from the central control. Thus, the entire system is in harmony with internal and external changes. Various herd algorithms have been developed by mimicking the behavior of groups of insects or animals in nature and by establishing deterministic rules or random combinations.

Although Particle Swarm Optimization (PSO) and Artificial Bee Colony (ABC) are the most popular algorithms for solving complex optimization problems, these algorithms have serious

exploits such as early convergence and difficulty over local minimum points [3]. The reason for changing individual positions is related to the operators. Thus, during the evolution of such algorithms, the position of each agent for the next iteration is updated (in the case of PSO) or updated for other randomly selected individuals (in the case of ABC), showing an appeal to the position of the best particle as yet. As the algorithm evolves, such behavior causes the entire population to concentrate around the best particle or move away uncontrollably [4].

Interesting and exotic collective behaviors of social insects have attracted the attention of researchers for years. Social spiders are an example of social insect representation. The spider maintains social spiders with a complex set of collaborative behavior of members of the family. Most spiders are aggressive towards other members of their family, while social spiders tend to create long-lived communities, often referred to as colonies, to live in groups [5]. Each member of the social spider column performs various tasks according to their gender, such as hunting, mating, network design and social interaction. Here the network is an important part of the column. Because the network is used as a common living space for all individuals, it is also used as a communication channel between individuals. Moreover, important information is transmitted by small vibrations over the network [6].

In this study, SSO algorithm which is a new algorithm based on intelligence is examined in detail. The SSO algorithm is based on the cooperation and behavior of social spiders. In this algorithm, it is seen that the colony's biological laws are based on the cooperation and interaction of the individuals with each other. The algorithm considers two different search agents (spiders): females and males. Depending on the sex, the simulation based on the different cooperation of each individual within a column is expressed by a series of evolutionary operators. The most important difference between the proposed approach and the algorithm based on current herd intelligence is that each individual model is modeled considering the gender.

The results of The SSO algorithm is compared with two different heuristic algorithms (ALO, MFO) under equal conditions. The results of this test, carried out with unimodal and multimodal quality testing functions, are reported in detail via tables and graphs.

II. SOCIAL SPIDER OPTIMIZATION ALGORITHM

A. Biological Structure of SSO Algorithm

The social insect community is a complex system of business associations that is self-organizing within a set of constraints. Within collaborative groups, behaviors such as allowing task privatization among group members, advocating resources and using the environment have been observed [7]. As an integrated unit, the social insect colony function undertakes the task of building the enormous structure of the global program at the same time as having the ability to operate in a distributed fashion. In social insects, it is necessary to recognize that global borders are a result of the internal interaction between the members [8].

The grading and display of the social behavior of several species of spiders has been documented [9]. The behavior of spiders can be generalized in two forms, alone and social spiders [10]. This classification is based on the level of cooperation they exhibit [11]. On the one hand, spiders alone maintain and build their networks by contacting other individuals of similar species, while on the other side, social spiders form columns that remain together on the social network with spatial relationships to other group members [12].

B. Mathematical Model and SSO Algorithm

The Social Spider Optimization Algorithm proposed by Cuevas is based on the behavior of social spiders [13]. The search field is considered a common network and the position of a spider represents the optimal solution. An interesting feature of social spiders is the female-oriented population. The number of male spiders reaches almost 30% of total colony members. Female spiders are randomly selected N_f at 65-90% of all population (N). For this reason, N_f is calculated as shown in Equation 1:

$$N_f = [(0.9 - rand \times 0.25) \times N] \quad (1)$$

Here $rand$ is a random number between 0 and 1. The number of male spiders N_m is in Equation 2 as follows:

$$N_m = N - N_f \quad (2)$$

Each spider takes a weight based on the fitness value of its solution. This weight value is calculated in Equation 3:

$$w_i = \frac{fitness_i - worst}{best - worst} \quad (3)$$

Here $fitness_i$ is calculated by evaluating the positions of all the spiders ($i = 1, 2, 3, \dots, N$). $worst$ and $best$ values were found as the best and worst values, respectively, by scanning the entire population.

The common network (search field) is used as a mechanism for communicating information between colony members. The information is encoded as small vibrations and depends on the distance between the weights and the spider that produces them. This relationship is shown in Equation 4:

$$V_{ij} = w_j \times e^{-d_{ij}^2} \quad (4)$$

Here d_{ij} is the distance of the euclidean between i and j spiders. Three special relationships can be considered:

- Vibration $Vibc_i$ is calculated according to Equation 5 and the individual perceived by the i individual as a result of the information transmitted by c has two important features. Compared to the nearest i member, it has a higher weight ($w_c > w_i$). This situation is shown in Figure 1. (a).

$$Vibc_i = w_c \times e^{-d_{ic}^2} \quad (5)$$

- Vibration $Vibb_i$ is calculated according to Equation 6 and the property of the individual perceived by the i individual as a result of the information transmitted by b is that the entire population (N) has the best fitness value. This situation is shown in Figure 1. (b).

$$Vibb_i = w_b \times e^{-d_{ib}^2} \quad (6)$$

- Vibration $Vibf_i$ is calculated according to Equation 7 and is the closest female individual to the individual i who is perceived by the i individual as a result of the information transmitted by f . This situation is shown in Figure 1. (c).

$$Vibf_i = w_f \times e^{-d_{if}^2} \quad (7)$$

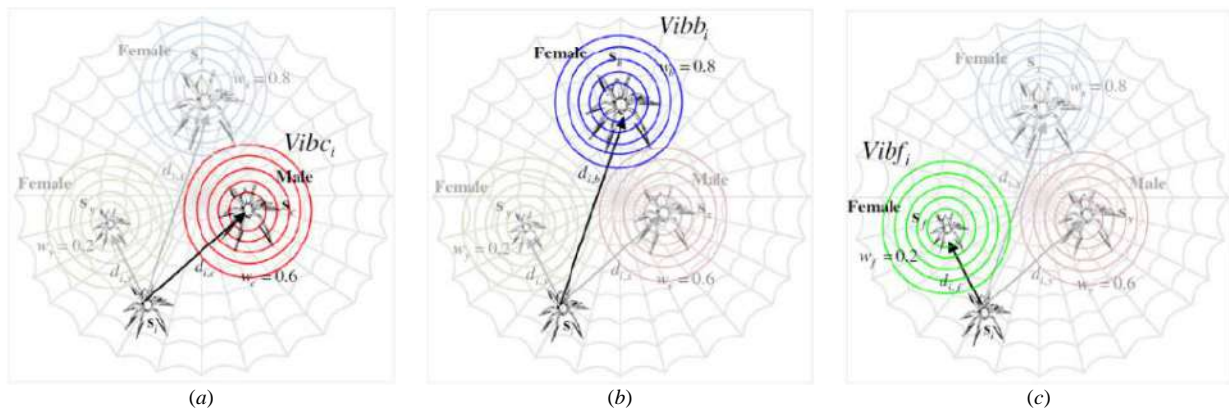

Fig. 1. The formation of $Vibc_i$ vibration (a), the formation of $Vibb_i$ vibration (b) and the formation of $Vibf_i$ vibration (c) [14].

Social spiders perform cooperative interaction on other colony members depending on sex. A new operator is described in Equation 8 to simulate the common behavior of female spiders. The pull-in-thrust motion is developed on the other spiders according to their vibrations spread over the common network:

$$f_i^{t+1} = \begin{cases} f_i^{(t)} + \alpha V_{i,c}(s_c - f_i) + \beta V_{i,b}(s_b - f_i^{(t)}) + \\ + \gamma \left(\sigma - \frac{1}{2} \right) & \text{if } r_m < PF; \\ f_i^{(t)} - \alpha V_{i,c}(s_c - f_i^{(t)}) - \beta V_{i,b}(s_b - f_i^{(t)}) + \\ + \gamma \left(\sigma - \frac{1}{2} \right) & \text{if } r_m \geq PF, \end{cases} \quad (8)$$

Here r_m , α , β , γ and σ the numbers are uniform random numbers between 0 and 1. f_i^{t+1} is expressed as a standard for the position of $t+1$ female spider at step i . s_c indicates an instantaneous parameter of the PF and s_b represent the highest weight and best member of the entire population, respectively.

The male spider population is divided into two classes: dominant and non-dominant. The dominant class has a better suitability value than the spider dominant, and these spiders are attracted to the common network center by the nearest female spider. On the other hand, non-dominant male spiders tend to concentrate male population in center C as a strategy to exploit the resources wasted by dominant men. This situation is shown in Equation 9:

$$m_i^{(t+1)} = \begin{cases} m_i^{(t)} + \alpha V_{i,f}(s_f - m_i^{(t)}) + \gamma \left(\sigma - \frac{1}{2} \right) & \text{if } w_{N_f+i} > w_{N_f+c}; \\ m_i^{(t)} + \alpha \left(\frac{\sum_{h=1}^{N_m} m_h w_{N_f+h}}{\sum_{h=1}^{N_m} w_{N_f+h}} \right) & \text{if } w_{N_f+i} \leq w_{N_f+c} \end{cases} \quad (9)$$

Here, s_f represents the female spider that is the closest to the i . male spider. At the time of step $t+1$, m_i^{t+1} shows the position of i . male spider.

Mating is done by dominant male and female members in the social spider column. When r is taken as a radius (calculate according to Equation 10), if the dominant male spider finds a female member in r , it mates and forms a new young.

$$r = \frac{\sum_{j=1}^n p_j^{high} - p_j^{low}}{2n} \quad (10)$$

Here, n (the number of variables to be optimized) is the size of the problem, p_j^{high} and p_j^{low} are the standard for upper and lower bounds, respectively. After the new spider has formed, it is compared to the best spider of the colony. If the new spider is better, the bad spider is replaced by a new one.

III. EXPERIMENTS AND RESULTS

There are many benchmark test functions to measure the success of the algorithms. The selected benchmark functions and their characteristics are shown in Table 1.

TABLE I. BENCHMARK FUNCTIONS

Functions	Lower and Upper Limits	Min	D	Type	Equation
f_1 -Sphere	[-5.12, 5.12]	0	30	UM	$\sum_{i=1}^n x_i^2$
f_2 -Rosenbrock	[-30, 30]	0	30	UM	$\sum_{i=1}^{n-1} [100(x_{i+1} - x_i) + (x_i - 1)^2]$
f_3 -Powell	[-4, 5]	0	24	UM	$\sum_{i=1}^{n/4} \left[(x_{4i-3} + 10x_{4i-2})^2 + 5(x_{4i-1} - x_{4i})^2 \right] + (x_{4i-2} - 2x_{4i-1})^4 + 10(x_{4i-3} - x_{4i})^4$
f_4 -Rastrigin	[-5.12, 5.12]	0	30	MM	$\sum_{i=1}^n [x_i - 10 \cos(2\pi x_i) + 10]$
f_5 -Ackley	[-32, 32]	0	30	MM	$-20 \exp \left(-0.2 \sqrt{\frac{1}{n} \sum_{i=1}^n x_i} \right) - \exp \left(\frac{1}{n} \sum_{i=1}^n \cos(2\pi x_i) \right) + 20 + e$
f_6 -Griewank	[-600, 600]	0	30	MM	$\frac{1}{4000} \sum_{i=1}^n x_i^2 - \prod_{i=1}^n \cos \left(\frac{x_i}{\sqrt{i}} \right) + 1$

In this study, the biological structure and mathematical model of the SSO algorithm are investigated. The SSO algorithm were compared with ALO and MFO under equal conditions as the benchmark test functions.

ALO, MFO, and SSO algorithms for each function specified in Table 1 were run 30 times. Table 2 presents the best, worst, average, median, and standard deviation of the three algorithms as a result of this experiment. The superiority of SSO can be seen from this table.

TABLE II. COMPARISON OF ALGORITHMS

Functions	Algorithms	The Best Value	The Worst Value	Mean	Median	Standard Deviation
f_1	ALO	2.13E-009	1.07E-007	3.20E-008	1.98E-008	2.73E-008
	MFO	2.66E-008	5.24E+001	6.99E+000	5.54E-007	1.52E+001
	SSA	1.41E-003	1.06E-002	5.51E-003	5.26E-003	2.08E-003
f_2	ALO	1.92E+001	1.47E+003	2.86E+002	9.34E+001	4.19E+002

	SSA	2.95E+002	9.63E+002	5.09E+002	4.75E+002	1.49E+002
f_3	ALO	7.60E-002	2.17E+000	7.43E-001	6.26E-001	4.78E-001
	MFO	8.75E-003	3.74E+003	6.40E+002	1.47E+002	1.01E+003
	SSA	1.43E+000	8.47E+000	4.03E+000	3.81E+000	1.85E+000
f_4	ALO	2.68E+001	1.38E+002	8.27E+001	7.86E+001	2.82E+001
	MFO	7.86E+001	2.46E+002	1.54E+002	1.55E+002	4.29E+001
	SSA	3.52E+001	5.78E+001	4.66E+001	4.89E+001	6.30E+000
f_5	ALO	6.67E-004	4.46E+000	1.97E+000	2.01E+000	8.76E-001
	MFO	1.09E-002	1.99E+001	1.44E+001	1.90E+001	7.86E+000
	SSA	3.11E-001	1.15E+000	7.43E-001	7.17E-001	2.03E-001
f_6	ALO	2.27E-004	4.71E-002	1.33E-002	8.42E-003	1.36E-002
	MFO	1.01E-004	1.80E+002	2.11E+001	2.34E-002	4.56E+001
	SSA	7.41E-001	1.03E+000	9.73E-001	1.00E+000	7.27E-002

The performance of the SSO algorithm has been investigated using the unimodal and multimodal benchmark testing function.

The convergence graphs for the average fitness values of the algorithms run 30 times for each function are shown in Figure 2.

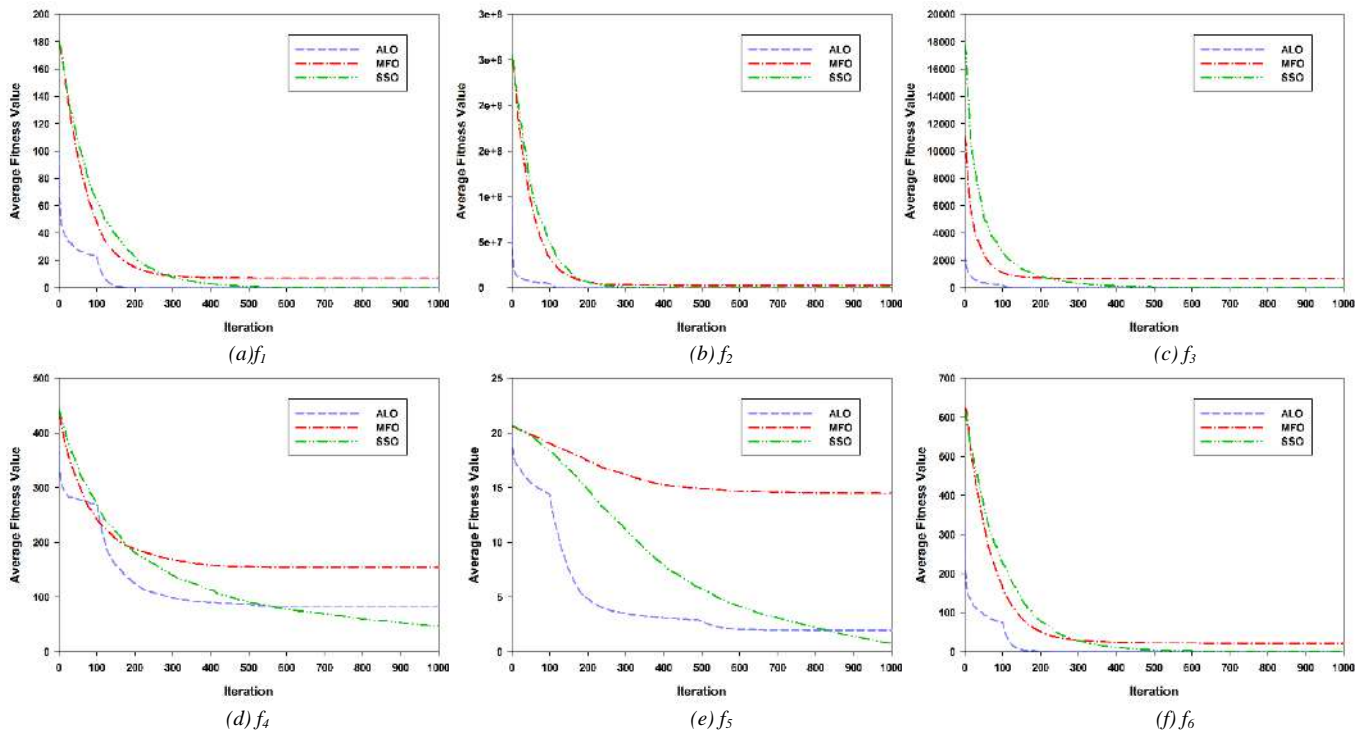

Fig. 2. Convergence graphs of average fitness values for benchmark functions(f_1 , f_2 , f_3 , f_4 , f_5 , f_6).

As shown in Figure 2. (a), (b), (c), the convergence speed of the SSO algorithm for UM functions is slightly slower than that of other algorithms. However, as shown in Figure 2. (d), (e), (f), the convergence speed of the SSO algorithm for MM functions is higher than that of other algorithms.

IV. RESULTS

The performance, stability, and sensitivity of the SSO algorithm are compared with different optimization algorithms (ALO, MFO) using the six different benchmark test function. The results show that the covariance of the SSO algorithm is lower than that of the ALO algorithm. However, we can say that it is equivalent to the MFO algorithm. The convergence speed of the SSO algorithm is much better than the MFO algorithm.

The most important conclusion to be drawn from this study is that the more remarkable results can be obtained if the parameter values are set well for all algorithms.

Abstract— In this study, Social Spider Optimization Algorithm (SSO) which is a metaheuristic algorithm is used to reduce the error rate in determining the surface roughness (Ra) which is one of the most important conditions in the processing process. The correct setting of the cutting parameters is very important to obtain better surface roughness. Using the Multiple Regression Method, the SSO algorithm was used to determine the correlation of the initial parameters to each other. Using the Multiple Regression Method, the mean percent deviation of the test set was 9.8% while it was 9.1% by adjusting the initial parameters with the SSO algorithm. With the improvement of this statistical model by the SSO algorithm, the accuracy of 90.1% of the test data sets has been increased to about 91%. Two different sets of data were used randomly for the test set. The greatest feature of the SSO algorithm used in this study is the simulation of the co-existing biological lives of the spiders.

Keywords— Optimization, Heuristic Algorithms, Swarm Intelligence, Social Spider Algorithm (SSO), Surface Roughness

I. INTRODUCTION

Most of the optimization problems in the literature assume that the parameters, constraints or variables affecting the system are fixed during the solution of the problem. However, in real life applications, the situation is different. In real life conditions, the parameters, variables or constraints to be used in the solution of the problem may vary with time or probable reasons, and a new problem arises when the problem has not been solved yet. These problems are called optimization problems in the literature. The goal here is to find the best solution or the best solution to be found under changing conditions instead of finding the best solution.

Movement of associations occurs through mutual communication of the individuals in the herd. These movements are exhibited in nature by some animals such as fish, birds and ants. The dual relations between individuals can be expressed in the simplest way by three rules: the approach of the individual to the other individuals at a certain distance, as close as possible, and the departure to prevent their collision [1].

Until today, metaheuristic methods are often used to solve different types of problems in different subjects. It can be defined as a problem optimization problem involving the finding of unknown parameter values so as not to violate certain constraints. In optimization problems, the initial step is to set the set of parameters called decision variables.

There are many optimization algorithms in the literature. Particle Swarm Optimization (PSO), an intuitive optimization algorithm, is population based and developed by Dr. Eberhart and Dr. Kennedy [2]. Krill Swarm Algorithm, metaheuristic algorithm has gained a lot in the near term based on the literature in order to solve real life problems. The algorithm performance continuously-variable-number in the literature have been used in non-linear optimization problems [3]. The Artificial Bee Colony (ABC), examines the cooperative behavioral technique of bee colonies [4]. Bacterial Foraging Optimization Algorithm (BFO), bacteria social aggregator behavior (metacognitive) [5], Firefly (FF), is firefly beetles mating behavior [6] and Cuckoo Optimization Algorithm (COA), is based on the basic social behavior, such as life style of the cuckoo [7].

In this study, biological and mathematical structure of SSO algorithm is examined. In order to improve the method used for CNC milling, it is aimed to benefit from the strong structure of SSO algorithm. As a result of studies on two different test data, it is desired to reduce the error rate. Correct setting of the initial parameters increases the accuracy of the existing problem.

II. SOCIAL SPIDER OPTIMIZATION ALGORITHM

As a social insect, spiders perform collaborative interactions with other colony members [8]. These collaborative behaviors depend on the sex of the spider. Because vibrations are tied to the distance and weight of the members that trigger them, strong vibrations are produced by both the big spiders and the nearest neighbors [9]. This is illustrated in Figure 1.

Fig 1. Schematic representation of the SSO algorithm data-flow

The bigger the spider is, the better the well thought colonial member. The ultimate decision of interaction or hate on a designated member is influenced by several factors such as the other random event and curiosity reproduction period in the room, which is taken according to the internal state of the network [10].

Mating is not only the survival of the colonies, but also an important process allowing the exchange of information between members. Mating in the social spider colonies is carried out by dominant men and female members. In this case, if the dominant male spider has one or more female members located within a certain area, the pups mate with all the teeth to produce [11, 12]. The evolutionary operators and structure of the SSO algorithm are as shown in Figure 2.

Algorithm 1 SOCIAL SPIDER ALGORITHM

```

1: Assign values to the parameters of SSA.
2: Create the population of spiders pop and assign memory for them.
3: Initialize vtar for each spider.
4: while stopping criteria not met do
5:   for each spider s in pop do
6:     Evaluate the fitness value of s.
7:     Generate a vibration at the position of s.
8:   end for
9:   for each spider s in pop do
10:    Calculate the intensity of the vibrations V
        generated by other spiders.
11:    Select the strongest vibration vbest from V.
12:    if The intensity of vbest is larger than vtar then
13:      Store vbest as vtar.
14:    end if
15:    Perform a random walk towards vtar.
16:    Generate a random number r from [0,1).
17:    if r < pj then

19:    end if
20:    Attenuate the intensity of vtar.
21:  end for
22: end while
23: Output the best solution found.

```

Fig 2. SSO algorithm pseudo code

Colony levels are produced as a result of internal interaction, despite the complexity existing among all colony members in global co-operation [13]. Such internal interactions include the simple behavioral sequence followed by each spider in the colony. Behavioral rules are divided into two classes as social interaction (cooperative behavior) and mating [14].

A social spider colony consists of two main components. These are members and commercial networks. Members divide into two different categories, men and females. The most interesting feature of social spiders is that they have a predominantly female based population. Some studies show that the number of male spiders barely reaches 30 percent of total colonies [15]. Depending on their sex, each member in the colony displays different activities such as building and maintaining commercial networks for social communication and development [16]. Interaction between members is both direct and indirect [17]. Direct interaction implies the exchange of fluids, such as reproduction, or the interaction of the bodies. Indirect interaction is used as the middle of the commercial network communication, so information transmission is important [18]. All steps of the SSO algorithm are shown in the flow chart in Figure 3.

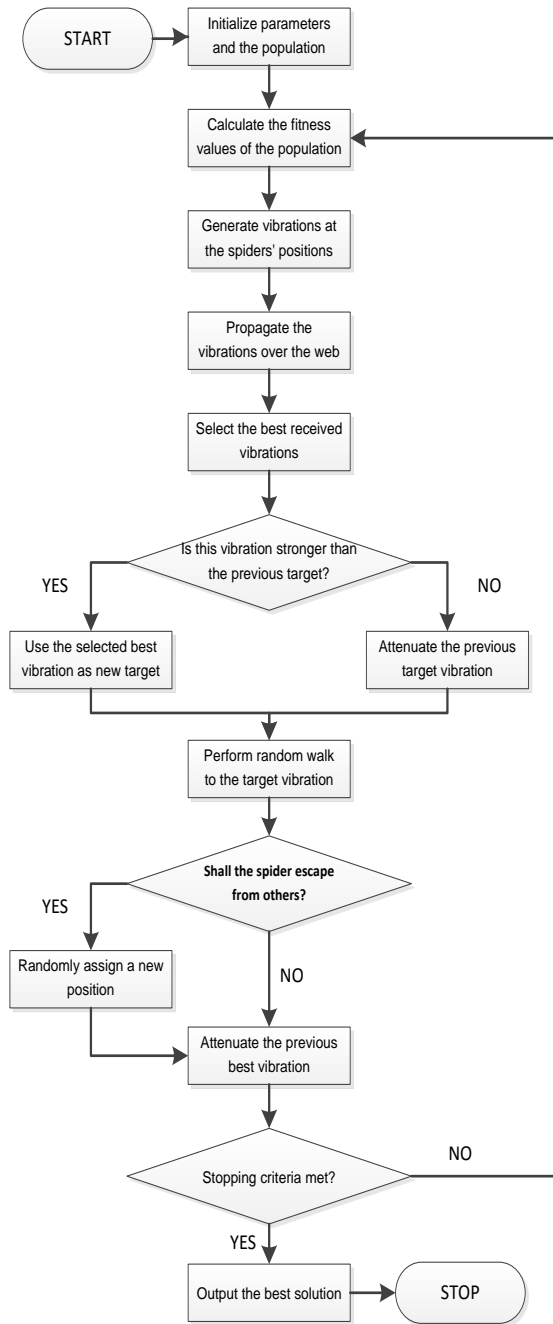

Fig 3. The flow chart of the SSO algorithm

III. METHODOLOGY

In this study by Rashid on 84 samples, the samples are divided into two random data sets [19]. There are 60 examples in the part 1 data set (Table II) and 24 examples (Table I) in the part 2 data set to test the flexibility of the SSO algorithm. All examples consist of four elements: spindle speed, feed rate, cutting depth and measured surface roughness (R_a). A regression model was constructed using the three-way interaction Equation 1:

$$Y_i = \alpha_i + \beta_1 X_{1i} + \beta_2 X_{2i} + \beta_3 X_{3i} + \beta_4 X_{1i} X_{2i} + \beta_5 X_{1i} X_{3i} + \beta_6 X_{2i} X_{3i} + \beta_7 X_{1i} X_{2i} X_{3i} \quad (1)$$

Where Y_i : Surface roughness (R_a), X_{1i} : Spindle speed (S), X_{2i} : Feed rate (F), X_{3i} : Depth of cut (D). Values α and β are constants set by the SSO algorithm.

TABLE I. PART 1 DATASET

N	Spindle Speed X_1 (rpm)	Feed Rate, X_2 (mm/min)	Depth of Cut, X_3 (mm)	Actual R_a
1	1500	152	0.76	1.224

23	1000	588	1.27	3.307
24	1250	588	1.27	2.773

The percent deviation (Equation 2) and the mean percentage deviation (Equation 3) are used to evaluate the correctness of the multiple regression prediction model produced by the SSO:

$$\phi_i = \frac{|R\hat{\alpha}_i - R\alpha_i|}{R\hat{\alpha}_i} \times 100\% \quad (2)$$

Where ϕ_i : percentage deviation, $R\hat{\alpha}_i$: actual R_a , $R\alpha_i$: the estimated R_a generated by SSO.

$$\bar{\phi}_i = \frac{\sum_{i=1}^m \phi_i}{m} \quad (3)$$

Where $\bar{\phi}_i$: average percentage deviation, m : number of samples.

TABLE II. PART 2 DATASET

IV. EXPERIMENTS AND RESULTS

In this study, firstly, the general structure of the SSO algorithm is examined. The proposed model for the determination of the surface roughness in the CNC milling process is reinforced by the SSO algorithm. The error rates in the measurements made using Perthometer S2 are 9.8% for part 1 data set (Table I). With the model created by SSO, this ratio has been reduced to about 9.1%. In addition, the accuracy of measurement by the Perthometer S2 for the part 2 data set (Table II) is 90.1%. With the help of the SSO algorithm, this value has been increased to about 91%. The SSO algorithm was run 30 times for each data set and these results were obtained.

V. RESULTS

There are many studies in the literature for solving the linear equations of the SSO algorithm. As a result of this study, it is seen that there are no undesirable situations such as early convergence and local minimum in SSO algorithm. It can be said that the SSO algorithm is suited for solving engineering problems.

BRAIN TUMOR DETECTION BASED ON IMAGE PROCESSING AND STATISTICS

Zehra KARHAN, Durmuş Özkan ŞAHİN, Erdal KILIÇ
Department of Computer Engineering
Ondokuz Mayıs University
Samsun, Turkey
zehra.karhan, durmus.sahin, erdal.kilic@bil.omu.edu.tr

Abstract— *Magnetic resonance (MR) imaging technique is used to assess the accuracy of evaluation of brain tumors during diagnosis. In the stage of diagnosis of brain tumors, identify the tumor region and determine its properties together with its areas and bounds are important. This diagnosis is usually made manually by people (radiologists-doctors). In this study, a technique has been proposed based on image processing and statistical, it can be used at the stage of diagnosis, it can detect that the tumor is benign or malign and detected objectively and classified high percentage of accuracy. Thus, tumor detection can be performed quickly and in a short time as the patient has fulfilled the requirements. In this tumor diagnosis with image processing and statistical basis, for the feature extraction, we first used segmentation and then Gray-Level Co-occurrence Matrices (GLCM) method. Stage of Classification; K-Nearest Neighbor, Naive Bayes (NB), Support Vector Machine (SVM) using linear kernel and Maximum Likelihood Estimation (MLE) algorithms are used. To enhance the image before the feature extraction, the image is passed through the filter and is utilized from morphological operations and segmentation to distinguish the region of interest. As a result, the experimental results show that MLE classifier is more successfully than other classification methods for BRATS (Brain Tumor Image Segmentation) 2015-dataset with a 75% correct classification rate.*

Abstract—Data storage devices are areas that people and institutions use to store data. The erasing of critical information without proper methods creates significant security vulnerabilities in the information security. The simple erasing of the data that is not needed for storage is incomplete in terms of digital forensics. Many software and hardware tools allow the recovery of erasing data. Safe and permanent erasing of unwanted data is important for forensic information. Many hardware and software tools have been produced for this purpose. These tools use certain defined standard methods. In order to reliably erasing data, it is necessary to use accepted data erasure methods in the field of digital forensics. In this study, software and hardware tools used to erasure secure data are shown. The differences of the methods used and performance of erasure process are evaluated

Keywords— *erasure methods; data recovery ; forensics; information security*

I. INTRODUCTION

The rapid development of information technologies has led to an increase in the amount of data. People, institutions, countries keep all operations and data in the digital environment in storage media [1]. The significance of the stored data varies depending on the field used. Unauthorized acquisition, use or publication of high-severity data can cause losses such as reputation, time, money in terms of people and institutions. For this reason, data must be stored in secure tools and erased in a method that cannot be recovered. If the data is not permanently deleted, it is possible to recover with various software and hardware tools. The safety of the data has to be ensured with the storage of the data in digital media [2]. At the same time, regulations are in place to ensure the safety of critical data in the legislation of countries. If the data are not being used, it is necessary to safely erase them from storage devices. Data on disks using the ATA, SCSI technology via commands, software tools and various hardware can be erased. Files stored on discs can be deleted one by one or all of them with various techniques [3]. Software solutions are implemented by writing data over and over with algorithms that work to prevent residual data in the physical or logical areas of the drive. The entire disk can be cleaned using ATA and SCSI commands. Many of the methods used in this area have been developed to erase magnetic disk unit. The storage of data in Solid State Disk (SSD) technology is not like the storage methods in magnetic disks. While magnetic discs write via the read / write head on data platter, the

SSD determines the area in the disc where the controller writes, the controller in the SSD disk determines the area to write [3,4].

There are different methods to make the disc unusable or permanent erasure of data. In this study, the erasure methods proposed in the literature are examined and the erasure principles are presented. At the same time, differences in methods and erasure processes are evaluated.

II. SOFTWARE OF DATA ERASURE METHODS

Many methods for data erasure have been developed [5-7]. The erasure of the data in a storage device is performed according to the rules in the methods developed using hardware or software tools. DoD 5220.22M, developed by US Department of Defense and NCSC-TG, US Air Force AFSSI-5020, US Army AR 380-19, US Navy NAVSO P-5239-26, RCMP TSST OPS-II, Canada CSECITSG-06, UK HMG IS5, ISM 6.2. 92, NZSIT 402, German VSITR, Russian GOST P50739-95, Gutmann, Schneir, Pfizner methods are recommended for safe data erasure [6-8].

A. *Us DoD 5220.22-M and NCSC-TG-025*

Us DoD 5220.22-M and NCSC-TG-025 were developed by the US Department of Defense and the national security agency. The methods are software based. Other data is written on the data in the storage units to perform erasure. Thus, recovery of deleted data from the device by file recovery methods are prevented. Data is mostly not available in hardware data recovery methods. The Us DoD 5220.22-M and NCSC-TG-025 methods operate in 3 stages and performs similar process. At the first stage, "0" is written to the whole disc and verified. "1" is written to the device to and the write is verified in the second step. At the last stage, random characters are written and the writing process is verified. Thus, the deleted data from the disk becomes unrecoverable [9].

B. *AFSSI-5020*

AFSSI-5020 is a method developed by US Air Force. The AFSSI-5020 method is similar to the methods of Us DoD 5220.22 and NCSC-TG-025. However, the number written to the device, sorting and verification procedures are different from the other two methods. This method works in 3 stages. In this method, "0", "1" and random characters are written and then verification is performed [10].

C. AR 380-19

AR 380-19 is an erasure method developed by Us Army. This method is realized in 3 stages. In the first step, random characters are written. In the second step, the selected special character is written. In the last stage, more than one selected character is written and verified. Thus, the disk is safely erased in 3 steps. Verification is only done in the last stage [10].

D. NAVSO P-5239-26

NAVSO P-5239-26 is a wiping method developed by Us Navy. This method works similarly to the AR380-19 erasure method. There are differences only in the array of the erasing steps. There are differences only in the locations of the erasure steps. In the method, a special character such as 0 or 1 is written in the first step. In the second stage, the complement of the selected character in the first stage is written. In the last stage, the random character is written and the writing is verified. The NAVSO P-5239-26 method is one of the standard methods used by many data erasure programs [10].

E. RCMP TSSIT OPS-II

RCMP TSSIT OPS-II is a method by Royal Canadian Mounted Police Technical Security standard. In this method the erasure process is defined in 7 steps. It writes 0,1,0,1,0,1 respectively and verifies by writing random character at last stage [11].

F. CSEC ITSG-06

It is an erasure method developed by Communications Security Establishment of Canada. The CSEC ITSG-06 method operates in three stages. In the first step, binary 1 or 0 is written. In the second stage, the complement of the selected character in the first step is written. For example, if 1 is selected in the first step, 0 is selected in the second step. At the end, the random character is written and the write is verified [12].

G. HMG IS5

There are two types of HMG-IS5 methods as Baseline and Enhanced. Baseline works in two steps, enhanced three steps. Baseline writes binary 0 in the first step. In the second stage, it writes random characters and verifies the writing. Enhanced writes binary 0 value in the first stage and 1 value in the second stage. At the last stage, he writes random characters and verifies the writing [13].

H. ISM 6.2.92

ISM 6.2.92 is a standard published by the Australian Government Information Security Manual. The ISM 6.2.92 method works in one step. Random characters are written and verified. In the method, when the disk capacity is below 15GB, it requires writing 3 times to each piece of information on the storage device [10].

I. NZSIT 402

It is a method developed by the New Zealand Government Communications Security Bureau. It contains the same steps as the ISM 6.2.92 method. The NZSIT 402 method is single-stage. In the method, Random characters are written and verified. This ensures permanent erasure of the data [12].

J. VSITR

The VSITR method is used as the German standard. It works in 7 stages. In the method, each data field on the device are written "0" and "1" in three rows. At the end, random characters are written. Verification is not performed in this method [12,14].

K. GOST R 50739-95

GOST R 50739-95 is the Russian standard. This method writes zero to sectors in the first instance. Random characters are written in the second step. Verification is not performed [15].

L. Gutmann Method

The Gutmann method is a method proposed by Peter Gutmann. A 35-stage write process is defined to prevent recovery of data on the storage device. All of the steps include separate processing steps. According to other methods, the slowest method is the Gutmann method. Gutmann method is known as the safest method in terms of data recovery. The character patterns suggested for this algorithm are shown in Table 1 [1].

TABLE X. GUTMANN METHOD PATTERN

M. Bruce Schneier Method

It is an erasure method proposed by Bruce Schneier. The method works in 7 stages. In the first stage, "binary 1", in the second stage "binary 0", in the next 5 steps a random character sequence is written. Verification is not performed in the method [16].

N. Pfizner Method

Pfzner method is developed by Roy Pfzner. It works in 33 stages. Random characters are written in all steps. It is similar to the Gutmann method. Verification is not done [12].

The erasure methods used in Table 2 are shown comparatively.

TABLE XI. COMPARISON OF ERASURE METHODS

No	Methods	Erasure Steps	Verify
1	Us DoD 5220.22-M	3 Pass 0x00, 0x01, Random	3 (per pass)
2	NCSC-TG-025	3 Pass 0x00, 0x01, Random	3 (per pass)

16	Write zero		No
17	Random Data		No

O. Software Tools for Secure Erasure

There are many software programs used for deleting secure data. The software uses the deletion methods mentioned in the previous section. The used software and supported erasure methods are shown in Table III [9-16].

TABLE XII. SOFTWARE TOOLS COMPARE

III. HARDWARE METHODS FOR SECURE ERASURE

A. Degausser Usage

Degauss devices aim to destroy data by removing or reducing the magnetic field effect in all devices that store data magnetically, such as hard drives. The Degauss device neutralizes the data on the magnetic disks with strong magnetic field. This method is the most guaranteed method to permanently erase the data in the disk. Degauss devices provide a controlled magnetic field measured by Gauss and Oersteds (Oe) units. The OE shows how hard a magnetic storage device can be wiped. In other words, OE is a mathematical term that indicates the magnetic field strength and density. The Gauss value is a mathematical value that indicates the intensity of the magnetic field generated by a degauss device. In general, the gauss value on a degauss device should be at least twice the Oe of the magnetic storage device to be erased. Degauss devices are available in many different brands and models. However, the erasure method works the same in all products. It is known as

the most guaranteed method to permanently erasure data [1,13,17].

B. Physical Destroy

Physically destroying a storage device is the only option to ensure that the data is not accessible. Physically destroying a storage device is the most important option to ensure that no data is available.

Several methods have been described by the National Institute of Standards and Technology for physically destroying hard drives such as disintegrate, pulverize, incinerate, melt [18].

IV. CONCLUSION

In this study, methods for permanently erasing data that do not require in digital storage device are shown. For this purpose, various software and hardware methods are used. In the study, tools used for permanent erasing and methods supported by these tools are presented. Hardware tools are more successful than software destruction methods for erasing data. The most effective method of guaranteeing permanent deletion of the data on a storage device is physical destruction. For this reason, the use of physical erasure methods is the safest solution for organizations with very critical data.

Abstract - Nowadays, beekeeping is at the forefront of agricultural activities, which are widely performed in the world. Beekeeping activities are also widespread in Turkey due to the favorable ecological and climatic characteristics. However, due the development of technology and the reduction of beekeeping activities because of environmental and climatic characteristics all over the world, it has become an important field of study in scientific activities. In this study, a software model for a remote controlled beehive design is presented. In order to solve the communication distance between hives and beekeepers, a software architecture has been studied on the platform where the system can be managed remotely

{ctastimur, mkarakose, eakin}@firat.edu.tr

Abstract—Rails are one of the most important components of railway transportation. It is needed that the rails can be observed at regular interval in order to ensure the safety of railway transportation, prevent the disruption of transportation, and avoid accidents. To be inspected of rail surface by using manual techniques, both damage the rail surface and lead to disruption of railway transport.

Rail profile analysis methods that utilize contactless image processing techniques are available in the literature in order to avoid these problems. This paper presents a comparison of rail defect detection methods that are available in the literature. These methods in the literature have been compared in terms of feasibility, performance, accuracy, elapsed time, and image processing techniques used. The advantages and disadvantages of these methods relative to each other are examined in this article.

Keywords—Rail defects; image processing techniques; defect detection; rail surface analysis

I. INTRODUCTION

Railway transportation is considered as one of the safest transportation types all over the world. The railroad transportation is spreading rapidly. As railway transportation has become widespread throughout the world, the importance given to the maintenance and safety of railways has also increased. Railways are composed of several components. The most important component is rail. Train accidents happened every year in the world due to heavy task. And the train accidents resulted in serious destruction of property and injury or death of passengers and crew members [1]. Many of the railway transport accidents happen because of driver's tiredness, bad weather conditions, and defective rail components, etc. To prevent these accidents, importance is attached to the detection of faulty regions in the tracks, and other rail components.

Safety of railroad transportation can be enhanced by utilizing intelligent systems that provide additional information about the exact location of the train, its speed and upcoming obstacles. The rails face more and more risk of damage with the increase of speed [2]. Therefore, the rails should be closely inspected for internal and surface faults. Rail profile analysis using manual methods both damages the

rail surface and temporarily disrupts railway access. For this reason, rail profile analysis for railway transportation has been done using contactless image processing techniques. Methods, which detect the rail failures by means of contactless image processing techniques, are available in the literature. Sambo et al. [3] presented a novel algorithm that detect rail surface rolling contact fatigue (RCF) damage and automatic incorporation in a crack growth model recommended an important contribution to the development of modern techniques for non-destructive rail inspection.

Mao et al. [4] developed a sensor fault detection scheme for rail vehicle passive suspension systems, using a fault detection observer, in the presence of uncertain track regularity and vehicle noises that are modeled as external disturbances and stochastic process signals. Faghih-Roohi et al. [5] proposed a deep convolutional neural network solution to the analysis of image data for the detection of rail surface defects. They compared the results of different network architectures characterized by different sizes and activation functions. Hu et al. [6] detected uneven brightness and noise, the heavy rail surface defects, according to the characteristics of heavy rail surface defects, based on the mathematical morphology of multi-scale and dual-structure elements. Compared with the traditional edge detection operators, the results show that their method owns strong anti-noise performance, can detect the small defect edge accurately under noise.

Shen et al. [7] investigated the feature extraction of the turnout defects based on the bogie acceleration measurements. They established the normal turnout model and faulty turnout model based on SIMPACK and then analyzed the acceleration signal in time- frequency domain. The results showed that the power spectral density (PSD) and all the frequency-domain features are useful for detecting the poor fit defect of the switch point. Vijaykumar and Sangamithirai [8] developed a method that detect the surface defect on railheads. The proposed method used Binary Image Based Rail Extraction (BIBRE) algorithm to extract the rails from the background. The extracted rails were enhanced to achieve uniform background with the help of direct enhancement method. The enhanced rail image used Gabor filters to identify the defects from the rails. Thresholding was done based on the energy of the defects.

Yaman et al. [9], took images from two cameras placed at different angles on the established experimental structure. The images were preprocessed using the Otsu method. Then, rail surfaces are detected using Canny edge extraction and Hough transformation algorithms. The rail surfaces detected in the images taken from the two cameras are combined to detect failures on the track surface. The accuracy of the proposed method is enhanced by images taken from two different cameras. Block diagram of this study is given in Fig. 1. Tastimur et al. [10] offered Morphological feature extraction based image processing algorithm in order to determine the breakdowns of rails. The rail was determined through applying the image processing methods and Hough transform to the received images of rail. Headcheck breakage, apletic and undulation of defects was determined by proposed method. Faulty regions was determined through extracting features of regions in images by applying Morphological operations to detected rail images. Jie et al. [11] represented present a new vision based inspection technique for detecting special Rolling Contact Fatigue (RCF) defects that particularly occur on rail head surface. Wei et al. [12] proposed a rail defect detection method based on vibration acceleration signals. Molodova et al. [13] developed a method that the focuses on the early detection of short surface defects called squats and uses axle box acceleration (ABA) measurements.

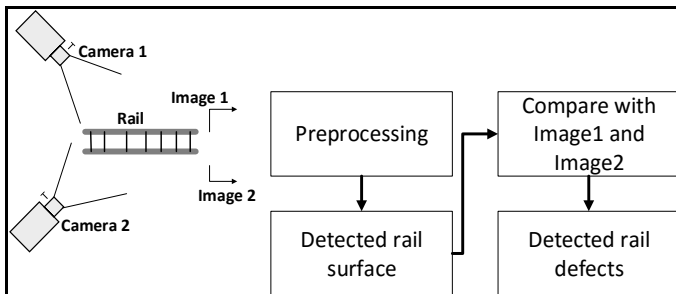

Figure 1. Block diagram of rail failure detection in the literature [9].

In this paper, we have compared several methods that exist in the literature to each other. It is examined rail fault detection algorithms, the performance of these algorithms, and the advantages and disadvantages of these algorithms in relation to each other. Moreover, these algorithms have been compared in terms of feasibility. Comparative tables are presented in the following sections.

II. RAIL SURFACE DEFECTS

Failures that have occurred in the rails can be expressed as wear, scour, breakage, undulation, headcheck, and oxidation [14]. Horizontal and vertical abrasions occur on the surface where the rails are exposed to the wheel. If the amount of wear on the rails is greater than 33 degrees, railings will be changed or curbing will be done because of climbing. Rail erosion occurs in horizontal curves, in scissors tongues and in scissors tongue. Raw abrasions are divided into vertical and lateral

wear. Vertical wear are erosion in the form of spreading and crushing, which occurs in the rail mushroom of curves, in the corners of the scissors and on the rail heads in the seals. Lateral abrasion occurs on the inner cheeks and scissors tongues of the outer rail under the influence of centrifugal force in the curves [15].

Headcheck defect is found around the gauge corner of outer rail and this fault ascending inclines to happen when cracks reach 30 mm in surface length [16]. The undulation failure can be expressed that different collapses happen in the rail surface [14]. The scour fault that can happen in the rail is one or several places of the rail due to the spinning of the locomotive. It should be exchanged rails exceeding the amount scour [14]. Rail oxidation is that crusting, decay, rust and small holes occur in the rail by effecting humidity, soil and water [14].

Figure 3. An example of headcheck failure that occur in the rail [16].

Figure 4. An example of undulation defect that occur in the rail [14].

Figure 5. An example of scour defect that can happen in the rail [16].

Figure 6. An example of wear defect that can happen in the rail [18].

Figure 7. An example of oxidation defect that can happen in the rail [19].

III. THE RAIL DEFECT DETECTION METHODS

Many methods that detect rail surface defects exist in the literature. These methods employ contactless image processing techniques. So that the rail surface is not damaged. Besides, possible accidents are prevented by early detection of many rail failures. Rail fault detection methods that are frequently used in the literature are presented below.

A. Rail Damage Detection using Neural Networks

An onboard measurement system is done for measuring the rail robot's excursions from the rails midlines and the rail-robot's heights above the rail [1]. In this method, to deal with the nonlinearity of the measurement models, the coupling between the outputs, and the noise contamination, a neural network method is proposed for building high precision measurement models [1]. In addition to different measurement models for different types of rail tracks are also built based on the proposed neural network module. Signal processing and neural network module of the method used in [1] appear in Fig. 8.

Figure 8. Signal processing and neural network module in [1].

B. Rail Fault Detection based on the Morphology of Multi-scale and Dual-Structure Elements

Heavy rail surface defects are detected based on the mathematical morphology of multi-scale and dual-structure elements according to the characteristics of heavy rail surface defects, uneven brightness and noise in [6]. When this method is compared with the traditional edge detection operators, the results show that this method owns strong anti-noise performance, can detect the small defect edge accurately under noise. Using the morphology of multi-scale and dual-structure elements, defects such as scratches, rolled-in scale, and uneven rolling on the rails are detected [6].

C. Rail Defect Detection using Gabor filters

In the [8], Binary Image Based Rail Extraction (BIBRE) algorithm is used to extract the rails from the background. The extracted rails are enhanced to achieve uniform background with the help of direct enhancement method [8]. The direct enhancement method enhance the image by enhancing the brightness difference between objects and their backgrounds [8]. The enhanced rail image uses Gabor filters to identify the defects from the rails. The Gabor filters maximizes the energy difference between defect and defect less surface. Thresholding is done based on the energy of the defects. From the thresholded image the defects are identified and a message box is generated when there is a presence of defects [8]. The faulty rail image taken as input and the faulty region detected are shown in Fig. 9 [8].

Figure 9. The faulty rail image and detected defects [17].

D. Rail defect detection with images taken from two cameras

In the [9], the images are taken from two cameras, which of them are placed at different angles on the experimental setup. The preprocessing stage is made by applying OTSU method to obtained images [9]. The rail surface is determined by using Canny edge detection and Hough transform. Faults occurred on the rail surface are detected by combining images taken from two cameras [9]. The accuracy of the proposed method was increased by using the images taken from two different cameras [9].

E. Detection of Surface Defects Using Wavelets

The signature tunes identified from numerical simulations are validated by field measurements in [13]. These signature tunes are employed in automatic detection algorithm for squats [13]. For the investigated Dutch tracks, the power spectrum in the frequencies between 1060-1160Hz and around 300Hz indicate existence of a squat and also provide information of whether a squat is light, moderate or severe. The detection algorithm in [13] is based on scale averaged

wavelet power. The averaging of the wavelet spectrum is performed at frequency bands related to squats [13]. The thresholds for detection of squats on Dutch track are obtained empirically [13].

F. Detection of Rail Faults using Morphological Feature Extraction

An algorithm using Morphological feature extraction based image processing is offered in order to determine the breakdowns of rails in [10]. The rail is determined through applying the image processing methods and Hough transform to the received images of rail [10]. Head check breakage, apletic and undulation of defects are determined by method in [10]. Faulty regions is determined through extracting features of regions in images by applying Morphological

operations to detected rail images [10]. In [10], all steps of the offered method is applied to the images of rail under different direction and lighting.

IV. COMPARISON STUDY OF THE RAIL DEFECT DETECTION METHODS IN THE LITERATURE

Studies in [1], [6], [8], [9], [10], and [13] have been compared in several respects. These respects are algorithm's accuracy rate and operation time, feasibility, techniques used in fault detection, detectable failures, hardware resource requirement, used software development environments, and images used in the algorithm. The advantages and disadvantages of these algorithms relative to each other are given in the following table.

Table 1. A comparison of these methods in literature

Study in the literature	Techniques used in fault detection	Detectable failures	Hardware resource requirement	Used software development environments	Feasibility	Algorithm's performance criteria
[1]	Neural Networks Proximity Sensors Levenburg-Marquart algorithm Signal Processing	Detect nonlinearity of the measurement models (defects)	Hardware are required (Proximity Sensors)	-	High	High accuracy rate
[6]	Mathematical morphology of multi-scale Dual-structure elements Edge detection algorithms	Scratch defect Backfin defect Uneven rolling Rolled-in scale	Hardware are required (CCD Camera)	-	Medium	Strong anti-noise performance Peak signal to noise ratio is 24.5 dB
[8]	Binary Image Based Rail Extractio	Scour defect	Hardware are required	Matlab	High	Accuracy rate 89.9%

	<p>n (BIBRE) algorithm</p> <p>Gabor filters</p> <p>Threshol ding</p> <p>Texture analysis</p>		(Digital camera of 12 megapi xels)			
[9]	<p>Otsu method</p> <p>Canny edge detection</p> <p>Hough transform</p> <p>Gauss Filter</p>	Wear defect	<p>Hardw are require d</p> <p>(Specia l light sources and laser camera)</p>	Matlab	High	<p>84.3 millisec ond elapsed time</p> <p>Standar d deviatio n 1.5</p> <p>The approximate speed of the system for 1 frame is 12fps</p>
[10]	<p>Morphol ogical feature extraction</p> <p>Hough transform</p> <p>Edge detection</p> <p>Laplacian filter</p> <p>Gradient computin g</p>	<p>Headche ck defects</p> <p>Breakage defects</p> <p>Apletilic defects</p> <p>Undulati on defect</p>	No hardwa re require	Matlab	Medi um	<p>0.6 sec.</p> <p>Accura cy rate 85.3%</p>
[13]	Axle box accelerati on (ABA) measure ments	Squats defect	No hardwa re require d	-	Medi um	<p>Accura cy rate</p> <p>78% for light squats</p>

	Wavelet power spectrum					100% for severe squats
	Low-pass filtering					

The algorithms in the literature are superior and weak to each other. It is suitable for on-line rail damage detection and measurement applications in [1]. Moreover different measurement models for different types of rail tracks are also built based on the in [1] neural network module. To deal with the nonlinearity of the measurement models, the coupling between the outputs and the noise contamination, a neural network method is proposed for building high precision measurement models in [1].

When studies in [9] and [10] are compared, study in [9] is superior to study in [10] in terms of elapsed time. Study in [10] is superior to study in [9] in terms of the type of failure detected. When studies in [6] and [13] are compared, study in [6] is superior to study in [13] in terms of the type of failure detected and study in [6] is weak according to study in [13] in terms of the hardware required. The number of failures detected among comparative methods is at most [10]. Superiority of method in [6] over other methods is that this method owns strong anti-noise performance. While the advantage of algorithm in [8] among other tasks is that the enhanced image has uniform background and defects highlighted from the illuminated background, the advantage of algorithm in [9] among other tasks is that failures on the track surface can be clearly identified by combining images taken from two cameras. The implementation in [13] has been checked with the real-life tests in the Netherlands.

Abstract— As a result of increasing internet usage, people who use over 100 different language creating resources and data on internet. In that situation, language identification is a very crucial problem on the Web also is a very important part of Natural Language Processing. This paper presents different approaches for language identification from beginning of the story to today. Also, we compare these different approaches in terms of implementation of a platform, accuracy, speed and complexity. We review over 10 methods and some of them are short words or common words, bi-graph and tri-graph models, letter combinations, n-grams, two-and three-letter clusters, multi-stream language identification methods. That is obviously come up that Artificial neural networks is the most successful method for language identification and machine learning. We give detailed comparison and their results.

Keywords— *language identification; agglutinating; Artificial neural networks*

I. INTRODUCTION

In the web, language identification and as a continuation translation have more and more important because of increasing internet usage rate. Also everyday documents which are written over 100 language uploading and accessing from other users via the Internet. Actually, language identification is a more complex problem as classification and recommendation. There is a lot of approach for language identification over years.

First of all, expert claim that language identification of written language is different than language identification for speech language. We are focus on writing language.

Language identification is not a new topic so there is a lot of different approach and method. There is the different type of document for Language Identification. One of them is monolingual document. In that type document, only one language are used for preparing document. However a big part of the academic article also document have preparing as multiple languages (multilingual). Working on monolingual document generally more easily than Multilanguage. The main differences from them is mono document requires only one language knowledge however Multilanguage are knowledge of several languages [1]. Also there are some other general problems for Language Identification[2].

Document length: Unfortunately, working on small data for Language Identification is a very problematic situation. That is why, vocabulary diversity is used for Language Identification in almost all methods. For example, micro blog websites like twitter limits users to write below 140 characters [3, 4, 5].

Noisy text: noisy in data is the one of the popular problem in data science for all areas like signal processing. Also text is a data and noises like abbreviation, short forms of words and tags are problems [4, 5]. Filtering these text is challenging. Also except of other areas, character encoding is one of main problem in texts [6].

Multilanguage Document: Sometimes documents are written in more than one language. In that time, approach have to successfully split different language regions [1].

Common words and phrase: Language occur repeating some words. Some words are used more frequently than others. Also some words can be used in different two language. Dedection common words and phrase, and removing them from methods is a very important.

Related and similar languages. Some languages root are same there for word diversity and dialects of these languages are closely similiary. Also lexical and grammatical features of these language is similar. Identification language between similar language is a crucial problem.

There have been many approaches for language identification. Generally short words or common words, bi-graph and tri-graph models, letter combinations, n-grams, two-and three-letter clusters, multi-stream language identification methods have been used for this task [7][8][9][10][11][12]. [13][14][15][16][17][18]. These approach generally based on characteristic letter and linguistic information also some approach using n-gram models, decision trees and Hidden Markov Models. Language Identification approaches can be categorize as feature-based models, support vector machines and similarity based classification [19].

Artificial neural networks (ANN) are using and applied for many different application in a variety areas due learning capability, generalizing and fast real-time computation features. Also, language identification is a appropriate task for for Artificial neural networks. In this paper, we make summary general approach for language detection and identify the language of a document based on neural networks.

The article is organized as follows: In Section 2, related works has been described. In Section 3, Artificial neural networks (ANN) is expressed. Section 4. The work as then concluded in the last section.

II. RELATED WORKS

A. Physical Quality of Geomaterials

Language Identification considered as a combining of Natural Language Processing and text classification. Both classification and NLP training set like predefined labels usually are used W. B. Cavnar and J. M. Trenkle [10] proposed N-gram based method for text classification also this method is used in many works for LI [20, 4, 21, 22, 23, 24]. N gram mainly is N-character longer string and N-grams of different lengths. In generally, N gram methods training set for all language to create language profile System measure similary of the input model to pre defined languages due to training set and selects the most similar language. A lot of N-Gram based approach are used for LI. Bashir Ahmed and friend [20] used ad-hoc cumulative N-grams in 2-grams to 7-grams to identification language in 12 languages. According to their paper, speed of their approach is more good than Naïve Bayes method

Erik Tromp and friends [4] propose a graph-based N-gram approach to identification language for medium and small texts. Almost all other approaches give importance to word occurrence. However this approach give importance both word occurrence and words order. Tromp apply their method on Twitter messages which are written in six languages detect language with very good accurate than the other N-gram based approaches. Ali Selamat and friend proposed An improved N-grams approach which are original N-grams approach and improved N-Gram Approach are combined [21]. They use distance measurement based feature from the original N-grams also Boolean matching approach from the improved N-grams methods. Yew Choong Chew and friends [22] improved N-gram algorithm for Language Identification for Asian languages based on non-Latin script. The performance of the algorithm was accuracy rate of 94.04% and can be used for 182 languages from Asia, Africa, America, Europe and Oceania. Except for these there are some unpopular works for identification of Indian languages [3,6,23,25].

Abdelmalek Amine and friends [26] have developed an algorithm which combine k-means and artificial ant class algorithm for especially using in multilingual document. They used N-Grams and/also similart text in completely unsupervised manner. Rafael DueireLins and friends [27], using closed word clases like Articles, Interjections,

Numerals and Prepositions for recognition strategy in English, French Portuguese and Spanish. Bruno Martins and friends [28] works on heuristics and a new similarity measure with N-gram to identify language. Marcos Zampieri [24] published article which proposed bag-of-words approach for language detection using Multinomial Naïve Bayes (MNB). MarcoLui and friend [1] using a generative mixture model which is similar with supervised topic modeling for multilingual documents

Kheireddine Abainia and friends [5] focus on filtering noisy text and they propose hybrid approach to removing noisy short texts. They combine term-based and character-based methods for filtering in noisy texts.

In general, four approaches exist:

The linguistic approach: Character based language detection is simply and basic method for language identification [29,30,34]. However these type of methods are pretty unsuccessful than others because of several problems [31]. For example "ü" and "ı" characters are contained from Turkish and Polish.

In the lexical approach all word compare to target words in lexical analyse for dedecting language. Also there is a lot of problem in this method. Almost all language lexicon is not complate (missing some words) also spelling mistakes or typing error break this method. For example, OCR which reproduce from scanning document, text results is very low with this method.

The grammatical approach: language has a grammatical rules like using prepositions, conjunctions but only %50 of grammatical rules regularly using correctly [32]. This approach is really faster but it have several problems like the texts should be segmented into words also have to removed stop words [33].

The statistical and probabilistic approach: N-Grams approach are contained by this category. Usually they focus on frequency or probability of occurrence and calculate the probability that a text which based on text classification [35,36,37,38] Actually, n-grams-based approach seems to be a widespread solution.

III. ARTIFICIAL NEURAL NETWORKS (ANN)

Artificial neural networks actually based on human biology and brain activity. Computer scientist try to simulate this biological approach to algorithm. Artificial neural networks gather information and easily understand and detect patterns and interactions between data and learn from data. There are many different type of Artificial neural networks for different application [39].

Figure 1. General Path for ANN [40]

Multilayered perceptron neural networks (MLPNNs) one of the simplest and fundamental model in Artificial neural networks. As a result of this, MLPNN is the most popular neural network model [39].

As shown in Figure 1, there is three types of layers which are contain by MLPNNs. First layer is an input layer which processing elements in the input layer when read something like input signals. In the hidden layer, input signals and derived signals weighting with the connections. This function has similarity with threshold function and tangent hyperbolic function.

In Artificial neural networks training is needed so approaches try to optimize the weights with decreasing sum of squared error (E) between the desired and actual values of outputs. Each weight consist of neighborhood and other connection also they are easily adjusted by adding an change with adding or reducing connection Therefore, training take several iteration until a satisfactorily small value of mistake.

At last but not least according to Google lab papers, google Translation API and Language Identifical API use Artificial neural networks and Google has Language Identifical with Artificial neural networks patents.

IV. CONCLUSION

The free dumping of municipal waste were carried on the slopes of landfill bottom layer of slag-fly ash, such as compacted fine-grained parts-upper geotextile and disturbed samples of bottom layer were taken. The experiments were conducted on compacted layer. The grain size distribution curves of the samples showed fine grains unit weight over 80% which limited consistency of coarse was less.

By the cutting box test effective cohesion (c) the effective shear strength and friction angle (ϕ°) of bottom layer and soils were determined.

Water content in the ground, the ratio of clay and fly ash affected significantly. As the evaluated according to the percentage of clay and fly ash in the samples showed cohesive or low cohesive property. The saturated unit weight is given in Table 2. Fixed level permeability test instrument is used to determine the permeability of the ground. Degree of permeability of the soil was determined by evaluating the test results (Table 3). As examined in Table 3, S2, S3 and S4 floors were permeable ground. Proctor tests showed the slag-fly ash effect on compaction,

V. CONCLUSION

The bond between the grains at geolayer and the compaction was critical in strength. The weathering of rocks in the study area is weakening quickly change the height and tilt angle of the slopes to erosion and slope. Dissociation seen in geolayer materials in the study area also offers a negative contribution to permeability problems. The compression strength could be easily tested by indentation on the landfill as shown in Figure 2. The durability of the landfill bottom layer was tested easily on the chart of fly ash and slag mixture content as given in the Table 2.

As a result of the geotechnical analysis performed in the study area should be considered in the future danger of very large stacks and site reclamation methods are suitable to be determined. In addition, the working area of the project due to be opened to urban use contraceptive methods studied and developed instability poses a special importance.

Abstract— This paper presents a comparative study of two designs and analysis: Two Tier Architecture (2TA) and Three Tier Architecture (3TA). By using Optimized Network Engineering Tool (OPNET) modeler network-efficiency is done evaluation. OPNET, a professional simulation tool, is relied on to check the system with many clients from networks for both 2TA and 3TA. The outcomes demonstrate that 3TA is more capable than 2TA in term of data assessment is done utilizing OPNET modeler, which gives a convenient and easy-to-utilize platform for simulating extensive criterion networks. So, it will give more achievement when extended with many clients from networks with eight or sixteen clients. The models are utilized to study how the performance of the network is influenced by the different design decisions that are made to upgrade the system. This paper likewise examines ways in which the OPNET modules have been produced so that students could learn computer network concepts, and not exactly how to use OPNET software.

Keywords— Network Network ,OPNET,Three Tier Architecture (3TA)

I. INTRODUCTION

Network simulators have developed in development since them introductory showed as performance, establishment and expectation apparatuses. Simulators are usually utilized as network management apparatuses, for which packet level analysis is not generally employed. In spite of this, more studies are needed to build up rules for researchers so that they may choose and customize simulator to suite fine-grained packet level analysis [1, 2]. The breach of credibility that studies based on simulation devices need to handle which is one motivation behind this paper. The simplicity and facility that simulators give in assessing “radical” changes in a network environment cannot be ignored. There are impressive number of simulation tools in the market that have main characteristics such as exactness, speed, ease of use, and monetary expense. It concentrates on the accuracy of the simulation in comparison to a real network for packet level investigation. OPNET (Optimized Network Engineering Tools) is a comprehensive programming environment for demonstrating, simulating, and analyzing the performance of communications networks (define the Internet). Recent

articles [7] have described how it has been utilized as a part of education and research. Features of OPNET include object-oriented editors that mirror the structure of genuine networks, and support for most network type and technologies. OPNET has become the business standard tool for designing networks and assessing network performance under different test conditions. Thus, students will profit from introduction of this product. Configuring network models with OPNET requires many steps, and this can be overpowered for new users. Then student performs investigations on the essential model. The following stride involves adjustments of the fundamental network model and investigations of the modified networks. Along these lines the students can focus on learning computer network concepts, and gradually be acquainted to learning the stage on how to build network models with it. We introduce the modeling approach to another issue of assessing the execution of measure for distributed network systems. Our objective is to build up a simulation environment that would empower such an assessment. So, this is an introductory project. OPNET simulators have developed in development since they initially appeared as execution, administration and expectation tools. Simulators are normally utilized as network administration tools for which packet level investigation is not commonly employed. However, more studies are needed to build up rules for researchers so that they may select and customize a simulator to suit fine-grained parcel level analysis [1, 2].

The paper is organized as follows. Section II gives an overview of the developed model and presents its key components and functionalities. In Section III, simulation setup is introduced and the outcomes obtained with the OPNET modeler are discussed. In Section IV, the paper is concluded with few remarks on future work.

II. RESEARCH METHODOLOGY

Each electronic system needs both of software and hardware parts. It is preferred to have two different types of computers. The servers-side computers must be more powerful than clients-side ones (but if the client hosts are powerful too, it is not a problem). So, it is important to describe all software and applications utilized for designing

the proposed system. Also, required hardware features for the proposed system must be depicted. The system is implemented utilizing hosts with various features in order to give more practical applications and to be more close to the genuine situation. OPNET modeling and simulation flow diagram is shown in Fig. 1.

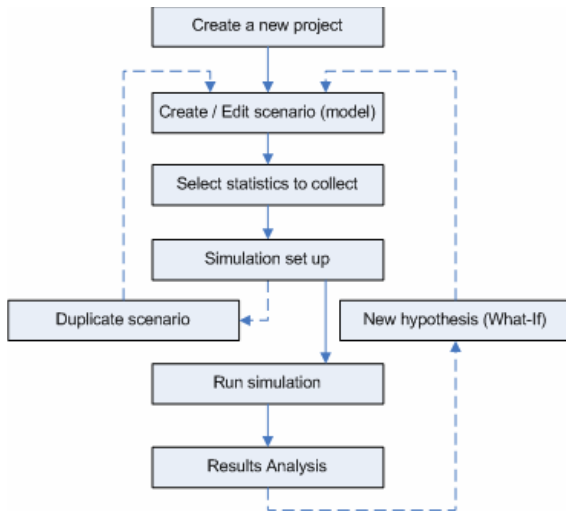

Fig. 1. OPNET modeling and simulation

A. Required Software for Windows-7

- Operating System: Windows-7
- Applications: OPNET Modeler
- Web Browser: HTTP server and Database server

Web communication environment consists of following elements:

1. Servers: Continually running programs that serve information to the web.
2. Clients: Web browsers that allow users to access the web.
3. Protocols: Database and hypertext transfer protocol (http)
4. Networks: Connected devices to a local area network and a wide area network with the form of Internet.

B. Architectures Diagram

Some of the modern design models of the software application [5] are illustrated in Fig. 2. and Fig. 3.

Fig. 2. Two tier architecture

Fig. 3. Three tier architecture

Each of structures shown in Figs. 2 and 3 has its specific features. In the structure of Fig. 2., there is one server-host used for both of web-applications and database system, while the structure of in Fig. 3. includes two hosts for the servers-side, which one of them is specified for the web-application and the other for database system. Splitting the servers-side provides more security to the system. The focused point of this proposed system is to determine the performance of different organizations of network. The performance measures include Total-Network-Delay (TND), Server Delay (SD) and Server-Load (SL).

C. Evaluation Parameters

The evaluation parameters utilized in performance network are as follows:

- **Load:** It represents all control packets sent by the nodes in the network for finding and keeping up the server during the emulation. Loading capacity can be utilized to compare the scalability and efficiency as well as the ability to configure network congestion in various networks. Server protocols with extensive loading capacity have more probability of packet collision and delay.
- **Average delay:** This parameter refers average lag time of the packet going from the source node to the goal node. It consists of the buffer delay in the server finding

process, the transmission delay in the MAC layer and the transmission time.

III. RESULTS AND DISCUSSIONS

There are two main parts of the assessment. Firstly, the similar scenarios are applied for 2TA. Then, scenario is applied for 3TA. Both of scenarios utilize eight and sixteen clients and Windows 7. The consumed-time and the data flow for the general network and the server(s) are resolved.

Results obtained from evaluation-scenarios using OPNET tool are as follows.

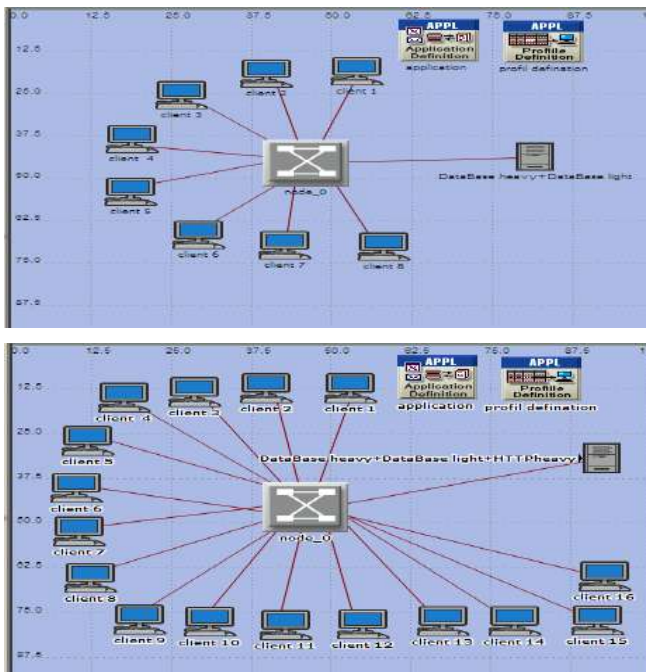

Fig. 4. Two tier architecture (A) utilizing 8 clients. (B) Utilizing 16 clients

TND, SD and SL are considered here that are related to the system performance measurements. From Table I, Fig. 5 and Fig. 6, it is clear that general delay of the network is more than that of the server-host (which are typical and expected outcomes). In general, server load can be noticed obviously because both of web application program and database system are put in one server-host (for 2TA).

TABLE XIII. TOTAL-NETWORK-DELAY AND SERVER-LOAD FOR 2TA

No. of Clients	Total Network Delay (sec.)	Server Delay (sec.)	Server Load (Bits/sec.)
8	0.0038	0.0048	1800000
16	0.0038	0.0048	3000000

Fig. 5. Total-Network-Delay comparison of the two evaluation-scenarios for (A 8 clients, B 16 clients) 2TA

Fig. 6. HTTP-Server-Delay comparison of the two evaluation - scenarios for (A 8 clients B 16 clients) 3TA

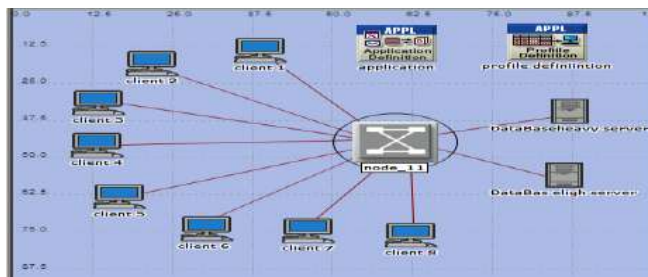

Fig. 7. Server-Load comparison of the two evaluation-scenarios for (A 8 clients, B 16 clients) 2TA

(A)

(B)

Fig. 8. Three tier architecture (A) utilizing 8 clients. (B) Utilizing 16 clients

TABLE XIV. TOTAL-NETWORK-DELAY AND SERVER-LOAD FOR (A 8 CLIENTS B 16 CLIENTS) 3TA

No. Of Clients	Total Network Delay (sec.)	Server Delay (sec.)	Server Load (Bits/sec.)
8	0.0038	0.0048	100000
16	0.0039	0.0049	200000

(A)

(B)

Fig. 9. Total-Network-Delay comparison of the two evaluation (A 8 clients B 16 clients) -scenarios for 3TA

(A)

(B)

Fig. 10. HTTP-Server-Delay comparison of the Two evaluation-scenarios for (A 8 clients B 16clients) 3TA

Fig. 11. HTTP-Server-Load comparison of the two evaluation-scenarios for (A 8 clients B 16 clients) 3TA

Fig. 7 outlines the impact of increasing number of clients on the amount of server load in term of (bit/sec). Subsequently, there is an instant proportion between number of client and server load. Fig. 8 represents the assessment-scenarios for 3TA utilizing eight and sixteen clients and OPNET tool. Table II represents Total-Network-Delay (TND), Server Delay (SD) and Server-Load (SL). Figs. 9, 10 and 11 represent TND, SD and SL comparisons of the two evaluation-scenarios for 3TA using OPNET tool. It can be appeared from Table II that the TND is greater with respect to those values of 2TA because of adding an extra server. Likewise, the SD values are less than those of 2TA because just http-server is considered (i.e. the delay of server that contains only the web application program). The http-server load will have higher load than that of 2TA because of the extra server in 3TA. The impact of these outcomes is outlined obviously in the plotted curves in Figs. 9, 10 and 11 that are extracted from Table II. Fig. 9 shows the impact of average values of TND for 3TA, and the differences can be taken note. Fig. 10 represents the average values of http-server-delay utilizing 8 and 16 clients. It is clear that there are no large differences among these values because just this server will face all received packets and the impact of communication between this server and database server can be ignored. The impact of increasing number of clients on the http-server is depicted in Fig. 11. This relation is instant proportion with increasing server load.

The overall evaluation of the proposed system shows that the 3TA is perfectly reliable with optimum results for both mentioned techniques. This section deals with two main parts.

The first part deals with the comparison related to both architectures of the proposed system (2TA and 3TA) whereas the second part deals with the evaluation of the obtained results compared with those of previous works.

IV. CONCLUSION AND FURTHER WORK

In this paper, the problem and motivation for modeling design/analysis networks was discussed and proposed an OPNET model for assessing measure in distributed network. System how effectively in the lessening of important factors, e.g. process-devoured -time, overhead-effort, expended -cost, reducing the issues of conjunction traffic, and even decreasing the side effects of environment causes depending on the obtained got from this system that demonstrated by evaluator programming called OPNET tools. The performance of the system utilizing 3TA was more precise than that of 2TA. As a result of utilizing two servers in 3TA, high security is provided by part both of application-server and DB-server. Adding to that, utilizing OPNET simulator as an expert assessment and designing tool and a vital performance assessment tool demonstrated the proficiency of 3TA than that of 2TA. Depending on the proposed system that has been designed, implemented and assessed. Also, thus, this office can be connected together to build an office. Designing and implementing human resources administration system is related to the administration part. Applying the details proposed by this system about extra services for example: operation rooms.

Özetçe— Güç spektrum yoğunluğu analizi (GSYA) ve Hilbert Dönüşümü (HD), Beyin-Bilgisayar Arabirimi (BBA) uygulaması için SteadyStateVisuallyEvokedPotentials (SSVEP) tanımayla başarıyla uygulanmıştır. Bu çalışmada SSVEP sınıflandırma işleminde yön ve uyaran frekansı tespiti için veri seti üzerinde aynı yön ve uyaran frekansına göre sinyal kümeleme işlemi yapılmıştır. Bu sinyaller 4-18 Hz arası bant geçiren filtreden geçirilip, HD uygulanmıştır. Daha sonra GSYA işlemi uygulanarak YSA ile sınıflandırma işlemi yapılmış ve ortalama %90 üzeri başarı elde edilmiştir. Önerilen GSYA-HD yönteminin üstünlüğü, gerçek zamanlı bir SSVEP tabanlı BBA'nın sınıflandırma konusunda geliştirilmesinin umut verici olduğunu göstermektedir.

Anahtar Kelimeler—Hilbert Dönüşümü; EEG; SSVEP; Yapay Sinir Ağları; Sınıflandırma

Abstract—PowerSpectralDensity Analysis (PSDA) andHilbertTransform (HT) has beensuccessfullyappliedto SSVEP recognitionforbrain-computerinterface (BCI) application. I. GİRİŞ

İnsan beyni yaklaşık 100 milyar nöron hücrelerinden oluşan bir ağıdır. Farklı olaylar, farklı duyguları oluşturan farklı nöral bağlantılar oluşturur. Hangi nöronun uyarıldığına bağlı olarak bazıbelirli bağlantılar çok daha güçlü ve etkin olurken, diğerleri daha zayıf olabilir.

EEG sinyallerinin temelde genlik, frekans ve bazen faz yapısına dayalı olarak ortaya konan avantajları dikkate alınarak karakteristik özellikleri çıkarılır. EEG sinyallerinden öznitelikleri çıkarmak için çeşitli yöntemler geliştirilmiştir. Geliştirilen yöntemler arasında Zaman-Frekans (T-F) tabanlı olanların daha başarılı olduğu tespit edilmiştir. T-F tabanlı yöntemler, durağan olmayan sinyalleri zaman frekans alanı üzerindeki 2 boyutlu bir görüntüye dönüştürerek sinyallerin olası tüm özelliklerini açığa çıkarır [1].

EEG sinyalleri, T-F alanında gösterilen bu görüntülerden istatistiksel veya dokusal bazı genel ve yerel özellikler çıkarılarak bu amaç için tasarlanmış herhangi bir sınıflandırıcı aracılığıyla sınıflandırılır [1]. SSVEP, denek belli frekansta titreşen bir uyarıya dikkat ettiğinde titreşim frekansı ile aynı frekansta Oksipital bölgede kafa derisi üzerindeki harmoniklerinde ortaya çıkan periyodik bir beyin aktivitesidir [2].

Beynin nöral aktivitelerinin frekans tepki fonksiyonunu test etmek için SSVEP kullanılabilir. Ancak oküler motor bozuklukları veya ciddi nöromüsküler problemleri olan hastalar için SSVEP tabanlı BBA kullanılamayabilir [3].

Göz retinası belirli bir frekansta bir uyarıcı tarafından uyarıldığında, beyin; katları veya harmonikleri ile aynı frekansta bir elektriksel aktivite üretir [3]. Bu uyaran küçük genlikte sabit bir Görsel Uyarılmış Potansiyel (VEP) üretir. SSVEP' ler kullanıcının bakış yönüne de bağlıdır ve dolayısıyla kas kontrolünü gerektirir. Bu tür potansiyelleri üretmek için, kullanıcı belli bir frekansta salınım yapan titreşen bir uyarıcıya bakar [4].

Regan'a göre sabit yoğunluklu farklı frekanstaki titreşim bir uyarı, düşük (5-12 Hz), orta (12-25 Hz) ve yüksek (25-50 Hz) frekanstaki veya daha da yüksek frekans bantları ayrı ayrı sinyallerle SSVEP'leri tetikleyebilir [5]. BBA'lar son yıllarda SSVEP ile tasarlanmıştır. Olaya bağlı potansiyel veya sensorimotor ritim EEG ile kaydedilmiştir [6]. Görsel uyarılmış potansiyellerin saptanmasındaki iyileştirmeler GSYA olarak bilinen Fourier güç spektrumu ile çok boyutlu analiz edilerek önemli gelişmeler kaydedilmiştir [7], [8].

Doğrusal ve durağan olmayan bir sinyalden zaman-frekans bilgisi çıkarmak için Ampirik Kip Ayırıştırması (AKA) ve HD, sinyal analiz metodu olarak, Huang ve arkadaşları tarafından uygulamaya koyulmuştur [9]. Bu metod FastFourierTransform'undan (FFT) sonra önemli bir gelişme olarak görülmüştür. 2007'den beri, simüle edilmiş uyarı sinyallerinin (şablonlar) kullanılması SSVEP'lerin tanımlanmasında etkili olmuştur ve standart öznelik çıkarma, eşik değeri ya da karar ağaçları kullanımına göre daha yüksek performans elde edilmiştir [10].

2014'te Zhang ve arkadaşları Multivariate Synchronization Index (MSI) adlı yeni bir yöntem geliştirdi [7]. MSI, uyarı frekansını tanımak için bir potansiyel indeks olarak karışık sinyaller ve referans sinyaller arasındaki mevcut senkronizasyonu tahmin eden bir tekniktir. SSVEP tabanlı BBA, FFT ile GSYA kullanılıp SSVEP'i tanıyarak, öznenin kaydedilen EEG sinyallerinin bilgisayar komutlarına dönüştürülmesi için geliştirilmiştir. Sıradan bir SSVEP-BBA'da, kullanıcılara farklı frekanslarda yanıp sönen birkaç uyarı sunulmakta ve denekten bakış yönünü ve dikkatini uyarana vermesi istenmektedir. Bu tür SSVEP-BBA'lar genelde "bağımlı" olarak adlandırılır. Çünkü kas aktivitelerinden sayılan göz hareketlerinin farklı yönlerde değiştirilmesi istenmektedir [11]. Bununla birlikte "bağımsız" SSVEP-BBA'lar da vardır. Bunlar başın nöromusküler kontrolü veya göz hareketlerini yerine getiremeyen kişilerin dikkatleri tarafından kontrol edilir. Bu dikkatin gizli şekilde oluştuğu anlamına gelir. Bu tür SSVEP-BBA'lar da genelde "bağımsız" olarak adlandırılır.

Denek dikkatinin belirgin renklerde iki nokta kümesinden birine gizli kaydırılmasında SSVEP genlik ve faz tepkisinin modülasyon etkileri, Zhang ve arkadaşları tarafından araştırılmıştır [11]. Görsel dikkat yoğunlukla göz hareketleri aracılığıyla kontrol edilir ve dikkat edilen nesneler genellikle nettir, belirsiz değildir.

II. MATERYAL VE METOTLAR

BBA kullanıcının beyin sinyalleriyle bilgisayar arasında doğrudan iletişim sağladığı bir arayüzdür. Kas hareketine dayalı olmayarak alternatif iletişim kanalı üreten bir teknolojidir. BBA ile kaydedilen beyin sinyalleri belirli ön işleme tabi tutularak bazı özellikler çıkarılır. Bu özellikler ile sinyal reel komutlara dönüştürülür. Geleneksel EEG sinyal analizi filtreleme, özellik çıkarma ve sınıflandırma olmak üzere üç aşamadan oluşur. Bu çalışmada SSVEP tabanlı EEG sinyal veri seti uyarı frekans ve bakış yönüne göre

ayrıştırılıp, 4-18 Hz. arası bant geçiren filtreden geçirilerek HD uygulanmıştır. Son olarak GSYA işlemi uygulanıp, sadece prefrontal ve oksipital bölgelerinde olan AF3, AF4, O1 ve O2 kanallarından alınan sinyaller kullanılarak YSA ile sınıflandırma işlemi yapılmıştır.

A. STFT Spektrogram

STFT spektrogramı normalize edilmiş ve STFT katsayılarının karesi alınmış olarak tanımlanır. Matematiksel olmayan bir tanıma göre, STFT katsayıları, sinyali küçük parçalara bölmek için zaman domeninde kayan bir pencere kullanarak elde edilebilir ve daha sonra frekansları belirlemek için her bir parça Fourier dönüşümü ile analiz edilir [12]. Böylece zamanla değişen bir spektrum elde edilebilir. Matematiksel görünümde, STFT şu şekilde tanımlanabilir:

$$X(n, \omega) = \sum_{m=-\infty}^{\infty} x[m]w[n-m]e^{-j\omega m} \quad (1)$$

denklemde $x[m][n-m]$, $x[m]$ giriş sinyalinin n zamanındaki kısa süreli bir parçasıdır. Ayrıca ayrık STFT;

$$X(n, k) = X(n, \omega) \Big|_{\omega = \frac{2\pi}{N}k} \quad (2)$$

olarak tanımlanan denklemde, N , ayrık zamandaki örnek sayısını gösterir. Bu nedenle, logaritmik ölçekte spektrogram;

$$S(n, k) = \log |X(n, k)|^2 \text{ olarak tanımlanır.}$$

B. Hilbert Dönüşümü

Hilbert dönüşümü, FFT'nin aksine, durağan olmayan ve doğrusal olmayan zaman serilerinin analiz edilmesi için çok uygundur.

HD'nin kullanılması ile, analitik düzlemdeki sinyalin faz farkı ve potansiyel anomalinin kompleks gradyanları arasındaki dönüşümü hesaplanır.

$$H(u(t)) = \lim_{\epsilon \rightarrow 0} \frac{1}{\pi} \int_{|s-t| > \epsilon} \frac{u(s)}{t-s} ds \quad (3) [13].$$

C. Yapay Sinir Ağları

Birçok nöron içeren, fiziksel olarak insan beyninden ilham alınan ve ondan karakterize edilen yapay sinir ağları (YSA) modeli ve ilişkili nöron bağlantılarının da gösterildiği tipik bir mimari Şekil 1'de gösterilmiştir. Bu nöronlar genelde ağ oluşumunda kullanılırlar. Ayrıca, her bağlantı ağırlık denen sayısal bir değer ile ilişkilendirilir. Her ağırlık, ağda transfer edilen ve sinyal ile çarpılan belirli bir değere sahiptir [14].

Nöronun çıktısı, aktivasyon fonksiyonuyla belirlenir. Literatürde doğrusal, tanjant sigmoid gibi birçok aktivasyon fonksiyonu kullanılır [15]. YSA'ların genelleme kabiliyeti

vardır; Bu nedenle eğitilen ağı bilinmeyen bir girdi uygulandığında uygun bir çıktı üretebilirler.

Şekil 1 YSA Model Yapısı

$$y(t+1) = a \left(\sum_{j=1}^n w_{ij} x_j(t) - \theta_i \right) \quad \text{ve}$$

$$f_i \triangleq net_i = \sum_{j=1}^n w_{ij} x_j - \theta_i \quad (4)$$

Burada $x = (xX1, xX2, \dots, xXn)$ nöronun n giriş parametrelerini, W_i , X_i girişi için ağırlıkları, θ bias değeri, $a(i)$ aktivasyon fonksiyonunu temsil eder. YSA'lar; veri madenciliği, iletişim, doğrusal olmayan sistemlerin modellenmesi, tıbbi uygulamalar ve paralel işleme yetenekleri nedeniyle desen eşleştirmeleri için kullanılmışlardır [16].

D. Veri Seti

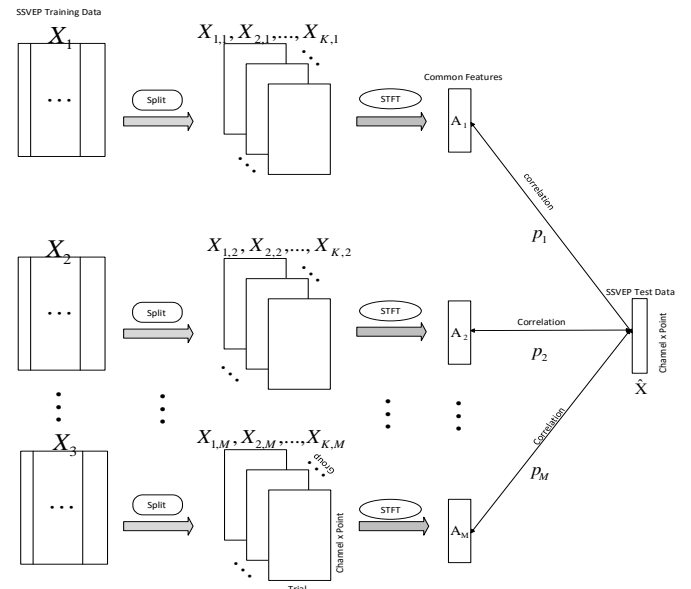

Bu çalışmada SSVEP tabanlı EEG veri seti kullanılmıştır. Bu veri seti MAMEM tarafından sağlanmıştır. Bu veri birçok araştırmacı tarafından sınıflandırma, oyun ve robot kontrolü gibi çeşitli amaçlarla kullanılmıştır. Bu çalışmaya araştırma ve teknoloji merkezi (CERTH) mevcut çalışanlarından 11 gönüllü katılmıştır. Yaşları 25 ila 39 arasında ve 8'i erkek, 3'ü kadın olup bilinen herhangi bir nöro-kas veya zihinsel rahatsızlığı olmayan deneklerdir. Deney uyarıcıları aynı anda beş farklı (6.66, 7.50, 8.57, 10.00 ve 12.00 Hz) frekansta titreşen beş mor kutudan oluşmuştur [17]. Yüksek kaliteli EEG verileri Emotiv Epoc ile 14 kablosuz kanalı (USB bağlantısı üzerinden) ve 128 Hz'lik bir örnekleme oranı kullanılarak kaydedilmiştir. Elektrotların, 10-20 uluslararası Sisteme karşılık gelen topoğrafik gösterimi Şekil 2'de gösterilmektedir.

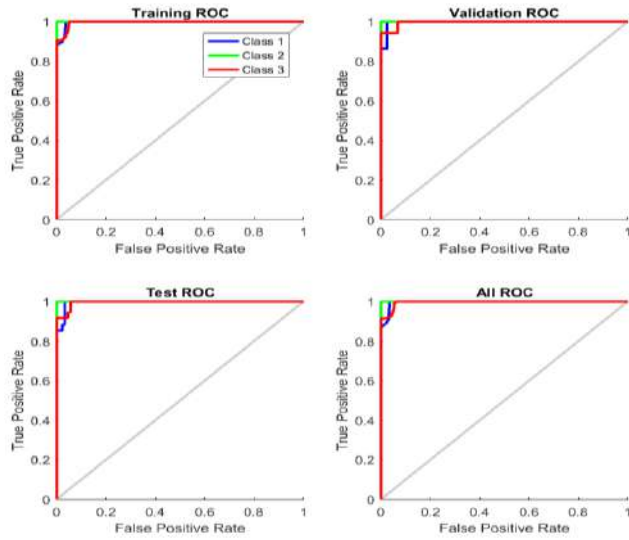

Şekil 2 10-20 Uluslararası Elektrot topoğrafik gösterimi

III. EEG SİNYAL ANALİZİ VE SONUÇ

Bu çalışmada veri seti içerisinde yön ve uyarın frekansına göre kümeleme yapılmıştır. Şekil 3' de gösterildiği gibi $X_1 - X_m$ Emotiv Epoc+ cihazından MAMEM tarafından alınan sinyallerdir. Bu sinyaller ayrıştırılarak aynı frekans ve yönde uyarın sinyaller beş sınıf oluşturacak şekilde bir araya getirilmiştir. Sinyal kümesi haline getirilen bu sinyallere 4-18 Hz bant geçiren filtre uygulandı, Hilbert dönüşümü hesaplanmıştır ve STFT' si alınmıştır. Daha sonra her sınıfın ayrı ayrı entropi, ortalama ve standart sapma değeri alınarak öz nitelikleri elde edilmiştir. Bu öz nitelikler ile SSVEP tabanlı farklı frekanslardaki (6,66, 8,57, 12 Hz) görsel uyarınlar ve sol, sağ ve yukarı olmak üzere farklı yöndeki göz hareketinden oluşturulan 3 küme YSA ile sınıflandırıldı ve ortalama % 90 üzeri başarı oranı elde edilmiştir. Şekil 4 de ise bu sınıflandırma sonucunun ROC eğrisi gösterilmektedir

Şekil 3 SSVEP tabanlı EEG sinyal işleme

Şekil. 4 YSA Sınıflandırma ROC grafiği

IV. TEŞEKKÜR

Bu çalışma İnönü Üniversitesi Bilimsel Araştırma Projeleri Koordinasyon Birimi Tarafından Desteklenmiştir. Proje numarası: 2016 -29 dur.

Abstract—Geometry optimization of Carbon Nanotubes (CNTs) is a very time-consuming process, even in the simulation environment, due to Density Functional Theory (DFT) calculations. The main aim of this research is to reduce DFT calculation time using an Adaptive Network-Based Fuzzy Inference Systems (ANFIS) based model for atomic coordinates from days to minutes. The dataset was created with the combination of the atomic coordinates of carbon atoms and chiral vectors using CASTEP software. The accuracy of the proposed models is evaluated with Mean Square Error (MSE), Mean Absolute Error (MAE), Standard Error of the Estimate (SEE) and Correlation Coefficient (R) metrics. The dataset is studied separately with and without using 10-fold cross-validation. The ANFIS prediction model yielded lower MSE and MAE results than previous study which uses only artificial neural network based prediction models.

Keywords—Neuro-fuzzy applications; Carbon Nanotube; Prediction.

1. INTRODUCTION

Nowadays, semiconductor technology is directed to carbon and carbon-derived structures which are IVA group of semiconducting elements and this situation makes simulations of structures to be synthesized important. For these simulations, the methods of preterm delivery (ab initio) are being implemented with each passing day. There is a need for alternative approaches that will facilitate operations in the face of complex computations of these methods.

Density functional theory (DFT) calculates atomic coordinates faster than other mathematical approaches and reaches more accurate results and therefore it is the most successful method. Nevertheless, the elapsed calculation time measured in this study using BIOVIA Materials Studio CASTEP [1] for high number of atoms is quite long [1]. Due to calculation capability limits of workstation computers, calculations may even take several days. Thus, to reduce the calculation time, researchers need to buy and use more

powerful but expensive workstations and parallel computer grids. In literature, many researchers remark this calculation time problem in their studies. General view of the researchers who studied on geometry optimization using DFT can be summarized as “DFT calculations are time consuming” [2–5].

This research has the motivation that is the calculation time reducing from days to minutes for atomic coordinates. Also, it is clear that the calculation time cannot be reduced up to this level using the current mathematical methods. In this work, the problem is investigated in another perspective. An accurate and fast prediction of the atomic coordinates is done instead of calculation. In some researches predicted atomic coordinates may be enough in accuracy. In that cases the proposed approach with direct result outcomes may be the fastest solution. The prediction mechanism to reach faster results with limited accuracy may be obtained by using neuro-fuzzy methods.

In this study, the main aimed objective is developing a prediction model using Adaptive Network-Based Fuzzy Inference Systems (ANFIS) to estimate the atomic coordinates of Carbon Nanotubes (CNTs). Two distinct datasets named as input dataset and output dataset are prepared to be used in prediction models. The 5 parameters of input dataset are initial atomic coordinates (u , v and w) and chiral vector (n and m). On the other hand, the 3 parameters of output dataset are calculated atomic coordinates (u' , v' and w'). CASTEP software is used for three processes: the CNTs simulation, the geometry optimization calculation and the creation of output file for each chiral vector including the initial and calculated atomic coordinates. Mean Squared Normalized Error (MSE), Mean Absolute Error (MAE), Standard Error of Estimation (SEE) and Multiple Correlation Coefficient (R) are determined to evaluate the performance of prediction models.

The organization of the study is presented as follows: This section covers short reviews of CNTs, Ab Initio Method, and DFT. In Section 2, summaries of the researches performed on this topic are given briefly as past works. In Section 3, the materials used in this study and ANFIS, specifically the ANFIS toolbox in MATLAB are explained. The results of

fuzzy/neural approach used in atomic coordinate prediction is discussed in Section 4. In last, Section 5 contains concluding remarks.

A. A. Single-Wall Carbon Nanotubes (SWCNTs)

Fullerenes[6], graphene[7] and CNTs [8] are very constant sp^2 carbon bonded materials at nanometer size and their discoveries motivated to make investigations in this field. Graphene and CNTs have many common physical properties which are derived from graphene. Carbon atoms of graphene are densely arranged in a regular sp^2 -bonded atomic-scale honeycomb (hexagonal) pattern. For other sp^2 carbon bonded materials (allotropes) like fullerenes and CNTs, this pattern is a basic structure. The theoretical difference of CNT is being a cylinder fabricated of rolled up graphene sheet. It has two types according to wall types. Single-wall carbon nanotubes (SWCNTs) were reported in 1993 [9] and have only one wall. Iijima[10] were first discovered multi-wall carbon nanotubes (MWCNTs) in 1991 and these nanotubes have more than one wall (Fig.1)[11].

Fig. 1. Schematic structure of SWCNT (A) and MWCNT (B)[11]

The diameter of a SWCNT differ from 0.4 to 3 nm and its length is generally of the micrometer range. Usually they come together to form bundles (ropes). They organized hexagonally in a bundle structure and form a crystal-like construction [8]

SWCNTs can exist in three forms named as armchair, chiral, and zigzag according to wrapping to a cylinder way (Fig.2). Chiral vector is a pair of indices (n, m) that directly effects electrical properties of nanotubes and characterizes the structure of SWCNTs. The integers, n and m , determine the number of unit vectors along two directions in the honeycomb crystal lattice of graphene. According to the general opinions, the nanotubes are called as zigzag nanotubes when $m=0$. If $n=m$, then they are called as armchair nanotubes and for all other states they are named as chiral[11].

Fig. 2. Models of three atomically perfect SWCNT structures[11]

The tube diameter d [4, 5] and the direction of rolling a graphene sheet are determined by the chiral vector $C_h = na_1 + ma_2 \equiv (n, m)$, where a_1 and a_2 are the base cell vectors of graphite (Fig. 3). Thus, the carbon tube diameter (Eq. 1) can be calculated by

$$d = \frac{a\sqrt{m^2 + mn + n^2}}{\pi} \quad (1)$$

where a is the lattice constant in the graphite sheet [11].

Fig. 3. The chiral vector C [11]

A nanotube is classified as 'metallic' or highly conducting nanotubes if $n - m$ is a multiple of 3, otherwise it is a semimetallic or semiconductor. However, an armchair formed nanotube is always classified as metallic.

B. B. Ab Initio Method, Density Functional Theory and CASTEP

The atomistic viewpoint becomes a very critical issue for both scientists and engineers after the materials behavior at nanoscale are dominated by the effects of single atoms. Nevertheless, to achieve the straightforward manipulation of the nanostructure is rather complex and for this reason it is difficult to measure the experimental results of mechanical properties at nanoscale. So, to investigate the mechanical properties of nanostructures, the importance of computer modeling becomes more important every day for new technologies development. The interaction between atoms is considered dynamically and statically with dynamic and static models, respectively. Ab initio and tight-binding methods, and classical molecular dynamics simulations are three types of the dynamic methods[12].

Ab initio method needs a wave function description for the electrons because it treats separately the electronic and ionic degrees of freedom. The ab initio is an expensive and time-consuming method and for this reason some approximations like the DFT are incorporated instead of many-body interacting wave functions. DFT is based on the fact that the ground-state electronic energy is a unique function of the electronic density [12].

Hohenberg and Kohn [13] and Kohn and Sham [14] developed a simple method, DFT, that describes the effects of exchange and correlation in an electron gas. The total energy, that contains exchange and correlation, of an electron gas is a unique functional of the electron density and this fact proved by [13]. The ground-state energy of the system is the minimum value of the total-energy functional. The exact

single-particle ground-state density is this minimum value which is obtained from the density. It is showed that an exactly equivalent set of self-consistent one-electron equations is used instead of the many-electron problem by [14].

The ground state energy is given in Eq. 2

$$E = \sum_i \epsilon_j - \frac{1}{2} \int \frac{n(r)n(r')}{|r-r'|} dr dr' - \int v_{xc}(r)n(r)dr + E_{xc}[n(r)] \quad (2)$$

where E_{xc} is the exchange correlation energy, V_{xc} is the exchange correlation potential energy, $n(r)$ is the electron density and the ϵ_j and n are the self-consistent quantities [15].

The CASTEP software [16] is used to perform electronic structure calculations as a first principles quantum mechanical code. A wide range of materials like surfaces, crystalline solids, liquids, molecules and amorphous materials can be simulated with CASTEP within the density functional formalism [17].

Depending on the finite speed and memory of the used computer, CASTEP can calculate the properties of any material that formed from an assembly of nuclei and electrons. This is an ambitious approach that aims to rely on quantum mechanics instead of to use experimental (empirical) data [17].

CASTEP has numerous capabilities and it is a fully featured first principles code. The total energy derived from many other quantities is the basic quantity aiming to calculate any physical property of the system from first principles.

2. RELATED WORK

In recent years many researchers studied on CNTs to obtain perfect CNTs and widen their application areas. Some of the studies are focused on geometry optimizations of the CNTs. Also many of the researchers that study on CNT calculations, incorporate artificial intelligence methods into their works. Nowadays, this incorporation trend has been increasing.

DFT calculations in CASTEP were used by many researchers for CNT studies. Bauschlicher and Ricca [2] utilized from DFT and the second-order Møller-Plesset approaches to study the interaction of NH₃ with graphite and a (9,0) CNT. They used CASTEP for DFT calculations and denoted that the optimization calculations are very time consuming even running in parallel. Hong-Xia et al. [18] achieved the structure of heterojunctions made up of an (8, 0) CNT and an (8, 0) boron nitride nanotube, and an (8, 0) CNT and an (8, 0) silicon carbide nanotube through geometry optimization implemented in the CASTEP with two distinct studies. They designed a two-probe system of the heterojunction and calculated its transport properties with a method combining nonequilibrium Green's function with DFT. They limited the bias range -3.0 to 3.0 V to avoid from the time consuming calculations. A numerical study of conjoined structures of graphene nanoribbons and CNTs

were performed by [4]. They performed all calculations in CASTEP. As the calculations were time consuming, they were made for relatively small super-cells, including several hundreds of atoms. Mao and Zhong [19] investigated the geometries and electronic properties of junctions constructed from armchair and zigzag CNT insertion graphene matrix using first-principles DFT calculations. The study was implemented in the CASTEP and based on the first-principles plane-wave pseudopotential DFT. Because of the larger number of atoms in the supercell and expensiveness of the calculation time, more K points along the tube axis are considered in the calculation of the band structure instead of the structural optimization.

There are many studies can be seen in the literature working on CNTs that use ANFIS. A new methodology is presented by Al-Khedher et al. [20] to investigate the correlation between indentation resistance of MWCNT turfs, Raman spectra and the geometrical properties of the turf structure. They used adaptive neuro-fuzzy phenomenological modeling for the study. Ahadian and Kawazoe [21] proposed an ANFIS for modeling of water flow in CNTs. An input-output mapping based on both human knowledge in the form of fuzzy if-then rules and stipulated input-output data pairs can be constructed by the presented ANFIS approach. They obtained good performance with the designed ANFIS. A set of novel models employing field effect transistor structures using graphene has been proposed and the current-voltage characteristics of graphene have been employed to model the sensing mechanism by Akbari et al [22]. For the current-voltage characteristic, another model is provided using an ANFIS. The study showed that the proposed model and the experimental data exhibit satisfactory agreement with each other and Escherichia coli bacteria can detected by this biosensor with high levels of sensitivity. Alibabaiy et al. [23] applied ANFIS for modeling and simulation of CNT metal-oxide-semiconductor field-effect transistors. They mentioned that the computational time is reduced with ANFIS model while the accuracy of physics-based model like nonequilibrium Green's function formalism is kept. In last, they imported the proposed ANFIS model into HSPICE software as a sub-circuit and the results showed that the ANFIS model is suitable to be incorporated into Spice-like tools for nanoscale circuits simulation. A network is trained by Savari et al. [24] to simulate pressure drop and convective heat transfer coefficient in a circular tube with a constant heat flux. They obtained experimental data in the presence of non-covalently and covalently functionalized MWCNT-based water nanofluids. They modeled the experimental results by the ANFIS method and investigated the proposed method of ANFIS modeling in terms of validity. Lastly, they proposed a valid ANFIS method for MWCNT-based water nanofluids in a circular tube with constant heat flux. The hardness of copper/carbon nanotube nanocomposite is predicted by Sahraei et al. using Two different proposed fuzzy inference systems (FISs) [25]. A predictive framework is simulated for

current case study with engaging of two different machine learning algorithms. The requirements for fast adaption of the consequent parts of FIS are provided by the classic least square optimization method. In the second method, the rudiments of neural computing through layering the FIS and back-propagation optimization algorithm is used. The results showed that the knowledge required to predict the hardness of copper/CNT nanocomposite can be extracted using the adopted fuzzy systems. The buckling instability of perfect and defective CNTs is predicted using an ANFIS by Fakhrebadi et al[26]. Firstly, they obtained the results for some cases using structural mechanics and due to the uneven trends of the results, they are fed into an to predict the buckling loads of the unmodeled CNTs. Some special cases are used to validate the capability of the predictive tool and the accuracy of the predicted results.

Although there are many studies summarized above regarding the use of ANFIS in CNT field, there is no study about calculation of atomic coordinates. Only, Aci and Avci[27] developed four artificial neural network (ANN) models that predicts atomic coordinate of CNTs. They obtained very satisfied results and showed that instead of mathematical calculations, ANN models can be successfully used to predict atomic coordinates of CNTs.

3. MATERIAL AND METHOD

C. A. Dataset

In this study, the used dataset is generated using CNT geometry optimization with CASTEP. Geometry optimizations of the simulated CNTs are calculated and saved in distinct files using CASTEP. The initial coordinates of carbon atoms are randomly generated. SWCNTs are built by user after selecting chiral vectors as shown in Fig. 4. Different chiral vectors, except zigzag and armchair, are selected for every CNT simulation. Also, carbon and 1.42 Å (default value) is selected as atom type and bond length, respectively. Then, as shown in Fig. 5, the CNT is simulated by CASTEP. The calculation interface of CASTEP depicted in Fig. 6 and the default parameters are used for the calculations.

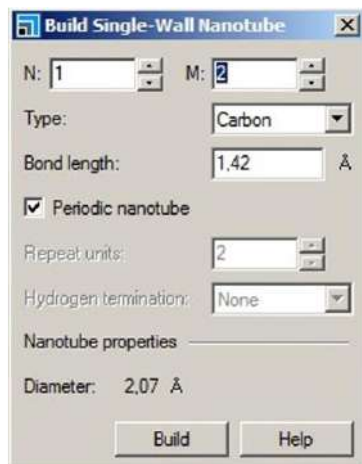

Fig. 4. Single-wall nanotube building in CASTEP[1]

Fig. 5. Simulated CNT in CASTEP[1]

The `elec_energy_tol` (electrical energy tolerance) parameter represents the change in the total energy from one iteration to the next remains below some tolerance value per atom for a few self-consistent field steps to finalize the computation. The calculation level of inputs and outputs are also determined with this parameter. The default value of the parameter is usually suitable and it is 1×10^{-5} eV per atom [1].

Fig. 6. Calculation interface of CASTEP[1]

All calculated data for each CNT simulation are saved in many files that are created after the calculation step. For creation of the input and the output datasets, SWNT.castep file is used as output file.

All calculations were run on a workstation that has a 2.0 Ghz power on 4 cored 2 processors and a RAM of 8 GB, using all cores under Linux operating system. The calculation time according to these calculations are approximately varies from 10 minutes to 5 days as given in Table 1 in seconds. These calculation times will take weeks and months for higher atom numbers.

The input dataset attributes, initial atomic coordinates (u, v and w) and chiral vector (n and m), are obtained from the output files. Also the output dataset attributes, calculated atomic coordinates (u', v' and w'), are extracted from same files. The dataset consists of 10,721 data samples and it is firstly divided into training, validating and testing data randomly. Their distribution is selected as 70–15–15% for training, validating and testing sets, respectively. Then, the accuracy is determined using cross-validation techniques that compared the actual and the estimated values. The datasets

are evaluated by means of tenfold cross-validation. The average error of estimates is predicted by cross validation using the dataset with one individual removed. 90 and 10% of the data are split as training and test data for cross-validated datasets, respectively. The evaluation of the generated prediction models are done whether using tenfold cross-validation or without using cross-validation. In Table 2, descriptive statistics summary (minimum, maximum, mean and standard deviation values) of the dataset is given.

D. B.Adaptive Network-Based Fuzzy Inference Systems (ANFIS)

Jang and Sun [28], [29] first developed the adaptive network-based fuzzy inference systems (ANFIS) to take advantage of the best attributes from neural networks and fuzzy systems. ANFIS is a FIS that uses neural network algorithms to adapt itself in order to achieve better results. As an advantage of ANFIS against neural networks is accepting linguistic information and adapting itself using numerical data [30].

Any FIS structure includes a fuzzification interface, a rule base, and a database for the membership functions definitions used in the rules. Also, a fuzzy reasoning method to perform the inference procedure, and a de-fuzzification interface are the other parts of the structure. Neural network training techniques are used by an ANFIS for adjusting the membership functions. The rule base is usually in the form of fuzzy if-then rules [30].

A Sugeno-type [31] FIS is used by MATLAB's implementation of ANFIS. An adaptive neural network technique is used to train the Sugeno-type FIS parameters.

Inputs are mapped through input membership functions and associated parameters by ANFIS. Then through output membership functions and associated parameters to outputs, can be used to interpret the input/output map. The parameters associated with the membership functions change through the learning process. A gradient vector facilitates the computation of these parameters. A measure of how well the FIS is modeling the input/output data for a given set of parameters is provided by this gradient vector. When the gradient vector is obtained, any of several optimization routines can be applied in order to adjust the parameters to reduce some error measure. The sum of the squared difference between actual and desired outputs usually defines this error measure. Either back propagation or a combination of least squares estimation and backpropagation for membership function parameter estimation is used by ANFIS [32].

A matrix of the training data forms the input training data and the last column is the target output data. Test input data is used also in the same way. While the fuzzy toolbox provides many membership function types, Generalized bell-shaped membership function (gbellmf), Gaussian curve

membership function (gaussmf) and Pi-Shaped Membership Function (pimf) (Fig. 7) performed the best for the prediction of atomic coordinates. The block diagram of one FIS that is used in the u' coordinate estimation is illustrated in Fig. 8.

After the five inputs enter the ANFIS then they processed for the u' coordinate prediction. Similar FIS models are also designed for prediction of v' and w' coordinates

Fig.7. Membership Functions: (a) gbellmf (b) gaussmf (c) pimf

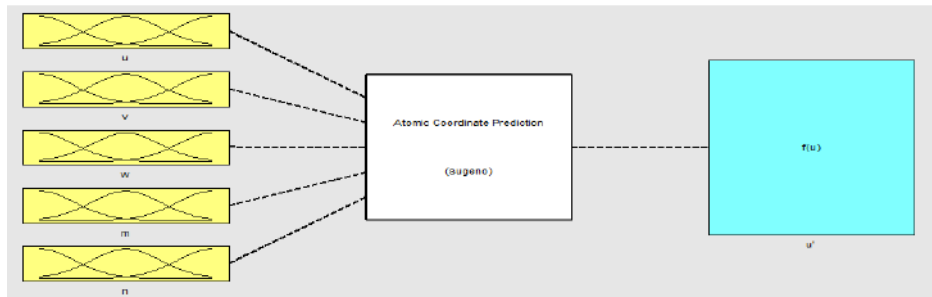

Fig. 8. FIS of u' coordinate prediction

4. RESULTS AND DISCUSSION

E. A. Performance Measures

Four performance measures are evaluated for the prediction model. Correlation between target and predicted values are measured by R and the average of the squares of the errors are measured by MSE . The closeness of the predictions to the target values is measured by MAE and the standard error of the estimates of the prediction models are calculated by SEE . In Eqs. 3, 4, 5 and 6, the mathematical equations of the used performance measures are given as

$$R = \sqrt{1 - \frac{\sum_{i=1}^n (O_i - P_i)^2}{\sum_{i=1}^n (O_i - O_m)^2}} \quad (3)$$

$$MSE = \frac{1}{n} [\sum_{i=1}^n (O_i - P_i)^2] \quad (4)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |O_i - P_i| \quad (5)$$

$$SEE = \sqrt{1 - \frac{\sum_{i=1}^n (O_i - P_i)^2}{n}} \quad (6)$$

where O_i and P_i is the observed and predicted values, respectively, O_m is the average of the observed values and n

is the number of data points used for testing. MATLAB (R2015b 64 bit) [32] was utilized for designing proposed models and obtaining performance measures.

F. B. Performance results of the ANFIS Model

Before the ANFIS model is developed, the input and output data is normalized and presented on a scale from 0–1. After that, noisy data is removed by using exhaustive search method [33]. *gbellmf* has been used for prediction of u' and v' coordinates whereas *pimf* has been used for w' coordinate prediction with the non-cross-validated dataset. When 10-fold cross-validation is considered, the best results were obtained from *pimf* for u' and w' coordinates and *gaussmf* for v' coordinate.

The observed and predicted coordinates for the test set plotted in Fig.9. the following points can be made, based on the performance results of u' , v' and w' coordinates prediction using the ANFIS prediction model with the non-cross-validated dataset (Table 3):

- The best result is obtained from w' coordinate prediction (MSE=4.962E-08, MAE=1.534E-04, SEE=2.228E-04, R=1.000E+00).
- All of the performance results are very similar for u' and v' coordinates prediction.

- As is clearly seen from Fig. 9, the observed and predicted values of three coordinates very close to each other.

Table 3. Performance results of u' , v' and w' coordinates prediction using anfis model with the non-cross-validated dataset

Coordinates	Performance Metrics			
	MSE	MAE	SEE	R
u'	1.077E-05	2.224E-03	3.282E-03	9.999E-01

v'	1.101E-05	2.294E-03	3.318E-03	9.999E-01
w'	4.962E-08	1.534E-04	2.228E-04	1.000E+00
Average of three coordinates	7.277E-06	1.557E-03	2.274E-03	9.999E-01

(a)

(b)

(c)

Fig. 9. Plots of observed versus predicted values of u' coordinate (a), v' coordinate (b) and w' coordinate (c).

Tables 4, 5 and 6 show the MSE, MAE, SEE and R results of the ANFIS prediction model by means of 10-fold cross-validation for u' , v' and w' coordinates respectively. The summary of the detailed 10-fold cross-validation results are given in Table 7. The following comments can be made based on the results:

- As is seen from the tables, the performance of w' coordinate prediction is better than u' and v' coordinates prediction in terms of MSE, MAE and SEE metrics. For R metric, the values of w' coordinate prediction are better or approximately equal to the performance of other coordinates.
- The results of u' coordinate prediction showed the second best results and the worst results are taken from v' coordinate prediction
- The best MSE (4.386E-08) is achieved with w' coordinate prediction at second fold.
- Very close performance results were obtained for u' and v' coordinates prediction in terms of SEE and R.

Average of three coordinates	4.157E-06	8.401E-04	2.305E-03	9.999E-01

5. CONCLUSIONS

In this work, an ANFIS based prediction model is proposed to predict the atomic coordinates of CNTs. A dataset is created to carry out the prediction model using CASTEP. The dataset of 10,721 data samples contain atomic coordinates (u, v and w) and the chiral vector (n and m) as totally five inputs and three final atomic coordinates (u', v' and w') as outputs. The dataset is organized into two types for evaluation strategy: cross validated dataset and non-cross validated dataset. Training of the prediction models is done by 90% of the cross validated dataset. The rest of the dataset usually serves as an independent test set by which the generalization performance of the prediction models. The dataset is randomly split to three, in which there are 70-15-15% training, validating and testing sets, respectively for the non-cross validated dataset. MSE, MAE, SEE and R values have been calculated for the developed model for performance evaluation.

The proposed prediction model performed good level of success when we look at all results with a general view. The first aim of this study is to use predicted atomic coordinates instead of simulated ones. This aim is reached by i) obtaining very low MSE, MAE and SEE values; ii) getting very high R

values when the average values are considered for the cross validated dataset. The second aim is to achieve better results than the previous study that used ANN[27]. This aim is also reached by getting lower MSE and MAE values than the previous study. It has been understood that the ANFIS-based prediction model performs better than ANN-based models in atomic coordinate estimation.

Abstract—In this study, an effective method is presented to detect deception by using only verbal features of the human voice. The data set benefitted in this study contains different real-world video clips. After extracting speech signals from the video clips, the Hamming Windowing method is applied to each signal. Discrete Wavelet Transform is used to obtain time-frequency features of the speech signals. Each speech is labeled as truthful (1) or deceptive (0). A 5-level signal decomposition with Daubechies-4 mother wavelet is employed for the feature extraction stage. To reduce the size of the feature set, some statistical parameters such as standard deviation, energy, entropy, kurtosis and skewness of the decomposed signals are obtained. After obtaining the feature set, finally, the Extreme Learning Machine, a fast and effective classifier, is applied to the feature set to classify the truthful and deceptive speeches. The various simulations clearly show us; the proposed method has higher performance than the previous studies performed in the literature.

Keywords—deception detection; feature extraction; discrete wavelet transform; extreme learning machine.

I. INTRODUCTION

Deception is a well-known term that involves acting in such a way leading another person to believe something that is not true. Deception is a very common occurrence in daily life. Concealing or misrepresenting the truth are sometimes a big problem especially for the judgment, intelligence services, police departments, call centers, customer services, banking etc. To cope with this problem, deception detection has an increasing amount of attention recently. While some researchers use only verbal techniques to detect deception [1], some other researchers use nonverbal features by investigating some physical and emotional actions of peoples [2]. On the other hand, another group of researchers uses both verbal and nonverbal features [3]. Previous attempts on detecting lies are performed by using trained experts [1]. But the performance of these methods is very poor. In fact, deception detection is a very

difficult task and humans can detect deception in the range of 45-65% [2], [3]. Another drawback of these approaches is that they require a large amount of time and effort for the analysis

[1]. Peoples usually intend to identify deception with non-verbal cues and give less attention to the verbal cues [4]. It was reported that audible and verbal clues are better than the visual and emotional clues [5]. However, some researchers show that thermal imaging is a good indicator to detect deceit by observing blood flow to human face [6], [7]. Actually, liars have some feelings of anxiety, fear, shame or anger much more than truth tellers [6]. These feelings may give important clues to the experts directly or indirectly by using different sensor data [8], [9]. In addition, some researchers tried to identify deception from the writing by using syntactic stylometry and obtain 91.2% accuracy [10].

Recently, computer based deception detection methods have attracted much more attention than the others mentioned above. Because of their capability of analyzing big and complex datasets which include non-linear relationship, the machine learning algorithms such as artificial neural networks (ANN), support vector machines (SVM), extreme learning machines (ELM), etc., may give better results of deception detection than the conventional methods. The main problem to establish an automatic deception detection algorithm is to give distinctive features of speech signals to the classifiers as inputs. To cope with this problem an efficient speech processing algorithm is required.

In this study, a new and effective deception detection method is presented. The proposed approach detects deceptive and truthful speeches with higher accuracy rate than previous studies performed in the literature. A dataset which is called "Real Life Trial Data" and contains 61 deceptive and 60 truth trial video clips is used in the study [4] [5]. Because of the fact that we will use only speech signal, we extract speeches from the clips. After applying Hamming Windowing method to the speech signals, discrete wavelet transform (DWT) is employed to obtain time-frequency information from each signal. Then,

some statistical parameters such as energy, entropy, kurtosis, skewness and standard deviation are used to build a feature dataset. Finally, ELM is employed to classify deceptive and truthful voices. After a lot of trials, the results obtained show us the proposed method can achieve the task of automatic deception detection with an accuracy above 95%.

II. DECEPTION DETECTION

We use machine learning approaches to assess the performance of extracted features from the real life dataset which includes truthful and deceptive speeches. As mentioned above, these speeches extracted from video clips.

The most commonly used machine learning methods are artificial neural networks, support vector machines, extreme learning machines and decision trees. We perform detection of deception by using extreme learning machines (ELM) classification algorithm. The simulations were implemented by using the Matlab software. The feature matrix obtained in the classification process has a great significance. In the feature extraction stage, DWT is employed. The proposed algorithm for deception detection is depicted in Fig.1.

Fig. 1. Proposed method for deception detection.

A. Feature Extraction

The speech data are primarily windowed. The most commonly used windows are the Hamming, Hann and Blackman functions [6]. These functions help to emphasize the middle parts of the signal parts. On this count, parts that do not work in the extraction of the attribute are discarded. Windowing is very important at the output of the attribute. It is then transformed by wavelet transform. Then the mean, standard deviation, skewness, kurtosis, energy and entropy are calculated. The attribute matrix is obtained from the obtained values. In the next sections, the mathematical definitions of these methods are presented briefly. The obtained results will be given in Section III.

B. Hamming Window

One of the most primary filter type used in digital signal processing (DSP) is finite impulse response (FIR) filter. FIR filters are restricted to discrete-time implementations. A simple way to obtain a FIR filter is called as “windowing method” and start with an ideal desired function as [6],

$$H_d(e^{j\omega}) = \sum_{n=-\infty}^{\infty} h_d[n]e^{-j\omega n} \quad (1)$$

where $h_d[n]$ is the corresponding impulse response sequence and can be stated as,

$$h_d[n] = \frac{1}{2\pi} \int_{-\pi}^{\pi} H_d(e^{j\omega}) e^{j\omega n} d\omega. \quad (2)$$

To obtain a casual FIR filter by using $h_d[n]$ a new system $h[n]$ with impulse response can be defined as,

$$h[n] = \begin{cases} h_d[n], & 0 \leq n \leq M, \\ 0 & \text{otherwise.} \end{cases} \quad (3)$$

We can represent $h[n]$ the product of desired impulse response and a fined duration window as,

$$h[n] = h_d[n]w[n] \quad (4)$$

where $w[n]$ is the window function. Then, the Hamming window can be defined by the equation given below as,

$$w[n] = \begin{cases} 0.54 - 0.46 \cos(2\pi n/M), & 0 \leq n \leq M, \\ 0 & \text{otherwise.} \end{cases} \quad (5)$$

C. Wavelet Transform

The WT is a mathematical technique which is used for a lot of signal processing application [7]. WT is more powerful than conventional methods such as Fourier transform in the processing of the non-stationary signals because of the capability of analyzing waveforms in both time and frequency domain. The band of wavelet analysis is adjusted so that both low frequency and high-frequency components are windowed by different scale factors [8]. The continuous wavelet transform (CWT) of the $f(t)$ function can be defined as [7], [8];

$$CWT_{\psi} f(a,b) = \int_{-\infty}^{\infty} f(t) \psi_{a,b}(t) dt \quad (6)$$

where, ψ is mother wavelet [8] and written as,

$$\psi_{a,b}(t) = |a|^{-1/2} \psi\left(\frac{t-b}{a}\right) \quad (7)$$

In the discrete time domain, the continuous mother wavelet can be dilated and translated discretely by selecting $a = a_0^m$ and $b = nb_0 a_0^m$, where a_0 and b_0 are fixed constants with $a_0 > 1$, $b_0 > 0$, $m, n \in \mathbb{Z}$. Then ψ re-defined as;

$$\psi_{m,n}(t) = a_0^{-m/2} \psi\left(\frac{t - nb_0 a_0^m}{a_0^m}\right) \quad (8)$$

Then, discrete wavelet transform (DWT) is written for any function $f(t)$ as,

$$DWT_{\psi} f(m, n) = \int_{-\infty}^{\infty} f(t) \psi_{m,n}(t) dt \quad (9)$$

D. Multiresolution Analysis (MRA)

MRA is the representation of wavelets and scaling functions at different resolution levels to decompose and reconstruct the investigated signal. In MRA there are two filters which are the low pass (LPF) and high pass (HPF) in each decomposition level.

The original signal can be divided a series of orthogonal high-frequency and low-frequency spaces by using a set of orthogonal scaling function $\varphi(t)$ and mother wavelet $\psi(t)$ [8]. By this way, MRA gives the time-frequency picture of the decomposed signal $f(t)$ at different frequency levels. The original signal $f(t)$ is decomposed as:

$$f(t) = \sum_k c_j(k) \varphi_{jk}(t) + \sum_{j=1}^k \sum_k d_j(k) \psi_{jk}(t) \quad (10)$$

In this equation, j shows the wavelet decomposition level whereas c_j and d_j are the weighted sequences of the space projection of $f(t)$ respectively [9]. Two-level decomposition of the original signal is shown in Fig.2.

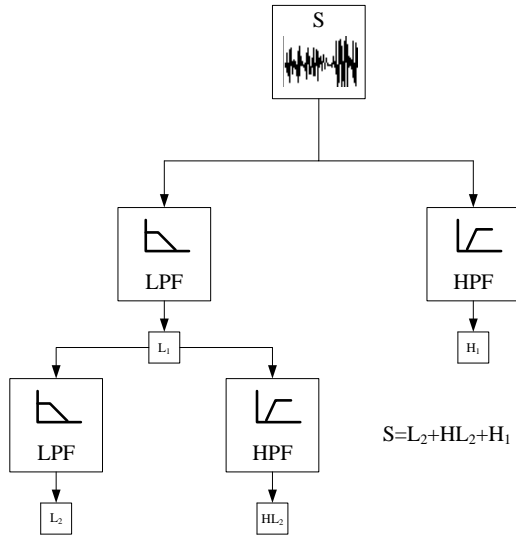

Fig. 2. Filter bank representation of the DWT dilation.

E. Extreme Learning Machines

Extreme learning machines (ELM) is a single hidden layer feed-forward neural network which is proposed by Huang at al., [10]. The ELM is a very fast training method and has a simple nature in which the input weights and biases are randomly initialized and then the weights between the hidden layer and output layer are optimized [10]–[12]. As a new and simple method, ELM can surpass the other time-consuming algorithms such as the conventional back propagation algorithms [13].

ELM with L hidden nodes and activation function $g(x)$ can be expressed mathematically for a given data set containing N training samples $\{(x_i, y_i)\}_{i=1}^N$, where input $x_i \in \mathbb{R}^n$ and corresponding desired output $y_i \in \mathbb{R}$, as;

$$\sum_{i=1}^L \beta_i g(w_i x_j + b_i) = y_j \quad j = 1, 2, 3, \dots, N \quad (11)$$

where $w_i = [w_{i1}, w_{i2}, \dots, w_{in}]^T$ is the randomly chosen input weight vector connecting the i th hidden neuron and the input neurons, b_i is the randomly chosen bias of the i th hidden node, and β_i is the weights between the hidden layer and output layer.

$$H\beta = y \quad (12)$$

$$H = \begin{bmatrix} g(w_1 x_1 + b_1) & \dots & g(w_L x_1 + b_L) \\ \vdots & \ddots & \vdots \\ g(w_1 x_N + b_1) & \dots & g(w_L x_N + b_L) \end{bmatrix} \quad (13)$$

$$\beta = [\beta_1, \beta_2, \dots, \beta_L]^T \text{ and } y = [y_1, y_2, \dots, y_L]^T.$$

The main purpose of ELM method is to find optimum β values [10], [13]. However, in most cases, H is a non-square matrix. So, Eq.(12) may not be solved by taking the inverse of H directly. One solution of this equation is to find the optimal least squares solution of $\hat{\beta}$ by minimizing the associated loss function, i.e., $\min \|y - H\beta\|_2^2$.

$$\hat{\beta} = H^\dagger \quad (14)$$

where H^\dagger is the Moore–Penrose generalized inverse of the hidden layer output matrix ELM with L hidden nodes and activation function H [11]. Since the number of training samples is usually greater than the number of hidden nodes i.e., $N > L$, Eq. (12) can be rewritten as

$$\hat{\beta} = (H^T H)^{-1} H^T y \quad (15)$$

III. EXPERIMENTAL RESULTS

A. Dataset

In this paper, we used the dataset called "Real Life Trial Data" [4]. This dataset was created by Rada Mihalcea, Verónica Pérez-Rosas and friends. This dataset was created from court records where deceptive and truth statements can be observed and verified very easily. These records are in the form of video. The defendant or witness in the video should be clearly

identified. Audio quality is enough for hear the voices and understand what the person is saying. When the videos are labeled, the accused and witness statements are taken into account. Police views are also taken into account. It is precisely determined by these three factors that the statement is true or false. The final dataset consists of 121 videos including 61 deceptive and 60 truthful trial clips.

The average length of the videos in the dataset is 28.0 seconds. The average video length is 27.7 seconds for the deceptive clips and 28.3 seconds for the truthful clips. The data consist of 21 unique female and 35 unique male speakers, with their ages approximately ranging between 16 and 60 years. Video files were converted into audio files. The frequency value is 16000 Hz, the bit rate value is 128 kbps and the mono channel is specified. The final set of transcriptions consists of 8,055 words, with an average of 66 words per transcript [4].

B. Application of the Proposed Method

Firstly, all speech signals were normalized between -1 and 1 interval. Then, the Hamming windowing method was applied to each normalized signals as a FIR filter. The length of Hamming window was selected as 15 msec. The original speech and windowed signals for both truth and deceptive examples are shown in Fig.3 and 4 respectively.

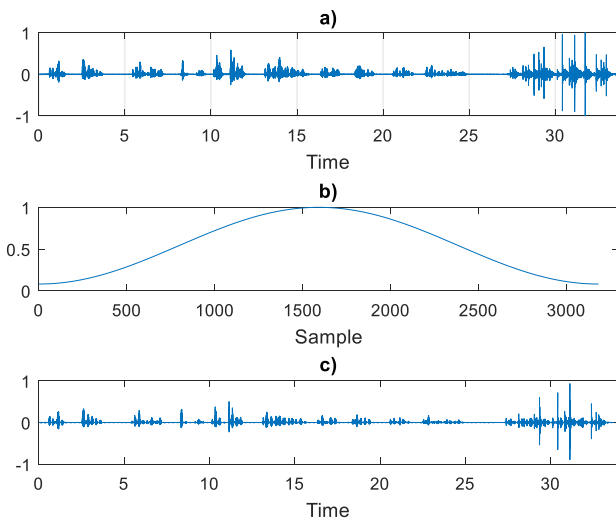

Fig.3. The original and windowed signals of a truth speech a) original signal, b) Hamming window, c) windowed signal.

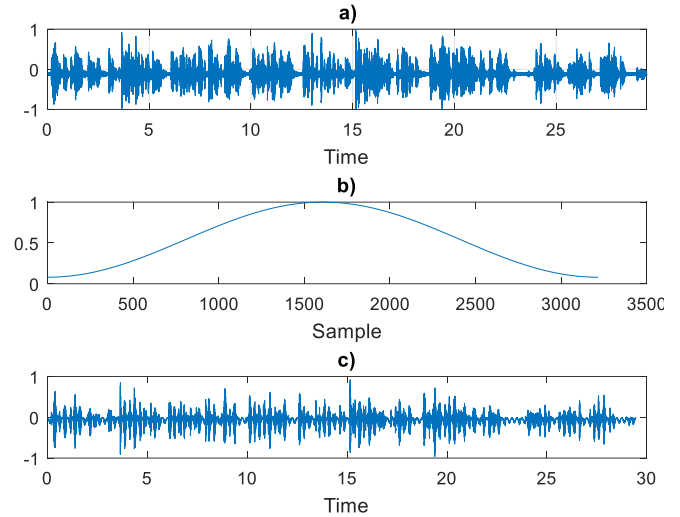

Fig.4. The original and windowed signals of a deceptive speech a) original signal, b) Hamming window, c) windowed signal.

In the next step, DWT was used to extract the distinctive features of the speeches. 5-level decomposition with Doubechies-4 mother wavelet (dB4) was used in the MRA. 5-level DWT decomposition for a deceptive speech signal is shown in Fig. 5. As it is obvious that there a lot of data for in each speech signal, we must find a way to represent these signals as a short way without losing important features. For this purpose, we calculated 5 statistical parameters as energy, entropy, kurtosis, skewness and standard deviation of the decomposed signals to obtain final feature dataset. Then final dataset was divided two groups randomly to be used in training and testing of ELM.

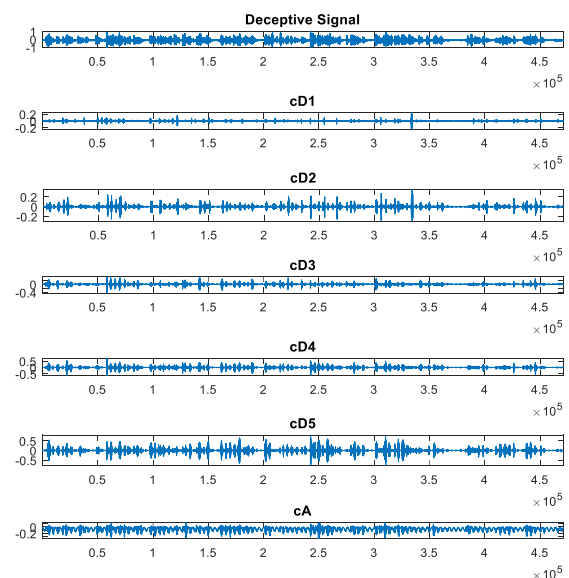

Fig.5. Wavelet coefficients for deceptive signal

Where cD_i represents i th detail coefficients whereas cA represents the approximation coefficients. It has to be noticed that first detail coefficient (cD_1) has the highest frequency and

cA has the lowest frequency according to multi-resolution analysis as mentioned above. Fig. 6 shows the ELM results without windowing. 80 percent of Dataset was used for training and 20 percent for testing. Number of neurons selected 100.

Fig. 6. ELM results without windowing

As can be seen from the Fig.6, the classification results are not satisfactory. Only 13 of 24 speeches were classified with the correct class label (0-deceptive, 1-truthful).

Fig. 7 shows the ELM results with windowing. 90 percent of Dataset was used for training and 10 percent for testing. Number of neurons selected 50. In this simulation, ELM classified all testing samples correctly. This result is the achievement of the windowing process before the DWT decomposition.

Fig. 7. ELM results with windowing.

In Fig.8., the results of ELM with 100 neurons are depicted. 80 percent of the data is used for training whereas 20 percent is used for testing of ELM. As shown from the figure, only two

examples belonging to the truth speeches are misclassified as deceptive.

Fig. 8. ELM results with decreased training data.

IV. CONCLUSION

A machine learning based algorithm is proposed to discriminate truthful and deceptive human speeches. The speech dataset used in this study was extracted from video clips. After normalization stage, Hamming windowing method was applied to each signal. Discrete wavelet transform was employed to obtain distinctive features from the speech signals. To reduce the size of feature space, some statistical parameters such as signal energy, entropy, kurtosis, skewness and standard deviation were obtained. Finally, ELM was employed for the classification task. The feature dataset was divided randomly to validate the performance of the proposed method. Therefore, we obtain 91,66% performance ratio when 24 speech examples were tested. Our method achieved 100% accuracy when 10-percent of the dataset was tested. We also examined the effect of windowing process. The obtained results show that the performance of ELM classifier decreases to 54,16% in this case.

As mentioned above, the feature dataset obtained in this study was divided as randomly to investigate the robustness of the proposed method. In the next studies, we will study both on the preparation of dataset for training stage and also on selecting more effective features from the feature space.

ACKNOWLEDGMENT

We are grateful to Rada Mihalcea, Verónica Pérez-Rosas and their friends for sharing us the data collection used in this study.

Abstract—Compared to the population increase in the metropolitan areas, the demand for in-city transportation is rising and the quality expected from the service is increasing. Knowing the demand for each station and route in the public transportation service will provide a great advantage for strategy setting and infrastructure building for the relevant institutions and companies. In this study, using artificial neural networks, estimates of daily passenger numbers for two regions of Istanbul, both Anatolian and European, have been evaluated and the error rates of the predictions obtained have been evaluated. For this, passenger information on each dutiable vehicle has obtained from İETT (Istanbul Electricity Tramway and Tunnel Enterprises) as station name, date-time, line name and number of persons, and weather report and temperature information have been also obtained from the General Directorate of Meteorology. In addition, holidays, elections and official holiday data have been collected. All these data have been combined in a single database. Transformations were converted to numbers and normalization was applied so that each value is expressed at equal importance. As a result, an artificial neural network model with 14 inputs and one output was obtained. In the hidden layer, it is aimed to reach the lowest average absolute error by performing tests with different numbers of nerves. These results reached the lowest error with the number of 9 on the third layer of the third layer 17, on the second layer 14 of the three layer model. The number of people in the group were gathered in 11 groups and the lowest absolute error of 1.0301 was reached for the results of four stations, while the highest mean absolute error of 1.5877 was reached. Thus, estimates with 90.64% accuracy were obtained.

Abstract— Eye tracking method is one of the important products of science which aims to facilitate human life. In this research, it is aimed to determine the existing situation by examining the working principles of eye tracking systems from daily using practices and literature. In this study, it was aimed to evaluate the findings obtained by investigating eye tracking technologies. Advantages and disadvantages of the systems which was used for this purpose was evaluated. It's intended to given suggestions and future directions in terms of eye tracking systems.

Keywords— eye tracking, eye movement, technology, innovation

I. INTRODUCTION

Human development is based on finding out what is happening in the environment, identifying problems and finding solutions. Thanks to this development, many obstacles that have made life difficult in the past have been removed and progress has been made. In the simplest terms, eye tracking is the measurement of eye activity. Eye tracking method is one of the important products of science which aims to facilitate human life[1]. There are studies showing that eye tracking systems can be used as an input element in control software as well as in psychological and neurological inferences by following changes related to eye movements. In this study, the studies performed with eye tracking systems and the findings obtained from these studies were evaluated. After the evaluation, the deficiencies and needs in the field related to the work to be done regarding eye tracking systems have been determined. In the scope of the study, Integration of disabled people, identification of psychological and neurological problems, individual recognition in commercial activities, ergonomics design, game development, integration of military systems [2].

II. EYE TRACKING SYSTEMS

In this section, firstly the human vision system is discussed, then the development of eye tracking systems and the study structure of eye tracking devices are examined.

A. Human Vision System

The ease of access to the developments and devices in the eye tracking system has also increased the number of studies on eye tracking technology [3]. The eye, which consists of optical components such as retina, cornea, eye baby, and eye lens, is one of the most important sensory organs of human life that communicate with the outside world, and 80% of human perception is realized with eyes[4].

Fig. 1. Structure Of The Eye

The rays reflected from the objects at the visual angle reach the cornea layer first. An important part of the light-breaking ability of the eye occurs in the cornea layer and the incoming rays are transmitted to the eye baby. The rays that are refracted by the eye lens focus on the retina layer through the vitreous at the back of the eye sphere. Turns the light into

electrical signals on a 127 million light-sensitive retina layer. Electrical signals reach the eyes of the vision with the aid of the optic nerve that is formed by the convergence of the nerve endings. The image that reaches to the vision center of the brain as an electrical stimulus is detected and assessed in the vision center. In order to be able to realize as clearly as possible, it should fall on the yellow spot. The fovea, located on the yellow stain, allows only 2% of the field of view to be seen and allows humans to communicate with the outside world in this small proportion[4]. All the eye and head movements that people make in order to communicate with the outside world are the movements they make to cross the foveal center with the area to focus on. All the movements and the general structure of the eye that people perceive for visual perception are called Human Visual System.

B. Development of Eye Tracking Systems

The first studies on the examination of eye movements took place in the early 1900's[5]. In 1901, the first serious work on this field was examined by Cline and Dodge and the motion of the eye in the horizontal direction with the corneal reflection falling on the photographic film[6].

Fig. 2. In 1901, First Study With Eye Tracking

In 1905, Judd, McAllister and Steel made a study of a cismin placed in the eye and the horizontal and vertical movements of the eye were recorded [7]. During the 1930's, eye movements were examined at the time of reading and the effects of reading speed and eye movements of formal factors such as type, character size and page order were investigated [8]. Towards the mid-1900's, research was conducted on the eye movements of the pilots and it was attempted to have knowledge of how Kokpitte used flight equipment and equipment during aircraft landing and launch[9].

Fig. 3. First Usability Studies For Cockpit Staff

Developed by Hartridge and Thompson in 1948, fixes the problems caused by eye tracker and head movements[10].

Fig. 4. Hartridge and Thomson's Eye Tracker in 1948

When it came to 1970's, it was understood that the eye tracking technique could be used in psychology and studies were carried out to investigate the relationship of eye movements with perceptual and conceptual events. As analyzes in this context took too long, developments in psychology have progressed more slowly than in other areas of work. The alignment of eye and head movements must be known so that tracking and recording of eye movements can be performed automatically. In this context, Honeywell and EG & G companies, which are close to the point of research and development activities with American Air and Naval Forces, have developed systems that eliminate user restrictions and do not have physical contact with the user. This makes data collection and analysis tasks easier.

Fig. 5. Honeywell and EG&G's Eye Tracking Model

With the widespread adoption of home computers in the 1980s, the work towards interactive use of eye tracking technology has also gained momentum. The most concrete example of the use of eye movements as an input element in a computer is a computerized writing system based on eye movements developed by Stephen Hawking in 1997 with Intel's support (In Fig.6). With this system, Hawking can transform the words that it wants to express by using eye movements on the screen and through ACAT software developed by Intel[11]. Eye tracking systems nowadays provide convenience for many usability studies. Researchers in availability studies are looking for ways to make more use of this technology, especially as applications such as the internet, social media, video conferencing become more commonplace.

Fig. 6. Stephen Hawking's Eye Tracker

As a result of the literature review, eye tracking systems are classified as follows.

- Electronic Based
 - Electrooculogram (EOG)
- Mechanical Base
 - Scleral Coil
 - Mirror Reflector
- Optical/Video Based
 - Single point
 - Limbus
 - Pupil
 - Two point
 - Corneal
 - Pupil

The most used method is to place skin electrodes around the eyes and measure the potential differences in eye. This technique has wide range but poor accuracy. It was better for relative than absolute eye movements. Mainly used in neurological diagnosis.

Fig. 7. Electrooculogram (EOG)

The Mechanical Based eye tracking system was on contact lenses with mirror planes. It was reflecting IR-Light. It can be used with coil system. It has a magnetic field. This technique was very accurate. But it was uncomfortable for users who are not used to wear lenses. This can be usable only for laboratory studies.

Fig. 8.Coil Technique

Video based Pupil/Corneal Reflection is the most used eye tracking method. When looking at the camera, the reflection on the cornea layer appears near the center of the pupil. When the eye moves upward in relation to the reflection in the central corneal layer, the pupil reflection vector also forms upward.

C. Eye Tracking Device Working Principle

Pupil Center Corneal Reflection (PCCR) is an eye-tracking method that has become popular in recent years for usability and human-computer interaction studies and enables us to measure eye gaze. [12][13].In this method, infrared rays are sent from an LED in the infrared camera to the target. Most of the rays return from the retina layer, so strong reflections come into play. As a result of the rays transmitted from the LED, the eye baby is displayed as a bright and clear circle. The cornea reflection of the pupil is seen as a small glare.

Fig.9. Corneal Reflection With Pupil [14]

Fig. 11. Corneal Reflection Positions[14]

The working principle of this method is that the reflection from the cornea layer to the center of the pupil is directly related to the vector giving the eye-gaze direction, so the direction of looking at the eye is determined. This vector is known as the pupil reflection vector (In Fig.8).

Fig.10. Pupil Centre Corneal Reflection[15]

When looking at the camera, the reflection on the cornea layer appears near the center of the eye baby. When the eye is moved upwards, the eye moves upward in relation to the reflection in the central corneal layer, and the pupil reflection vector also forms upward. Depending on the movements in the right, left, and downward directions, the pupil reflectance vector changes. When looking directly at the camera, the image of the pupil is formed at the middle point of the reflection on the cornea layer, and the pupil reflection vector is reset. The PCCR method is developed on this logic, giving precise and highly reliable results[12].

III. SCOPE OF APPLICATION

- A. Collective Integration with Interactive Applications of Disadvantaged Individuals
 - Communication via computer in patients with ALS (amyotrophic lateral sclerosis)
 - Communication with autism patients through head-to-head and eye tracking computer,
 - For computer-mediated communication in cerebral palsy patients (Spastic cerebral palsy, Athetoid cerebral palsy etc.),
 - Communication via computer in traumatic brain injuries,
 - Rett syndrome is an eye for communicating with patients through the computer,
 - For stroke patients to participate in social life through an eye computer,
 - For communicating by partial paralysis and spinal cord paralysis via computer,
 - Heavy rheumatism is used to communicate with patients through the computer.
- B. Detection of Psychological and Neurological Problems
 - For communicating via computer in children with neurological developmental distress,
- C. Developing Individuals Recognition and Marketing Policies in Commercial Activities
- D. Ergonomics Design
- E. Increasing Game Development and Interaction
- F. Simulator Applications

IV. CONCLUSION

There are many methods for tracking a person's eye movements. Systems based on tight-fitting contact lenses can provide accurate tracking but are awkward and potentially dangerous to the subject. Corneal and limbus eye trackers can measure very small eye movements, but their absolute accuracy is poor. We can choose different methods according to application area. Looking at the eye tracking systems, it is seen that the systems that are worn by the user (monitoring with special lenses attached to the eye, monitoring with the aid of EOG). Although these are not suitable for Human Computer Interaction, optical monitoring systems are used for personal use and presented to the user. It has been observed that the eye was monitored by the help of the infrared rays sent to the user or with the help of the camera. These systems are more suitable for HCI. It is seen that the eye-tracking systems developed for users are usually based on usability tests. Eye tracking systems appear to be used in the literature, especially for gaming applications, web site usability studies, marketing policies in commercial activities, Training and Simulators and for ALS, or stroke patients. This study also formed the basis of our study in distance education class control and participation rate determination using eye tracking technology.

Abstract—Studies on sports in recent years have shown that processes, concepts, rules, and events in various sports can be considered and modelled as novel efficient search and optimization methods with extremely effective exploration capabilities in many cases, which are able to outperform existing classical and computational intelligence based optimization methods within different types of search spaces. These novel and interesting sports based algorithms have shown to be more effective and robust than alternative approaches in a large number of applications. In this work, performance comparisons of sports based optimization algorithms, namely League Championship Algorithm (LCA) and Soccer League Competition Algorithm (SLCA) have been demonstrated within benchmark function for the first time. These algorithms are relatively interesting and novel and many efficient versions of them may be proposed for many different complex search and optimization problems.

Keywords—League Championship Algorithm, Soccer League Competition, Optimization, Benchmark Functions

I.

INTRODUCTION

Optimization is the process of searching for the optimal solution. Analytical, enumeration, and heuristic methods can be used for optimization task. Heuristic refers to experience-based techniques for problem-solving and learning. Heuristics are problem-dependent and designed only for the solution of a specific problem. A metaheuristic is a higher level heuristic that may provide a sufficiently good solution to any optimization problem [1]. General purposed metaheuristic methods can be categorized according to ten different inspiration fields such as biology, physics, swarm, sociology, music, chemistry, sports, plant, water, and mathematics. Furthermore, there are hybrid methods which are combination of these [2]. Categorization is depicted in Figure 1.

Fig. 1 Computational intelligence search and optimization methods

Processes, concepts, rules, and events in various sports, especially in football, have also been considered and modelled as novel efficient search and optimization methods with extremely effective exploration capabilities in many cases. League championship algorithm and soccer league competition algorithm are sports based computational intelligence algorithms.

In this work, performance comparisons of sports based optimization algorithms, namely League Championship Algorithm (LCA) [3] and Soccer League Competition Algorithm (SLCA) [4] have been demonstrated within benchmark function for the first time.

II. SPORT INSPIRED METAHEURISTICS

Processes, concepts, rules, and events in sports, modeled as computational intelligence algorithms, are able to produce completely new and effective search and optimization procedures, with extremely effective exploration capabilities in many cases, which are able to outperform existing classical and metaheuristic based optimization approaches. This section describes all of the existing computational intelligence algorithms based on sports.

A. League Championship Algorithm (LCA)

LCA is one of the interesting sports inspired population based algorithm for global optimization which tries to imitate a championship situation where artificial football clubs participate in an artificial league for a number of weeks [3, 5].

Each team (individual) in the league (population) represents a feasible candidate solution for the interested problem. These teams compete in an artificial league for several weeks (iterations). Based on the league schedule at each week, teams play in pairs and the outcome is determined in terms of win or loss based on each team playing strength (corresponding to the fitness value) resultant from a particular team formation (solution). In the recovery period, keeping track of the previous week events, each team devises the required changes in its formation to set up a new formation (a new solution is generated) for the next week contest and the championship goes on for a number of seasons (stopping

criterion). Table I shows same meaning terms of both evolution and sports terminologies.

LCA is the firstly proposed sports based computational intelligence algorithm and works with a population of candidate solutions. Hence, in the initialization step a league (population) of L (the league size) teams (solutions) is generated and their playing strengths (fitness values) are computed. Each team is composed of n players corresponding to the number of decision variables of the related problem. In this step, the teams' best formations take the initialization values. Then, competition step is started. Based on the league schedule, the artificial teams compete in pairs for $S \times (L - 1)$ weeks where S is the number of seasons and a week is noted as t . After each competition or game between team i and team j , based on the playing strength of each team, the outcome is given in terms of win or loss.

TABLE XV. METAPHORS

Sports Terminology	LCA
1 League	Population
2 Week	Iteration
3 Team I	i -th member in the population
4 Formation	Solution
5 Playing strength	Fitness value
6 Number of seasons	Maximum iterations

LCA performs the SWOT (Strength, Weakness, Opportunity, and Threats) analysis for the variation operators. In the recovery step, each team elaborate a new formation taking into account the team's current best formation and previous week events. In LCA, the selection is performed with a greedy approach. It replaces the current best formation with a more productive team formation with a better playing strength. In other words, if the new formation is the fittest one, hereafter consider the new formation as the team's current best formation. The algorithm stops after the termination criterion is met and the team who has the best fitness value (playing strength in LCA) wins the championship [3, 5]. Flowchart of LCA is shown in Figure 2.

B. Soccer League Competition

Soccer League Competition Algorithm (SLCA) inspired by professional soccer league is based on the competitions among teams and internal competitions among players of each team [4]. Team's power depends on the power of its players. Players within a team compete with each other to attract the head coach's attention by improving their performance which leads to a growth in the quality and power of their team. In each team, there is a key player, called Star Player (SP), which has the best performance among other players in the team. Furthermore there is a unique most powerful player in each league and is called the Super Star Player (SSP).

After every match, players in winner and loser teams of each match adopt different strategies for improving their

future performance. These strategies have been performed by four operators in SLCA.

Imitation Operator: When a team wins a match, fix players try to imitate the team's SP, and the SSP of the league. They aim to experience a promotion to the SP or, optimistically, occupy the place of SSP in the league. Solution vectors relating to the fixed players in the winner team move toward the best solution of the own team and the best solution vector of the league for this purpose.

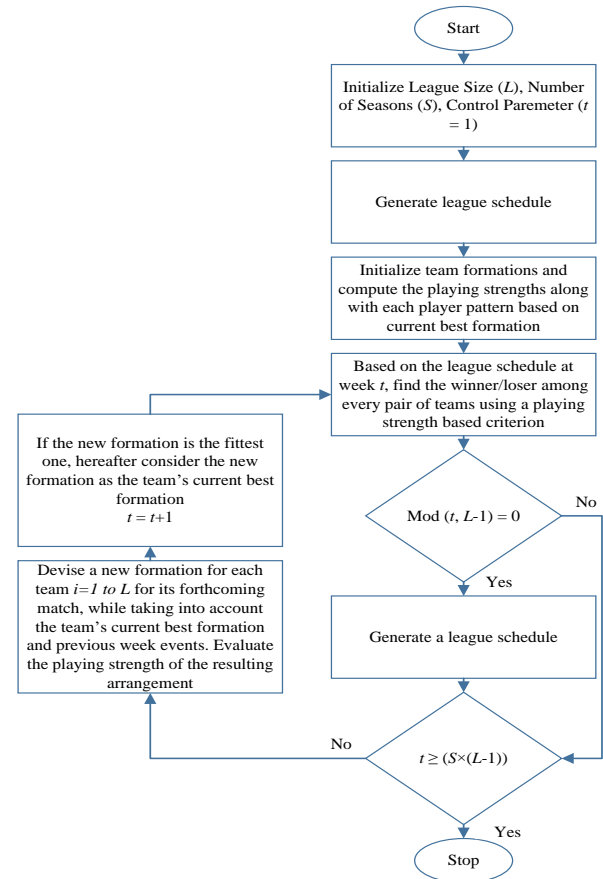

Fig. 2 Flowchart of LCA

Provocation Operator: Winner's substitutes try to have a performance approximately equal to the average level of fixed players in the team. In other words, higher provocation for advancement gives them more chance of being a fixed player in the future.

Mutation Operator: Loser teams seek for ways of improving their performance for reaching better results in future matches. For this reason, fixed players of these teams have to revise their playing style. To perform this operation, the positions of some players are randomly changed for creating diversification in solutions.

Substitution Operator: Head coach usually considers new combinations of substitutes in order to stop the failures in the future. Similarly, a random-based approach is applied to reflect the head coach impact in SLCA. To do this, a pair of new substitute vectors is being tested. If a suitable solution is obtained, this effective pair is entered to the team [4].

Flowchart of SLCA is depicted in Figure 3.

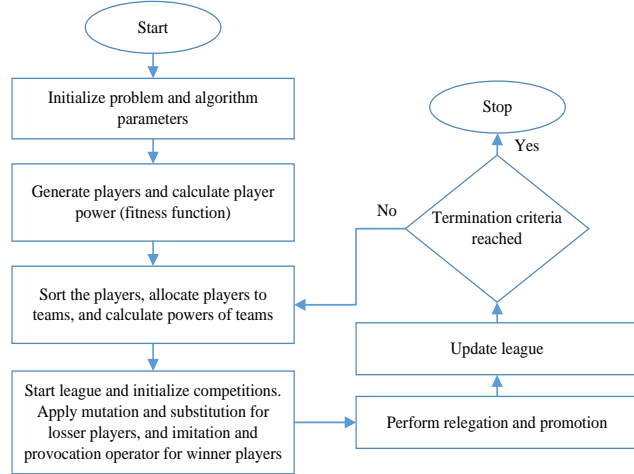

Fig. 3 Flowchart of SLCA

III. BENCHMARK FUNCTIONS

Benchmark test functions are used to evaluate and compare the characteristics of optimization algorithms in terms of convergence, precision, robustness, and general performance as a rule. The nature, complexity and other properties of these benchmark functions can be easily obtained from their definitions. The difficulty levels of most benchmark functions are adjustable by setting their parameters [6]. The selected benchmark functions and its properties have been demonstrated in Table II. The dimensions for all functions have been determined as 30. Sphere function is unimodal with less complexity and it can be used to evaluate the converging behaviors of algorithms [7]. Schwefel function is multi-modal function with many local optima and it can be used to test the global search ability of the algorithms in avoiding premature convergence [8].

Their graphs with two dimensions have been shown in Figure 4 and Figure 5.

IV. EXPERIMENTAL RESULTS

Obtained results for Sphere function from LCA and SLCA have been demonstrated in Table III and Table IV. Both algorithms have been run 10 times with different numbers of starting search points (10, 20, 30, 50, and 100). During each run, the maximum number of function evaluations is 10^5 . The maximum number of algorithm iterations is equal to the result of dividing the maximum number of function evaluations to the number of starting search points. Mutation rate and mutation probability for SLCA have been selected as 0.2 and

0.1 respectively. Numbers of main players and reserve players are equal to the dimension of the problem for SLCA. Retreat coefficient, approach coefficient, and P_c for LCA have been selected as 0.5, 0.1, and 0.7 respectively. It can be seen that when the maximum number of iteration is fixed, with low population size, performance of LCA is better than that of SLCA. Increasing the number of initial search point results in poor performance of the LCA whereas results in better performance of the SLCA.

TABLE XVI. BENCHMARK FUNCTIONS

Function Name	Definition	Interval
Sphere	$\sum_{i=1}^D x_i^2$	$-100 \leq x_i \leq 100$
Schwefel	$f_2(x) = n \times 418.9829 + \sum_{i=1}^n -x_i \sin(\sqrt{x_i})$	$-500 \leq x_i \leq 500$

Fig. 4. Sphere function with two variables

Obtained results for Schwefel function from LCA and SLCA have been reported in Table V and Table VI. Both algorithms have been run 10 times with different numbers of starting search points (10, 20, 30, 50, and 100). During each run, the maximum number of function evaluations is 10^5 . The same parameter values of the algorithms have been used for this function. From these tables, it can be concluded that performance of LCA is better than that of SLCA in multi-modal Schwefel function.

V. CONCLUSIONS

Processes, concepts, rules, and events in various sports, especially in football, have been considered and modelled as novel efficient search and optimization methods with extremely effective exploration capabilities in many cases. League championship algorithm and soccer league

competition algorithm are sports based computational intelligence algorithms. In this paper, their global optimization performances have been compared within unimodal and multimodal unconstrained benchmark functions. When the maximum number of iteration is fixed, with low population size, performance of LCA is better than that of SLCA on unimodal function. Increasing the number of initial search point results in poor performance of the LCA whereas results in better performance of the SLCA. Besides, performance of LCA is better than that of SLCA in multi-modal function.

These algorithms are very new computational methods and they can be improved in many ways. They can be combined with heuristic methods or other global optimization algorithm and their hybrid versions may be proposed for efficient results for different search and optimization problems. More validation studies should be performed to discover the capabilities of these algorithms in dealing with the search and optimization problems. On the other hand; design, development, and implementation of novel algorithms is an important task under the philosophy of improvement in the scientific field and always searching better. There are positive challenges in terms of their efficiency and best possible use of these algorithms. This paper may lead to many future contributions in exciting and emerging area of engineering problems.

Abstract— Computer systems and personal health applications. There is a primary research area that makes a difference in wireless sensor network (WSN) technologies to improve the quality of life. The current development of WBAN and IWBAN systems provides advantages and disadvantages and a snapshot for future work. The role of WBAN technology in the maintenance and quality care of WBAN technology is described in the article because of the increasing population density of the elderly, which is increasing day by day, without needing sickness or diseases that cause chronic illnesses. The article is an example of the latest technologies related to designs such as reliability, scalability, energy efficiency and security, as well as an analysis of the diversity and disadvantages of these systems.

Keywords—Wireless Sensor Networks, Wearable Sensors, Health.

I. INTRODUCTION

Wireless Sensor Network technology has the potential to change the quality of life through work done in areas such as health, entertainment, travel, industry, care-requiring patients and emergency management.

The combination of wireless sensors and sensor networks with computing and artificial intelligence research have built a cross-disciplinary concept of ambient intelligence in order to overcome the challenges we face in everyday life[1]. One of the main challenges facing the World in recent years has been the increase in the elderly population in developed countries. According to the Population Reference Bureau [2], over the next 20 years, the 65-and over population in the developed countries will become almost 20% of the total population. Hence the need to provide quality care and service in these countries for a rapidly growing population of elderly people, while reducing the healthcare costs is an important issue for governments and health service providers in such countries.

It is a vehicle that uses wearable and implantable body sensor networking systems to accomplish these goals without interfering with the day-to-day activities of people.

Body sensor network systems can help people by providing healthcare services such as medical monitoring,

memory enhancement, control of home appliances, medical data access, and communication in emergency situations [3, 4]. Monitoring people with wearable technologies and body sensor networks that can be placed on the body. Immediate delivery of emergency situations in risky patients to central systems will increase early detection of diseases. It can be used not only for elderly people and chronic patients but also for babysitting services.

Researchers in various interdisciplinary fields such as computing, engineering, and medicine fields are working together in order to ensure that the broad vision of wearable and implantable body sensor networks (WIBSNs) for smart healthcare, as illustrated in Figure 1, can be fulfilled.

Figure 1 WIBSN

The importance of integrating wireless telecommunication technologies such as 3G, Wi-Fi Mesh and WiMAX with health technologies has been addressed by some researchers. For this purpose, Alzheimer's disease, such as people with cognitive disorders are considered for continuous monitoring of people. While some applications focus on posture detection and location tracking, some use biological and environmental sensors to identify patients' "health status."

In addition, significant research is being conducted on the development of wearable technology or small wireless sensor devices implanted in the human body. The range of wearable and implantable biomedical devices will significantly

increase in recent years, thanks to improvements in micro-electro-mechanical systems (MEMS) technology, wireless communications, and digital electronics. These studies will lead to the development of sensor nodes that include sensing, data processing and communication components of low-cost, low-power, low-cost sensors. The lower power consumption, as well as the lower cost of components, will make the products more affordable and increase their usability, and will also provide energy efficiency.

The connections with leads and cables used in most current monitoring devices present obvious drawbacks in that they restrict the mobility of patients and, in addition, they may cause skin irritations or infections, and therefore contribute to deterioration of health conditions. Sensor networks thus represent a significant improvement compared to conventional sensors [6]. Despite the fact that a wireless connection is not a requirement for physiological parameter monitoring with implanted sensors, the issue mentioned above is one of the main motivations for this trend to use wireless technology in modern biomedical implanted systems [7]. Examples of physiological data collection platforms with wireless connectivity include a wide range of biomedical applications. Coosemans et al. [8], for example, have described a system for continuous wireless intracavitary pressure monitoring of the bladder, while other authors have assembled neural prosthetic devices [9-10].

Tang et al. have described their vision [11] of a future when one device will be able to build a WSN with a large number of nodes, both inside and outside the human body that may be either predefined or random, according to the application. This vision can only be applied through the use of common communication protocols for wireless sensor networks. The standardized hardware and software architectures can support compatible devices, which are expected to significantly affect the next generation of healthcare systems. Some of these devices can then be incorporated into the wireless body area network (WBAN), providing new opportunities for technology to monitor health status [12].

This article investigates wearable wireless sensor networks (WWBAN) and body-deployable body sensor network (IWBAN) systems that provide more comprehensive monitoring of patients more sterily, providing alternative contextual information and warning mechanisms for possible anomalies. In addition, this article highlights the latest trends in the future of intelligent applications for monitoring patients, the advantages of sensor networks and body-area network technology.

II. RELATED WORKS

Many implementations of body area networks used for body sensor communication have recently been reported in the literature [13-16]. Many of these studies are mainly

focused on MAC protocols. The system in Figure 2 uses an architecture that provides point-to-point communication of data from multiple sensors on the body to the main node. Transmission docks are synchronized using signaling signals transmitted within predetermined periods.

Figure 2 Data stream in an integrated WWBAN [13]

The mechanisms reported in Figure 3 include adaptation of the standard IEEE 802.15.4 / ZigBee-based MAC to the body.

Figure 3 The Structure of the Zigbee Based Mac Protocol

The work reported in [15,16] investigated on-body MAC-routing cross-layer issues via distributed transmission coordination in the presence of specific routing structures. In [15], the authors presented an energy-efficient slotted MAC in the presence of a Wireless Autonomous Spanning tree Protocol (WASP) that is used for on-body packet routing.

The protocol in [16] adopts a similar tree-based cross-layer approach, but is designed specifically for reducing packet delivery delays over an on-body spanning tree. Another advantage of this protocol is that the WASP, which is used for packet routing, also performs body movement through reconstruction and maintenance.

Knowledge-based strategies are generally designed to deliver single copy packages. In order to be able to make efficient referral decisions, it is necessary to use information about dynamics. In hybrid systems, when a packet arrives at another node, the routing rule must determine whether a copy

of the packet or packet has been transferred to that node. In this case, the energy consumption of the nodes should not be ignored.

The above mentioned implementations are applied to networks that extend to the local area wide area. The objective of the work described in [14] is to apply the key DTN routing concepts, as identified above, in an ultra-short-range body area environment. The challenge is to develop mechanisms for capturing the locality of on-body node movements caused by human postural mobility.

BASNs have carried out a variety of interesting applications in the fields of health, sports and entertainment where human centered perception is possible. The authors identified the heart rhythm, detected irregularities, and identified emergencies in technology that would notify the staff. These studies are not too far from the research labs, but they show the promises of the important field WBANs.

III. WIRELESS SENSOR NETWORKS

A. History and Overview

Most of the devices we use on a daily basis, from wristwatches to PDAs, mobile phones to cars, are controlled by embedded systems. Today, with the advantages of technological developments, more than 99% of manufactured microprocessors are used in embedded systems. The concept of ambient intelligence reflects the vision that technology will not only develop but be embedded, invisible, and fully hidden in our natural surroundings, but present whenever we need it, enabled by simple and easy interactions [21,22].

Wireless sensor networks [23,24] are usually considered one of the technological foundations of ambient intelligence. Agile, low-cost, ultra-low power networks can capture a significant amount of information from the surrounding environment. Sensor networks can be seen as the sensory system of the intelligent environment of the human body. Sensor networks can share data collected from the built-in sensors with neighboring nodes or data collection stations.

Current sensor network applications in ambient intelligence range from the environmental monitoring of ecosystems and industrial processes for tracking assets and people to the maintenance of buildings, etc. [25]. In these applications, each application domain has different requirements and constraints depending on the nature of the problem. In this article, we will focus on a specific model of practice, such as the monitoring of people based on human body implacable sensors, to come up with the use of wireless sensor networks in healthcare and to overcome new challenges. There are important reasons for this choice. Human watching is a very important issue for everyone. It introduces new challenges, such as unobtrusive, safe and low energy consumption requirements. Finally, the media in

which AR-GE activities are most active is one of the areas of intelligence application.

The design, implementation, and deployment of WSNs requires input from a wide range of disciplines such as medicine, engineering, and computing, as mentioned earlier in the paper, in addition to consideration of the numerous application-specific constraints. In the last five years, significant progress has been made in the development of WSNs, and some WSN-based commercial products have already appeared on the market. We refer readers interested in studies on software and network architectures to any of the many excellent surveys that have recently been published on these topics [26, 27].

A sensor network consists of a large number of sensor nodes, which are deployed either inside the phenomenon to be monitored or very close to it. Sensor networks represent a significant improvement over traditional sensor networks, which are deployed in the following two ways [28]:

- If the sensors are far from the scene to be monitored, large sensors must be used that use some complicated methods to distinguish targets from environmental noise.
- Only a variety of sensors can be used to perform detection. The locations of the sensors and network topology must be carefully designed. The data related to the event are sent to the central nodes where the time series, the calculations are made and the data are combined.

B. Wireless Sensor and Ad Hoc Networks

Wireless Ad Hoc Networks, creation techniques, can be used for wireless sensor network applications. Many protocols and algorithms have been proposed for traditional Wireless Ad Hoc Networks. However, the unique features and application requirements of the proposed protocol and algorithms are not appropriate for sensor networks. In this subsection, we briefly compare sensors and ad hoc networks to highlight the important role of wireless sensor networks in monitoring the human body. To explain this point, the differences between sensor networks and ad hoc networks can be summarized as follows:

- **Number of Sensor Nodes:** The number of sensor nodes in a sensor network can be much larger than nodes in a temporary network.
- **Activity:** Sensor nodes may be positioned intensively.
- **Fault:** Sensor nodes are prone to failure.
- **Network Topology:** The topology of a sensor network changes frequently. If a network sensor fails, new topologies and data transmission paths may need to be selected.
- **Communication Capability:** Sensor nodes often use broadcast communication paradigm. Most ad

hoc networks are based on point-to-point communication.

- **Computation:** Sensor nodes are limited by their power, computation capacity and memory.

C. WSN Applications

In wireless network systems; the integration of sensors embedded microcontrollers and radio interfaces into a single chip has ensured a new generation of wireless sensor networks for many applications. The features described in the previous section provide a wide range of applications for sensor networks. Wireless sensor networks can be used for military applications, habitat monitoring, machine health monitoring and guidance, traffic pattern monitoring and navigation, plant monitoring in agriculture [29], and infrastructure monitoring. One of the most exciting applications is health monitoring [30, 31]. This article focuses on health practices and body sensor networks that are predominantly wearable and can be placed in the body. A number of physiological sensors that monitor vital signs, environmental sensors, and a location sensor can be integrated into a wearable wireless body area network (WBAN) [32]. In addition, the concept of micro-sensing and wireless connectivity of network nodes promises many new application areas. The practices are classified into military, environmental, health, home and other commercial areas. It is possible to spread this classification to a wider range. However, since the focus was on the body sensor nets, the fan was narrowed. You can refer to reference [33] for other application areas.

1) Military Applications

The rapid deployment of sensor networks, self-organization and fault tolerance features make wireless sensor networks a very promising detection technique for military command, control, communications, computing, intelligence, surveillance, discovery and targeting systems. Some of the military applications of sensor networks follow friendly forces, equipment and ammunition. Nuclear, biological and chemical attack detection has recently been seen as critical attack methods.

2) Environmental Applications

Another important area of wireless sensor networks is the environmental applications that follow the movements of intelligent houses, birds, small animals and insects; To monitor environmental conditions affecting plants and animals; irrigation; Applications are being made for large scale soil monitoring, precision agriculture, flood detection, meteorological or geophysical surveys.

3) Home Applications

Home automation: as technology evolves, intelligent sensor nodes and actuators can be incorporated into devices such as vacuum cleaners, microwave ovens and refrigerators. The sensor nodes in the device have reached the point where they can communicate with each other via the Internet or

satellite and the external network. This not only makes life easier for people but also economically saves energy.

4) Health Applications

Some of the health applications of sensor networks involve providing interfaces for the disabled, integrated patient monitoring, diagnostics, drug administration in hospitals, tele monitoring of human physiological data, and tracking and monitoring doctors and/or patients inside a hospital [34-36].

Observation of Human Physiological Data: Physiological data collected by sensor networks can be stored for a long time so that they can be used later in medical research. In addition, sensors are used to monitor the behavior of older people. As an example, a health smart home was designed by the Faculty of Medicine in Grenoble-France to check the feasibility of such systems [38].

a) Monitoring of Physicians and Patients at the Hospital:

Each patient can be monitored by means of a small sensor node connected to them. A sensor node in a patient can sense heart rate while another can detect blood pressure. In Turkey, there are studies on systems to follow patients in intensive care units and to intervene in emergency situations by doctors. Doctors can also carry a sensor knot that allows other doctors to find them at the hospital, as well as a sensor node where the physician can monitor fatigue, concentration data.

b) Drug Monitoring in Hospitals:

With the sensors placed on the medicine or medicine boxes, information about which medicine will be given to the patient can be easily reached. In this way, wrong drug delivery or contamination will be prevented. Thus, patients will have sensor nodes that indicate allergies and need drug treatment. Computerized systems as described in [35] have shown that they can help minimize the side effects of drugs.

IV. WIRELESS BODY AREA NETWORKS (WBANS)

The WSNs used in the current system are expanding for medical applications and causing the technology to turn into body sensor networks (BSNs). Among biosensors, other health parameters used in the human body, electrocardiograms, electromyographies, body temperature and blood pressure, electro-dermal activity may be measured. For example, an accelerometer can be used to sense the calibration rate, movement, or muscle activity.

Thanks to mobile devices such as mobile phones and popular MP3 players; in 2001, Zimmerman [38] studied how such electronic devices operate at or near the human body. This increases the usability of the technology as it allows people to be transparent to these systems.

Medical environments in which the conditions of many patients are constantly monitored in a real-time environment are the targets of WBANs. Wireless monitoring of the physiological signals of a large number of patients is one of the existing requirements for the establishment of a complete WSN in health systems. The main goal of WBANs is to provide biofeedback data, the ability to continuously monitor health parameters such as body/intra-body temperature, heartbeat rate, arterial blood pressure, in an unobtrusive and efficient way [39].

A typical WSN system that senses and transmits signals from a human body:

Figure 4 Health sensor network available application

Figure 5 Future implementation of health sensor targeted by wireless body network

Such sensor networks may vary from point to point or point to point depending on the application. While the distributed detection of an athlete's posture [40] would need point-to-point data sharing across various on-body sensors, applications such as monitoring vital signs as shown in Figure 5, will require all body mounted and/or implanted sensors [41,42] to route data multipoint-to-point to a sink node, which in turn can relay the information wirelessly to an out-of-body server.

The wireless body-area network consists of a series of miniature sensors, lightweight, low-power sensing devices, management electronics and wireless receiver receivers. For these components, which are indispensable and the most important part of the system, the power source must be small size, lightweight, environment friendly and long lasting.

A. Requirements for Wireless Medical Sensors in WBAN

Wireless medical sensors should satisfy the following main requirements such as wearability, reliability, security, and interoperability [43]:

1) Wearability

Wireless medical sensors must be lightweight and small to be monitored in a healthy way. Size and weight of sensors are mainly determined by the size and weight of batteries [44, 45]. However, the capacity of a battery is directly proportional to its size. This is seen as a disadvantage to developers. We can expect that the further development of the integrated circuits and the miniature technology of the pillars will help the user to improve the level of comfort.

2) Reliable Communication

Secure communication in WBANs is of great importance for medical applications. For example, instead of sending raw data from sensors, we can extract the attribute on the sensor and only transmit information about an event. In addition to reducing high demands on communication channels, reduced communication requirements save on total energy expenditure and thus extend battery life. However, calculations on the sensor can increase the energy consumption of the sensor even though the system reduces the complex energy consumption. The choice between communication and computing will provide the best system design for the application area.

3) Security

The security problems of the WBAN based telemedicine system arise at all three levels. At the lowest level, wireless sensor networks must meet the confidentiality requirements provided by law for all medical devices and ensure data integrity. A relatively small number of nodes in a typical WBAN and communications areas are able to accomplish these tasks, although keystrokes, authentication, and data integrity are difficult tasks in limited sources of medical sensors.

4) Interoperability

Wireless medical sensors should ensure that users can easily set up a robust WWBAN, depending on the health of the users. Standards governing the interaction of wireless medical sensors help vendors compete and eventually lead to more accessible systems.

B. Wearable Wireless Networks (WWBAN)

WSN technology has the potential to offer a wide range of benefits for patients, medical personnel and the community through continuous monitoring in an environment, early detection of abnormal conditions, and exploration of all collected information through data mining. This subdivision shows how the architecture and mechanics of the WWBANs can be used to provide a basic infrastructure that provides continuous, everyday health monitoring that is as invisible as one of the main points of this article. This sub-section also

describes some important application problems. Finally, we present some applications of wearable sensors, such as smart t-shirt (intelligent life) and bio potential acquisition system application.

WWBANs are an important part of a multi-stage or multi-layer system, as shown in Fig. The architecture incorporates the first stage of the wireless sensor integrated into the WWBANs, including the wireless node count, while the sensor node detects, processes and processes one or more physiological signals.

In the first stage, sensors are installed for different purposes. These sensors can be used to differentiate the user's situation and estimate the activity level.

Figure 6 WWBAN Architecture

In the second stage, there is a personal server application running on a mobile phone or a home personal computer that will be used to transfer data from the data collected by the sensor to the remote user. The personal server is responsible for a variety of goals that provide an interface for wireless medical sensors, users and the medical server. The WWBAN interface includes network configuration and management features. With this interface, it is possible to activate the different features provided by the system.

1) Wearable Intelligent T-Shirt Application

A number of wearable physiological monitoring systems have been developed to monitor the health status of the individual wearer or the elderly [17, 46-47]. A wearable physiological monitoring system called „Smart Vest“ to monitor various physiological parameters such as electrocardiograms, photo plethysmographs, heart rate, blood pressure, body temperature and galvanic skin response has been developed [48]. Figure 7 shows the general architecture of wearable systems for health and activity monitoring anywhere in a t-shirt with integrated wireless sensor nodes, a base station and a server personal computer for remote monitoring.

Figure 7 A wearable smart shirt system architecture

2) Wearable Biopotential Picking System Application

Experts explain that more than 98,000 people die in hospital each year because of medical errors in the US alone. Diagnostic and treatment errors associated with the conditions and disadvantages of systems that enable people to make mistakes are mentioned. In addition to this problem, the costs of existing health systems are also increasing significantly. Patients are connected to volume and network independent devices for monitoring bio potential signals. These devices cause the inconvenience to increase in cost due to the necessity of lowering mobility as well as being performed in a hospital environment.

Figure 8 shows a typical configuration using a readout circuit to extract signals from the human body using bio potential electrodes.

Figure 8 Biopotential reading cycle

3) Implantable Wireless Networks (IWBAN)

Conditions need to be determined without the need for patient intervention and the physiological status of the patient. Implantable biosensors are an important class of biosensors based on their ability to continuously measure metabolite levels, without the need for patient intervention and regardless of the patient's physiological state (sleep, rest, etc.) [49].

Thanks to the advanced technology of Microsystems technology over the past decade, the range of implantable biomedical devices has increased dramatically over the next decade. IWBANs are more attractive than WWBAN for many advantages. WWBANs have some disadvantages: they limit the mobility of patients; In addition, they can cause skin infections, thus contributing to poor health conditions. This problem is considered as one of the main motivations for the trend in modern biomedical implanted systems to use wireless technology [18].

There are a large number of researches which deal with implantable body sensor networks such as [65, 69, and 20]. One of the prominent applications of implantable sensor networks in healthcare is that IWBAN can help blind people [19] to improve their vision. Patients with non-visual impairment can see at a reasonable level using retinal prosthesis implants implanted in the human eye, as shown in Fig 9.

Figure 9 Implanted artificial retina

V. RESULTS

With this rapid progress in technology, wireless sensor networks and body sensor networks will begin to be used in our lives in the coming years. Wireless sensor nodes are predicted to revolutionize health care in one or more vital signs, medical care records that are transmitted almost instantaneously over the Internet. Technology that will play an important role in facilitating the lives of people with disabilities in the pre-diagnosis and treatment processes of many diseases is also a clear feature that cost management will also be effective. Despite the concentration of research efforts on various technical and economic issues, there are still many technical barriers to decide whether WBAN is

suitable, flexible, reliable, and safe and energy efficient for medical applications.

In developed applications, energy consumption, desired parameters, density in network traffic and a differentiation due to calculations are going to be reduced to maximum levels in technological and application methods in the following processes.

Each technology has its advantages and disadvantages depending on its usage area. Each of the WSN, WBANS, IWBAN and WWBAN technologies mentioned in our paper has different uses. While WWBAN provides an advantage of being used for parameters that must be measured by contact with the human body, it also has the disadvantage of causing allergic or skin irritations. In the course of application development, it may sometimes be necessary to take advantage of the advantages and disadvantages of the technology used. In such trade-off situations, staying in the choice of application for stable and efficient operation leads to different quests.

Abstract— Nowadays, with the increase of vehicle densities, violations in parked or partially parked areas become an important problem. Recently, sensors, communication or image processing based solutions have been developed especially for such problems with the increase of smart city applications. In this study, a real time and high performance image processing based approach is proposed for the problem mentioned. In the developed algorithm, first of all, the area where the parking violation is to be detected is used for background subtraction, and then the vehicles are detected by a size based feature extraction. In particular, the performance of the approach developed in terms of high accuracy and real-time interoperability criteria has been confirmed by experimental evidence. Considering the results obtained, it is seen that the proposed method works with high performance in different scenarios and different working conditions.

Keywords—Park violation; Image processing; Real time; Feature extraction.

I. INTRODUCTION

Nowadays, especially smart city and campus applications are entering into our lives, solutions of certain problems are provided with digital methods in city, campus and routes. Smart city applications provides solutions to problems in the cities which they are applied, like energy, security, health, traffic.

In the study, an algorithm was developed to provide control of some rules that were introduced to cities in order to make efficient use of parking spaces that are problematic in traffic. Parking spaces and parking problems are described as a major traffic weakness, especially on crowded routes. There are many studies in the literature that mention the importance of parking problem [1-3].

In one of these studies, the researcher examined the accumulation of the park in the city of Rajshahi metropolitan city of Bangladesh, where the park problem was quite experienced. As a result of the obtained data, the main recommendation for the solution of the parking problem in the city is that the vehicle owners are charged according to the parking times of the vehicles [1]. As can be seen here, efficient

use of the park time on routes with parking problems is an important issue for solving parking problems.

In another study, the impact of parking violations in St. Petersburg on St Petersburg's overall traffic problem was emphasized [2]. Yet another study emphasized that the intense demand for short-term parking in the major cities of India is a major problem and that appropriate parking policies should be developed to solve this problem [3]. All these examples in the literature emphasize the importance of parking problem in urban traffic patterns. Since the implementation of smart city applications in cities, some smart city applications have begun to be implemented in Turkey to solve the problem of parking. The Park Violation Detection System which is conducted it's R&D works by IMM and using in some areas in Istanbul can be shown as an example this [4]. The solution proposed in this study is a real-time video-based algorithm that determines parking time for routes and parking lots where the parking time is restricted or the parking time is charged, and whether the parking lot is in violation. There have been many studies in the literature on video-based parking infringement, availability of parking space and parking density [5-14]. Some studies in the literature have concentrated on the detection of video-based parking intensity on the route, but there is no question of finding a time violation in these studies [5-7]. In other some literature studies, the focus is on the proposal of a solution that determines the available parking spaces. There is no control over any park time violations in these studies too [8-11]. In another study, location based violations of vehicles were detected. In the mentioned study, it is not possible to determine time-based violations of vehicles while parked [12].

Figure 1. Block diagram of the a parking lot violation detection algorithm in literature

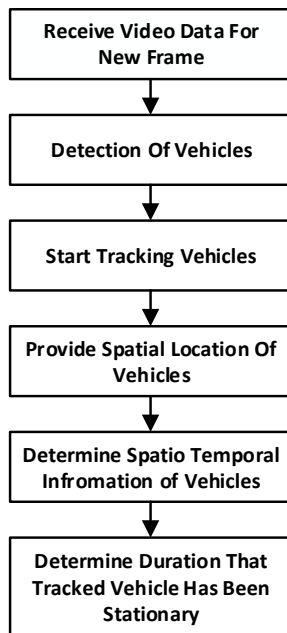

Figure 2. Block diagram of a parking time violation detection algorithm in literature

Figure 3. The general diagram of similar studies in literature.

In one of the studies done in the literature, time violation for video based short duration parks was detected [13]. The block diagram of the work is shown in Figure 2. When the studies in the literature are examined, the algorithmic steps applied to solve the problems interested are as in Figure 3.

The main difference that distinguishes this study from other studies in the literature is that the feature extraction step applied for vehicle identification is based on the size. Feature extraction, made for object detection in image processing

based solution proposals, are very diverse. For example, learning-based feature extractions have a high cost in terms of algorithmic complexity, although they are highly productive in terms of the results. The reason of the using size based approach in the feature extraction in this study is having a low cost of algorithmic complexity although its efficiency is enough for the object detection.

II. THE PROPOSED METHOD

In this study, an algorithm was developed to perform video-based detection of vehicles parking time and possible time violations. The developed algorithm has been tested on video taken on parkable routes and it has been observed to produce efficient results.

The algorithm first accepts the frame of area which no vehicles aren't on it as an background then make the coming image frames a subtraction which it depends the background frame. Subsequently, a feature extraction based on size is performed on the binary image obtained as a result of background subtraction, and the vehicles on the image are detected. After the extraction of the feature and the detection of the vehicles, it is determined whether the vehicles are parked and the parking time is determined with the help of the image frame value processed per second. If the obtained parking time exceeds the threshold of violation, the algorithm shows this situation on the image with the outputs it produces. The block diagram of the developed algorithm is shown in Figure 4.

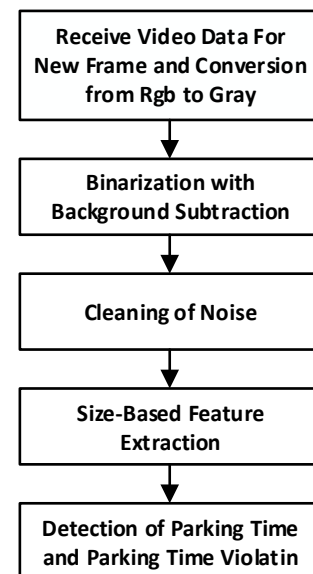

Figure 4. Block diagram of the algorithm which developed in this study.

Receiving Video Data For New Frame and Conversion from RGB to Gray

The first step of the algorithm is to take the video frame to process and convert the RGB color space to the gray color space. The main reason for this transformation is that image processing algorithms vary considerably with respect to the color space of the ease of implementation of the operations. However, in RGB images, each pixel occupies 24 bits in the memory source. But on a gray scale, each pixel of a view occupies only 8 bits. This causes the operations on the gray scale images to have a lower complexity cost than the operations on the RGB scale images. For the conversion from RGB color space to gray color space, the representation of the mathematical operation applied on each pixel is as follows.

Binarization with Background Subtraction

In the second step, the algorithm assumes that a previously introduced reference frame is a background and performs background subtraction. This reference image, presented as a background image, is on the gray scale and is a took image of a moment when no vehicles is found on the area . As a result of background subtraction, a binary image is obtained as output. It is very important that the remaining operations are performed on binary images. As it is known, computers and computer science perform their operations with binary-based methods. The binary system in computer science, uses the opposition of true-false for the logical operations , uses the opposition of the 1-0 for the math operations and it uses the opposition of black-white for the image operations. The mathematical representation of the background subtraction is as follows.

Cleaning of Noise

The algorithm has been tested on many different videos, especially for the vehicle detection step. However, on the video of the final test of all the features of the algorithm, some noises have been detected due to environmental factors after background subtraction. The feature extraction of the algorithm is size-based as mentioned before. The presence of noises exceeding the threshold field size, which provides feature extraction during testing of the algorithm, adversely affects the accuracy of the algorithm negatively. For this reason, a Canny edge detection filter and an median filter are applied on the binary image before the feature extraction step. In this way, more efficient display of the neighborhoods of the white pixels on the binary image is achieved and the neighborhood of the white pixels of noise quality is prevented.

Size-Based Feature Extraction

The biggest difference of algorithm from other algorithms performing the same task in the literature is that feature extraction is based on size. For the feature extraction, detection of the objects expressing the contour on the binary image subjected to the noise reduction process is performed first. After the detection of the objects which is expressing contour, algorithm calculates areas of these object in square pixel. Then a field threshold value check is performed intuitively. The last step of the feature extraction is to compare

the threshold field value with a threshold value of the aspect ratio value of the past objects. Objects that provide this criterion are considered vehicles. The block diagram of the feature extraction step is as shown in Figure 5.

Detection of Parking Time and Parking Time Violation

The last step of the algorithm is to determine the parking times of the vehicles detected as a result of the feature extraction and to check whether there is a violation of the detected vehicle. The fps value of the source video was used to determine the parking time of the vehicles. First, if each frame of the video is treated like a coordinate plane, this plane is divided into 100 equal areas. For each of these divided areas, a logic variable is defined that expresses true and false couple whether or not the fields have vehicles on it. However, for each field, a variable is defined that acts as a kind of counter that keeps detection of vehicle in how many frames . The determination of whether or not the vehicle is on the area is carried out according to the coordinates of the center of gravity of the objects detected as vehicles. The algorithmic steps for detecting the parking time and detecting the parking time violation are shown in Figure6.

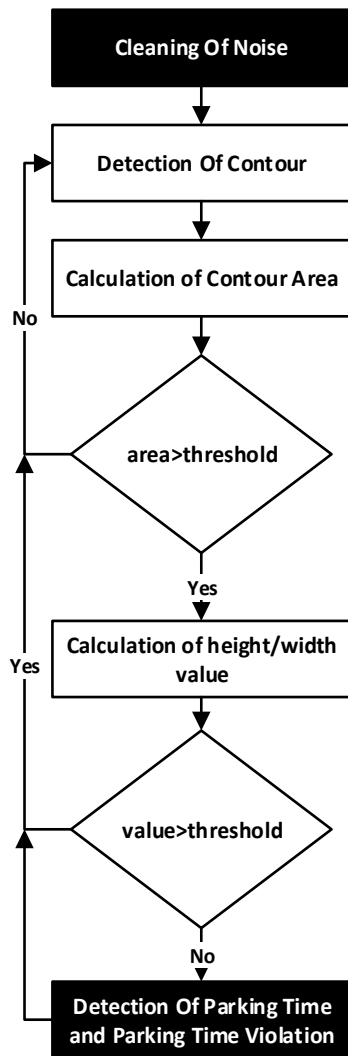

Figure 5. Block diagram of the size based feature extraction in the algorithm which studied in this paper

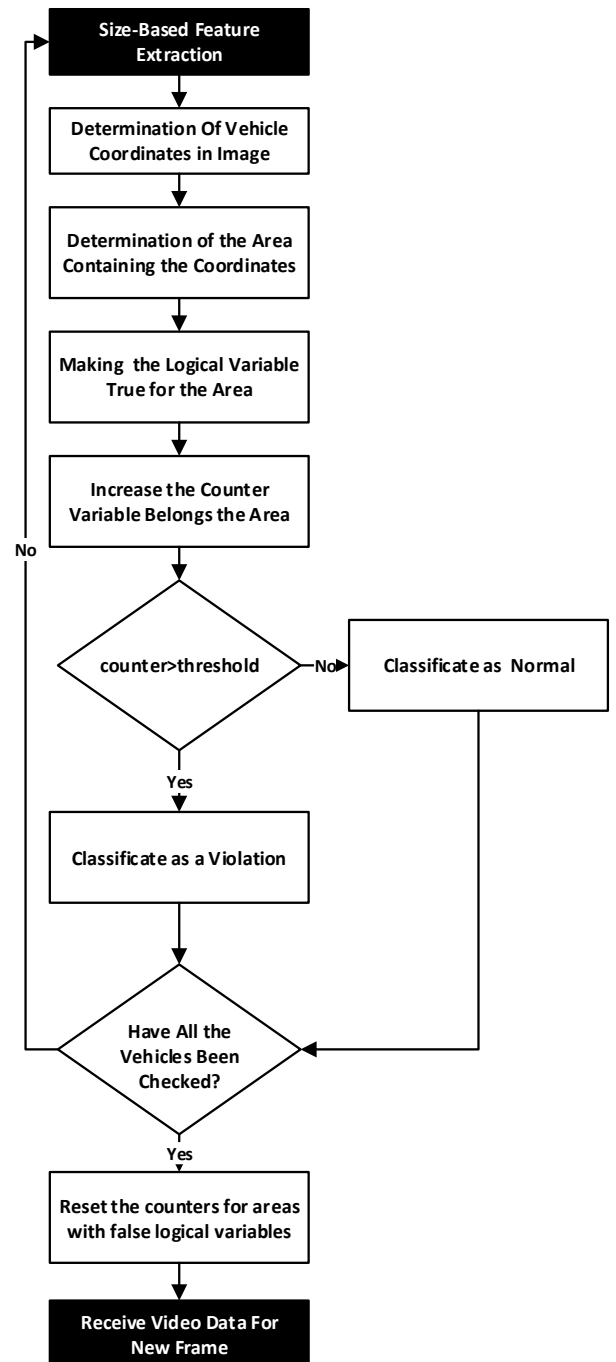

Figure 6. Block diagram of the parking violation detection step in algorithm which studied in this paper

III. EXPERIMENTAL RESULTS

The developed algorithm was tested on the images of the cameras belonging to a private property parking lot. The test of the algorithm was performed in two separate steps. The first one was completed by updating some of the threshold control

values that were given intuitively according to the result of the feature extraction tests and the results of these tests. The square pixels in different positions on the image of the vehicles detected in images for different scenarios are shown in Figure 7. As a result of the obtained data, the lowest measured field value for all scenarios and instruments was found to be 1892 pixels square. The threshold field value was set at 1500 pixels square so that vehicles with smaller footprints could be detected. However, height / width ratio was used as a second factor in extracting features of vehicles. The height / width ratio was set to 0.1 in an intuitive manner. The second test step was on the verdict of whether the identified vehicles were in breach according to the threshold of the violation given. In tests based on different violation threshold times, the algorithm obtained correct results according to the given threshold. (Vehicle: The vehicles which detected in video; Region: Regions where areas of vehicles detected on the square are measured)

TABLE XXI.

	Vehicle1	Vehicle2	Vehicle3
Region1	6703px2	4892px2	6002px2
Region2	6167px2	4652px2	5838px2
Region3	6923px2	5215px2	6336px2
Region4	6321px2	4702px2	4927px2
Region5	3121px2	2005px2	2102px2
Region6	2336px2	1892px2	2009px2

The developed algorithm gives different image output in different steps. First of these outputs shows the background frame in the gray scale. The mentioned output is shown in Figure 8. As another output, the algorithm yields the resulting binary image of the background subtraction. The output is shown in Figure 9. After the background subtraction, the canny filter and the median filter are removed for noise removal. The image is shown in Figure 10. After this step, there is an output which it includes the detected vehicles. In this output, if a detected vehicle is in a violation, vehicle is shown in the output, framed by a red rectangle. If the vehicle is not in a violation, it is shown in the output, framed by a green rectangle. The output which is before the parking time violation, is shown in Figure 11. The output which is after the parking time violation, is shown in Figure 12. All output shown belongs to the same scenario, and the algorithm for the park time violation threshold is 20 seconds.

Figure 7. Outputs of different steps in the algorithm which studied in this paper

IV. CONCLUSIONS

In this study, a solution to the inefficient use of parking times was developed, and an algorithm was developed to detect parking violations for areas where parking periods are restricted or charged and to check for any violations. Since the widespread use of smart city applications, solutions based on digital methods such as image processing have been increasing in the literature to solve the problems related to traffic. The algorithm developed in this study can be enriched by some methods to produce a free parking proposal output, which can be forwarded to vehicle drivers with some intelligent communication technologies. Of course, the main difference that distinguishes this study from other studies in the literature is the feature extraction based on the dimension for vehicle detection. There are many types of parking violations that can be detected by digital means other than time-based parking violations. Therefore, it is also possible to perform location based parking violation detection using the same feature extraction.

Abstract -- Test packages such as Crypt-X, Diehard, FIPS 140 and NIST have been developed in order to check statistical properties of random numbers generated by random number generators. However, users are required to have sufficient programming knowledge so as to apply these test packages. Besides, users are to attain required programs and compilers in order to run released test codes. These situations sometimes can be quite complicated for many users; thus, randomness tests cannot be implemented. To eliminate the complexity drawback of these tests, a user friendly program of NIST test package, which can be run on Windows operating system and does not require any compiler or package, was developed in C# language. The program is exhibited in a web environment that all users are able to access.

Keywords -- Random number, Random number generation, NIST statistical test

1. INTRODUCTION

Randomness is basically being unpredictable. In other words, it means unpredictability in cryptography and being unrelated in terms of samples in statistics [1, 2]. Random numbers are defined for a certain range; they have equal probability of generation and they are statistically independent numbers. Random numbers are commonly used in simulation, sampling, numeric analysis, decision making, entertainment, computer programming and cryptography fields. Random numbers should satisfy several properties such as they are to be unpredictable; they are not to be periodic; they should have good statistical properties and uniformity [3].

Various random number generators were developed to obtain random numbers; namely, pseudo-random number generators (PRNGs), true random number generators (TRNGs) and hybrid random number generators (HRNGs). Pseudo-random number generators start with a seed value and are subject to an algorithm to generate long random number streams. True random number generators use real physical phenomenon as a noise source and generate random numbers. Hybrid random

number generators use the random number from TRNG as a seed value in PRNG and generate random numbers by combining two systems [4].

Various test packages such as FIPS140, Knuth, Ent, NIST, Diehard and Crypt-X have been developed to check randomness of random number streams from random number generators. Generally, FIPS140 and NIST tests were preferred to check random number streams. Many users preferred FIPS140 test packages especially because it is easy to use and implement. On the other hand, a lot of users have not chosen to utilize NIST test, which is a more acceptable standard and able to check long random number streams, due to difficult implementation despite published codes of this test. The reason for this situation is that users were required to have sufficient level of programming knowledge in order to understand and run the codes. Besides, even executable programs of randomness tests need additional packages during the run. Many users are not able to utilize randomness tests due to mentioned reasons.

In this study, a program of tests which can operate in Windows environment were developed in C# programming language by examination of NIST test documents in order to eliminate complexity of tests. The minimum requirement of the program is .Net framework to operate in Windows environment, and .Net framework is already installed in Windows XP and upper Windows versions. Therefore, users do not have to install any additional package for the developed program. The program was designed to have a user friendly interface. Linear Congruential Method, a common PRNG in literature, was benefited to demonstrate usage of the developed program. Statistical tests of the random number stream from LCG were carried out by NIST tests in the program.

Random number generation methods were mentioned in Section 2. LCG was addressed to show generation of random bit sequence. In Section 3, NIST statistical test packages were mentioned. In Section 4, the developed NIST software was

explained and test results of the number stream by LCG were given. Conclusion was given in Section 5.

II. RANDOM NUMBER GENERATION METHODS

Random numbers are produced by random number generators. Random number generators are systems or devices which generate unpredictable, uncorrelated, aperiodic and statistically independent number streams. They are critical in modelling of complex phenomenon, sampling, numeric analysis and decision making. Generated numbers should not have high storage requirements, and they should not take long time to reach a desired level of true randomness. Numbers generated in this way can be sufficiently "random" for an application, while they can be insufficient for some applications [5].

Random number generators are classified in three groups as pseudo-random number generators, true random number generators and hybrid random number generators.

PRNG uses seed value from some entropy sources as a random input and it generates bit sequences which computationally cannot be differentiated from bits sequences generated by TRNG. The output value of these generators cannot reach the input seed value since these generators are deterministic. Besides, sequences may start repeating themselves after a certain time period. Thus, these systems have periodicity. Storage amount required by the system must be great in order to design an aperiodic system. However, it also slows down the system. The security of system in PRNGs depends on unpredictability of seed value and complexity of functions used in system. In addition, parameters used in functions should be carefully selected. Linear feedback shift register, middle-square method and linear congruential generator (LCG) are some commonly known algorithms used in PRNG [3, 6-8].

TRNGs define the entropy source (seed) as nondeterministic natural physical phenomenon and use it to generate random numbers. Generally, it includes conversion of analog noise into digital signal. The randomness and properties of random numbers generated by TRNGs are dependent on the randomness

of the physical phenomenon. Being slow, expensive and dependent on hardware are disadvantages of TRNGs. However, TRNGs have been used in many applications due to being unpredictable, aperiodic and providing good statistical features [4, 6-8].

The hybrid random number generator is a system where TRNG and PRNG work together in a way that random number generated by TRNG is used as seed value in PRNG.

In this study, LCG, one of the methods used in PRNG, was used to generate bit sequence. The equation of LCG can be seen in (1). LCG is defined to be a recursive relation to generate integer sequence such as X_1, X_2, \dots between 0 and $m-1$ [9].

$$X_{n+1} = (aX_n + c) \bmod m \quad (1)$$

$$R_n = X_n / m \quad n=1,2,\dots \quad (2)$$

X : random numbers generated in $(0, m-1)$

a : Multiplier

c : Increment

m : Mod

R : random numbers generated in $(0,1)$

$X_0=100$ as seed value, $a=65535$, $c=0$ and $m=2^{31}$ in LCG. LCG which is designed in FPGA environment is shown in Figure 1. To design LCG in FPGA environment, ready modules are used which is performed by Altera. These modules are respectively *Lmp_constant*, *Lmp_mult* and *div* module. These modules are respectively fulfill fixed number of impressions, multiplication and mode making process. First *Lmp_constant* modules with constant a , x_0 and m values are defined in circuit. MUX is used to allow the introduction of the system in the next iteration, the value x_n which is produced from output in the system. Multiplication with *Lmp_mult* module is realized. With *div* module mod taking, with *div2* division process have been fulfilled. Generated $S(n)$ values were subject to expression in (3) and a sequence of 1000000 bits composed of 0 and 1 was obtained.

$$S(n) = \begin{cases} 0 & R_n < 0.5 \\ 1 & R_n \geq 0.5 \end{cases} \quad (3)$$

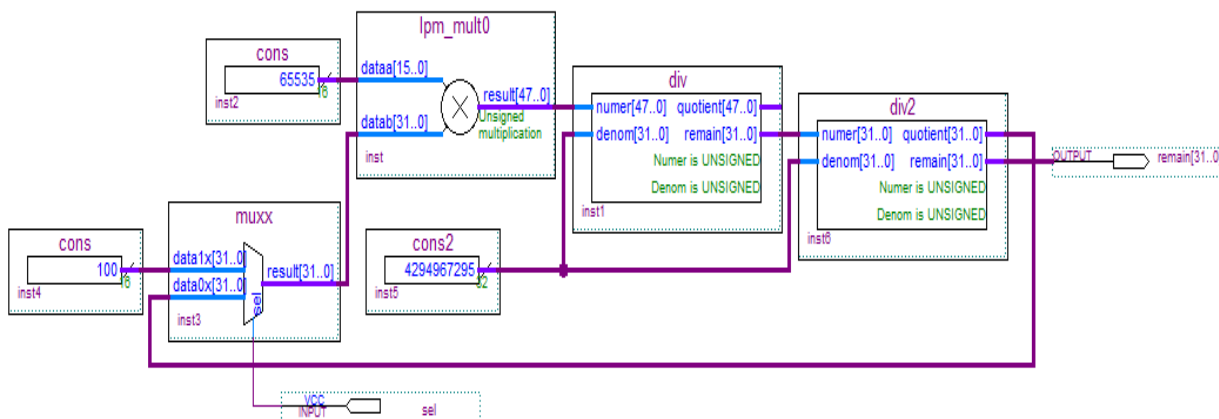

Figure 1. Implementation of LCG on FPGA

III. NIST STATISTICAL TESTS

NIST tests are based on hypothesis testing as other tests [10]. Hypothesis tests are a kind of procedure deciding whether claims about population features are logical. In other words, NIST test was developed to measure randomness of long binary bit sequences generated by random number generators.

A statistical test is formulized to check validity of a particular null hypothesis (H_0). The null hypothesis is that the tested sequence is random. Apart from the null hypothesis, the alternative hypothesis claims that the sequence is not random. As shown in Table 1, every applied test results in a decision or result that the null hypothesis is accepted or rejected.

Table 1. General results of hypothesis testing

Real Situation	Result	
	H_0 is accepted	H_a is accepted
Data is random (H_0 is correct)	No error	Type I error
Data is not random (H_a is correct)	Type II error	No error

If data is really random, the result will very soon be clear that the null hypothesis is rejected (It is accepted that data is not random). This result is known as type I error. If data is not random in fact, the acceptance of the null hypothesis is named as type II error (It is accepted that data is random). Results which accept H_0 when data is really random are correct. Similarly, results which reject H_0 when data is not random are correct.

The probability of making type I error is expressed as α . This is also significance level of the test. The null hypothesis is rejected when p value is lower than α value. The probability of making type II error is expressed as β . When sequence is in fact not random, the test will show that sequence is random with β probability. Test statistics are used to find p value which is more like a summary of proof force against the null hypothesis. Each p value for tests is the probability of a perfect random number generator which can generate sequence with lower randomness than the tested sequence, and each p value gives the kind of being nonrandom. If p value is obtained to be 1 for a test, it means that the sequence has perfect randomness. If p value is 0, then it is understood that the sequence is not completely random. A significance level (α) might be chosen for tests. If p value $\geq \alpha$, then the null hypothesis is accepted; for instance, the sequence is random. If p value $< \alpha$, the null hypothesis is rejected. The value of α is selected to be 0.01 in NIST tests.

Evaluation procedure for a single binary sequence was shown step by step in Table 2.

Table 2. Evaluation procedure for a single binary sequence step by step process [19].

Process	Comments
1. State your null hypothesis.	Assume that the binary sequence is random.
2. Compute a sequence test statistic.	Testing is carried out at the bit level.
3. Compute the P-value.	$P\text{-value} \in [0, 1]$.
4. Compare the P-value to α .	Fix α , where $\alpha \in (0.001, 0.01]$. Success is declared whenever $P\text{-value} \geq \alpha$; otherwise, failure is declared.

NIST test is a statistical test package containing 16 tests. These tests focus on nonrandom structures in a sequence. The order of usage of 16 tests is optional. However, it is suggested that frequency test is to be initially applied. If frequency test has failure, it is highly probable that other tests will also fail [10]. Explanation of NIST Statistical Test Suite is given in Table 3.

Table 3. Nist statistical test suite explanation

NIST Statistical Test Suite	
Test	Defect Detected
Frequency	It examines 1 and 0 balance in bit sequence.
Frequency Test within a Block	It is based on observation of number of 1 in m-bit block.
Runs Test	It is related with total number of runs in bit sequence.
Test for the Longest Run of Ones in a Block	It examines lengths of 0 and 1 blocks in sequence. It focuses on the longest group of 1 in m-bit blocks.
Binary Matrix Rank	A matrix is formed by using blocks in constant length so that each block defines a line. Linear dependency between blocks is examined by calculating rank of matrix.
Discrete Fourier Transform	Discrete Fourier Transformation of the current bit sequence is performed and its periodicity is examined.
Non-overlapping Template Matching	It examines whether m-bit block repeats in sequence. If it repeats, new m-bit blocks are formed from the block that is repeated.
Overlapping Template Matching	It examines whether m-bit block repeats in the sequence. If it repeats, the block is shifted by 1 bit and new block is formed.
Maurer's Universal Statistical	It examines how much the sequence can be compressed without loss of data.
Linear Complexity	It examines the complexity of the bit sequence by checking feedback register.
Serial Test	It examines number repetitions of 2m m-bit repeating blocks.
Approximate Entropy Test	It compares the frequency of two repeating blocks in consecutive lengths (m and m+1) with the expected frequency of a random sequence.
Cumulative Sums Test	This test is based on research of random walk maximal excursions which are defined to be cumulative sum of adjusted (-1, +1) digits in the sequence. The aim of the test is to determine whether cumulative sum of partial subsequences in the tested sequence is too large or too small compared to the expected value of a random sequence. This

	cumulative sum can be regarded as random walk.
Random excursions	This test focuses on number of K-visits cycles in cumulative sum of random walk
Random excursions variants	In this test, number of visits done to a special state is measured in cumulative sum random walk. The aim of the test is to observe deviations in the expected number of visits to special states in a random walk.

IV.THE DEVELOPED SOFTWARE

NIST test package was used to statistical properties of bit sequences generated by random number generators. The program was developed in C# language and has been used in several studies [11,12]. No additional package is required to run the program. It is enough for users to run the setup file in order to install the program. The Interface design of the program is shown in Figure 2. Bit sequence generated by LCG was tested by this program. Test results are given below.

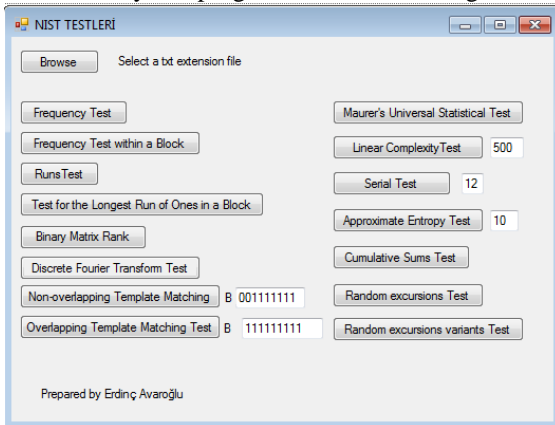

Figure 2. The Screen output of NIST program

The generated bit sequence should be inserted into a text file as shown in Figure 3. Bit sequence should be inserted in a way that each line should have 1 character (in one-column matrix format) and there should not be any space between instances. By using “file select” menu on the software, selection of the file to be tested is done. The length of bit sequence is automatically set by the program itself. After the file selection, test procedure is performed by using other menus. Test results were given in Table 4. According to given results, random number sequences must pass all the tests which are subjected to NIST test. Otherwise the test will be considered unsuccessful.

Figure 3. Content of the selected file

Table 4. Test results from LCG

Test Name	P value		Result
Frequency (Monobit) Test	0.524		Passed
Frequency Test within a Block	0.816		Passed
Runs Test	0.238		Passed
Test for the Longest Run of Ones in a Block	0.093		Passed
Binary Matrix Rank Test	0.495		Passed
Discrete Fourier Transform Test	--		Unpassed
Non-overlapping Template Matching Test	0.358		Passed
Overlapping Template Matching Test	0.250		Passed
Maurer's Universal Statistical Test	0.404		Passed
Linear Complexity Test	0.676		Passed
Serial Test	0.830		Passed

	9	0.213	

V.CONCLUSION

Random number streams obtained from LCG were subject to NIST tests and the program successfully operated. The most important feature of the developed software is that the program does not require any additional package installation, has a user friendly interface and can be used comfortably by an average computer user to test generated random bit equences. The setup file of the program can be downloaded at

http://web.firat.edu.tr/cemuh/download/MTURK/nisttes_tenglish.rar..

In the next stage, the program will be able to run at web environment so that downloading can be eliminated.

Abstract-The numbers generated must be unpredictable, reproduced and show good statistical properties in order to security of cryptographic systems. Random bit streams with these properties are generated using true random number generators. However, bit streams obtained from TRNG are correlated due to environmental factors. In order to solve these kind of problems, post processing algorithms are applied to the generated bit streams. For this purpose, post processing algorithms are examined and NIST test results of the bit streams passed from the Post processing are given.

Keywords- Random number generator, post processing, H function, statistical test

I. INTRODUCTION

Random Numbers are numbers produced by statistically random selection of a part of a clusters or elements of an array. Random numbers are needed in fields such as sampling, simulation, numerical analysis, entertainment and cryptology. Random numbers are especially required for cryptographic applications. Because the security of cryptographic systems depends on the fact that the resulting random bit streams must be unpredictable, reproduced and show good statistical properties. Various random number generators (RSUs) are designed to generate random numbers. These random number generators are classified as True Random Number Generators (TRNG) and Pseudo Random Number Generators (PRNG) [1].

The Pseudo Random Number Generators start from a seed value and algorithmically generate random numbers. The advantage of PRNG is that it generates a very large number of random numbers in a short period of time, is cheap and does not require hardware. However, Despite these advantages of SRSUs, If the seed value is known and the functions used are not complicated enough, It is disadvantageous that the numbers generated can be estimated. True random number generators generate random numbers using real physical processes that can not be controlled and can not be predicted as entropy source. While The disadvantage of the TRNGs is that they are slow, costly, and hardware-dependent, the advantage of the TRNG is that the random bit streams generated are essential for

cryptographic applications, providing unpredictable, reproduced and show good statistical properties. Because of these advantages, it has been used in many applications in cryptology [4]. The properties and randomness of the random numbers generated by TRNG depends on the quality of the entropy source. However, because entropy resources used in TRNG are affected by environmental changes, bit streams generated Show statistical weakness. In order to overcome these weaknesses, the generated bit stream was subjected to post processing. However, the post processing leads to a decrease in the bit rate, while eliminating the correlation between bit streams [1–3].

In this study, the post processing for corelation of bit streams generated from GRSUs was investigated. Von Neumann, XOR and H functions are explained. The ring oscillators were used as the entropy source, and the NIST test suite was used to test the randomness of the generated streams.

TRNG and post processing are discussed in Chapter 2. In Chapter 3, the ring oscillator used as an entropy source is mentioned. The NIST test results were given the bit stream produced after the post processing in Chapter 4. Chapter 5 gives the results.

II. TRUE RANDOM NUMBER GENERATOR

TRNG uses non-deterministic natural physical phenomena as a source of entropy. The general design of TRNG is shown in Figure 1. TRNG converts the analog noise signal into a digital noise signal by sampling. Random numbers generated from TRNG showed weak statistical properties due to environmental factors. The signals generated for the purpose of this weakness have been passed through the post processing [1].

Figure 1. The general design of TRNG [5]

The basic block structure of TRNG is described below.

A. Noise (Entropy) Source

There are noise sources in various types used in TRNG. The entropy source for TRNG is the source of physical randomness. There are many noise sources used in TRNG:

- * Electrical noise: thermal noise, flicker noise and jitter noise are used.
- * Quantum mechanical properties of photons
- * Human-induced interactions: mouse and keyboard movements

B. Sampling

In this section, conversion of analog noise signal to digital noise signal is performed. Sampling is called the Harvesting Mechanism. Usually D-type flip flops are used as samplers.

C. Post Processing

In order to increase the randomness of random numbers generated as a result of the sampling, post processing algorithms are applied. Entropy distributions of random bit stream applied to post processing have a regular distribution. Von Neumann, XOR and H function final operations, which are the most frequently used post processing, are described below.

XOR: XOR Verification is a simple linear function. It is applied on n bits ($n = 2$) blocks to produce an output bit. While eliminating the correlation on the output bit, it also caused the output bit efficiency to decrease by $1/n$ times. The advantage of this verification is the possibility of providing simplicity and constant output bit rate [4].

Von Neumann: It is the oldest and simplest post processing method. He's been out of his bit streams irregularities. As shown in Table 1, Von neumann produces uniformly distributed 0 and 1 bits. This validation is to bring entropy closer to ideal value 1. The bit rate is reduced by $1/4$ of the input bit rate [5].

Table 1. Von Neumann [4]

Input Bit Pairs	Von neumann output
00	discard
01	0
10	1
11	discard

H-Function: The h function is a type of post-processing that achieves more successful results than the XOR finishing. Randomly generated numbers are processed in groups of 16 bits, with a base of 2. the first 8 bits of Each 16 bit is subjected to XOR with shifted left by 1 bit of the first 8 bits. With the result obtained from this operation,

the last 8 bits are XORed. As a result of these operations, 8 bit output is produced [6].

In the example given in Table 2, the bit stream generated for the post processing taken 16 bits with a_0, a_1, \dots, a_{15} . The first 8 bits of 16 bits are a_1 , the last 8 bits are 2 bits as a_2 . In the a_{i-1} cell, a bit shift operation of the first eight bits is performed. H function is shown in Equation 1

$$H(A1,A2)=XOR(XOR(A1,rotateleft(A1,1)),A2) \quad (1)$$

In Figure 2., the function of H function is given.

Figure 2. H Function [6]

In Table 3, as indicated in Table 2, the bits that are divided into 8 bits and shifted 1 bit to the left are taken separately and XOR operation is applied. In Table 4, the results of the bit streams with H function are given. When the results are examined, it is seen that the bit rate of the H function is reduced by $1/2$.

Table 2 process in the input bit stream

Entered random bits (16 bit)	A1	A1 rotate left 1 bit (A1-1)	A2
110100101011 1000	110100 1 0	1010010 1	101110 0 0

III. RING OSCILLATOR

One of the methods used as a source of randomness in TRNG systems is RO. The clock signals obtained from the RO shows deviations from the correct positions. This variability is called jitter. The jitter signal period generated by the RO is equal to $2 \times N \times \tau_p$. Where N is the number of inverters used and τ_p is the propagation delay of the used inverter elements. Often jitter is an undesirable feature in a system. However, because the jitter is random, the use of jitter in TRNG is ideal. Besides, jitter produced by ring oscillator is not good quality [7]. Post processing is used in TRNG systems for this shortcoming. Figure 3 shows a ring oscillator design implemented in FPGA environment.

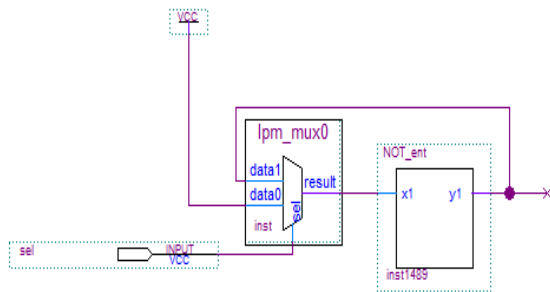

Figure 3. Ring Oscillator

A bit stream was achieved using the Sunar HO design, which was performed [7] and the overall design shown in Figure 4.

FIGURE 4. SUNAR RO

IV. STATISTICAL TEST RESULT AFTER POST PROCESSING

Bit arrays produced using Sunar HO in Chapter 3 may show weakness due to environmental factors such as

temperature, pressure. In order to overcome these weaknesses, Von Neumann, XOR and H function are applied. These post processings are performed using the program used in Figure 5. Whether the resulting bit streams are random is determined by applying the NIST 800-22 test suite.

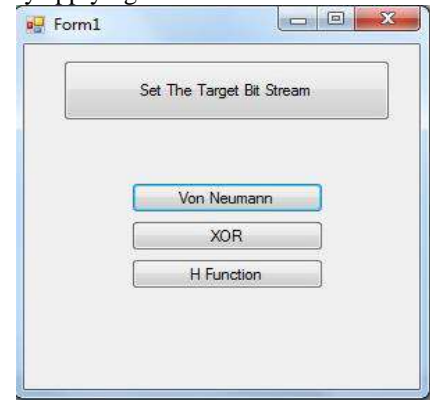

Figure 5. Post Processing Software

NIST test results are given in Table 5.

Table 5. NIST Test Result

V. CONCLUSION

In this work, we present the results of applying the post processing to a stream obtained from the real random number generator and the results of this application. For this purpose, Von Neumann, XOR and H function post processings, which we have implemented in our software, have been applied to bit streams produced using HO. Even though the pure bit streams pass the tests, quality bit streams required for cryptographic security will be obtained after the post processing. It is also seen to be an important step in the post processing of TRNG. In future studies, it is aimed to present software to other users in web environment by making software in other finishing algorithms.

Effect of Magnesium Additive Element on the Hydrogen Storage Characteristics of La-Ni Based Alloys

Alanur BİNAL AYBAR, Mustafa ANIK

Eskisehir Osmangazi University,
Department of Metallurgical and Materials Engineering
Eskisehir, Turkey
abinal@ogu.edu.tr, manik@ogu.edu.tr

Abstract—In this study A_2B_7 type La-Ni based alloys were synthesized directly from sintered mixture in the molten $CaCl_2$ electrolyte by the electro-deoxidation method at 750°C . The effect of Mg additive element for La on hydrogen storage characteristics of electro-deoxidized $(La_{1-x}Mg_x)_2(Ni_{0.8}Co_{0.2})_7$ ($x = 0, 0.125, 0.25$) alloys have been studied. Mg substitution for La changed the sintered structure. Sintering (at 1200°C for 3 h) caused the hygroscopic La_2O_3 to disappear and the non-hygroscopic $LaNiO_3$ and $Mg_{0.4}Ni_{0.6}O$ to form depending on the substitution element content. The X-ray diffraction analyses revealed electro-deoxidized materials have multi-phase structure. The X-ray diffraction peaks indicated $LaNi_5$, La_2Ni_7 , and $La_{1.5}Mg_{0.5}Ni_7$ phases were the main phases present in the synthesized alloys. $(La_{1-x}Mg_x)_2(Ni_{0.8}Co_{0.2})_7$ ($x = 0, 0.125, 0.25$) alloys had promising discharge capacities changed between 331 mAh g^{-1} and 356 mAh g^{-1} . The results obtained in this study showed that the electro-deoxidation technique is very promising in the synthesizing of the high performance hydrogen storage alloy.

Keywords—electro-deoxidation; hydrogen storage; A_2B_7 structure type; La-Mg-Ni system

I. INTRODUCTION

Partial substitution of alloy elements by other transition metals was used to improve the electrochemical hydrogen storage properties of La-Ni alloys [1]. La-Mg-Ni based hydrogen storage alloys, attracted great attention as a negative electrode material for nickel/metal hydride batteries, [2,3]. Among different types of La-Mg-Ni based alloys, A_2B_7 -type alloys are believed to have superior overall electrochemical properties [4]. La-Mg-Ni-based hydrogen storage alloys are typically prepared by melting [5-7]. Generally, after this processes products need annealing for several time to get structural homogeneity [8,9]. Clearly the production route is long and the cost is high [10].

Many hydrogen storage alloys have been directly synthesized by electro-deoxidation technique from their oxides in molten salt [11-20]. Reported studies have showed that the energy consumption of the FFC Cambridge process is generally lower and operation is simpler than many existing technologies [21-23].

In this work electro-deoxidation method was used to prepare A_2B_7 type La-Mg-Ni-Co hydrogen storage alloys. Effect of Mg additive element on the electrochemical hydrogen storage characteristics of La-Ni based alloy was determined.

II. MATERIAL AND METHOD

Commercially available La_2O_3 , NiO, MgO and CoO powders were obtained from Alfa Aesar. Required amounts of the oxide powders were mixed homogeneously in anhydrous ethanol includes 3% (by weight) polyethylene glycol (PEG) with a planetary ball mil. The powder was then dried overnight at room temperature. Dried powder was cold pressed into pellets of 10 mm in diameter, under a pressure of $1.5 \text{ tonne cm}^{-2}$. The oxide mixture pellet of $La_2O_3+NiO+CoO+MgO$ was then sintered at 1200°C for 3 h.

100 gr $CaCl_2$ was mixed with 1 gr CaO and placed into graphite crucible. Before electro-deoxidation process $CaCl_2$ -CaO powder mixture was dried under Ar gas. Drying was carried out by slow heating to 150°C and holding at 150°C for 15 h and then slow heating to 300°C and holding at 300°C for 15 h and then finally slow heating to the target temperature of 750°C for the electro-deoxidation experiments.

In order to fully remove the water and the possible redoxactive impurities, pre-electrolysis were carried out at 2.5 V and 750°C for 4 h. During the pre-electrolysis graphite crucible was used as anode and another graphite rod was used

as cathode. The electro-deoxidation was conducted at 3.2 V for various times at 750°C. The potential control was carried out by the programmable direct current source.

After the electro-deoxidation experiments the pellet electrodes were removed from the molten melt. The solidified salt on the pellet was washed out by tap water. After slight surface grinding the pellets were kept in 1 M HCl for few minutes. Finally the deoxidized pellet samples were dried at 100°C for 24 h under vacuum.

The deoxidized pellet samples were ground into fine powder (alloy powder). Working electrodes were prepared by mixing 0.1 g alloy powder with 0.3 g nickel powder and then cold pressing into pellets of 10 mm in diameter, under a pressure of 10 tonne cm⁻². The working electrode was wrapped by Ni mesh and a Ni lead wire was attached to Ni mesh by spot-welding to prepare a hydrogen storage alloy electrode (negative electrode). Hg/HgO reference electrode was used in 6 M KOH solution. Tests were performed with GAMRY Model Reference 3000 potentiostat/galvanostat unit. The charge current density was 100 mA g⁻¹ and the charging was carried out down to the severe gassing potential. The charging was followed by a 10 min rest before the discharging. The discharge current density was 25 mA g⁻¹ and the discharge cut-off potential was -0.5 V_{Hg/HgO}.

The phase structure of the synthesized alloy powders (well mixed to get homogeneity) was examined by the X-ray diffractometer (Bruker axs D8) using Cu K α radiation. The powder morphologies were observed by ZEISS SUPRATM 50 VP Scanning Electron Microscope (SEM).

III. RESULTS AND DISCUSSIONS

A. The Molten Salt Electrolysis

The XRD patterns of the sintered samples prepared to obtain (La_{1-x}Mg_x)₂(Ni_{0.8}Co_{0.2})₇ (x = 0, 0.125, 0.25) alloys are provided in Fig. 1.

Partial substitution of La by Mg changes the sintered structure. NiO and LaNiO₃ are present in all samples. In addition to these oxides Mg_{0.4}Ni_{0.6}O are present in Mg including alloys. Instead of hygroscopic La₂O₃, the formation nonhygroscopic LaNiO₃ and Mg_{0.4}Ni_{0.6}O during sintering makes possible synthesizing of A₂B₇ type alloys by electro-deoxidation technique in molten CaCl₂ salt.

Fig.1 XRD patterns of the sintered samples prepared to obtain La₂(Ni_{0.8}Co_{0.2})₇, (La_{0.875}Mg_{0.125})₂(Ni_{0.8}Co_{0.2})₇ and (La_{0.75}Mg_{0.25})₂(Ni_{0.8}Co_{0.2})₇ alloys

The XRD patterns of the 20 h electro-deoxidized (La_{1-x}Mg_x)₂(Ni_{0.8}Co_{0.2})₇ (x = 0, 0.125, 0.25) alloys are also presented in Fig. 2. LaNi₅ phase can be seen in all compositions in this work. At (La_{1-x}Mg_x)₂(Ni_{0.8}Co_{0.2})₇ (x = 0) alloy; after 20h electrolysis LaNi₅ and La₂Ni₇ form as the electro-deoxidation product.

Fig.2 XRD patterns of the 20h electro-deoxidized samples prepared to obtain La₂(Ni_{0.8}Co_{0.2})₇, (La_{0.875}Mg_{0.125})₂(Ni_{0.8}Co_{0.2})₇ and (La_{0.75}Mg_{0.25})₂(Ni_{0.8}Co_{0.2})₇ alloys

When Mg substitutes is added in (La_{1-x}Mg_x)₂(Ni_{0.8}Co_{0.2})₇ (x = 0.125, 0.25) alloys, after 20h

electrolysis LaNi_5 and $\text{La}_{1.5}\text{Mg}_{0.5}\text{Ni}_7$ form as the electro-deoxidation product. This shows that during the electrolysis the sintered structure is completely deoxidized. The X-ray diffraction analyses revealed electro-deoxidized material has multi-phase structure. Depend on the production method this phases can be changed in literature [1,5,24].

Scanning electron micrographs of the as-sintered oxide powder and 20 h electro-deoxidized powder of $(\text{La}_{0.875}\text{Mg}_{0.125})_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ alloy are provided in Fig. 3a and 3b, respectively. Since the morphologies of other compositions are very similar to those of ones in Fig. 3a-b, they are not provided. As-sintered powder has typical fine oxide powder appearance in Fig. 3a. At the end of 20 h electrodeoxidation process, however, the large crystalline metallic powder morphology develops as in Fig. 3b. The porous structure of the developed alloy is also apparent in Fig. 3b.

Fig.3 Powder morphologies of $(\text{La}_{0.875}\text{Mg}_{0.125})_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ alloy after (a) sintering and (b) electro-deoxidation for 20 h.

B. The Hydrogen Storage Characteristics of the Synthesized Alloys

Fig. 4. shows charge/discharge curves of 20h electro-deoxidized $(\text{La}_{1-x}\text{Mg}_x)_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ ($x = 0, 0.125, 0.25$) alloy electrodes for 15 charge/discharge cycles.

Fig.4 Discharge capacities of 20h electro-deoxidized $(\text{La}_{1-x}\text{Mg}_x)_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ ($x = 0, 0.125, 0.25$) alloys depending on the charge/discharge cycle.

It can be seen that all the synthesized alloys can be activated in few cycles to reach their maximum discharge capacities and as x increases, the maximum discharge capacity gradually increases. The maximum discharge capacities of $\text{La}_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$, $(\text{La}_{0.875}\text{Mg}_{0.125})_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$, and $(\text{La}_{0.75}\text{Mg}_{0.25})_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ alloys are 331 mA h g^{-1} , 337 mA h g^{-1} and 356 mA h g^{-1} , respectively. The reported discharge capacity for $\text{La}_{1.5}\text{Mg}_{0.5}\text{Ni}_7$ alloy synthesized by the induction melting method changes between $309.5 \text{ mA h g}^{-1}$ and $358.2 \text{ mA h g}^{-1}$ [5,24].

IV. CONCLUSION

$(\text{La}_{1-x}\text{Mg}_x)_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ ($x = 0, 0.125, 0.25$) alloys were synthesized directly from sintered oxide mixture by the molten salt electro-deoxidation method at 750°C , and the effect of Mg substitution for La on the electrochemical properties of the alloys has been investigated. The following conclusions may be derived:

- Sintering converted the hygroscopic La_2O_3 as a result of the reaction with NiO totally into the non-hygroscopic LaNiO_3 and $\text{Mg}_{0.4}\text{Ni}_{0.6}\text{O}$.
- Mg substitution for La in La-Ni alloys can enhance electrochemical hydrogen storage characteristics of $\text{La}_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$.

- The discharge capacity of $(\text{La}_{0.75}\text{Mg}_{0.25})_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ alloy was higher than these of both $\text{La}_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$, $(\text{La}_{0.875}\text{Mg}_{0.125})_2(\text{Ni}_{0.8}\text{Co}_{0.2})_7$ alloys.
- Electro-deoxidation is an effective method of synthesizing La-Ni based alloys for hydrogen storage materials.

Abstract—In this study, the effects of silica fume addition to 15 wt. % fly ash (Seyitömer thermal power plant fly ash) containing brick properties were investigated. Silica fume is a by-product of producing silicon metal or ferrosilicon alloys in smelters using electric arc furnaces. Different brick mixtures which were containing clay – silica fume - 15 wt.% fly ash were prepared according to Table 1 and Figure 1. Prepared brick samples were sintered in a laboratory kiln at 950 °C firing temperature.

Table 1. Brick mixtures

Recipe Code	Fly Ash (wt. %)	Silica Fume (wt. %)	Brick Clay (wt. %)
S1	15	5	80
S2	15	10	75
S3	15	15	70
S4	15	20	65

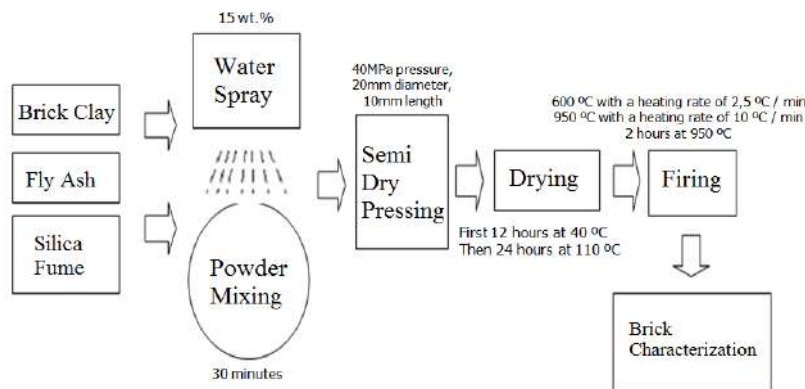

Fig 1. Flow Chart of Production Process

Physical and mechanical properties of the samples were determined. It has been seen that the addition of silica fume increases the water absorption and porosity values (Fig 2) and decreases the compressive strength values (Fig 3). The amount of SiO₂ is increasing in the bricks to which silica fume is added in an increasing amount. The decrease in the clay content reduces the amount of the flux in the brick mixtures. Because of this the sintering temperature rises and the amount of liquid phase formed decreases. The pores cannot be closed when the amount of liquid phase is low. Depending on the increasing amount of pores the water absorption values increases and strength values decreases. Increasing of the porosity of the bricks helps to improve their thermal insulating properties.

Fig 2. Variation in water absorption and apperent porosity values in relation to silica fume content.

Fig 3. Variation in compressive strength values in relation to silica fume content.

SEM analysis of resultant products was also investigated. As a result of this study, it has been shown that appropriately qualified bricks can be produced with using 15 wt.% fly ash and different amounts of silica fume. The use of waste such as fly ash and silica fume in the production of bricks will prevent environmental pollution and contribute to the economy of the country.

Abstract— Since 1991, the discovery of carbon nanotubes has opened new fields of study for many scientific disciplines, especially in materials science, chemistry and physics. Very good electrical, magnetic and mechanical properties of carbon nanotubes are involved in the use of carbon nanotubes on a wide scale. Despite the existence of multiple carbon nanotube production methods, each has its own advantages and disadvantages. Besides providing impurity in the production of carbon nanotubes, studies are being made on how to obtain carbon nano structures that can be produced fast in the desired geometries by cheap routes. Advanced equipment is needed to make carbon nanotubes in desired geometries. In many synthetic methods, there is still no controlled synthesis associated with the diameters and lengths of the tubes. Arc discharge method, laser melting method and chemical vapor deposition method are some of the methods of producing carbon nanotubes. The Chemical Vapor Deposition (CVD) method from these methods is often used due to some advantages. Some of the advantages are cheap cost, easy to obtain, homogeneity, adjustment of experiment parameters.

After the discovery of nanotube production by the CVD method, factors that affect the productivity on this method has begun to be investigated. Some factors that effect CVD process are the length of the test period, type of hydrocarbon source, the chemical properties of the material to be encapsulated, the test temperature, the type of inert used gas.

In this study, we determined the factors such as temperature, material impurity and hydrocarbon slipperly and experiment period and we carried out the 30 - minutes periodic increments and examined the results. In this study, at 700 °C, boron powder in 95-97 % purity by using acetylene gas as the hydrocarbon source carbon were encapsulated by the CVD method , during 30, 60 and 90 min. By using SEM and elemental analysis method it was searched to find whether carbon nanotubes were occurred or not and percentage of carbon structures' in whole structure was investigated.

In the experiment that was carried out 30 and 60 minutes, a few carbon nanotubes structures appeared and in the experiment that was carried out 90 minutes, carbon structures were significant clear in the SEM images (Fig 1). As a result of elemental analysis It was determined that in the carbon encapsulated process lasted for 90 min. carbon phase's percentage was % 14.70, in the carbon encapsulated process lasted for 60 min carbon phase's percentage was % 7.79 and in the carbon encapsulated process lasted for 30 min carbon phase's percentage was % 5.98.

Abstract— Glass ceramics are preferred in many applications due to their advantages such as hardness, high temperature, abrasion resistance and electrical conductivity. Glass ceramics are materials with fine crystal structure. Due to these properties they have good surface smoothness. Good surface smoothness allows glass ceramics to be used as an electronic base. Glass ceramic bases are frequently used in thin and thick film technology. The first study on the BSCCO (Bi-Sr-Ca-Cu-O) system using the glass ceramic method was carried out by Komatsu. et al. Studies related to the BSCCO glass system have been carried out by different working groups for many years. The thermal, mechanical, electrical and magnetic properties of the system were investigated by making various contributions to the BSCCO system.

In this study, the effect of Bi-Ga partial displacement on materials $\text{Bi}_{(1.8-x)}\text{Pb}_{0.2}\text{Ga}_x\text{Sr}_2\text{CaCu}_2\text{O}_y$ (Bi-2212) glass-ceramic superconductor was investigated. This study consists of sample preparation, casting, sintering and analyses-procedures. In sample preparation stage, on the condition of different rates of ($x=0.025, 0.1, 0.3, 0.8$), 4 samples were prepared and prepared powder samples were mixed in automatic mixer. Then, melt solution was obtained after we got sample powders in furnace within room temperature and keep it waited in a furnace at 1150°C . Then we withdrew the melted materials from furnace and we got glass material by leaving it in shock cooling at the end. Obtained glass materials were sintered in Oxygen atmosphere within 845°C for 120 hours. The magnetic susceptibility of sintered materials was measured and surface morphology was analysed by scanning electron microscope (SEM).

It can be seen the growth of crystal structure based on increase of Ga rate. Besides, amorphous structures were also occurred in $x=0.1$ sample. The more the value of x increased, the less features of superconductive materials owned (Fig. 1).

At the result of susceptibility measurement, it was determined that the increase of Ga rate leads to the decrease of critical temperature value. In this situation, we can come to the conclusion that it can be seen the deformation of crystal structure; decrease of amorphous structure, and the superconductivity properties can be affected negatively. Moreover, the increase of the value of ΔT with direct proportion through partial displacement demonstrates the increase of impurity in previously formed structure (Fig. 2).

spoyraz@nku.edu.tr

Abstract—Through a facile, simple, yet efficient, affordable and ultrafast (30 s) microwave (MW) energy heating process, hierarchical composites made up of carbon fibers (CFs) decorated with multi-walled carbon nanotube (MWCNT) forest were produced at ambient conditions in one-step. Morphological features of the as-produced composites were characterized in details by using scanning and transmission electron microscopy (SEM, TEM) and the elemental analysis (EDX) techniques. Both the composite material characterization results and the versatile and easily controllable nature of the above mentioned process strongly support its promising success for the fabrication of such hierarchical composites that could be effectively used for the next generation advanced engineering applications.

Keywords—microwave energy; carbon nanotube; carbon fiber; hierarchical polymeric composite

I. INTRODUCTION

Not only because of its excellent mechanical strength but also its thermal and electrical conductivity, light weight and high processability, CF and its products have been extensively utilized as a building material in various advanced engineering systems such as aerospace ships, communication satellites, planes, hybrid vehicles, wind turbine blades, sports equipment, prosthetic limbs and so on [1]. As an expected result of its unique fibrous structure, CF usually serves as a reinforcing component to enhance the multi-scale properties of the above mentioned bulk composite materials made up of both thermoset and thermoplastic polymers, metals and concrete, as well [2]. A great deal of research effort has been devoted to enhance the reinforcing performance of CFs, in order to; (i) reduce or even eliminate the problems that are often caused by phase separation and also shearing upon excessive and repeating stress, and (ii) to achieve strong, light-weight, durable and high performance composite materials that can be used for a wide variety of real-life engineering applications [3-5]. In recent years, CNT growth on CF surface has been proposed as a promising solution in order to address the

needs and tackle the challenges in the above mentioned matters, since a nanostructured, 3D CNT forest surrounding the CF surface can both provide sufficient number of anchoring points and can significantly increase the effective specific surface area to reach a better adhesion performance between CFs and the bulk material matrix [6-8]. Moreover, with the addition of distinct mechanical, thermal, and electrical features of the CNTs into the structure, enhanced transverse and shear resistance can also be expected from the as-produced CNT/CF hierarchical composites, as a result of the intense interfacial interactions that exist between the as-grown CNT forest and CFs.

In general, the CNT forest is grown on the CFs' surface by following either a bottom-up method such as chemical vapor deposition (CVD) or a top-down method such as lithography [9, 10]. Although these methods can provide highly precise and uniform products, they usually suffer from their complex production process and from their need of harsh process conditions, i.e. high vacuum, high temperature, high pressure and hazardous chemicals' use. Additionally, these methods' overall fabrication processes are not easily scalable and are very time consuming, as well. Thus, the as-obtained sample amounts are usually limited and this restricts the common uses of such methods for the applications at industrial level. In order to eliminate these obstacles and to realize a practical application for the CNT/CF composites preparation, in this study, a well-established MW energy-assisted fabrication technique, which can rapidly grow a homogenous MWCNT forest decoration on CFs surface, is proposed [11]. The as-prepared CNT/CF composites from this method offer promising and wide range application potential for various advanced engineering and scientific fields including fiber reinforced composites' preparation for wind energy harvesting, super-capacitance, microelectronics, telecommunication, transportation, sports equipment and medical applications.

II. METHOD

A. Materials Used

Plain weave CF fabric, acetone (JT Baker), toluene (JT Baker) and ferrocene (AlfaAesar) were all used as purchased without further purification, unless otherwise specified.

B. Pre-treatment and Preparation of CF Mesh Samples

Prior to the MW energy-assisted rapid CNT forest growth process, several 1"×1" CF fabric samples were continuously heated in a conventional kitchen MW oven (Panasonic Inverter) at full power (1250 W) for 60 s, in order to; (i) remove the protective thin sizing layer, and (ii) to reveal as much reactive sites as possible on CFs' surface for the following process steps (Figure 1). Next, 0.2 M ferrocene solution was prepared by dissolving 0.11 moles of ferrocene in 550 mL of toluene, for the homogenous deposition of the carbon and catalyst source precursor chemical on the as-treated CF samples. After that, CF fabrics were individually soaked into this solution for 10 min under continuous gentle shaking. Eventually, all the samples were drip dried on a nylon string before the ultrafast MW heating process (Figure 2).

C. MW Energy-assisted Ultrafast CNT Forest Growth Process on CFs

The as-prepared CF fabric sample was tightened vertically between a pair of glass rods on a handmade PVC stand, and then it was placed on the glass MW tray. Here, the evenly deposited thin ferrocene layer was clearly observed on the CF fabric with an orange tint. The glass tray was then placed into the MW oven chamber. The CF fabric on the PVC stand was irradiated at the maximum power level, while intensive reactions were observed inside, as indicated by the sparking flames and dense chemical vapor emission. After getting heated by MWs for 30 s, the CF fabric sample with the as-grown CNT forest decoration on its surface was taken out and then gently rinsed with acetone to remove any impurities and unreacted chemicals (Figure 3).

D. Characterization of the As-prepared Composite Material

Morphological and elemental analyses of the as-obtained composite materials were done by using a JEOL JSM-7000F scanning electron microscope (SEM) equipped with an energy dispersive X-ray (EDX) detector. An EMS 550X auto sputter coating device was also utilized for surface Au

Fig. 1. Scanning electron microscopy (SEM) images of CFs; **A.** before and **B.** after MW pre-treatment.

Fig. 2. **A.** Schematic representation of the MW energy-assisted ultrafast CNT forest growth process on CFs, **B.** SEM image of a single CF covered by CNT forest on its surface.

sputter coating of composite samples, which were readily prepared on carbon tape mounted sample holders, prior to their analysis. The in-depth morphological property analysis of the as-prepared composites was performed on a JEOL 2100F transmission electron microscope (TEM), operated at 200 kV. Here, CF strands from the as-treated fabric sample were carefully removed and dispersed in ethyl alcohol by ultrasonication for 10 min. in order to separate the as-grown CNTs from the CFs. Next, droplets (~5μL) from the supernatant surface were collected with a pipette and then transferred onto a carbon coated copper Formvar grid and left to get dried at ambient conditions before TEM testing.

III. RESULTS AND DISCUSSIONS

After the MW heating process, a dense CNT forest layer was intensively grown on the CF fabric surface and covered almost the entire fiber surface with a radially aligned and entangled assembly look, which is clearly exhibited in the SEM images shown in Figures 4A and 4B. At higher magnifications, the nano/micro interface between CNTs and CF can be clearly observed, as the dense CNT forest was grown perpendicularly from the CF surface (Figure 4C).

The CNT forest's coverage on the CF fabric surface was high, since the growth was observed to span along the full fiber axis length. Both long-winding and short-rigid CNT types were grown in this forest, indicating the heterogeneous nature of the catalytic growth process induced by MWs [11].

Fig. 3. Digital images of a CF fabric sample; **A.** before and **B.** after the MW energy-assisted ultrafast CNT forest growth process.

Fig. 4. SEM images of; **A.-B.** Hierarchically structured CNT/CF composites, **C.** CFs covered by the as-grown CNT forest on their surfaces, **D.** zoomed-in view of the marked area in Figure 4C.

Morphological property details of the as-obtained CNTs were also investigated, and their average diameter was calculated to be ~ 50 nm while their length could extend up to couple of microns (Figure 4D). The high aspect ratio of these CNTs thus provide an ultra-high surface area, which enables enhanced interfacial interactions and enable multi-scale functions for the composite, through the formation of new interfaces.

In good agreement with the relevant previous literature results [12-14], the tip-growth mechanism was also effective on the current CNT forest's growth on CF fabric samples. The characteristic matchstick-like morphology, which is composed of hollow and multi-walled stem with oxidized iron nanoparticle (NP) tip, of the as-grown CNTs in this forest (Figure 4D) clearly indicates the effective tip-growth mechanism, as well.

After proving the as-proposed MW-energy based ultrafast CNT growth technique's success on generating CNT/CF hierarchical composites via SEM characterization, the in-depth morphological and elemental features of these

structures were further characterized by both TEM microscopy and EDX analysis. Collected results from these analyses are shown in Figure 5. The TEM image in Figure 5A provides more detailed information about the as-grown CNTs by showing their hollow stems that encapsulate catalyst iron NPs. This morphological structure was obtained during the tip-growth process, whose working mechanism would be explained along the following paragraphs. As it also can be seen from the TEM image in Figure 5C, a single ~ 25 nm \times 5 nm iron catalyst NP was encapsulated within the as-grown MWCNTs' wall, which was made up of ultrathin graphene layers. The EDX analysis results of both the as-grown MWCNTs and the encapsulated catalyst iron NPs are shown in Figures 5B and 5D. These diffractograms provide more evidence for the presence of the as-grown MWCNTs and iron NPs that are made up of C and Fe elements, respectively. Also, there are two sharp peaks with Cu indicators in these diffractograms, both of which were caused by the copper grid used for the TEM imaging process as the sample holder.

It is thus revealed that the MW-energy assisted ultrafast heating technique was successful on generating CNT/CF nano-micro hierarchical composite structures with high yield and density and within a short period of time. It is strongly believed that the ultrafast CNT growth mechanism on the CF fabric sample surface majorly depends on the high reaction temperature between ferrocene particles and CFs upon MW irradiation. That is to say, as soon as absorbing the MW energy; (i) highly conducting CF fabric sample started sparking and arcing, (ii) then its surface temperature was rapidly increased above 1000 °C, and (iii) this caused a large amount of heat release within a few seconds. As a result, the fine ferrocene particles on the sample fabric surface got decomposed into its iron and cyclopentadienyl ligands through an instant chain reaction, in gas form. At this point, the iron NPs served as catalysts while the cyclopentadienyl groups were realigned and served as the carbon source for the formation of MWCNTs, respectively [11-14]. After all, the dense CNT forest was grown on the CF fabric surface through this liquid-solid-vapor transition mechanism.

IV. CONCLUSION

Hierarchical CNT/CF composites with aligned nano-micro interfacial structure were fabricated within seconds by applying MW irradiation. Homogenously grown CNT forest was obtained on the CF fabric surface with high yield, high aspect ratio, and high coverage density. The as-produced hierarchically structured CNT/CF composites offer promising potential for widespread advanced applications including medical applications, supercapacitors, transportation, microelectronics and so on. The as-proposed highly efficient and cost-effective MW energy-assisted fabrication technique also secures the industrial scale production of relevant next generation composites, as well.

Synthesis of Thermochromic VO₂ Thin Films for Use in Smart Glass Systems

Eren Doğan, Muhammed, Berkay Güven, Miray Çelikkilek Ersundu, Ali Erçin Ersundu
 Department of Metallurgical and Materials Engineering
 Yildiz Technical University
 Istanbul, Turkey
 ersundu@yildiz.edu.tr

Abstract—Most of energy consumed in the world has been lost from the exterior of the building and more than half of this energy is lost from the windows. For this reason, smart glass systems are being developed to save energy in buildings. Vanadium dioxide (VO₂) thin films demonstrate thermochromic property by changing their optical properties with temperature. Therefore, there has been a lot of research on VO₂-based thin films for their use in smart glass systems. VO₂ exhibits thermochromic behavior with a reversible semiconductor-metal phase transition when it undergoes a structural transformation from monoclinic to tetragonal at around 68°C by having higher infrared reflectance above this critical temperature. Although this critical temperature is fairly high for outdoor applications, VO₂ is still the most suitable candidate for smart window applications. In this study, sol-gel based thermochromic thin films were synthesized on soda-lime glass substrates by dip-coating method using vanadium oxy acetylacetonate (VO(acac)₃) as a starting material. Doping metallic elements to VO₂ has the ability to decrease the critical thermochromic temperature. Hence, in this study VO₂ was doped using tungsten chloride (WCl₆). W-doped VO₂ thin films having different compositions (0.5, 1, 3, 5 molar ratio %) were annealed under N₂ atmosphere at 550°C for 30 minutes. VO₂ thin films were characterized by XRD analysis using thin film attachment. The morphology of thin films were observed using SEM. The transmittance value differences at room temperature and 100 °C were determined using UV-VIS spectrometer having custom made in-situ temperature attachment.

Keywords— vanadium oxy acetylacetonate; thermochromic thin films; sol-gel; W-doping; smart glass systems

Abstract- Melting behavior and coefficient of thermal expansion (CTE) of volcanic particle (VP) filled high-density polyethylene (HDPE) composites were reported. Melt mixing followed by injection molding was used to manufacture VP/HDPE composites. Melting behavior of HDPE and its composites were investigated by differential scanning calorimetry (DSC). Melting enthalpy values of the composite samples were found to be varied with VP incorporation. Otherwise, the incorporation of VP into the HDPE did not have a significant effect on the melting temperature values of the HDPE composites. CTE analysis was performed between 25 to 100°C by a dilatometer. CTE of the composites display substantial reduction with the increasing of VP content in HDPE, while with increasing temperature CTE increases linearly. Additionally CTE reductions illustrated an increase in dimensional stability of HDPE as VP added to it.

Keywords- HDPE; thermal; volcanic particle; filler

I. INTRODUCTION

High-density polyethylene (HDPE) is among the most widely used polyolefin polymers because of its moderate strength, low cost, excellent process ability and high chemical resistance [1-2]. However, with the insufficient thermal properties, HDPE is usually compounded with various fillers such as; CaCO₃, silica, clays, mica, talc, graphite, bentonite etc., because compounding fillers with thermoplastic materials in order to introduce a desired property is a conventional practice and useful method [3-6]. Inorganic particle reinforced polymer composites have the advantages of the polymeric properties together with the characteristics of homogeneously dispersed inorganic particles [7]. This inorganic particle filled polymer composites with the enhanced mechanical, thermal and electrical properties could be consumed in various industries such as; automobile, medical, packaging and electrical etc., [8-10]. Volcanic particles (VP) created during volcanic eruptions are readily accessible and can be economically mined with very low cost and limited negative environmental impact. Turkey and Italy are the leading

producers of VP, followed by Greece, Iran, Chile, Syria, and the United States [11].

VPs are known as mesoporous material, which usually has high specific surface area, significant porosity and an appropriate pore structure. Due to these properties the use of VPs as an alternative filler material in polymers can lead to both, a global cost reduction of final product with enhanced properties and a possibility for countries to use their natural VP resources. There are some research engineers at Hyundai and Kia which have used a ground VP in a polypropylene and rubber composite to reduce costs and achieve a cloth-like appearance [12]. So, it was thought that by filling such material with thermoplastics, useful composite materials can be produced that have improved thermal properties when compared to thermoplastics containing conventional fillers. It has been found that there is no study in the literature about the effect of VP addition on the thermal properties of HDPE. For this reason for the first time in literature, in this study thermal behavior of VP/HDPE composites were investigated by differential scanning calorimetry (DSC) and coefficient of thermal expansion (CTE) measurements.

II. MATERIALS AND METHODS

A. Materials

The polymer used in this study was high-density polyethylene (HDPE) Marlex® HHM 50100. It has a density of 0.951g/cm³ and a melt flow index of 0.35g/10 min (2.16kg at 190°C). A black masterbatch M117605 with carbon content of 40% was used for HDPE. VP with density of 2.82g/cm³ and size of “<25µm” were taken from Kula/Turkey. SEM and energy dispersive spectrometer analyzes were shown in Fig. 1.

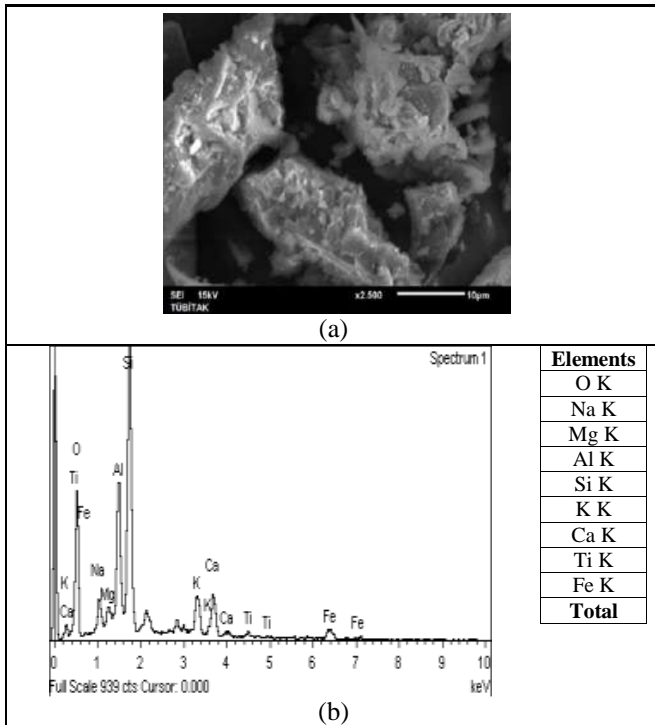

Figure 1. SEM image (a) and spectrometer analysis (b) of VPs

As seen in Fig. 1-a, VPs have high specific surface area with indented view. According to spectrometer analysis in Fig. 1-b, VPs were estimated as rhyolite due to silica (SiO_2) rich composition.

B. Sample preparation

HDPE composites were prepared by melt compounding and injection molding processes. DSM micro-compounder (conical co-rotating twin-screw extruder) (DSM Xplore, Gleen, The Netherlands) was used for compounding HDPE and VP filler material with various contents such as 0, 6, 12, 18 and 24 wt.%. At the completion of mixing, the melt compound was extruded into the heated barrel of a DSM injection molding machine (DSM Xplore, Gleen, The Netherlands), which used a plunger driven by compressed air to inject the melt into a standard dog-bone tensile specimen mold held at 40°C with an injection pressure of 8 bar. Micro-compounding and injection molding parameters were given in Table 1.

C. Differential scanning calorimetry (DSC)

Melting behavior analysis was carried out by a differential scanning calorimetry (Mettler Toledo DSC1). DSC samples were prepared by shaving approximately 10mg from the injection molded tensile specimens and then were sealed in aluminum pans. Heat scanning was performed from -50 °C to 240°C under nitrogen atmosphere (nitrogen purge with a flux of 50 ml/min) with the heating rate of 10°C/min.

Table 1. Micro compounding and injection molding process parameters

Process Machines	Process Parameters	Unit	Level
Microcompounder	Barrel temperature	(°C)	210
Microcompounder	Compounding round	(rpm)	50
Microcompounder	Compounding time	(min)	4
Injection Molding	Mold temperature	(°C)	40
Injection Molding	Injection pressure	(bar)	8
Injection Molding	Holding pressure	(bar)	8
Injection Molding	Holding time	(s)	5

According to obtained thermograms average values of five repetitions for melting temperatures (T_m) and melting enthalpies (ΔH_m) were determined and discussed. The apparent enthalpy of melting per gram of HDPE in the VP added composites was calculated by Equation (1):

$$\Delta H_{HDPE} = \Delta H_C / W_{HDPE} \quad (1)$$

Where, W_{HDPE} is the mass fraction of HDPE in composites and ΔH_C is the apparent enthalpy of melting of VP added HDPE composites.

D. Coefficient of thermal expansion (CTE) measurement

In order to predict dimensional stability of HDPE and its composites dilatometry test was performed between 25°C and 100°C at a heating rate of 5°C/min by the dilatometry machine of Netzsch DIL 402C. At least three samples for each material were tested and the results are presented as an average for tested samples.

III. RESULTS

A. Melting behavior of VP/HDPE composites

Fig. 2 illustrates DSC results of HDPE and its VP added composites. DSC thermogram of HDPE in Fig. 2-a showed that melting state was started at 50°C and then was ended at 150°C. In this melting state, 155.3 J/g melting enthalpy value was achieved to melt the entire polymer. Melting temperature and melting enthalpy variation according to VP content was illustrated in Fig. 2-b. It is clear that melting temperature values did not changed significantly with VP addition, therefore it can be said that melting temperature is dominantly depends on polymer matrix of HDPE instead of VP filler. A better comparison can be obtained by using the enthalpy of melting per gram of HDPE in the composite sample was calculated according to the Equation (1). As it is seen, melting enthalpy value was significantly increased to 170 J/g with 6 wt.% VP content, however further incorporation of VP decreased this value from 170 to 155 J/g. It is important that, the melting enthalpy values did not decreased below the value of neat HDPE up to 24 wt.% VP content.

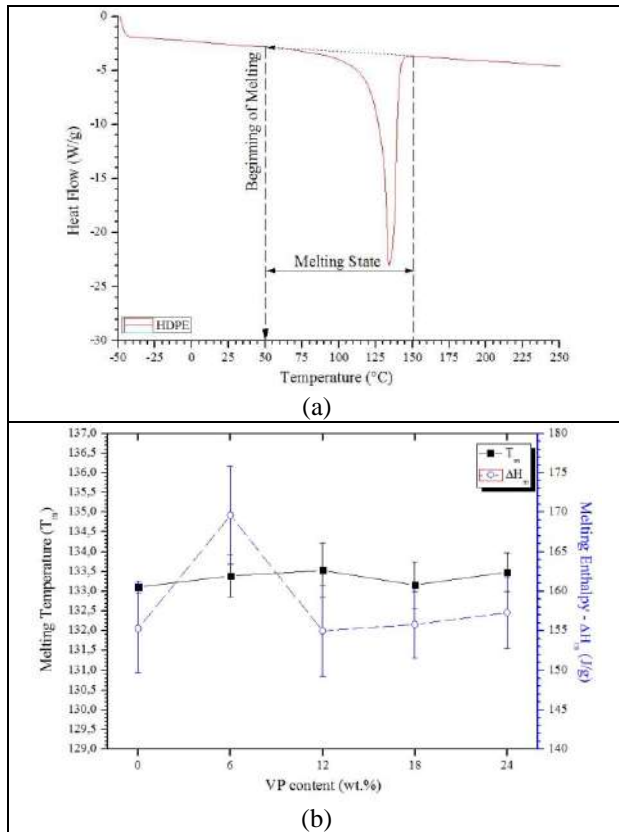

Figure 2. DSC results, a: thermogram of HDPE; b: melting properties as a function of VP content

This phenomenon is believed to be the result of a good agreement between nucleating and retarding effects of VP on the host polymer HDPE during the crystallization [13-14]. This result also showed that crystallinity was firstly increased with low content of VPs, which exhibited a strong nucleating effect and acted as heterogeneous nucleating sites at the VP-HDPE interfaces [13]. In addition to this, if the VP content increased to a high content, the filler particles in the matrix hindered the movement of macromolecular chains. Therefore the crystallinity was reduced. However, it is still could not be decreased under the degree of neat HDPE

B. CTE of the VP/HDPE composites

CTE results of VP/HDPE composites were determined as a function of temperature and VP content as shown in Fig. 3. It is clear that CTE of all composite samples was linearly increased with the temperature up to 50°C. This result can be explained by the onset of melting phenomenon similarly reported by P. Ghosh in Ref. [15]. However, CTE values began to decrease as a function of temperature after melting was started. In addition to this, for all compositions CTEs were steadily decreased with VP incorporation entirely at all temperature levels. As is expected, the HDPE composites with increasing VP contents showed consistently lower CTE

Fig. 3. CTE versus temperature for HDPE and its VP added composites

values than the composites with lower VP contents. This reduction depends on the difference between the CTE of the polymer matrix HDPE and the filler VPs. Similar to the literature reports, this reduction can be attributed to lower CTE of VPs, respect to HDPE matrix [16-17]. Additionally the reduction of CTE was also contributed to the strong interfacial adhesion between the HDPE matrix and VP filler particles [16].

IV. CONCLUSION

In order to investigate the role of VPs in the thermal behavior of HDPE composites, series of HDPE composites with different VP contents were prepared. DSC and CTE results were obtained experimentally and discussed in detail. As a result following inferences were done:

- DSC results suggest that VP particles played a heterogeneous nucleation role with relatively low content in the HDPE matrix, resulting in enhancing the crystallization capability.
- After 6 wt% VP content, crystallization capability was decreased with further VP incorporation, however it is still almost equal to the value of HDPE.
- CTE of VP/HDPE composites was increased linearly up to onset melting temperature and then was decreased as a function of temperature.
- VP incorporation has decreased the CTE values due to the difference between the CTE of HDPE and VP.
- Reduction of CTE was also showed that a strong interfacial adhesion was achieved between the HDPE matrix and VP filler particles.

Abstract— This article presents research on the influence of calcium carbonate (CaCO_3) particle contents on the scratch behavior of high density polyethylene (HDPE). Melt compounding was carried out using a twin-screw micro compounder and injection molding with various CaCO_3 particle contents such as 0, 6, 12, 18 and 24 wt.%. Scratch testing was performed using the testing apparatus and methodology outlined in ASTM D7027–05 at scratch velocities of 30 mm/min using a radius of 50 μm stainless steel ball bearing scratch tip. Coefficient of friction values and scratch hardness of various CaCO_3 particle filled HDPE composites were determined. Results showed that coefficient of friction values increased nearly 16% for 24 wt.% CaCO_3 particle filled composites compared to neat HDPE. After scratch tests, optical microscope analysis was done for determining the variation of scratch damage mechanisms because of CaCO_3 particle filling content.

Keywords— Scratch Behavior, Calcium Carbonate, Coefficient of Friction, Optical Microscope

I. INTRODUCTION

Polyethylene is a largely used thermoplastic because of its physical and mechanical properties, good workability and low cost. However, the polyethylene has low deformation and melting temperature that restrict its use [1]. There are various types of polyethylene (molecular weight (MW), molecular weight distribution (MWD), density, percentage crystallinity, and degree of long chain and short chain branching) having the same basic repeating unit with different properties and applications [2]. High density polyethylene (HDPE) which is used in this study is a thermoplastic made from petroleum and thipfy the largest portion of polyethylene manufactured. HDPE is more rigid and harder than low density polyethylene

(LDPE) [3]. Polymers have been using instead of metallic materials for friction wear parts for many years. However, unmodified polymer could not please the demands a rising from situations where an integration of good properties such as mechanical and tribological is essential [4]. One of the potential alternative processes to reduce HDPE wear rate is improving the tribological properties of HDPE by reinforcement methods. Inorganic particles such as molybdenum disulphide (MoS_2), alumina (Al_2O_3), titanium dioxide (TiO_2) and silicate (SiO_2) were commonly added in polymers to increase wear resistance, some of which have been reported in the literatures for HDPE [5-7]. Pettarin et al.[5] assessed the effect of the addition of commercial MoS_2 on the tribological behavior of high molecular weight high density polyethylene (HMW-HDPE). The results showed that the incorporation of MoS_2 to HMW-HDPE improves its sliding and abrasive wear performance with a content of MoS_2 for minimum wear rate around 10 wt.%. Taşdemir and Yerleşen [6] studied the mechanical, morphological and tribological properties of high density polyethylene based composites filled with glass spheres (hollow) and HDPE/glass sphere (filled with alumina and silicate) particles. From results, HDPE filled with a high level content of fillers showed higher wear rate than pure HDPE under dry sliding wear test. Abbas and Muslim [7] investigated the mechanical properties (hardness and wear) and physical properties (thermal conductivity and water absorption) for HDPE/ Al_2O_3 , HDPE/ TiO_2 composites and HDPE/ Al_2O_3 / TiO_2 hybrid composites with different weight percentages of fillers prepared by hot pressing method. Wear results showed that the wear rate of composites decrease with the increasing the weight percentages of fillers, hybrid composites have less wear rate compared to other composites.

The scratch test is a very old experimental procedure used to study the surface mechanical properties and the tribological performances of materials. Scratch testing is applied to polymers for about 10 years because polymers are more often used to increase the scratch and wear resistance in many applications, in particular, in petroleum and gases industries as a pipe coating [8]. Scratch performance of polymeric materials is dependent on the scratch stress field associated with the indenter geometry and properties of the polymeric material [9]. Additional factors such as percent crystallinity, lubricant, filler, and additives also influence the scratch performance of thermoplastic olefins [9]. Despite the enhancement in other mechanical properties such as tensile or flexural properties, inorganic particle fillers may improve the coefficient of friction and scratch hardness of thermoplastic polymers; hence, deeper investigations into the scratch response of CaCO₃ filled HDPE based composites seem to be necessary. However, little information is available on the detailed correlations between the effect of CaCO₃ filler incorporation and scratch hardness of HDPE. Surampadi et al. [10] studied the determining role of scratch indenter radius on surface deformation of high density polyethylene and CaCO₃ reinforced composite. They compared the scratch indenter's type (Loop, Needle, Hoffman) with the scratch hardness of CaCO₃ filled HDPE. However, there is not any information about the coefficient of friction values or the effect of CaCO₃ content. In the current study, the scratch tests were conducted on CaCO₃ filled HDPE composites with different contents (0, 6, 12, 18 and 24 wt.%) of CaCO₃ in order to determine the scratch properties such as scratch hardness and coefficient of friction. The scratch damage mechanisms and scratch widths were also observed and determined with optical microscope.

II. MATERIALS AND METHODS

A. Materials

The polymer used in this study was high-density polyethylene (HDPE) Marlex® HHM 5202BN. It has a density of 0.951 g/cm³ and a melt flow index of 0.35 g/10 min (2.16 kg at 190°C). Compound filler used MD9765, a masterbatch containing 78% micro calcium carbonate (CaCO₃) was supplied from Maskom Masterbatch &Compound Technologies Co, Turkey. It was prepared as granulate form and it has a carrier resin of polyethylene for the micro CaCO₃. It should be noted that surface of CaCO₃ is not treated. A black masterbatch M117605 with carbon content of 40% was used for HDPE.

B. Sample Preparation

Table 1. Micro compounding and injection molding process parameters

Process	Process Parameters	Unit	Level
Microcompounder	Barrel temperature	(°C)	210
Microcompounder	Compounding round	(rpm)	50
Microcompounder	Compounding time	(min)	4
Injection Molding	Mold temperature	(°C)	40
Injection Molding	Injection pressure	(bar)	8
Injection Molding	Holding pressure	(bar)	8
Injection Molding	Holding time	(s)	5

HDPE composites were prepared by melt compounding and injection molding processes. Micro-compounding and injection molding parameters were given in Table 1. DSM micro-compounder (conical co-rotating twin-screw extruder) (DSM Xplore, Gleen, The Netherlands) twin-was used for compounding HDPE and CaCO₃ filler materials with various contents such as 0, 6, 12, 18 and 24 wt. %. At the completion of mixing, the melt compound was extruded into the heated barrel of a DSM injection molding machine (DSM Xplore, Gleen, The Netherlands), which used a plunger driven by compressed air to inject the melt into a standard dog-bone tensile specimen mold held at 40 °C with an injection pressure of 8 bar.

C. Scratch Tests

“CSM Micro Scratch Tester” was used for the evaluation of the scratch behavior of various CaCO₃ particle filled HDPE composite samples. Rockwell S-218 with a spherical diamond notch was used for tests (50 µm radius). The indenter was held on a pivoted beam so that it could be positioned orthogonally to the flat sample. The sample surface was positioned so that it is parallel to the indenter motion by a specific, automatically, controlled process. The unit was controlled by a computer, which also controls the various test parameters. By using dead weights, normal load was applied to the samples which are fixed on a leveling mount attached to a displacement stage. For eliminating surface roughness and skin thickness effects, a preload of 0.03 N was applied by the indenter. By using a load of 15 N at a velocity of 30 mm/min through a length of 10 mm, a scratch damage occurred on the surface. Three independent repetitions for each sample tests were carried out and average was used for evaluation. The scratch behavior of CaCO₃/HDPE composites was evaluated by using coefficient of friction and scratch hardness.

D. Observations of Scratch Damage Mechanisms

For determining the general damage mechanisms, the scratched surface of each CaCO₃/HDPE composite sample was inspected using an optical microscope (Nikon L150). In addition, for stating the variation on scratch hardness values of HDPE due to CaCO₃ particle contents, scratch widths were also determined by using optical microscope.

III. RESULTS AND DISCUSSIONS

The typical curves of coefficient of friction values of various CaCO₃ particle filled HDPE composites versus scratch length were shown in Fig. 1. The scratch resistance of a material indicates its ability to withstand mechanically induced surface damage when the material interacts and comes in contact with another material of higher hardness. In indentation, the direction of applied force is normal to the surface, whereas in scratch deformation, sequential accumulation and release of tangential force makes the deformation behavior non-uniform [11]. Also, in a scratch deformation process, a significant amount of plastic deformation occurs and the indenter is only supported in the front or leading part, while the material behind the indenter partly supports the indenter in the rear half [11].

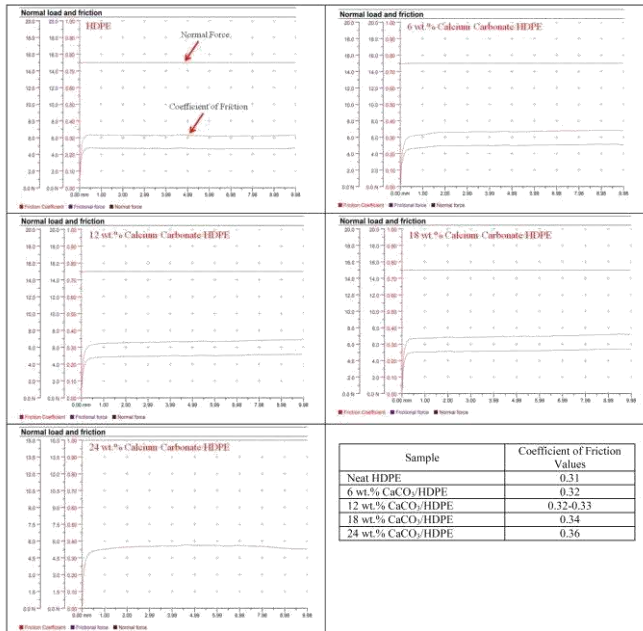

Figure 1. The variation of coefficient of friction values of CaCO₃/HDPE composites

The coefficient of friction is defined as the ratio of the tangential force to the normal force [12]. The coefficient of friction changes from 0 to nearly 0.30 continuously at the beginning of scratching, which is corresponding to the loading stage [12]. Then it keeps invariant at 0.3-0.36 due to CaCO₃ particle content for about 10 mm scratch length during the steady scratching process. An abrupt change takes on subsequently after the steady state because of the detachment of the indenter tip during the unloading stage when the scratching completed. The average values of the steady stage were taken as the effective frictional coefficient [12]. The coefficient of friction values are in steady variation to increasing with CaCO₃ particle contents. The scratch resistance of CaCO₃/HDPE composites increased due to the CaCO₃ particle contents with 24 wt.%. Maximum coefficient of friction value was determined with 24 wt.% CaCO₃ particle content as 0.36. As compared to neat HDPE, coefficient of friction value was increased nearly % 16 with 24 wt.% CaCO₃ content. The increment of the coefficient of friction values implies the potential increase of abrasive wear resistance to hard counterparts.

Scratch paths of various CaCO₃ filled HDPE composites were illustrated in Fig.2. It was easily recognized that scratch widths of each sample were nearly same along the scratch paths. Beside this, the scratch widths of the samples were decreased with the CaCO₃ content. At 24 wt.% CaCO₃ content, the scratch width was 85.75 μm. On the other hand, the scratch width value of neat HDPE was 98.8 μm. Because of rigid CaCO₃ particles, the scratch indenter did not penetrate the sample surface easily. The CaCO₃ particle made the composite sample harder than neat HDPE.

To characterize scratch resistance of CaCO₃/HDPE composite samples, scratch hardness can also be used. Scratch hardness, which is also a measure of the scratch resistance, was calculated using [13]:

$$H = x \cdot (4.F/\pi.w^2) \quad (1)$$

Where H is the scratch hardness in N/mm², F_N is the scratch load in N, and $\pi w^2/4$ is the projected load-supporting area, in mm², w is the residual scratch width. Thus, the scratch hardness was given by: where x is a parameter that assumes a value of 1 for purely elastic contact and 2 when the contact is plastic. Other types of material behavior involving visco-elastic and visco-plastic contacts will have a value for the parameter x between 1 and 2 [13]. In the present study, x was assumed to be 1. It may be noted that Equation (1) involving scratch width is sensitive to the nature of the material. There is a direct relationship between the scratch width and scratch hardness. Materials with higher scratch hardness were expected to exhibit higher scratch resistance to scratch damage. Table 2 presents the calculated scratch hardness of CaCO₃/HDPE composite samples. Average scratch width of each sample was measured from optical microscopic photographs as also given in Table 2. From Table 2, it was determined that scratch hardness values were improved due to CaCO₃ content. It was thought that because of adding hard particles to soft polymer matrix (HDPE), the surface of the material behaved as a rigid material. By this way, the scratch hardness value of 24 wt.% CaCO₃/HDPE composite sample was increased with 32.75% as compared to neat HDPE.

IV. CONCLUSION

The scratch behavior of CaCO₃/HDPE composites was investigated. The variations of coefficient of friction, scratch widths and scratch hardness were determined and listed below individually;

- The coefficient of friction values were improved from 0.31 to 0.36 with rigid CaCO₃ incorporation. Due to hard CaCO₃ particles, the surface of the composite material showed resistance to scratch indenter.

Table 2. Average widths and scratch hardness of CaCO₃/HDPE composites

Composite Sample	Average widths (μm)	Scratch hardness (N/mm ²)
Neat HDPE	98.8	1956.53
6 wt.% CaCO ₃ /HDPE	96.25	2061.58
12 wt.% CaCO ₃ /HDPE	92.50	2232.12
18 wt.% CaCO ₃ /HDPE	88.60	2432.95
24 wt.% CaCO ₃ /HDPE	85.75	2597.37

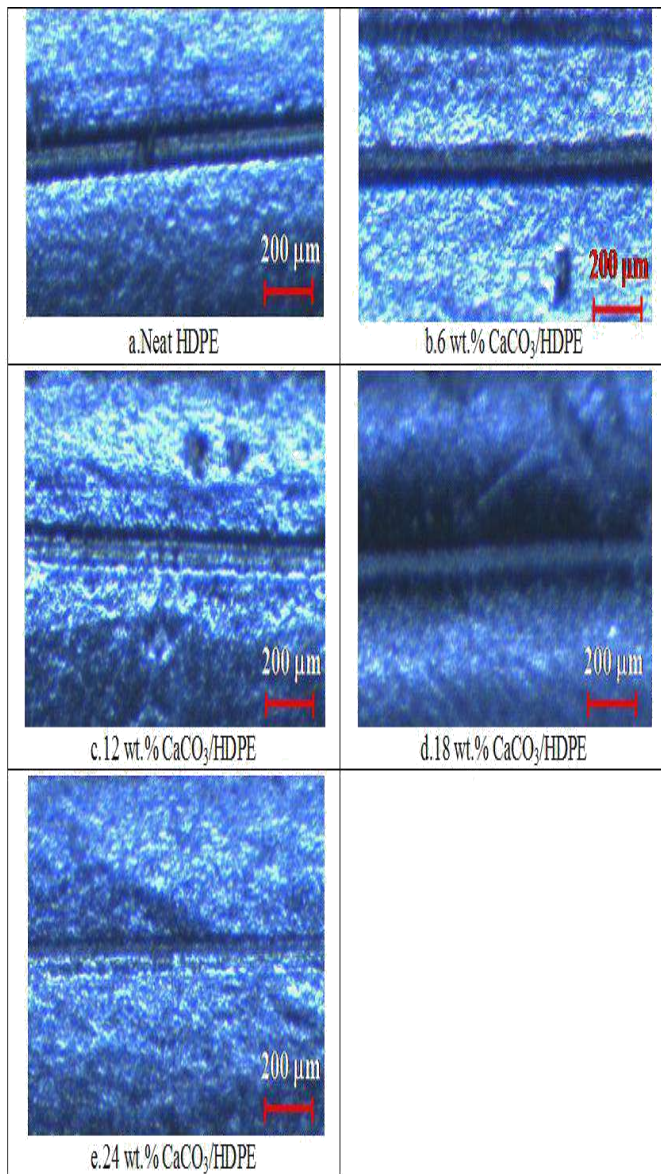

Figure 2. Scratch paths of $\text{CaCO}_3/\text{HDPE}$ composites

- Scratch widths were decreased with higher CaCO_3 contents. By this way, scratch hardness of the composite material was significantly increased. Maximum scratch hardness value was found as 2597.37 N/mm^2 for 24 wt.% $\text{CaCO}_3/\text{HDPE}$. As similar to coefficient of friction results, the main effect on the scratch hardness values of $\text{CaCO}_3/\text{HDPE}$ composite samples was the hard particles of CaCO_3 . Because of these rigid particles in the matrix, the indenter could not penetrate the material surface easily.

Abstract— *The heat treatment is mainly applied to improve the dimensional stability and durability of wood material. It is known that the heat treatment affects the anatomical structure of wood but these effects depend on the wood species and process conditions that are used. Therefore, in recent years, there has been great interest to determine the changes in the anatomical structure of wood species by using the different wood modification methods. In this study, the effects of heat treatment method on the anatomical structure of *Fraxinus* spp. (ash wood) wood were studied. The materials were obtained from a local sawmill in Duzce, Turkey and different temperatures (120 °C, 150 °C and 180 °C) and durations (2h, 6h and 10 h) were applied. Changes in the microstructure of the wood samples were detected by using a light microscope. Wood samples were kept under vacuum in the presence of alcohol, glycerin, and water at room temperature to be softened for sectioning process. The samples were cut into thin sections by using a sliding microtome. Those microscopic sections were then stained with safranin and fast-green- for to obtain good contrast between lignified cell walls (red color) and cellulose (green color). A microscopic slide of ash wood was taken from the Xylarium of Faculty of Forestry, Istanbul University (ISTUFw) served as control, which was already stained with safranin. All the microscopic evaluations were realized only visually on cross, radial and tangential sections. The results showed that the defects in microstructure of wood samples increased with increasing heat treatment temperature and time. The defects in microstructure of wood samples were mostly occurred in the early wood part of the growth rings, the largest damages were observed in the fibers and vessels depend on the increase of heat treatment temperature and time.*

Abstract— A Co-Co(OH)₂ modified electrode was formed on a copper current collector in ambient conditions. The composite film of Co-Co(OH)₂ illustrates anodic characteristic for energy storage devices. Cobalt was firstly deposited potentiostatically on copper substrate from pyrophosphate electrolyte and then this modified electrode was potentiodynamically treated OH⁻ included solution for the purpose of Co(OH)₂ formation. Co-Co(OH)₂ modified film however was obtained. This film was dominated by Co(OH)₂ at positive potential (anodic side of voltammetry) and the film is dominated by Co at negative side (-1.1 V) in OH⁻ included electrolyte. OH⁻ ions diffuses into the Co-Co(OH)₂ film during oxidation and these ions diffuses out of the film during reduction. As OH⁻ ions do not react with copper substrate, the Co-Co(OH)₂ electrode deposited on copper current collector is a promising anode material for energy storage devices. Specific capacitance of cobalt based modified electrode depends on film thickness. The redox reaction between the modified electrode and OH⁻ electrolyte has diffusion controlled mechanism meaning that film has a fast charge and discharge property. Capacity values are generally constant up to first 250 scans until the film is evolved. Capacity retention of the film is 84% (after 450 cycles). A specific capacitance of the Co-Co(OH)₂ composite electrode in 6 M KOH at a scan rate of 5 mV s⁻¹ is 549 F g⁻¹. 73% of capacitance is reached when the scan rate is increased from 5 mV s⁻¹ to 100 mV s⁻¹.

Keywords— energy storage; composite modified electrode; alkaline treatment; copper current collector; anode material.

Metals and Alloys Deposition on Aluminium Based Substrate from an Ionic Liquid

Abstract— The methods for coating a metal on an aluminium or aluminium based alloy substrate are limited. In this research a novel method is studied to obtain a metal and an alloy coated aluminium substrate. A type of ionic liquid called Ethaline (formed from choline chloride + ethylene glycol in a 1:2 molar ratio) composed of only ions is used as a deposition electrolyte. The strategy of this process was firstly to remove Al_2O_3 layer naturally formed on aluminium surface (about 20 nm) and then reduce a metal or an alloy on bare aluminium surface which does not have Al_2O_3 layer anymore. When bare aluminium or aluminium alloy is in contact with atmosphere or an aqueous solution, Al_2O_3 thin layer immediately formed on aluminium surface. To avoid aluminium from atmosphere, removing Al_2O_3 layer from bare aluminium and deposition a new metal on bare aluminium should be carried out within the same electrolyte (an in-situ technique) and this electrolyte has to be water free. To electrodeposit a metal or an alloy on aluminium alloy substrate, an anodic voltage (greater than +1.5) is applied potentiostatically for removing Al_2O_3 layer in Ethaline. After this process, the extreme cathodic potential (less than -1.5 V) is applied for the formation of a required metal or alloy on newly prepared aluminium alloy whose Al_2O_3 this layer has been removed. In this study; Cu, Ni, Mn, Zn and some of their alloy combinations were deposited on aluminium surface. These metals and their alloys were selected as models. This technique could be however applied for other metals and alloys.

Abstract— Zinc based alloys (Co-Zn, Mn-Zn, Ni-Zn, Cu-Zn and Bi-Zn) were electrodeposited from pyrophosphate medium on Pt electrode in order to examine their corrosion behaviors. Apart from Ni-Zn, the passivation behavior of all these alloys was investigated. Among all zinc based alloys studied in this research, one of passivable zinc based alloys (Cu-Zn) was deposited and their growth and corrosion behavior was explored in detail. Carbon steel working electrode was used to elucidate precise electron transfer mechanism during deposition and stripping of pure Cu, pure Zn and brass. Brass films were prepared by potentiodynamical and potentiostatical techniques. Growth potential affects the morphology and structure of crystals. Brass coatings are more porous than its pure components. Monocrystalline structure of (111) Cu-Zn alloys were obtained by changing deposition potential. Zinc contents in brass increased upon a decrease in applied voltage. However, growth potential and ratio of zinc in brass do not affect the passivation behavior of resulting alloys. The coatings obtained by applying different growth potential were immersed into tap water for 24 hours to compare its corrosion behaviors with carbon steel having pitting formation.

Abstract — *In the defense industry, metal coatings are not only applied for decorative but also protective purposes. The smooth surface with high service life is expected, too. Electroless nickel-PTFE plating with perfect corrosion resistance, adequate abrasion resistance and hardness also shows interesting tribological properties such as low friction and non-stick properties, at the mean time low roughness. Thus, this coating application is appropriate for the surface design of gun barrel of infantry troops' rifle compared to conventional manganese phosphate bath coating which does not offer a coating layer as homogeneous as electroless nickel-PTFE plating's. In this project, the application of this composite coating was made possible by successive implementation of electroless nickel plating and PTFE coating one after another. The two different grades of steel – AISI 4140 and 5140 Steels, respectively- were selected in order to compare the alteration of their mechanical properties after process application. The specimens were carefully cut by an abrasive cutter, one of the each specimen groups was reserved for metallographic examination before the procedure, the other specimens' surfaces were treated; afterward each specimen was mounted, subsequently ground and polished. The abrasion resistance of the specimens were tested for 24 h. The microstructure was observed by optical microscope before and after treatment. The microhardness and the surface roughness of each specimen were measured before and after each process. The coating thickness of each layer -electroless nickel and PTFE- on the samples were monitored by scanning electron microscope, the elemental analysis for each layer on the surface of the steels was conducted by EDS. The differences on the mechanical properties depending on the type of the steel used in procedure were studied.*

Abstract — *Boronizing is a thermochemical surface treatment in which boron atoms are diffused into the surface of a workpiece to form borides with the base material. This method is used in surface finishing and that can be efficient in terms of the surface quality of material. The surfaces that boronizing is applied on have increased hardness, increased abrasion resistance, high temperature insulation, low friction coefficient, the property of holding lower surface, corrosion resistance against acids, increased fatigue life and expansion coefficient proper for iron. When applied to the appropriate materials, boronizing provides wear and abrasion resistance comparable to sintered carbides. Cast irons used in glass production are the cheapest and the most easily formed materials in the mold materials that provide the expected properties. Cast iron molds' surfaces are damaged in the case of continuous contact of glass drop and these molds cannot be used after the harm of this damage. Heat differences that are composed by high temperatures and rapid cooling create thermal stress on the material of molds. Additionally the oxidation that occurs in high temperatures break the property of mold surfaces so this affects surface quality negatively and decrease the lifetime of the molds. There is a significant difference between the hardness value obtained from the layer of composed boron and the hardness value obtained from other surface finishing methods (nitriding, carburizing etc.). Hardness of the surface obtained from boronizing is 1800-2100 HV in steels, 3000 HV in titanium whereas it is between 600-1100 HV when other methods used. Current project includes the design of boronizing process that is applied to metal molds used in glass shaping in a well timed and cost effective way. One grade of cast iron -GG35- and one grade of steel - AISI 1035- respectively- were selected in order to compare the alteration of their mechanical properties after pack boronizing. The specimens were carefully cut by an abrasive cutter, one of the each specimen groups was reserved for metallographic examination before the procedure, the other specimens' surfaces were treated; afterward each specimen was mounted, subsequently ground and polished. The microstructure was observed by optical microscope before and after boronizing. The microhardness and the surface roughness of each specimen was measured before and after treatment. The abrasion resistance of the specimens were tested for 24 h. The coating thickness and diffusion of boron into deeper of the samples were monitored by scanning electron microscope, the elemental analysis for boron on the surface of the steels was conducted by EDS. The differences on the mechanical properties depending on the type of the steel used in procedure were studied.*

Abstract—The harsh conditions such as highly corrosive environment and elevated temperatures decrease the performance of the materials. To gain high performance at those conditions, improving the surface properties of the metallic materials instead of changing their bulk properties is a more economical and time saving process. Boriding is one of the thermochemical processes to enhance the surface properties of the steels and it guarantees high performance in extreme conditions. Boriding process provides high surface hardness, wear resistance and corrosion resistance for steels. Although the effects of alloying elements on the boronizing of steel are recognized, the individual influences of alloying additions on the boronizing mechanism of steel are not totally clear yet although some enlightening studies were reported recently. It was reported that the morphology, growth, phase composition, microhardness and thickness of the boride layer were affected by the alloying elements in the steels. To overcome the complex effect that arose due to the other alloying elements in steels, some systematical studies were carried out to reveal the specific effect of some alloying elements by boriding the binary alloys of Fe-M (M = Cr, Ti, Ni, V, Mn, Si, Mo, Cu, W, Co). Although, there are some studies on individual effect of Cr and Ni, the effect of addition of Cr along with Ni elements on boride layer properties is lacking in the literature. So, rod shaped Fe-8Ni, Fe-8Ni-1Cr and Fe-8Ni-16Cr alloys were prepared under controlled atmosphere by induction melting. The samples were pack boronized in Ekabor-II powder at 1000°C for 3 hours. The borided samples were characterized using OM, SEM, SEM-EDS, XRD and microhardness tester. The boride layer having saw-tooth morphology flattened with the increase of Cr content in the substrate. The formation of the FeB and Fe₂B phases was verified. The thickness of the boride layer decreased with amount of Cr and the thicknesses were found as 160 µm, 91 µm and 36 µm for Fe-8Ni, Fe-8Ni-1Cr and Fe-8Ni-16Cr, respectively. The transition region increased with increasing Cr contents in the Fe-8Ni-Cr ternary alloys. The presence of Cr and Ni in the main boride layer was verified by SEM-EDS analysis.

Abstract— Zirconium and its alloys are good alternative for biomedical and dental applications due to their high corrosion resistance and biocompatibility. However, dental and medical application of Zr based materials are limited because of their poor bioactivity. The bioactivity properties of zirconium based materials are improved by surface modification methods such as plasma electrolytic oxidation method (PEO) which is also called microarc oxidation (MAO). The technique is an effective, eco-friendly, economic and easy. The PEO method is a multi-controlled process and current, voltage, duty cycle, time, chemical composition of the substrate and the composition of the electrolyte are effective on the structure and composition of the coating. In this study, the effect of process current densities on the microstructure, phase content of the coating synthesized on pure Zr by PEO was examined. The PEO process was carried out using a homemade PEO unit with pulsed DC power supply in the Ca-P containing electrolytic solution for different the current density of 0.5-4 A/cm². The coating layers were characterized by using X-ray Diffractometry (XRD), Scanning Electron Microscopy (SEM) and Energy Dispersive Spectroscopy (EDS). The thickness of the coatings was increased by the process current and the thickness values were approximately 8 µm and 60 µm for 0.5 A/cm² and 4 A/cm², respectively. The XRD data revealed that, all the samples were formed at different process current densities contained m-ZrO₂ (monoclinic zirconia) and Ca_{0.134}Zr_{0.86}O_{1.86} (calcium zirconium oxide) phases. The new phase namely HA (Hydroxyapatite) was formed at 4 A/cm². The surface roughness values of the coatings were increased with current values and the surface roughness was 0.8 µm and 9.0 µm for 0.5 A/cm² and 4 A/cm², respectively. The amount of the Ca and P elements increased, while the amount of the Zr and O elements on the surface of the coatings decreased with increasing current density according to the SEM-EDS results.

Abstract— High temperature oxidation resistance is crucial for the alloys used in the jet engines and power plants. Especially, Ni-based superalloys are one of the candidates, which can meet the demands such as creep and corrosion resistance. In this study, NiAlCr and NiAlCr-Mg alloys were produced by induction melting under controlled atmosphere. The alloys were annealed for 96 h at 1050°C. The cyclic oxidation tests were conducted at 1027°C under airflow of 90 l/h. The oxidation products were analyzed by microbalance, X-Ray Diffractometer, Scanning Electron Microscope and Energy Dispersive Spectrometer. After conducting the first cycle oxide product formed on Mg free M0-A alloy was mostly composed of Al_2O_3 . Even after first cycle this alloy, extensive spallation of the oxide scales was observed. As the regions close to the alloy surface grow poor in Al with the lapse of time, a continuous layer of Al_2O_3 did not form. Instead, thermodynamically more stable $NiCr_2O_4$ phase formed as small crystals on the outermost surface of the oxide scale due to the oxidation of Ni and Cr elements simultaneously. With the addition of 2.5 at. % Mg to the alloy (M2-A) almost no spallation was observed. Addition of Mg inhibited the oxidation of Cr and Ni elements thus formation of distinct or complex oxide layers of these elements were hindered. The formation of continuous $MgAl_2O_4$ and MgO layers was observed first time on Ni-based alloys during high temperature exposure.

Abstract—Extrusion method is one of the most important of aluminium shaping methods. With the help of new techniques developed, extrusion parameters and consequently the quality of product has been improved. Necessary attention should be given for fabrication of extrusion dies since they give the final shape on semi-finished products. In this study, the thermal spray coating application using an oxy-acetylene thermal spray torch which delivers very precise anti-wear protective coatings. Alloy powders containing nickel, boron, silicon, cobalt and chrome were sprayed onto the part to be coated and were fused simultaneously using a welding torch. Bonding with the base metal by diffusion ensured that it did not reach its melting point. The dense coating was not affected by dilution and retained all its designed properties. AISI 1040 steel was selected in order to improve its surface properties and to show the alteration.

The specimens were carefully cut by an abrasive cutter, one of the each specimen groups was reserved for metallographic examination before the procedure, the other specimens' surfaces were treated; afterward each specimen was mounted, subsequently ground and polished. The abrasion resistance of the specimens were tested for 24h. The microstructure was observed by optical microscope before and after treatment. The microhardness and the surface roughness of each specimen were measured before and after each process. The coating thickness on the samples were monitored by scanning electron microscope, the elemental analysis for each layer on the surface of the steels was conducted by EDS. The differences on the mechanical properties depending on the coating composition used in the procedure were studied.

ABSTRACT

Carbothermal reduction and nitridation (CRN) is preferred because of taking place the reaction at a single stage and enabling the production of non-oxide ceramics. In this study, fabrication of silicon nitride and boron carbide composite material containing fine boron carbide particles distributed via the chemical reaction in the result silicon nitride matrix were achieved during the CRN combined with mechanical milling process. XRD analysis gave phase formation, alpha Si₃N₄ has dominant and characteristic peaks together B₄C peaks. The EDS mapping results showed that combination the mechanical milling and the carbothermic synthesising supported more homogeneous distribution of reinforcement particle (B₄C) in the Si₃N₄ matrix compared with conventional mixing methods.

Keywords: Silicon nitride, Boron carbide, Non-oxide ceramics, Silicon dioxide

I. INTRODUCTION

In the last two decades considerable effort has been made to develop and to modify mechanical properties of silicon nitride (Si₃N₄) ceramics. Si₃N₄ ceramics have relatively high fracture toughness, resistance to corrosion, resistance to wear, resistance to elevated temperatures. One of the most important properties of Si₃N₄ is the improved fracture toughness which is strongly related with the presence of highly enhanced aspect ratio of β-Si₃N₄ in the microstructure of silicon nitride ceramics [1-4]. Monolithic ceramics with highly anisotropic rod-like β-Si₃N₄ particles have potential as a low cost

alternative to fiber-reinforced ceramic matrix composites because they possess exceptional fracture resistance, yet they do not contain costly fibers [5].

Several Si₃N₄-based ceramic matrix composites (CMCs) have been tested for this purpose. Ceramic reinforcements (SiC, TiC, TiN, BN), in particulate or whisker forms, have been added in order to yield self-lubricating tribolayers by selective oxidation of these compounds, or simply to increase the fracture toughness of the ceramic body [7-8]. Hexagonal boron nitride (BN) ceramic is a well-known in-situ lubricating material because of the formation mechanism of oxide or hydrated layers on its surface. [9-11]. Thus, BN ceramics have a beneficial effect on the tribological performance of Si₃N₄-BN composites and BN has a significant contribution on the reducing the wear coefficient one order of magnitude to $K \approx 10^{-6} \text{ mm}^3 \text{ N}^{-1} \text{ m}^{-1}$, as to the Si₃N₄ matrix. [8]. BN starts to oxidise at 300°C, hindering the lubricating role of this dispersoid. At 400 °C, the wear coefficient rises to a catastrophic value of $K > 10^{-4} \text{ mm}^3 \text{ N}^{-1} \text{ m}^{-1}$ [12]. This oxidation effect was suppressed with adding carbon black having high chemical activity and working under Ar controlled atmosphere. Therefore, BN particles were preserved from exothermic oxidation reaction releasing energy.

This work focused on investigation of a new process for the homogeneously distributed Si₃N₄-BN composite powder. The produced ceramic composite powder aims to be used in fabrication of machinable ceramic materials. The key factor for

all process was $\text{SiO}_2 \rightarrow \text{Si}_3\text{N}_4$ conversion and its parameters such as stoichiometric ratio. It was a puzzler how to influence the contribution of boron nitride to the conversion.

II. EXPERIMENTAL

SiO_2 as silicon source, carbon black as reducing agent and BN powders as additive were used as starting materials. Silicon nitride and hexagonal boron nitride ceramic composite powders were produced at a relatively low temperature by using the carbothermal reduction and nitridation process. The nitridation rate was determined by X-ray diffraction (XRD). As well as the weight changes before and after nitridation were discussed in detailed. Scanning electron microscopy was used to reveal morphologies and distribution of the converted Si_3N_4 grains and as-received BN grains. There batches were used to determine optimum parameters and variables of the process, 0/100, 15/85, 30/70 (in wt. %) BN/ Si_3N_4 compositions, respectively. All batches were subjected to mechanical activation process. The powder mix was heated and hold at $>1400^\circ\text{C}$ for 4h.

III. RESULTS AND DISCUSSION

The efficiency of CRN process was evaluated in terms of weight loss in Table 1. The weight change results showed that is directly related to the amount of BN. This is because BN suppressed the conversion and the CRN reaction became more unstable. It can be due to missing unreacted reactants before completing the reaction.

TABLE 1. THE CHANGE OF EFFICIENCY FOR THE CRN PROCESS WITH BN RATIO

Composition (wt.%)	Before carbon burning (wt.%)	After carbon burning (wt.%)
15 BN	48,67	14,29
30 BN	33,00	30,77

XRD ANALYSIS

Conversion reactions was carried out under nitrogen gas flowing. After the conversion, the excess carbon was burn out at 900°C for 2h. The XRD result of the remain powder was given in Fig. 1. The synthesis of Si_3N_4 from silica plus carbon mixtures by CRN was considered to proceed as follows:

Fig 1. XRD analysis for $\text{Si}_3\text{N}_4/\text{BN}$ -85/15 (wt.%) at 1450 for 4h.

In Fig. 1, XRD peaks are belong to alpha and beta phases for silicon nitride. While α peaks are minor, β peaks are dominant in the yield powder which was converted at 1450 for 4h. One of the first sign of the addition of boron nitride into the starting material after the conversion was to increase the amorphous phase as seen in Fig 2. When BN ratio in the starting composition increase, the conversion kinetics partly supported formation of the metastable alpha silicon nitride instead of the formation of stable beta silicon nitride.

Fig 2. XRD analysis for $\text{Si}_3\text{N}_4/\text{BN}$ -70/30 (wt.%) at 1450 for 4h.

As shown in Fig 3, the phase analysis by X-ray diffraction (XRD) indicated that the BN addition could deteriorate the conversion to silicon nitride ceramic. The nitridation ratio of silicon slightly decreased with increasing the amount of BN.

Figure 3. The change of amount of the nitrided silicon with changing BN ratio

SCANNING ELECTRON MICROSCOPY AND EDAX ANALYSIS OF THE NITRIDED POWDERS

As can be seen in Fig. 4, highly rod-like silicon nitride grains are clear and these grains can be accepted as coarse which means grain with high aspect ratio. This grain is subjected to beta phase Si₃N₄ and is to give the improved fracture toughness. Hexagonal boron nitride particles are homogeneously distributed and uniformly covered all silicon nitride grain surfaces. This shows to reach the success that means more affected distribution and minimum interface mismatches between the silicon nitride matrix and the boron nitride particles. BN particles are very fine.

Figure 4. SEM micrograph and EDAX elemental analysis of the CRN yield at 1450°C for 4h

Elemental dispersive spectroscopy revealed that “1” and “2” points consist of Si, N and O elements. Si and N are main component of the Si₃N₄ compound but O element. This can cause from surface silica and it is well-known that is all but impossible to escape Si-N-Si-O bonding reaction in presence oxygen. “3” point consists Si, N, O, B and N elements. B and N stem from hexagonal boron nitride particles.

IV. CONCLUSION

The nitridation process of silicon powder was successfully carried out. Highly rod-like silicon nitride grains were obtained at 1450°C for 4h as optimum. Both XRD and SEM analyses revealed the nitridation conversion and morphologies of consisting silicon nitride grains and presence of the stable BN particles. More homogeneous BN distribution around the silicon nitride grains, which is one of the main object, was significantly achieved after reduction and nitridation reactions. The authors propose that the synthesized composite powders can be used to produce the ceramic composites having good machinability and dry sliding features.

Abstract— In this work, Powder mixing techniques for metal, ceramic and intermetallic powder mainly influence mechanical and microstructural properties. Mixer type affects size reinforcement particles and distribution of reinforcing phase in matrix material. The present study aims to design and to manufacture a new powder milling and mixer without conventional mechanisms. The machine was designed and assembled according to crankpiston principle. This system worked at high cycle/min rates, and circular rotation on horizontal axis. The work aims more efficiency and more homogeneous mixing system.

Keywords: mixer design, powder metallurgy, homogeneous distribution

I. INTRODUCTION

Rapid developments in the field of technology make it necessary to use new materials with superior properties compared to conventional materials. New materials have been produced under the name of "Composite Materials" which have superior qualities than other materials [1, 2, 3].

The composite material is a material formed by a mixture or combination of two or more micro- or macro-components separated by their shapes and chemical compositions and essentially insoluble in each other [4].

Composite materials are formed by combining different materials as shown in Figure 1 [5].

Fig. 1. Matrix Materials [6].

The use of different matrix and reinforcement materials has led to the development of different techniques in the production of MMCs. One of these techniques is powder metallurgy [7].

The purpose of powder metallurgy is to produce powders of metal and metallic alloys by mechanical and physico-chemical methods and to produce in various shaped parts from the powders via pressure and temperature without melting [8].

II. PRODUCTION OF METAL POWDER

The techniques used in the manufacture of metal powders determine many properties of powders. Depending on the method of production of morphology of the powder, it can be very different from the spherical to the complicated shapes. The surface condition of the powder varies according to the production method [9].

As well as being a metal powder production technique, grinding, which is also used to break the powder produced by other techniques, is made in the most ball mills. In this method of producing fine particles, the basic principle is to bring a high energy crushing between the material to be ground and a hard object.

Fig. 2. Ball Milling

The metal powder to be grinded in coarse sizes is placed in a container together hard and abrasive balls. The coarse-grained material is divided into very small fresh particles by the effect of impact by rotating or vibrating together with large diameter, hard and abrasion-resistant balls in the grinder vessel (Figure 2).

For a homogenous mixture, the volume of the balls to be placed in the container and the amount of material to be ground is very important parameter. Approximately half of the volume of the vessel and the amount of material to be ground must be approximately 25% of the vessel volume. Iron alloys, iron - chromium, iron - silicon etc. materials can mechanically be ground in ball mills [10].

III. TYPES OF GRINDERS USED

A. Planetary type grinder

Another milling system to make mechanically alloying (MA) is the "planetary" milling equipment (Figure 4). A couple of hundred grams of powder can be grinded in this shot. These mills are called as "planetary" because their chambers act like planets. They are placed on a rotating support disc and take their movement around their axis from a special mechanism [10].

Fig. 4. Planetary type ball mill

B. Atritor type grinder

The atomiser consists of a vertical cylinder with a series of mixers. Powder is deformed with the help of shaft arms and balls, and fractures and cold welds occur in these powders. Crushing of the balls with the container wall, between each other and the agitator shaft cause reduction in the powder size and form a homogeneous microstructure [10].

Fig. 5. Atritor type (vertical) ball mill [10].

IV. MECHANICAL GRINDING

At the basis of the size reduction process with mechanical grinders, crushings between the sample, the grinding medium and the sample are based on the final energy application. Figure 6 shows the grinder and the processes in it [12].

Fig. 6. Minimization of particles by mechanical grinding [13, 14].

The model in Figure 6 shows the crushing model and, as can be seen in Fig 6, the particles remain between the two colliding balls. The grinding media contains dense powder clouds, balls and powder particles. The first phase of re-arrangement and stacking of powders between the balls. Fine and irregular particles form with minimal deformation and fracture and slip from one particle to another. In the second phase of the cracking, particles are subjected to elastic and plastic deformation. At this stage, cold welding is observed in metallic systems. In the third stage, particles are broken by further deformation or fragmentation [15, 12].

In this work, a new method has been designed and produced outside of the existing mixing methods. The powders were mixed at high speed per minute on the horizontal axis with crankshaft working principle. In the previous methods, the limited number of materials encountered were disadvantages such as mixing, stacking, cold welding, as well as speeds of up to 800-1000 d / d, reaching 1000-3000 d / d.

This work aims to design a new type mixing system. The authors think that the system performs with high energy and relatively efficiency. All affected parameters were considered during the design of the high energy mixer.

V. EXPERIMENTAL

Materials and Method

Catia V5R20 and Solidworks programs to draw and to design were used in manufacturing the new grinding system. Crankshaft, connecting rod, slide bar and pins are fabricated from 4140 steel.

VI. RESULTS AND DISCUSSION

Designing and Manufacturing of The Mixer

The speed required for the system was provided using an inverter device that helps to set the frequency of the motor.

The PLC touch panel was used to make the inverter more simple and practical. The desired speeds can be easily adjusted on this screen.

The linear mixer relies on the ability to mix different powder materials with each other in a tube with the help of the balls used in existing systems. The tube is moved back and forth in the linear axis at high speeds. The agitator provides the necessary action for this operation by means of the crank-rod mechanism.

Fig. 7. Schematic demonstration of the new desing mixer

Fig. 8. The desinged machine

The crankshaft rotates the circular motion of the motor connected to the shaft to a linear motion by means of the crank, connecting rod. The tube placed on the sliding bar moves by adjusting with the help of the control panel at the desired speed between 0 and 3000d / d. In this respect, powder materials in the tube act by the propulsion force provided by the linear motion. Powder deposits that may form in the powder material during the movement and adverse conditions such as cold welding are lifted by the help of the balls in the tube. The absence of a mixer miller outside the

balls allows the movement of the powders to be only with the acceleration generated from the instantaneous velocity within the tube, allowing the parts to undergo less deformation and without excessive thermal rubbing. It has powder mixing capacity up to maximum 5kg.

VII. CONCLUSION

In previous methods, the disadvantages such as small amount of material mixing, batch forming, cold welding and thermal heat increase have been solved. In addition to these disadvantages, maximum speeds of 800-1000d/d have been reached, reaching speeds of 1000-3000d/d. This new type mixing and milling system was designed and manufactured with new style driving system.

Abstract— $\text{A}_2^{3+}\text{B}_2^{4+}\text{O}_7$ pyrochlores, in which A sites are generally occupied by rare earth ions, are more common than those of formula $\text{A}_2^{2+}\text{B}_2^{5+}\text{O}_7$. Partial substitution at A and B cationic sites as well as oxygen sites is possible. Vacancies in the crystal lattice at A and oxygen sites are possible to a certain extent. The possibilities of selecting A and B cations or introducing lattice defects in these solids gives rise to a wide variety of chemical and physical properties [1]. Among the pyrochlores, the lanthanide stannates $\text{Ln}_2\text{Sn}_2\text{O}_7$ (Ln= rare-earths) with the cubic structure $\text{Fd}\bar{3}\text{m}$ have emerged as important functional materials due to their catalytic activity, defect structures and high thermal stability. They act as potential panacea for the material research fields, such as metal–semiconductor transitions, magnetic frustration/spin ices, colossal magnetoresistance, luminescence and superconductivity [2]. They also have a number of attractive features for designing catalysts, sensors, dielectrics, fast ion conductors, superconductors, ferromagnet, nuclear waste encapsulation, and thermal barrier coatings and high temperature stability. Rare earth stannate pyrochlores exhibit good catalytic activity and high thermal stability, which make them promising when used as a catalytic promoter in the electrode for electrochemical decomposition of NO_x [3].

In this research, the rare-earth stannate pyrochlore was synthesized by high temperature solid state reaction method under open atmosphere. The phase formation process was investigated by thermal analysis (DTA/TG) until 1600°C . The X-ray diffraction (XRD) analysis resulted as the cubic phase structure with lattice parameters $a=b=c=10.374 \text{ \AA}$ and $\alpha=\beta=\gamma=90^\circ$. The photoluminescence (PL) analysis including excitation, emission and decay time were determined by a PL spectrometer under room temperature. The excitation wavelength at 296 nm of sample was based on ligand-to- Eu^{3+} charge-transfer transitions (LMCT). The emissions at 622 nm and 711 nm concerning the typical $^5\text{D}_0 \rightarrow ^7\text{F}_2$ and $^5\text{D}_0 \rightarrow ^7\text{F}_4$ transitions of the Eu^{3+} -ions, respectively (Figure 1) [4].

Keywords— Rare-earth stannate pyrochlore; Eu^{3+} ; solid-state reaction; photoluminescence.

Abstract— A Turkish manganese ore was characterized and its calcination behavior was studied. The ore contained 40.43% manganese and 6.67% iron. The XRD analysis of the Run-of-Mine ore revealed that it was composed mainly of pyrosulite, calcite, goethite, quartz. The ore also contained minor amounts of clay minerals. Thermal analysis of the sample recorded five endothermic peaks at different temperatures ranging from 100 to 900°C. In order to determine the transformations during the course of heating, ore samples were calcined at specified temperatures according to the thermal analysis of the ore. Mineralogical changes were traced by the use of XRD. The main reactions during the calcination were decomposition of goethite at 300-400°C, dehydroxylation of clay minerals at 400-500°C, decomposition of MnO₂ to Mn₂O₃ at 600-700°C, decomposition of calcite at 700-900°C and decomposition of Mn₂O₃ to Mn₃O₄ above 1000°C.

Keywords— Manganese ore; Characterization; Calcination

I. INTRODUCTION

Manganese is one of the most important additives in the iron and steel industry. It acts as both sulfide former and deoxidant. In addition, it improves hardenability, workability, wear resistance and mechanical properties of the iron alloys [1]. Manganese is generally added to the molten alloy in the form of ferromanganese and silicomanganese. About 85% of the produced manganese is used in steelmaking as ferromanganese [2]. Ferromanganese has conventionally been smelted in blast furnaces. Nevertheless, the blast furnaces have been replaced by electric arc furnaces over time (Fig. 1) mainly due to the lower average production cost per ton of the product.

Although not very large, there are lots of manganese reserve in Turkey distributed throughout the country [4] and some researches have been conducted on the production of ferromanganese from these ores [5]. In spite of the fact that some of the reserves are large enough to commercially be considered, ferromanganese is not smelted in Turkey thanks to the expensive electrical energy which increases the

production cost and discourages investment. A cost-effective alternative way for the electric arc furnace process may be the Rotary Kiln-Electric Furnace (RKEF) process through which the ore is dried, calcined and prereduced in a rotary kiln [4]. The hot calcine from the rotary kiln can be directly charged into the arc furnace. The objective is to carry out a part of the energy-intensive smelting process by the low cost hydrocarbon fuels in the rotary kiln thereby decreasing the electrical energy consumption in the arc furnace. In addition, the calcination and prereduction of the ore in the rotary kiln eliminate volatile matters and substantial portion of oxygen in the ore which in turn provides an enriched charge to the arc furnace.

Fig. 1. Evolution of global manganese production, by processes [2].

A successful application of the RKEF process for the treatment of manganese ores requires a comprehensive study of the ore behavior upon heating. However, there are only a limited number of researches [7, 8, 9] addressing the chemical and mineralogical changes of the ore during heating. Manganese ores show significant variations in chemistry and mineralogy and this intensifies the need for further investigations on thermal decomposition of these ores. This

article reports the results of a laboratory-scale research on the calcination behavior of a Turkish manganese ore.

II. EXPERIMENTAL PROCEDURE

A. Ore Preparation

Ten kilograms of a representative run-of-mine (ROM) ore was received. The ore was further crushed to -1 mm and divided into batches of about 50 g which were used in the experiments. One batch was finely ground which was used for characterization of the ROM ore.

B. Characterization of the Ore

The finely ground ore was analyzed for its Mn and Fe content by ICP. Mineralogical analysis of the ore was achieved by XRD. Differential thermal analysis (DTA) and thermogravimetric analysis (TGA) were carried out to study the thermal behavior of the ore. Twenty milligrams of the ground ore was heated from ambient temperature to 1000°C at a rate of 10°C/min- in air.

C. Calcination of the Ore

A muffle furnace was used for the calcination experiments. The ore was dried overnight before calcination. Forty five grams of -1 mm dried ore was charged into an alumina crucible and heated in air to constant weight at predetermined temperatures. The calcined samples were analyzed by XRD to determine the mineralogical changes during the calcination.

III. RESULTS AND DISCUSSION

A. Chemical Analysis

Manganese and iron concentrations of the ore are given in Table 1.

Table 1. Manganese and iron concentrations in the ROM ore.

Mn ⁺⁴	Mn ⁺²	Mn (Total)	Fe
37.77	2.66	40.43	6.67

B. XRD Analysis

The XRD pattern of the ROM ore is shown in Fig. 2. The ore was mainly composed of pyrosulite (MnO₂) and calcite (CaCO₃). Goethite and quartz were also present in minor quantities. In addition, small amounts of clay minerals, identified by a weak peak at 2θ about 9, were present in the ore.

Fig. 2. The XRD pattern of the ROM ore.

C. Thermal Analysis

DTA and TGA curves of the ore are shown in Fig. 3. Three weak endothermic peaks at about 100, 350 and 450°C together with three intense peaks between 600 and 800°C were recorded. Sample weight decreased mildly up to 600°C but decreased significantly between 600 and 800°C. Sample weight remained almost unchanged up to 950°C and again began to decrease at higher temperatures. The low-temperature endothermic peaks at about 100°C was related to the evaporation of free water. It was difficult to discuss about the nature of the other effects using only the current diagram. For this reason, calcination experiments were conducted at different temperatures and XRD was used to identify any possible reactions or transformations taking place during the course of heating.

Fig. 3. DTA/TGA results of the ROM ore.

D. Calcination Experiments

Fig. 4 illustrates how the sample weight changed during calcination at different temperatures. Only about 1.8% of the sample weight lost at 300°C. Heating of the sample at 500°C increased the final weight loss to about 3.5% and, at the same time, decreased the calcination time by about 15 min-.

Comparing the XRD pattern of the sample calcined at 300°C (Fig. 5) and that of the ROM ore in Fig. 1, it was concluded that the main fraction of the goethite dehydroxylated at this temperature. The remainder dehydroxylated when the sample heated at 400°C as the characteristic peaks of goethite completely disappeared at this temperature. The reaction can be written as below:

Fig. 4. Weight loss at various temperatures as a function of time.

Fig. 5. The XRD pattern of the samples calcined at 300, 400 and 500°C.

Although no change was detected between 400 and 500°C from XRD (Fig. 5), the weight of the sample continued to decrease in between. This weight loss may be attributed to the dehydroxylation of clay minerals which were present in minor quantities in the ore. Accordingly, the endothermic peaks at 350 and 450°C in DTA result (see Fig. 3) can be related to the dehydroxylation of goethite and clay minerals, respectively.

When the ore heated to 600°C, the final weight loss increased to about 4.8% while the calcination time also increased to more than 80 min. The increased time at 600°C implied that at least one new reaction began between 500 and

600°C. Calcination of the ore at 700°C resulted in a considerable increase in the weight loss. It was almost doubled when temperature increased from 600 to 700°C. This results are in agreement with the thermal analysis of the ore (see Fig. 3) according to which an endothermic reaction initiates just below 600°C and reached its maximum at about 675°C. This endothermic peak accompanied with a sharp decrease in the weight of the sample.

The XRD pattern of the samples calcined at 600 and 700°C are given in Fig. 6. This figure also includes the XRD pattern of the sample calcined at 500°C for comparison. A careful examination of these patterns revealed that the characteristic peaks of pyrosulite weakened as temperature rose and only a very small peak remained when it reached 700°C. At this temperature a new phase, bixbyite (Mn_2O_3), came to existence. Therefore, the strong peak at about 675°C and associated large weight loss in DTA results (see Fig. 3) were related to the transformation of MnO_2 to Mn_2O_3 based on the reaction below:

Fig. 6. The XRD pattern of the samples calcined at 500, 600 and 700°C.

The sample continued to lose weight at higher temperatures and the final weight loss reached about 11.7% at 800°C and 14.1% at 900°C. The longer calcination time at 800°C was indicative of a new reaction at this temperature. Examination of the XRD patterns of the samples calcined at 700, 800 and 900°C (Fig. 7) indicated that calcite decomposed above 700°C. Calcite decomposes to give CaO and CO_2 according to the reaction below:

Fig. 7. The XRD pattern of the samples calcined at 700, 800 and 900°C.

Although no other transformation could be detected from the XRD analysis, there were two endothermic peaks at about 720 and 800°C in the DTA results. One possible explanation may be that the decomposition of calcite was achieved via a two-step process.

The thermal analysis (see Fig. 3) showed that the weight of the sample remained almost unchanged above 850°C, but again began to decrease when temperature exceeded 950°C. Another sample was calcined at 1100°C for 60 minutes. Weight of the sample was recorded at the end of the experiment. The weight loss at this temperature was obtained to be 15.2%. The XRD analysis of this sample (Fig. 8) revealed that Mn_2O_3 transforms into Mn_3O_4 according to the reaction below:

Fig. 8. The XRD pattern of the sample calcined at 1100°C.

IV. CONCLUSION

Calcination behavior of a Turkish manganese ore was studied. The calcination process included dehydroxylation of hydroxide minerals and decomposition of carbonate and oxide minerals all of which are highly endothermic reactions. In the electric arc furnace process, the ore is directly charged into the furnace and calcination reactions, therefore, take place at the expense of expensive electrical energy. The rotary kiln-electric furnace (RKEF) process, which uses low cost hydrocarbon fuels, can be an alternative for the electric arc furnace process. Reduction behavior of the ore is not included in this article. However, in the rotary kiln, reduction reactions also take place because of its reducing atmosphere. Reduction reactions can even be encouraged by the addition of coal to the rotary kiln. This can additionally reduce the energy consumption in the electric arc furnace.

Abstract— In recent years, ionic liquids are frequently used to recover valuable metals from ores and secondary sources by hydrometallurgical method. However, besides precious metals, the dissolution of undesirable metals is a major problem in terms of cleaning the pregnant solution. Copper anode slime is an industrial waste which has economic value due to the presence of precious metals such as copper, gold, silver and platinum group metals. In this paper, the dissolution behaviour of base metals (Pb, Sn, Zn, Ni, Ba and Sb) in 1-ethyl-3-methylimidazolium hydrogen sulphate ($\text{Emim}[\text{HSO}_4]$, $\geq 95\%$) ionic liquid during the precious metal recovery from anode slime was investigated for different experimental conditions. The chemical analysis of anode slime indicated that it was consisted of 23.32% Cu, 20.51% Sn, 15.40% Pb, 5.87% Ba, 0.55% Sb, 0.13% Zn, 0.013% Fe, 2204.2 ppm Ag, and 21.9 ppm Au. According to mineralogical characterization, it was mainly composed of PbSO_4 , SnO_2 and Cu_2O . After several trials, the experimental results showed that Pb, Sn, Zn, Ni and Sb had low dissolution rate in ionic liquid. On the contrary, Ba dissolution rate increased with increasing ionic liquid concentration and temperature. According to the results, low dissolution rates of base metals make attractive this new leaching agent to recover precious metals from copper anode slime.

Keywords—Anode Slime; Leaching, Ionic Liquid, Dissolution

Abstract— In this study, sulfuric acid-activated montmorillonite mineral (SAM) was used as an adsorbent for the removal of Basic Blue 3 (BB3) from aqueous media. The natural montmorillonite mineral (NM) was activated by treating with a 6 M H_2SO_4 solution for 4 hours at 395 K. After sulfuric acid treatment the SAM samples were characterized using a BET surface analyzer and FTIR spectroscopy. The adsorption kinetics and equilibrium of BB3 from aqueous media on SAM were investigated in a batch system at various conditions, i.e., contact times (0-120 min), initial pH values (2-8), temperatures (298-318 K), and initial dye concentrations (100-350 mg/l).

The experimental results indicated that the optimum values of temperature, initial pH, initial BB3 concentration of aqueous media, and contact time were 298 K, 6 ± 0.02 , 350 ppm, and 60 min, respectively. The maximum adsorption capacity was determined to be 277 mg/g at the optimum conditions. Langmuir and Freundlich isotherm models were used to describe the equilibrium data mathematically. The isotherm constants were calculated at different temperatures. It was observed that the adsorption of BB3 onto SAM was described better by the Freundlich isotherm. Pseudo first-order and second-order kinetic model constants were calculated for the adsorption kinetics. The pseudo second-order model was the best-fitting model for the adsorption kinetics of BB3 on SAM. The thermodynamic parameters of adsorption, which were calculated using thermodynamic equations, indicated that the removal process was spontaneous at all values of temperatures and the exothermic nature of adsorption. The results of the study showed that, compared with commercial adsorbents, SAM could be used as a low-cost and suitable adsorbent for the adsorption of BB3 from aqueous media.

Keywords: Adsorption, basic blue 3, sulfuric acid-activated montmorillonite mineral (SAM), thermodynamic and kinetic parameters

I. INTRODUCTION

The textile industry is one of the fastest-growing major industries in Turkey. The wastewaters released from this industry contain high amounts of dyes and pigments, which generally have been synthesized and contain complex aromatic molecules. They contain a lot of double bonds and various functional groups [1]. Therefore these dyes and pigments are

not biologically decomposed due to their stable structures, so they accumulate easily in natural bodies of water [2]. When these wastewaters are discharged into aquatic media, serious environmental problems may be occurred such as impairment of the aesthetic nature, the reduction of the degree of penetration of light and decrease in the solubility of gases. [3]. Such effluents can also cause cancer, skin irritation, allergic dermatitis and mutations [2-4]. For that reason the removal of pigments and dyes from wastewater is very important for the protection of the ecosystem and the health of people who may use or be exposed to that waste waters. Many treatment techniques can be used for the removal of these pollutants from wastewater before they are discharged to aquatic media. These techniques include adsorption [5-11], membrane processes [12], oxidation processes [13], ion exchange [7,8], reverse osmosis [14], electrocoagulation [2], and coagulation [15]. Unlike other remediation techniques, the adsorption process is considered to be one of the most attractive treatment options because of its simplicity, ease of use, and high efficiency [16-18]. It is known that the cost, sustainable resource, accessibility and adsorptive capacity of the adsorbent are very significant parameters that affect the efficiency, effectiveness, and costs of the process.

The aim of this research was to investigate the adsorption kinetics and thermodynamic characteristics of Basic Blue 3 (BB3) on sulfuric acid-activated montmorillonite mineral (SAM). To do this, the SAM samples were firstly characterized with BET and FTIR techniques. Then, the effects of the adsorption parameters on the efficiency and rate of adsorption of BB3 on the SAM samples were investigated in a batch system. The thermodynamic and kinetic parameters were calculated using appropriate models.

II. MATERIAL AND METHODS

A. Preparation and characterization of adsorbent

The natural montmorillonite mineral was provided by a local industry in Elazig, Turkey. The mineral was dried at 105 °C in an oven and then divided into fractions based on the particle

sizes. The fraction between 50 and 100 mesh was activated using 6 M H₂SO₄ solution at 97 °C for 6 hr. After the activation process, the sulphuric-activated montmorillonite mineral (SAM) was washed with water until the sulphate ions were completely removed. The SAM samples were stored in desiccators for subsequent use in the study.

The SAM samples were characterized using BET Surface Area Analyzer (ASAP 2020, Micromeritics Inc., USA) and FTIR spectrometer (ATI Unicam Mattson 1000). The pH of zero point of charge (pH_{zpc}) of the activated montmorillonite mineral was measured by using the pH drift methods [19, 20]. FTIR spectra were recorded using an FTIR spectrometer by averaging 16 scans. IR absorbance data were obtained for the range of wave numbers from 400 to 4000 cm⁻¹. BET surface area of SAM samples analysis was determined by the adsorption of N₂ at 77 K.

B. Experimental Procedure

The stock solution of Basic Blue 3 (BB3) was prepared from 25 % dye content, Sigma Aldrich in a concentration of 1000 mg/L. All working solutions were prepared by diluting stock solution of BB3 using distilled water. During the experimental studies, (especially in studies in which the effects of pH were investigated), the pH values of the solutions were adjusted using 0.1 M solutions of NaOH and HCl.

The experiments were performed in 14 parallel erlenmeyer flasks using a thermostatic water bath and a mechanical shaker at an agitation speed of 180 rpm. The contents of all of the erlenmeyer flasks were prepared in the same conditions. Each experiment was conducted by mixing 50 ml of the BB3 solution with a certain amount of SAM in 100-ml erlenmeyer flasks. The adsorption of BB3 on SAM were carried out by investigated the affects of various parameters such as temperature of solution (298-318 K), initial pH (2-8), contact time (5-120 min) and initial concentration of BB3 (100-350 ppm). At the end of the desired contact time, each flask was removed from the water bath and the SAM was separated from the aqueous phase by centrifugation at 5000 rpm for three minute. The residual concentration of BB3 in the filtrate was analyzed by a UV-vis spectrophotometer. The experiments were performed in duplicate, and the average results were reported. The adsorption efficiency and the adsorption capacity of the SAM, q_e (mg/g), which is expressed as the quantity of BB3 adsorbed by using the SAM, were calculated using Eqs. (1) and (2), respectively.

$$\text{Adsorption efficiency}(\%) = \frac{C_o - C_e}{C_o} \times 100 \quad (1)$$

$$q_e = \frac{v \times (C_o - C_e)}{m}, \quad (2)$$

In that equations, m (g) is the mass of the SAM, v (L) is the volume of the BB3 solution, q_e (mg/g) is the adsorption capacity of SAM, C_o (mg/L) is the initial concentration of BB3 molecules in solution, and C_e (mg/L) is the final (equilibrium) concentration of BB3 molecules in solution.

III. RESULT AND DISCUSSION

The average pore diameter and single-point BET surface area were determined by the nitrogen adsorption method as 21.2 Å and 113.3 m²/g for the sulfuric acid activated montmorillonit mineral (SAM). Same quantities for the natural montmorillonite mineral (NM), were obtained as 65.4 Å and 73.6 m²/g.

Fourier transform infrared (FTIR) spectroscopy was used to identify the functional groups on the surface of montmorillonite mineral before and after activation, and the significant peaks are given in Table 1. Researchers have reported similar peaks for other clay minerals in the literature [21, 22].

It is well known that the point of zero charge (pH_{zpc}), which is indicative of the types of surface active centers and the adsorption mobility of surface, is an important factor in adsorption processes [23]. Fig.1, which was drawn using the drift method, shows that the value of pH_{zpc} was 5.1. The experimental results indicated that, when the pH of the BB3 solution was less than 5.1, the surface of the SAM was positively charged and could attract anions from the solution. When the pH of the solution was greater than 5.1, the surface of the SAM was negatively charged and attracted cations.

Figure 1. Zeta potential of SAM.

Effect of the initial pH of the solution and the contact time:

Figure 2 shows the relationship between contact time and the adsorption capacity of the SAM for different initial pH values. The figure indicates that the adsorption of the BB3 molecules was relatively higher in the first 30 min. After that period the adsorption efficiency declined because the active sites on the surface area available for adsorption was decreased. Also, the high adsorption efficiency during the initial stage have been due to the higher driving force's producing faster transfer of BB3 molecules to the surface of the SAM. In addition, the adsorption capacity of the SAM increased with contact time and reached its maximum value in the range of 85-99 mg/g for different initial pH values after approximately 60 min. After this time, the adsorption capacity remained almost constant, for that reason contact time of 60 min was considered the equilibrium time for BB3 adsorption.

Figure 2. Effect of contact time on adsorption capacity of SAM (initial BB3 con. 100 ppm; contact time: 120 min; SAM con: 2 g/L; temperature: 298 K)

It can be seen that the initial pH of the BB3 solution was a significant parameter (Figure 3), The adsorption capacity of BB3 molecules increased linearly up to a maximum value of

about 99 mg/g as the pH of the solution was increased up to 6.0. After that point the adsorption capacity decreased.

Figure 3. Effect of initial pH on adsorption capacity of SAM (initial BB3 con. 100 ppm; contact time: 120 min; SAM con: 2 g/L; temperature: 298 K)

These results indicated that the initial pH of the BB3 solution affected the surface charges of the SAM, the concentration of the counter ions on the functional groups of the SAM and the degree of ionization/dissociation of the SAM during adsorption [24-26]. These results are consistent with the pH_{zpc} value of the SAM samples ($pH_{zpc} = 5.1$). Similar results have been reported in the literature [27].

Figure 4. Effect of temperature on adsorption capacity of SAM (initial BB3 con. 100 ppm; contact time: 120 min; SAM con: 2 g/L; pH: 6±0.02)

The kinetic analysis of the adsorption: The effect of the temperature on the adsorption of BB3 molecules by SAM in is shown in Fig.4. It was observed that the adsorptive capacity of the SAM was increased as the temperature decreased from 318 K to 298 K. The equilibrium adsorption capacity of the SAM was determined to be about 97 and 89 mg BB3/g at 298 and 318 K, respectively. The increase in the removal of BB3 with decrease in temperature of solution showed that the adsorption process was exothermic.

Adsorption processes are time dependent; therefore, while designing the reactor for this process, the relationship between the adsorption rate and the contact time should be known. This relationship can be demonstrated by kinetic model equations. For that reason, the adsorption data were analyzed with pseudo first-order and pseudo second-order kinetic models. The pseudo first-order kinetic model of Lagergren is given as [28]:

$$\frac{dq_t}{dt} = k_1(q_e - q_t) \quad (3)$$

By integrating of Eq (3) for the boundary conditions from $t = 0$ to $t = t$, the following equation is obtain.

$$\ln(q_e - q_t) = \ln q_e - k_1 t \quad (4)$$

The pseudo second-order model is given by Eq. (5) [29]:

$$\frac{dq_t}{dt} = k_2(q_e - q_t)^2 \quad (5)$$

The linearized integrated form of Eq. (5) is given by Eq. (6):

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (6)$$

Where t (min) is the contact time; q_e (mg/g) and q_t (mg/g) are the amounts of BB3 on the surface of the SAM at equilibrium and at any contact time, respectively; and k_2 (g/mg min) and k_1 (min⁻¹) are the pseudo second-order and the pseudo first-order rate constants, respectively.

The values of the adsorption rate constant (k_1) can be obtained from the plot of $\ln(q_e - q_t)$ against t (Fig. 5). The rate parameters, k_2 and q_e , can be obtained from the plot of (t/q_t) versus t (Fig. 6).

Figure 5. Pseudo first-order kinetic plots for the removal of BB3 molecules

Figure 6. Pseudo second-order kinetic plots for the removal of BB3 molecules

Table 2. Kinetic parameters for the removal of BB3 by SAM

Temperature (K)	q_e (mg/g)	Pseudo-first-order kinetic model		
		R^2	$k_1 \times 10^3$ (min ⁻¹)	q_{ec1} (mg/g)
298	99.3	0.97	54.9	64.71
308	93.4	0.98	55.8	76.71
318	89.8	0.99	55.3	95.85
Temperature (K)	q_e (mg/g)	Pseudo-second-order kinetic model		
		R^2	$k_2 \times 10^3$ (g/mg min)	q_{ec2} (mg/g)
298	99.3	0.99	1.1	101.0
308	93.4	0.99	1.5	99.00
318	89.8	0.98	1.9	98.04

The values of k_1 , q_{ec1} , k_2 , q_{ec2} , and the correlation coefficient (R^2) are given in Table 2. The correlation coefficient (R^2) and the difference between the calculated adsorption capacity (q_{ec}) and the experimental adsorption capacity (q_e) indicate that the pseudo second-order kinetic model simulated the kinetic data better than the pseudo first-order kinetic model.

Thus, the rate constants (k_2) of the pseudo second-order model in the Arrhenius equation (Eq. 7) were used to calculate the activation energy of the adsorption process of BB3 molecules by the SAM.

$$\ln k_2 = \ln A - \frac{E_a}{RT} \quad (7)$$

Where A (g/mg min) is the Arrhenius constant; E_a (J/mol) is the activation energy; T (K) is the temperature of the solution; and R (8.314 J/mol K) is the ideal gas constant.

To calculate the activation energy (E_a) for the adsorption process, $\ln k_2$ was plotted versus $1/T$. The activation energy value (E_a) was calculated as about 19 kJ/mol, and this value indicated that physical adsorption is a dominate mechanisms on the removal process. On the other hand, it was observed that the values of q_{ec2} increased and the values of k_2 decreased with decrease in temperature. These results indicated that the

adsorption of BB3 by the SAM occurred more rapidly at higher temperatures.

The thermodynamic analysis of adsorption: The experimental data showed that the adsorptive capacity of the SAM was a function of the initial concentration of BB3 molecules in the aqueous solution. It was observed that the the adsorption capacity of BB3 increased from 130 to 180 mg/g at the range of initial concentrations values between 100 to 350 mg/L because the initial BB3 concentration provides an important driving force to overcome all mass transfer resistance. Similar results have been reported by Özer et al. [30]. An slight decrease in the BB3 adsorption using SAM was associated with an increase in temperature from 298 to 318 K, thereby suggesting that the adsorption process is thermodynamically stable. When the temperature of the solution decreased from 318 to 298 K, the value of the maximum adsorption capacity increased from approximately 89.8 to 99.3 mg/g for 100 ppm. and 210 to 280 mg/g for 350 ppm. These results show that these adsorption reactions were exothermic and appeared to have a favorable adsorption at a lower temperature. They stated that the decrease in adsorption with increasing temperature is a result of poor interaction between the dye and adsorbent as the interaction forces of hydrogen bonds and Van der Waals are not strong. Similar results have been reported by Vimoneses et al. [31] and Toor et al. [32].

The equilibrium adsorption isotherm is fundamentally important in the design of an adsorption system. In this research, the Langmuir [33] and Freundlich [34] models were used to explain the experimental data.

The Langmuir isotherm is given by Eq. (8):

$$\frac{C_e}{(x/m)} = \frac{1}{q_{\max} K} + \frac{C_e}{q_{\max}} \quad (8)$$

Where C_e (mg/L) is the equilibrium concentration of BB3, q_{\max} (mg/g) is the maximum adsorptive capacity of the SAM, K

(L/mg) is the Langmuir constant, and $(\frac{x}{m} = q_e)$ (mg/g) is the

adsorptive capacity of the SAM at equilibrium.

The Freundlich isotherm is given by Eq. (9):

$$x/m = K_f C_e^{1/n} \quad (9)$$

Equation (9) can be written in linear form as:

$$\ln(x/m) = \ln K_f + \frac{1}{n} \ln C_e \quad (10)$$

Where n is the adsorption intensity, and K_f (mg/g) is the adsorptive capacity.

The adsorption data were analyzed with the Freundlich and Langmuir sorption models. Figs. 7 and 8 show the Langmuir and Freundlich isotherm plots, respectively. The correlation coefficients (R^2) and the isotherm constants are given in Table 3.

Figure 7. Langmuir isotherm

Figure 8. Freundlich isotherm

Table 3. Langmuir and Freundlich isotherm constants for the removal of BB3 molecules

Temperature K	Langmuir Constants		
	q_{\max} (mg/g)	K (L/mg)	R^2
298	303.0	0.081	0.979
308	294.1	0.054	0.985
318	250.0	0.040	0.989

Temperature K	Freundlich Constants		
	K_f (mg/g)(L/mg) ⁿ	n	R^2
298	64.53	3.00	0.991
308	46.86	2.68	0.984
318	40.56	2.89	0.996

It was found that the Freundlich isotherm represented the equilibrium adsorption of BB3 by the SAM better than the Langmuir isotherm. The relationship between temperature and the adsorption equilibrium constant, called van't Hoff equation, is given as:

$$\frac{d(\ln K)}{dT} = \frac{\Delta H^\circ}{RT^2} \quad (11)$$

An integrated form of the van't Hoff equation is presented in Eq. (12):

$$-\ln K = \frac{\Delta H^\circ}{R} \left(\frac{1}{T} \right) + C \quad (12)$$

Eq. (13) is obtained when the constant is replaced by $(-\Delta S^\circ/R)$:

$$\ln K = \frac{\Delta S^\circ}{R} - \frac{\Delta H^\circ}{R} \left(\frac{1}{T} \right) \quad (13)$$

If $\Delta G^\circ = -RT \ln K$ is combined with Eq. (13) the following equation is obtained:

$$\Delta G^\circ = \Delta H^\circ - T \Delta S^\circ \quad (14)$$

Where ΔG° , ΔH° , and ΔS° are changes in free energy, enthalpy, and entropy, respectively; K is the adsorption equilibrium constant; T is absolute temperature; and R is the universal gas constant (8.314 J/mol K). The intercept and the slope of the plots of $\ln K$ versus $1/T$ were used to determine the values of ΔS° and ΔH° .

The thermodynamic parameters were calculated for the process. The change in entropy (ΔS°) and enthalpy (ΔH°) were determined to be 21.86 J/mol K and -27.78 kJ/mol, respectively. The change of free energy (ΔG°) was calculated as -21.27, -21.05, -20.80 kJ/mol for 298, 308 and 318 K, respectively by using Eq.(14). The positive value of ΔS° indicates the affinity of the SAM for BB3. Negative values of ΔH° and ΔG° reflect the feasibility and the exothermic nature of the spontaneous adsorption process. The negative values of ΔH° , which revealed that the adsorption is likely to be dominated by physical processes in nature involving weak forces of attraction [35-36].

IV. DISCUSSION

The sulfuric acid-activated montmorillonite mineral (SAM) was prepared by natural montmorillonite mineral (NM), and it was used for the removal of BB3 from an aqueous solution in a batch system. The thermodynamic and kinetic parameters were calculated using appropriate models.

- The experimental results indicated that the adsorption of the BB3 depended on the initial pH of the solution, the initial concentration of the adsorbate, the temperature, and the contact time. The optimum values of temperature, initial pH, initial BB3 concentration of aqueous media, and contact time were 298 K, 6 ± 0.02 , 350 ppm, and 60 min, respectively. The maximum adsorption capacity was determined to be 277 mg/g at the optimum conditions.
- It was observed that the adsorption of BB3 onto SAM was described better by the Freundlich isotherm. The pseudo second-order model was the best-fitting model for the adsorption kinetics of BB3 on SAM.
- The experimental results indicated that SAM can be used as an effective, low-cost, and eco-friendly alternative adsorbent for the adsorption of BB3 molecules from aquatic systems. Additional studies should be conducted to

investigate the feasibility of using the SAM as an adsorbent for other molecules of dyes and toxic heavy metals.

Abstract—This work was undertaken to produce a new construction materials which could have insulation and mechanical strength properties by using two different wasted materials. The waste expanded polystyrene (EPS) and marble powder were used as the aggregate in order to produce a new concrete material. After waste EPS is collected as packaging material, it is mixed with the cement of percentages; 20%, 40%, 60% and 80%. Marble powder is added to each of this cement at 0.0%, 0.5%, 1% and 1.5% of the weight of the mixture. 16 different samples were produced. At the end of 28 days of drying period, the samples were subjected to a number of tests so that their physical characteristics could be identified. As a result of these test, it was concluded that EPS ratio of the samples increased, their density, thermal conductivity, the compression and tensile strength decreased, while porosity increased. It was recommended that; using EPS aggregated and marble powder added concrete, (i) the waste EPS and marble powder can be evaluated as construction material, (ii) building heating and cooling energy will be saved.

Key words; *Waste expanded polystyrene, marble powder, light concretes, insulation material*

1. INTRODUCTION

Today expanded polystyrene can be used as insulation material in buildings; it is also widely used in packaging industry. As an important waste material in terms of environmental pollution, this material has to be recycled and re-economized. Revaluation of waste EPS as construction material is important both in terms of its contribution to economy and as a solution to environmental solution problem. Several studies have been made on the usage of EPS as construction material. A considerable portion of these studies are related to the use of aggregate in concrete. Some of these studies are summarized below.

Babu et al [1], examined the mechanical features of light concretes produced by using fly ash along with expanded polystyrene along with regular aggregate. Miled et al. [2], studied the impact of the change in the amount and dimensions of EPS found on aggregated concrete samples on the pressure resistance of the concrete. Bourvard et al [3], worked on the physical features of high-performance concretes consisting of

expanded polystyrene balls. Chen [4] studied on the characteristics of the light concrete which consists of polystyrene foam reinforced with steel fibre. Babu et al [5], investigated the mechanical behaviours of the concretes which were mixed with silica fume at different rates in order to increase the resistance of low-intensity concrete consisting of

EPS. Demirboga and Kan [6], displayed the changes in thermal conductivity, density and average drying contraction values of the concrete in the samples they produced by using 25, 30 and 100% EPS as aggregate in concrete. Rossignolo and Agnesini [7], studied the technical properties of concretes created with light aggregate mixtures of styrene-butadiene rubber (SBR) modified with two types of light aggregates. Kaya and Kar [8] investigated the physical characteristics of light concrete and gypsum coatings with waste EPS aggregates. Kaya and Kar [9] tested thermal and mechanical properties of the light weight concretes with EPS and tragacanth resin. Sariisik and Sariisik [10] determined the thermal conductivity value of concrete mixtures with cement, pumice and EPS. Khedari et al. [11] investigated a new lightweight construction material, composed of cement, sand and fiber of waste coconut.

In this paper, the mechanical features of samples produced by granulating the EPS particles which are liberated as waste material in packaging industry using certain amounts of cement and marble powder have been examined.

II. EXPERIMENTAL STUDY

A. Materials

Expanded Polystyrene Foam (EPS) is a foam-like- closed-pored thermoplastic material, typically in white colour, obtained from polymerization of styrene monomer (Figure 1). EPS products were acquired by bulking and amalgamation of polystyrene particles. "Pentane" gas was used for particle bulking and foam acquiring. Pentane is an organic component and after it ensures formation of many small particles within particles, it is exchanged by air in a very short time during and after the production. With the liberation of pentane, inert air is trapped in the abounding (3-6 billion in 1 m³ EPS depending on density) number of small pored cells. 98 percent of the material is air and the rest is polystyrene [8]. EPS is a close-pored material. Due to its very low level of water absorption, its features do not change even if it directly contacts with water. As it does not dissolve and disintegrate in water, the pore walls are water-proof.

Fig 1. Polystyrene and expanded polystyrene [8].

Marble Powder (MP) are obtained from Marble manufacturing facility in Elazig.

CEM IV/B(P)32.5 R pozzolanic cement were used to EPS and marble powder as a binder. Chemical components of cement are given in Table 1.

The prepared blends were mixed with sufficient amount of water and poured into the pre-assembled molds. The molds that were formed had the dimensions of 100x100x100 mm for mechanical tests and the dimensions of 20x60x150 mm for thermal tests (Figure 2)

Fig 2. Rectangular and cubical blocks samples

B. Thermal and mechanical Test

The thermal conductivities of specimens were detected by *Isomet 2104* unit, which makes measurements by using the hot wire method according to *DIN 51046*. Its range and sensitivity were 0.02-6.00 W/mK respectively and its precision was $\pm 5\%$ [9]. Each sample block was measured three times at three locations to show the average of nine values. The temperature was between 22°C and 25°C during measurement.

Compressive strength tests on the samples were undertaken according to the *ASTM C 109-80* standard. The tensile strength values calculated according to the *TS 500* standard by Eq. 1 [13].

$$f_{ctk} = 0.35\sqrt{f_{ck}} \quad (1)$$

Here;

f_{ck} : Compressive strength (MPa)

f_{ctk} : Tensile strength (MPa)

Elasticity module is mostly calculated by theoretical methods [12]. Elasticity module values are calculated according to the *TS 500* standard by Eq. (2) [13]:

$$E = 3.25 \cdot (f_{ck})^{1/2} + 14 \quad (2)$$

In this equation, E is the elasticity module (GPa), and f_{ck} is the characteristic compressive strength (MPa).

The water absorption test aimed to analyze the maximum water uptake amount. This characteristic is significant to designate whether the material is appropriate for use against freezing risks. The critical moisture amount is 30% of the total dry volume and the material does not deform when frozen below this amount. The tests were performed by complying with BS 812, Part 2 standard and keeping the samples in water.

$$\text{Water absorption} = \left\{ \frac{W_d - W_k}{W_k} \right\} \cdot 100 \quad (3)$$

In the equation, W_k is the dry weight of sample and W_d is the wet weight of sample.

The purpose of drying ratio test is to search the respiration abilities of the samples. After being left in water contained for 48 hours the samples were taken from the water, wiped with a wet piece of cloth and left to natural drying at 22°C room temperature. The drying ratio values are calculated by Eq. (4). Drying occurs through evaporation from the surface of the material; here it is about the movement of water from the depth of the material through capillary canals, meaning that moisture is expelled from the body through steam permeability resistance and drying occurs.

$$\text{Drying ratio} = \left\{ \frac{W_d - W_k}{W_d} \right\} \cdot 100 \quad (4)$$

III. RESULTS AND DISCUSSIONS

When Figure 3 is examined, it can be seen that density values of the samples decrease as EPS ratio increases. This reduction is directly related to the density of EPS. But density of the samples increase marble powder ratio decreases.

Figure 3. Density ratio of samples versus EPS and MP percentages

Considering Figure 4, it is clear that thermal conductivity drops as EPS ratio climbs. Thermal conductivity depending on EPS ratios, 20% and 80%, decreased by 81.79 %. In the case of

0% and 1.5% ratios of marble powder in the mixture the thermal conductivity increased as 28.16-17.94%.

Figure 4. Thermal conductivity variation according to EPS and MP

The Figures 5, 6, 7 shows that compressive strength, tensile strength and elasticity module values increases from 0 to 60% EPS and marble powder 1% ratios. But their values decreases after from the rate of the 1% marble powder. Because, cement and marble powder aggregate (1%) are creating a good mix

Figure 5. Compressive strength EPS and marble MP percentage relation in the specimens

Figure 6. Tensile strength EPS and MP percentage relation in the specimens

Figure 7. Variation of drying ratio of samples versus EPS and MP percentages

Almost all of the samples with resin added cement binders remained below 30%, which is the critical level for water absorption (Fig. 8). Therefore these materials can be used without the risk of freezing under 0°C temperature in places which is in contact with water.

Figure 8. Variation of water absorption ratio of samples versus EPS and MP percentages

Considering Figure 9, it is clear that the sample drying ratios diminish as the EPS particle addition ratio grows. The moisture contained in the material moves towards the surface by means of capillary channels. This indicates the material's respiration ability.

Figure 9. Variation of drying ratio of samples versus EPS and MP percentages

IV. CONCLUSION

This study was conducted to illustrate whether the use of waste EPS and marble powder in concrete was possible in place of natural aggregate materials.

Low-density concrete with EPS and marble powder aggregate can be used in panel walls, floorings and floor deck concretes as well as construction applications such as concrete briquettes, whereas blocks of plaster with the same additives can be used as insulation coating.

These materials should not be used as columns and beams components in buildings due to low compressive, tensile strength and elasticity module values of the samples.

Nevertheless, these concretes with low density are designated as flooring, ceiling and wall concrete.

The rate of water absorption of samples is less than 30%. From this result, it is concluded that these materials can be used as concrete and external plaster or inner plaster material that subjected to water

In conclusion, the concrete material containing EPS and marble powder can be used as building material and simultaneously solve the environmental pollution problem by recycling waste EPS and marble powder.

The Production of Vegetable Oil-Based Polyols and Modelling of Rheological Properties

Ercan Aydoğmuş, Müge Gür, Fethi Kamışlı
Firat University, Engineering Faculty
Elazığ, Turkey

ercanaydogmus@firat.edu.tr, gurmuge2301@gmail.com

Abstract— In this study, some vegetable-oil based polyols were produced from the different vegetables oils with the catalysts. The produced polyols compared with commercial polyols in terms of rheological properties such as viscosity, temperature, shear stress, shear rate. The rheological properties of the polyols were modelling with general equations based on experimental data. Canola, cotton, linseed, corn, hazelnut and soybean oils were used in the production of polyols. The polyol production was accomplished by oxygen bonding to the structure followed by hydroxyl bonding by breaking the double bonds in the oil. These steps were, respectively, the steps of epoxidation, hydroxylation and purification. In this study, variations of viscosities of soybean oil, cottonseed oil, corn oil, hazelnut oil, canola oil, linseed oil-based polyols and commercial polyols were determined a function of temperature. It is known that the viscosity of the fluid decreases as temperature increases. The tested polyols showed Newtonian and non-Newtonian fluids behavior at certain temperature range. According to the experimental data; the linear and non-linear regression were made to determine coefficients of regression in the model equations.

Keywords— *Vegetable oil; Polyols; rheological properties; modelling*

I. INTRODUCTION

Compared to petroleum-based polyols in polyurethane production from vegetable oil polyol produced with a smaller amount of isocyanate used. The polyurethane produced with the polyol produced from vegetable oil decreased compression resistance [8].

Wood powder was added as filler to the polyurethane derived from castor oil-based polyol. The polyurethane of the swelling time was compared with commercial polyols, and castor oil-based polyols. Effective thermal conductivity compared to commercial polyurethane material of the castor oil-based polyurethane material has been found to be lower. Increasing the filler has negative impact on the effective heat transfer coefficient. Density of polyurethane material was found to be between 36 and 39 kg/m³. TGA value of the thermal stability of the castor oil-based polyurethane material was found to be more commercially polyol product [12].

The goal of this study is to determine the rheological properties of different oil-based polyols and choose the best model complying with experimental data and the viscosity to each waste vegetable oil based-polyols are measured at different temperatures (25, 30, 35, 40, 45 and 50 °C) by using a rotary viscometer (Brookfield DV-II). Samples were sheared with several different rotational speeds at an increasing order. One of the most important parameters required in the design of technological processes in polyurethane industries is the viscosity of raw materials. Data obtained for apparent viscosity and rotational speed were used to describe the flow behavior by the model equations both in the forward and backward - measurement.

The polyols are produced from the waste vegetable oils in three consecutive steps which are epoxidation, hydroxylation and purification. The temperature of the system is kept under the control using a thermostat. When it is reached to the desired reaction temperature, the peroxides are added into the vegetable oils in acidic medium by the aid of dropping funnel in the certain time.

After the reaction is completed, the mixture is taken into separatory funnel and after for a while the mixture separates in two phases with the upper phase of the epoxidized vegetable oil. After the epoxidation step, neutralization with water and the hydroxylation starts. Especially hydroxylation with alcoholysis is frequently preferred in the production of polyols. The purification process is being carried with rotary evaporator to get rid of impurities such as water, heptane and etc. The polyols produced from the vegetable oil are being used in the production of polyurethane by checking the number of hydroxyl. The structures of the hydroxyl compounds were investigated with the FTIR spectrometer. The polyurethane was produced from the different vegetable oil-based polyols and commercial polyols. The characteristic properties of the polyurethane such as thermal conductivity, the structures of porosity, density were determined. The polyurethane produced from the different vegetable oils is compared one another in terms of thermal properties.

II. MATERIAL, METHODS AND MODELLING

In this study, a system consisting of a three necked balloon joe, thermometer, water bath, magnetic stirrer, condenser and funnel was used for the epoxidation reaction, which is the first step of obtaining polyols from vegetable oils used as raw materials. A three-necked balloon was used in the atmospheric pressure with a magnetic stirrer to heat the water bath to 325 – 330 K. A condenser system was attached to the ball of three necks and a thermometer is placed with the help of plugs. The refined oil was placed in the amount determined in a three-necked balloon with the aid of a funnel. Acetic acid, sulfuric acid and heptane were added with the necessary optimizations. Hydrogen peroxide was added dropwise to the system after reaching a temperature of 325 K, and the epoxidation step was carried out in 4 hours. After the reaction was complete, the epoxy-oil is separated off with the separating funnel. Since the epoxy-oil was acidic, the pH value was raised by washing with pure water. Neutralization was also achieved using a basic ion exchange resin. In the experimental system, the hydroxylation was carried out by adding the certain amounts of methanol, water and acetic acid to the three necked balloon. The mixture was heated to the boiling temperature of the methanol while it was stirred. When the boiling temperature was reached, epoxy-oil was added to the three necked balloon. Hydroxylation proceeded for about 2 hours. Neutralization was performed again after this step. In the last step, impurities such as water, methanol, heptane were removed by using vacuum evaporator. The hydroxyl value of the obtained polyol was determined according to ASTM D 4274 D method.

The viscosities of the polyols produced from different the vegetable oils were measured by using a rotary viscometer (Brookfield DV-II) at different temperatures (25, 30, 35, 40, 45 and 50 °C). Samples were sheared with several different rotational speeds (2.5, 5, 10, 20, 30 and 50 rpm) at an increasing order. Data obtained for apparent viscosity and rotational speed were used to describe the flow behavior by the model equations. Brookfield rotational viscometer (Model DV-II, Brookfield Engineering Laboratories) equipped with spindle 21 was used to measure viscosities of produced and commercial polyols. Enough samples nearly 8 mL in the beaker were used to immerse the groove on the spindle with guard leg. Temperature was kept constant at a desired value using thermostatically controlled electrical system. Shear rate ($\dot{\gamma}$) and shear stress (τ) were read from viscometer directly. Shear stress and shear rate can also be calculated by using Eq. (1), (2) and (3).

$$\dot{\gamma} = \beta \cdot N \quad (1)$$

$$\tau = \mu \cdot \dot{\gamma} \quad (2)$$

$$\tau = \kappa \cdot (\mu)^{\delta} \quad (3)$$

Where; N is rotational speed (rpm), τ is shear stress (Pa), μ is the apparent viscosity (mPa. s), κ is the consistency coefficient

(mPa.s), δ is flow behavior index and β is coefficient (dimensionless).

The viscosity of a blend as a function of temperature can be calculated using one of the equations given below. Here all the equations given below are used to determine how the viscosity depends on temperature. In order to choose the best model for each blend, R^2 is calculated for each model.

$$\mu_{\text{linear}} = a \cdot T + b \quad (4)$$

$$\mu_{\text{exponential}} = c \cdot \exp(d \cdot T) \quad (5)$$

$$\mu_{\text{power}} = e \cdot T^f \quad (6)$$

$$\mu_{\text{logarithmic}} = g \cdot \ln(T) + h \quad (7)$$

$$\mu_{\text{polynomial}} = i \cdot T^2 + j \cdot T + k \quad (8)$$

$$\mu_{\text{new}} = \exp(-T) + m \cdot T + n \quad (9)$$

III. RESULTS AND DISCUSSION

In this study, the temperature dependence of the viscosity of the vegetable oil-based polyols; model equations compared with experimental data. In Figures: 1, 2, 3, 4, 5, 6 and 7; the variation of apparent viscosities of polyols as a function of temperature were compared model equations with experimental results. Operating temperatures of the assay were measured by raising temperature stepwise in a water bath. The viscosities of vegetable oil-based polyols were measured by different rotational speeds at an increasing order. According to the experimental results regression coefficients of model equations (4), (5), (6), (7), (8) and (9) were determined.

In this study, variations of viscosities of soybean oil, cottonseed oil, corn oil, hazelnut oil, canola oil, linseed oil-based polyols and commercial polyols were determined a function of temperature. As expected that the viscosity of the fluid decreases as temperature increases. The tested polyols showed Newtonian and non-Newtonian fluids behavior at certain temperature range. Heating may rupture molecular entanglement and bonds may stabilize the molecular structure and reduce the effect of molecular volume in the vegetable oil-based polyols. As temperature increases, thermal energy of molecules increase and molecular distance develops due to reduction of intermolecular forces, hence viscosity of the fluid decreases.

As can be seen in Figures (1), (2), (3), (4), (5), (6) and (7) the viscosities of all types polyols irrespective of their production sources decrease substantially with increasing temperature. Heating may rupture molecular entanglement and bonds may stabilize the molecular structure and reduce the effect molecular volume in the polyols. In other words, as temperature increases, thermal energy of molecules increases and molecular distance develop due to reduction of intermolecular force and hence viscosity of fluid decreases. When thermal energy of molecules increases, molecular entanglement aligns easily and molecular structure stabilizes quickly since the molecules with high thermal energy move over one another easily.

As can be seen in Figure 8 the highest viscosity belongs to the commercial polyols while the lowest viscosity belongs to the polyol obtained from the raw hazelnut oil. The viscosities of polyols from high to low can be put in order as $\mu_{\text{commercial}} > \mu_{\text{canola}} > \mu_{\text{soybean}} > \mu_{\text{cottonseed}} > \mu_{\text{linseed}} > \mu_{\text{corn}} > \mu_{\text{hazelnut}}$, here $\mu_{\text{commercial}}$, μ_{canola} , μ_{soybean} , $\mu_{\text{cottonseed}}$, μ_{linseed} , μ_{corn} and μ_{hazelnut} denote the viscosities of commercial polyol and polyols obtained from raw canola oil, soybean oil, cottonseed oil, linseed oil, corn oil and raw hazelnut oil, respectively. Furthermore, it can be seen that all types of polyols show almost Newtonian behavior.

The regression coefficients and correlation coefficients of each model equation for each polyol obtained from different vegetable oils are given Tables 1, 2, 3, 4 and 5. As can be figured out from comparison of Tables, high values of R-squared were obtained for polynomial model irrespective of polyols obtained sources. Moreover, the developed new model has the highest values for R-squared.

In addition, density of vegetable oil based-polyols was measured to be 880 and 910 kg/m³.

The petroleum-based polyols and vegetable-based polyols have different hydroxyl numbers. The hydroxyl numbers of vegetable-based polyols were optimized by varying temperature, reaction time and catalyst.

The temperature dependent-apparent viscosity of vegetable oil-based polyols; model equations and experimental data were compared with one another.

The operating temperature of the assay was measured by raising temperature stepwise in a water bath. According to the experimental data; the linear and non-linear regression were made to determine coefficients of regression in the model equations.

Modelling Rheological Properties of some Molasses–Sesame Paste Blends

Ercan Aydoğmuş, Fethi Kamışlı
Firat University, Engineering Faculty
Elazığ, Turkey

ercanaydogmus@firat.edu.tr, fkamisli@firat.edu.tr

Abstract— In this study viscosities of some ratios of the molasses - sesame paste blends such as ratios of date, mulberry and grape with sesame paste blends at the different volume ratios (10, 20, 30, 40 and 50 %) were measured at different temperatures (25, 30, 35, 40, 45 and 50 °C) by using a rotary viscometer (Brookfield DV-II) since one of the most important parameters required in the design of technological processes in food industries.

Rheological properties of some molasses obtained for apparent viscosities and rotational speeds were used to describe the flow behavior of those blends

This study was to determine the rheological properties and develop models for some ratios of the sesame paste; mulberry, grape and date molasses blends at the different volume ratios and the viscosity of each blends was measured at different temperatures using a rotary viscometer. The viscosity of each blends as a function of the shear rate, those samples were sheared with several different rotational speeds at an increasing order.

In this study, the rheological properties of some molasses, sesame paste and their blends were investigated.

Keywords— Molasses, Sesame Paste, Rheology, Modelling

I. INTRODUCTION

Sesame paste is a pure product of sesame, without adding or removing any of its constituents. It has considerable antioxidant activity due to the major components of sesame oil. The antioxidants, sesamin and sesamol, are effective chemicals to suppress the formation of free radicals thus act as anti-carcinogenic substances. Moreover, sesame oil can resist oxidative deterioration and rancidity due to these antioxidants [1].

They determined the rheological and sensory properties of grape molasses-sesame paste blends as functions of concentrations of 2 %, 4 % and 6 % at 30, 40, 50, 60, 65 and 75 °C. They used the power law model to determine the relationship between the apparent viscosity and the shear rate. They concluded that all blends exhibited pseudo-plastic behavior. The molasses content and temperature influenced the flow behavior and consistency index values. They observed that the addition of molasses improved the emulsion stability of the blends. Temperature sensitivity of the consistency index was assessed by applying an Arrhenius-type equation [2]. They worked on the sesame paste-molasses blends by determining rheological properties of the blends at different

sesame paste concentrations (20 – 32 %) and temperatures (35 – 65 °C) by using a rotational viscometer. Sesame paste-molasses blends were found to exhibit non-Newtonian, shear thinning behavior at all temperatures and sesame paste concentrations. They concluded that the power-law model was successfully applied to the data for apparent viscosity versus strain rate. They determined that the flow behavior index, n varied in the range of 0.7 – 0.85 and the consistency coefficient, K was in the range of 282 – 2547 cP. Both parameters were significantly affected by temperature [3].

They investigated on the rheological behaviors of molasses samples (mulberry, grape, rosehip and carob molasses). Viscosity was measured at 5, 10, 15, 20 and 30 °C using a rotational viscometer in the shear rate range of 0–93 s⁻¹. They used the empirical power-law model to describe the rheological behaviors of molasses samples. In their work molasses samples were found to exhibit non-Newtonian behaviors. Arrhenius type equation was used to determine the effect of temperature on viscosities of molasses samples and thus E_a values of molasses samples were calculated. They observed that the activation energies varied from 18.509 to 74.658 kJ/mol depending on the solid contents (39.44, 60.48, 67.08, 69.68, 71.98, 74.22, 75.4 and 75.46 °Brix) [10].

II. EXPERIMENTAL STUDIES

Brookfield rotational viscometer (Model DV-II) equipped with different spindles were used to measure a viscosity as a function of shear rate. Enough samples were used to immerse the groove on the spindle with guard leg. The flow behaviors of several different blends were determined at 25, 30, 35, 40, 45 and 50 °C as forward measurement (speed increasing) and also as backward measurement (speed decreasing). Temperature was maintained at a certain constant value using thermostatically controlled electrical system.

Brookfield rotational viscometer used in the experimental work is available in our laboratory and °Brix level of each molasses was determined by using the refractometer.

III. MODELLING RHEOLOGICAL PROPERTIES

Brookfield rotational viscometer equipped with spindle 28 was used to determine viscosity of a blend as a function of shear rate. Enough samples nearly 12 mL in the beaker were used

to immerse the groove on the spindle with guard leg. Temperature was kept constant at a certain value using thermostatically controlled electrical system. The used rotational viscometer allow shear rate ($\dot{\gamma}$) and shear stress (τ) to be read directly from viscometer. Shear stress and shear rate can also be calculated by using Eq. (1), (2) and (3).

$$\dot{\gamma} = \beta \cdot N \quad (1)$$

$$\tau = \mu \cdot \dot{\gamma} \quad (2)$$

$$\tau = \kappa \cdot (\mu)^\delta \quad (3)$$

Where; N is rotational speed (rpm), τ is shear stress (Pa), μ is the apparent viscosity (mPa. s), κ is the consistency coefficient (mPa.s), δ is flow behavior index and β is coefficient (dimensionless).

The viscosity of a blend as a function of temperature can be calculated using one of the equations given below. Here all the equations given below are used to determine how the viscosity depends on temperature. In order to choose the best model for each blend, R^2 is calculated for each model.

$$\mu_{lin} = a T + b \quad (4)$$

$$\mu_{exp} = a \exp(b T) \quad (5)$$

$$\mu_{pow} = a T^b \quad (6)$$

$$\mu_{ln} = a \ln T + b \quad (7)$$

$$\mu_{pol} = a T^2 + b T + c \quad (8)$$

Equations have a lot of constants such as x , y and z .

IV. RESULTS AND DISCUSSION

A. Figures and Tables

TABLE I. CORRELATION COEFFICIENTS FOR MULBERRY MOLASSES

Shear Rate: 2,80/s Models	Constants			
	a	b	c	R^2
Linear (lin)	-182,0	59636	-	0,9147
Exponential (exp)	$3 \cdot 10^{11}$	-0,060	-	0,9926
Power (pow)	$6 \cdot 10^{49}$	-18,60	-	0,9936
Logarithmic (ln)	-56668	328275	-	0,9207
Polynomial (pol)	7,0714	-4573,4	740879	0,9883

Table I shows that values of constants in Eq. (4) – Eq. (8) and R^2 . As can be seen in Table I the power model for mulberry molasses has the highest value for R^2 ; therefore, it can be said that the best model for mulberry molasses is the power model if the value of R^2 is taken to be as an indicator of the most suitable model. The lowest value belongs to linear model and it can be said the worst model is the linear model due to the same reason.

The values of constants in Eq. (4) – Eq. (8) and R^2 for date are given in Table II. As can be seen in Table II the polynomial model has the highest value of R^2 and as explained earlier, it

can be said that the best model for variation of the viscosity of date with temperature is the polynomial model and the worst model is the linear model if a value of R^2 is taken to be as an indicator of the most suitable model.

TABLE II. CORRELATION COEFFICIENTS FOR DATE MOLASSES

Shear Rate: 2,80/s Models	Constants			
	a	b	c	R^2
Linear (lin)	-60,571	19757	-	0,8771
Exponential (exp)	$3 \cdot 10^{11}$	-0,064	-	0,9803
Power (pow)	$3 \cdot 10^{52}$	-19,86	-	0,9834
Logarithmic (ln)	-18877	109262	-	0,8845
Polynomial (pol)	3,0	-1923,6	308769	0,9919

TABLE III. CORRELATION COEFFICIENTS FOR GRAPE MOLASSES

Shear Rate: 2,80/s Models	Constants			
	a	b	c	R^2
Linear (lin)	-34,286	11096	-	0,8643
Exponential (exp)	$1 \cdot 10^{13}$	-0,079	-	0,9608
Power (pow)	$4 \cdot 10^{63}$	-24,49	-	0,9638
Logarithmic (ln)	-10685	61760	-	0,8717
Polynomial (pol)	1,7143	-1098,9	176245	0,9796

TABLE IV. CORRELATION COEFFICIENTS FOR SESAME PASTE

Shear Rate: 2,80/s Models	Constants			
	a	b	c	R^2
Linear (lin)	-23,714	8538,3	-	0,9155
Exponential (exp)	516,850	-0,020	-	0,9445
Power (pow)	$2 \cdot 10^{18}$	-6,115	-	0,9495
Logarithmic (ln)	-7385	43547	-	0,9218
Polynomial (pol)	0,9643	-622,54	101435	0,9962

Table III shows the values of constants for grape molasses in Eq. (4) – Eq. (8) and R^2 . As seen in the Table polynomial model for the changes of viscosity of grape molasses as a function of temperature is the best model since the highest value of R^2 belongs to this model and it can be said that the worse model is linear model due to the same reason.

The values of constants in Eq. (4) – Eq. (8) and R^2 for sesame paste are given in Table IV. The values for R^2 indicate that the best model for viscosity of sesame as a function of temperature is polynomial model if a value of R^2 is taken to be an indicator of the most suitable model.

Fig. 1 illustrates variations of viscosity of mulberry molasses as a function of shear rate at various values of temperature. As can be seen in the figure viscosity of mulberry molasses decreases with increasing shear rate at all values of temperature tested. As expected that the viscosity of mulberry molasses decreases with increasing temperature. As can be seen in the figure an increase in the temperature results in substantial decrease in the viscosity of mulberry molasses. Heating may rupture molecular entanglement and bonds may stabilize the molecular structure and reduce the effect of molecular volume in mulberry molasses. As temperature increases, thermal energy of molecules increase and molecular distance develops due to reduction of intermolecular forces, hence viscosity of the fluid

decreases. A decrease in viscosity with increasing shear rate indicates that the mulberry molasses exhibits pseudo plastic behavior at the all considered values of temperature. The decrease in viscosity as the shear rate is increase is related to the increased alignment of constituent molecules of the tested system [11]. The pseudo plastic behavior at low values of temperature (298 K) is more pronounced than that at high value of temperature (323 K).

Figure 1. Variation of viscosity of mulberry molasses as a function of shear rate at various values of temperature

The variations of viscosity of date molasses as a function of shear rate are illustrated in Fig. 2 for various values of temperature. As can be seen in the figure the viscosity of date molasses decreases with increasing temperature as expected. As can be also seen in the figure the viscosity of date molasses decreases with increasing shear rate at the all considered values of temperature. At high temperature ($T > 308$ K) the variation of viscosity with shear rate for date molasses is almost negligible. As expected, the effect of shear rate at low temperature is more pronounced than that at high temperature. As seen in the figure it can be said that date molasses shows pseudo plastic behavior at all values of temperature tested.

Figure 2. Changes of viscosity of date molasses as a function of shear rate at various values of temperatures

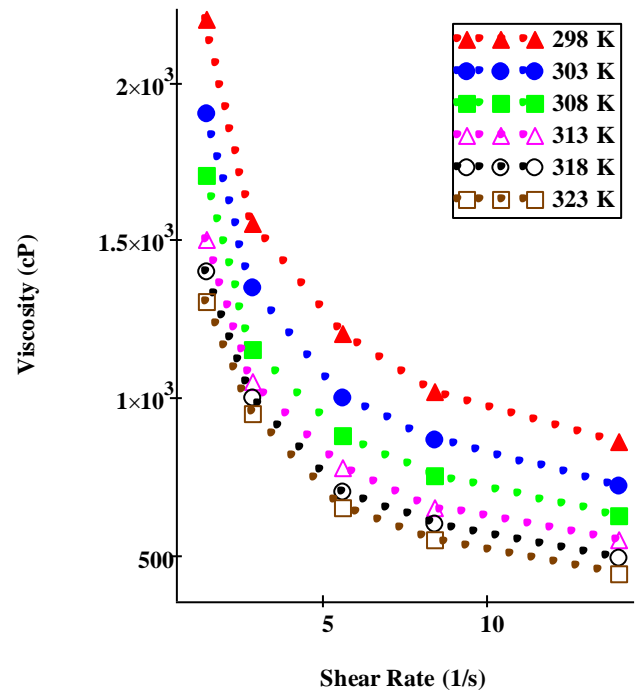

Figure 3. Variations of viscosity of sesame paste as a function of shear rate at various values of temperatures

Fig. 3 shows that variation in viscosity of sesame paste as a function of shear rate at various values of temperature tested. As can be seen in the figure the effect of shear rate on viscosity of sesame paste is very pronounced at all considered values of temperature and the viscosity decreases with increasing shear rate as evidenced in Fig. 3. As explained earlier a decrease in viscosity as shear rate is increased is related to the increase alignment of constituent molecules of the sesame consisting of oil and protein. A decrease in viscosity with increasing shear rate indicates the sesame paste exhibits pseudo plastic behavior at all temperature tested. It can be also seen in the figure the viscosity of sesame paste is very sensitive toward temperature and decreases with increasing temperature. The thermal energy of molecules increases and molecular distances develop because of reduction of intermolecular forces when temperature increases; therefore, the viscosity of fluid decreases.

Fig. 4 illustrates variations in viscosity of the blend consisting of sesame paste (80%) and mulberry molasses (20%) as a function of shear rate at the different values of temperature. As can be seen in the figure the viscosity of the blend decreases with increasing shear rate. As mentioned previously the alignment of constituent of molecules can be increased as shear rate is increased, which causes a decrease in viscosity of a fluid tested.

Even a high shear rate itself can cause an increase in temperature, in turn heating may rupture molecular entanglement and bonds may stabilize the molecular structure and reduce the effective molecular volume in protein and sugars resulting in a decrease in viscosity. As seen in the figure the viscosity of blend decreases with increasing temperature all values of shear rate tested in the present work. The viscosity of a fluid decreases with increasing temperature since, as expected, the thermal energy of molecules increases with increasing temperature and thus, molecular distances develop due to reduction of intermolecular force. At low values of temperature (298 K, 303 K), the effect of shear rate on viscosity is more pronounced than that at high values of temperature.

An entanglement of chain is progressively aligned with shear rate, an alignment that responds nearly instantaneously to changes in the imposed shear; therefore, viscosity of a fluid decreases with increasing shear rate. When alignment is completed at high shear rate, the apparent viscosity of a fluid become constant as evidenced in the figures given above. In other words, when a shear thinning fluid is disturbed by shear rate, the fluid structure deforms to align molecular entanglement while some of molecules break down as shear rate is increased.

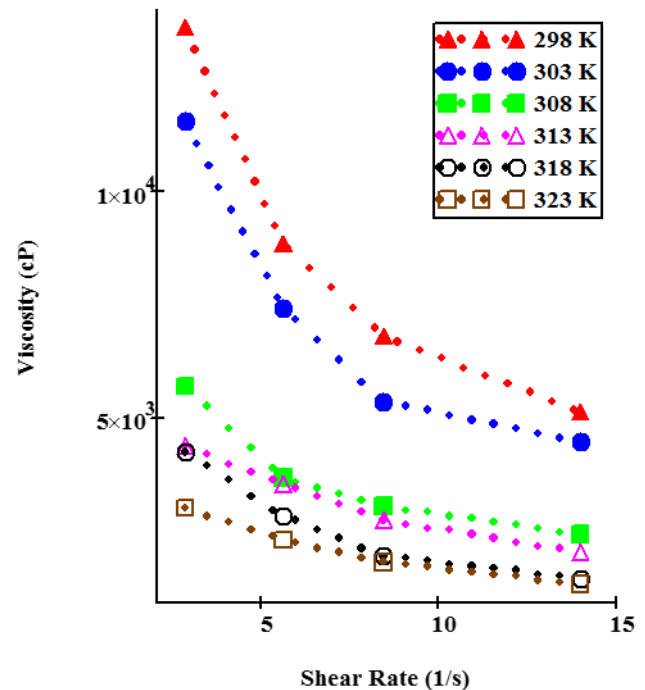

Figure 4. Changes in viscosity of the blend consisting of sesame paste (80%) and mulberry molasses (20%) as a function of shear rate at the different values of temperature.

V. CONCLUSION

Mulberry molasses, date molasses, grape molasses, sesame paste and the blend consisting of sesame paste (80 %) and mulberry molasses (20 %) were examined to determine their viscosities as functions of temperature and shear rate. In this context different equations were used to determine the relationship between temperature and viscosities of considered fluids. Furthermore, viscosities of those materials were measured as a function of shear rate at various values of temperature. It was found that all fluids tested in the present study exhibited pseudo plastic behavior. It can be concluded that temperature and shear rate are very effective parameter on viscosities of the considered fluids.

Graphene Nanoplatelet/MIL-101 Nanoadsorbents for Removal of Antibiotics

Şahika Sena BAYAZIT
Beykent University, İstanbul TURKEY
sahikasena@gmail.com

Abstract— Antibiotics in wastewater cause very serious problems. The antibiotic resistant bacterias increase and epidemic diseases can occur. So the water treatment is very important. Adsorption is a mostly used method for water treatment. Last decade, advanced adsorbents have been synthesized for this purpose. Different kinds of graphenes and metal organic frameworks take attention of researchers. In this study, graphene nanoplatelet and MIL-101 were used. Graphene nanoplatelet has high specific surface area and porosity. Also, MIL-101 has high specific surface area and porosity. The hydrothermal method was used for the preparation of graphene nanoplatelet/MIL-101 nanocomposite. And suitable purification methods were applied to the composite. XRD, TEM, SEM, BET surface area and FTIR analysis were used for the characterization of the composite. Ciprofloxacin antibiotic was chosen for the adsorption studies. Because ciprofloxacin is one of the most used antibiotic in worldwide. Adsorption variables were investigated for ciprofloxacin, in this study. And the results of bare MIL-101 and composite was compared. Composite gained higher adsorption capacity to bare MIL-101. When 1 mg of adsorbent was used for adsorption of 20 mg/L of ciprofloxacin solution, the adsorption capacity of MIL-101 was found as 15.81 mg/g but the composite was 61.56 mg/g.

Modeling of solid-liquid extraction of total phenolics from *Capsicum annuum* L.

Bilgesu Sahin, Sibel Yigitarslan
Suleyman Demirel University, Engineering Faculty
Isparta, Turkey
yildizsibel@sdu.edu.tr

Abstract— In this paper, the extraction kinetics of gallic acid equivalent of polyphenols from *Capsicum annuum* was investigated. Ethanol was used as a solvent for extraction at different temperatures and the extraction medium was set at mixed and unmixed conditions to observe the changes in the kinetics. Two different strategies were applied for modeling. In the first one, four different models; namely Peleg, Mass Transfer, Logarithmic, and Page's Models were used for mathematically describing the physicochemical behavior of the extraction. The yields of extraction ranged from 1.39-3.27 mg/g depending on the extraction conditions. Mass transfer was found the best model representing the experimental data. Molecular and effective diffusivities were calculated. In the second strategy, extraction was modeled with the aid of response surface methodology. Extraction yield surface showed a linear relation with temperature, time, and solid-to-liquid ratio. The optimum conditions of extraction were 70°C, 90 minutes and 1/50 g/ml, and 3.29 mg/g gallic acid equivalent of total phenolics were extracted at those conditions. The model equations of this process could contribute to optimize the industrial extraction process and design of drug-delivery systems.

Keywords— extraction; modeling; polyphenols; gallic acid; response surface methodology

I. INTRODUCTION

In recent years, several researchers have been focused on polyphenols of vegetables, fruits and herbs due to their contribution to human health. Phenolic compounds are capable of scavenging free radicals [1, 2], and are known as antioxidants [3]. Gallic acid, quercetin, kaempferol and catechin are well known phenolics [4-6], and they have been used especially in cancer treatments [7, 8]. One of the herbs containing gallic acid is *Capsicum annuum* L. (red pepper) from Solanaceae family. It contains calcium, phosphorus, sodium, iron, B₁, B₃, C vitamins, lipids, carbohydrates, proteins, fibers and organic compounds producing its characteristic color [9]. Researchers had been analyzed its phenolic content by HPLC analysis in detail [10, 11]. The amount and the type of phenolic components in a plant material depend on not only genotype, maturation and growth conditions of the plant [12-14], but also the type and conditions of extraction.

The studies on extraction of phenolics from *Capsicum annuum* focused on application of different type of solvents including pure methanol [15], methanol-water mixture [12, 16], pure ethanol [13, 14]. In those papers, since they paid attention to the types of flavonoids in a plant, they analyzed the extracts after hydrolyzing them. When extraction temperature was increased up to 65°C, the increase in the extraction yield was observed because of the increase in stability of phenolics due to non-enzymatic reactions [15].

All of the literature deals with the types of flavonoids in the plant, and there is scarce data on modeling of the extraction process of them. Mathematical modeling of the extraction is a useful engineering tool which facilitates the understanding, optimization, design and control of the processes with minimal time and energy consumption. There are two types in modeling of a process; namely mathematical models and Response Surface Methodology. Several equations have been proposed in the literature for mathematical modeling [17-20] and it seems that the best model differs due to the plant material and the extraction conditions. Response surface method is a combination of statistical and mathematical techniques used for analyzing several independent variables and also interactive effects among the variables on the response [21]. This method has been used in several different optimizations including adsorption, extraction, fermentation etc. in an efficient manner [22-26]. The advantages of the method are reduced number of experimental runs, cost and time [27, 9]. In addition, the final equation found by this method can adaptable to any situation faced in the industry. There is not any research aiming to combine them in a special extraction case for comparison.

This study aimed to obtain a model equation for extraction of phenolics from *Calendula officinalis* by applying two procedures for optimization. Peleg's, Page's, mass transfer and logarithmic models were applied in mathematical modelling. The molecular and convective diffusion coefficients were determined. In addition, response surfaces were constructed and the influences of temperature, solid-to-liquid ratio, and time on extraction yields were analyzed.

II. METHOD

A. Materia

In the experiments of classical extraction, *Capsicum annuum L.* was purchased from the herbalist has capable of growing this plant itself. Ethanol, Folin-Ciocalteu, and sodium carbonate were at analytical grade, and bought from Sigma-Aldrich.

B. Solvent Extraction

Ethanolic extraction was realized batch-wise in a 250 mL Erlenmeyer flask. Extraction temperature, solid-to-liquid ratio, and mixing rate were chosen as the parameters of single- and multiple-parameter experimental designs. At the end of the specified extraction conditions the content of the flask was filtered through 110 mm filters (FilterLab) and filtered samples were used for total flavonoid analysis.

C. Determination of Total Phenolics

The concentrations of the total polyphenols in the extracts filtered were determined using the Folin-Ciocalteu method. In the analysis 0.4 ml of the extract was mixed with 5.1 ml of distilled water and 0.5 ml of Folin ciocalteu reagent. 1.5 ml of sodium carbonate solution (20% by weight) was added into the medium immediately and after mixing they kept in dark during two hours at room temperature. The color resulted from the colorimetric reaction between gallic acid in the sample and the Folin reagent was analyzed by UV-vis spectrophotometer (Perkin-Elmer) at 765 nm. The gallic acid equivalents (GAE) of total phenolics were calculated from the calibration curve (Absorbance = 0.01532 x Concentration (μg/ml); $R^2=0.9989$) and the results were expressed as mg GAE/g dry herb.

D. Extraction Kinetics

Since the extraction curves (concentration of phenolics vs. time) have similar shape with the sorption curves, all of the extraction processes could be described with a non-exponential equation of Peleg [17]:

$$c_t = c_0 + \frac{1}{K_1 + K_2 t} \quad (1)$$

where c_t is the concentration of phenolics at time t (mg GAE/g), c_0 is the initial concentration of phenolics at time $t=0$ (i.e. $c_0=0$ in all experiments), t is the extraction time, K_1 is Peleg's rate constant (min.g/mg GAE), and K_2 is Peleg's capacity constant (g/mg GAE). In that equation, K_1 relates to the extraction rate (B_0) at the very beginning of the extraction ($t=t_0$):

$$B_0 = \frac{1}{K_1} \quad (\text{mg GAE/g}) \quad (2)$$

and K_2 relates equilibrium concentration (c_{eq}) at $t \rightarrow \infty$:

$$c_{eq} = \frac{1}{K_2} \quad (\text{mg GAE/g}) \quad (3)$$

Page's Model

Another model used for the mathematical modeling of the extraction proposed by Page as follows [19]:

$$c_t = \exp(-kt^n) \quad (4)$$

Logarithmic Model

In mathematical modeling of extraction processes, Logarithmic model can also be used as follows:

$$c_t = a \text{Log}t + b \quad (5)$$

where a and b are the logarithmic model constants.

Mass Transfer Model

Extraction occurs through two steps; Firstly, the solvent penetrates into the solid to dissolve the extractable material, and then the extractable material diffuses from inside the solid to the bulk liquid. The rate determining step of the overall process is the diffusion [28]. The rate of this step under unsteady-state conditions is defined by Fick's second law as:

$$\frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2} \quad (6)$$

where, c is the concentration of the solute (mg/g), t is time (min), D is the diffusion coefficient (m^2/min), and x is the distance of diffusion. This equation is valid when very dilute solution is used in the extraction and the diffusivity is assumed to be constant [29]. If the shapes of the solid particles are assumed to as perfect spheres having the same properties and also if the perfect mixing of the solid-liquid medium occurs, the time of mass transfer at infinity, the general solution of this equation becomes:

$$\text{Ln} \left(\frac{c_\infty}{c_\infty - c} \right) = 0.498 + \frac{9.87Dt}{R^2} \quad (7)$$

where, c is the concentration of the extracted material in the solution at time t (mg/g), c_∞ is the concentration of the extracted material at time $t=\infty$, and R is the characteristic distance (m); i.e. for spheres it is equal to the radius. This equation can be rewritten as:

$$\text{Ln} \left(\frac{c_{eq}}{c_{eq} - c} \right) = a + K_{obs}t \quad (8)$$

Since c_∞ is considered as equilibrium concentration, a is a constant (0.498), and

$$K_{obs} = \frac{9.87D}{R^2} \quad (9)$$

In this research, Equation 8 was used to fit the experimental data and to obtain a, K_{obs} and diffusion coefficient values.

Validity of Model Prediction

The consistency between the predicted and experimental data evaluated by using the coefficient of determination (r^2), which is defined as:

$$r^2 = 1 - \frac{\sum_{i=1}^n (y_i - y_{model})^2}{\sum_{i=1}^n (y_i - y_{mean})^2} \quad (10)$$

where, n is the number of samples, y_i is the actual experimental data of the i th sample, y_{model} is the model-fitting data of the i th sample, and y_{mean} is the mean value of all experimental data. A high r^2 value indicates high consistency between the fitted and experimental data.

E. Response Surface Methodology

In designing the experiments, firstly, the potential design factors of extractions, namely extraction temperature, solid-to-liquid ratio, time and mixing rate were studied to determine the most effective three parameters on the extraction yield by single-parameter procedure. It was found that mixing rate was not as effective as the other parameters (data not shown). Then, Box-Behnken design (BBD) was constructed for analysis of multi-parameter effects. The highest levels of respective parameters producing the highest yield were chosen as the center point values (coded as “0” in Table 1) of the optimization of the extraction, while the least and the highest values were used as minimum and maximum points (coded as “-1” and “+1” in Table 1), respectively. The chosen independent variables were coded according to (1).

Table 1. levels and codes of experimental parameters used in Box-Behnken design

Parameter	-1	0	+1
x_1 : Temperature ($^{\circ}\text{C}$)	30	50	70
x_2 : Time (min)	30	60	90
x_3 : Solid/liquid (g/mL)	1/30	1/40	1/50

$$x_i = \frac{x_i - x_0}{\Delta x} \quad (11)$$

where x_i is the dimensionless coded value of i th independent variable, x_0 is the value of x_i at the center point, and Δx is the step change value. The behavior of the system is explained by the following second-order polynomial model:

$$Y = \beta_0 + \sum_{i=1}^k \beta_i x_i + \sum_{i=1}^k \beta_{ii} x_i^2 + \sum_{i=1}^{k-1} \sum_{j=2}^k \beta_{ij} x_i x_j + \varepsilon \quad (12)$$

where Y is the predicted response, x_i, x_j, \dots, x_k are input variables, which affect the response Y , $x_i^2, x_j^2, \dots, x_k^2$ are the square effects, β_0 is the intercept term, $x_i x_j, x_j x_k$ and $x_i x_k$ are the interaction effects, β_i ($i = 1, 2, \dots, k$) is the linear effect, β_{ii} ($i = 1, 2, \dots, k$) is the squared effect, β_{ij} ($i = 1, 2, \dots, k$) is the interaction effect, and ε is the random error [30-31].

The Design-Expert 9.0 (Stat-Ease Inc., Minneapolis, MN, USA) software was used for regression and graphical analysis of the experimental data to fit the equations developed. Design of fifteen experiments consisting of three replicates at the central point was fitted into a polynomial model. The optimum values of the selected variables were obtained by solving the regression equation in which desired values of the process responses were set as the optimization criteria.

III. RESULTS AND DISCUSSIONS

The aim of the present study was to determine the mathematical equation fitting to the experimental results of batch extraction yields. Two different optimization methods were applied to reach this aim by plotting the values of gallic acid equivalent of total phenolics extracted versus time for different extraction conditions.

In the first approach, four different mathematical relations defining the physicochemical behavior of extraction were chosen; i.e., Peleg's, Mass transfer, Logarithmic, and Page's equations. The models were statistically analyzed and compared with their respective determination of coefficient (r^2) value. The constants of respective models and their r^2 values were summarized in Table 2.

As it can be seen from Table 2, Peleg's model was not as successful as other methods applied. Mass transfer model produced the highest value of determination of coefficient and the a-values were close to its exact value of 0.498. Although, values of determination of coefficient in mass transfer, logarithmic and Page's models were all acceptable, it seemed that logarithmic model caused more reliable results than the others because it produced nearly the same values for regression coefficients under different extraction conditions. In the literature, different models were found as the best model on the kinetic analysis of extraction depending on the different plants and extractable materials [19,32-34]. It is impossible to compare the kinetic results of this research with the one in the literature that focused on the extraction of total phenolics from *Capsicum annuum* since there is not any research focusing on it.

Table 2. model parameters of extraction kinetics

PELEG'S MODEL			
	K ₁	K ₂	r ²
70°C-molecular	3.0392	0.3048	0.8414
70°C-convective	1.1899	0.326	0.7463
MASS TRANSFER MODEL			
	K _{obs}	A	r ²
70°C-molecular	0.0361	0.4247	0.9804
70°C-convective	0.0370	0.5534	0.9187
LOGARITHMIC MODEL			
	A	b	r ²
70°C-molecular	1.2769	0.5614	0.9662
70°C-convective	1.1163	1.0375	0.9146
PAGE'S MODEL			
	K	n	r ²
70°C-molecular	0.2338	0.3723	0.9704
70°C-convective	0.4461	0.2227	0.9723

In the detailed analyses of the models, results were employed by plotting the calculated values of concentrations for each model and their respective experimental values (Figures 1-8) vs. time. As it was expected from its lower r² value, high discrepancies between concentrations estimated by Peleg's equation and experimental data were observed in both molecular (unmixed extraction medium; Figure 1) and convective extractions (mixed extraction medium; Figure 2). Comparing the other three models, the excellent fitness between the experimental data obtained under unmixed extraction medium conditions at 70°C and estimated concentrations of phenolics were obtained by mass transfer model (Figure 3). Either in logarithmic or Page's model equations caused less (especially in logarithmic model; Figures 5 and 6) or higher estimated values under all conditions (Figures 7 and 8). Figures clearly showed that, extraction yield increases rapidly at the beginning of extraction due to high driving force (concentration difference between solid and solvent), and that this increase getting lesser as the time passes due to decrease in driving force. In each case, extraction is reached equilibrium at the end. This behavior is explained by the mass transfer model appropriately. From Equation 9, the molecular and convective diffusion coefficients were calculated as $2.67 \cdot 10^{-10} \text{ m}^2/\text{s}$ and $2.73 \cdot 10^{-10} \text{ m}^2/\text{s}$ by using the average diameter of the particle size of 0.27 mm, respectively. According to the results, a 2.2% increase of diffusion coefficient with mixing was observed. This result was in accordance with the single-parameter effect

analysis in which mixing rate was found less effective than the other parameters on extraction yield. In addition, the yields were determined as 3.11 mg GAE/g and 3.27 mg/GAE for molecular and convective extractions, respectively. As a result, the increase in diffusion coefficient yielded nearly 5% increases in extraction.

Figure 8. The experimental data obtained at 70°C under mixed extraction medium fitted to Page's Model

In the second procedure of optimization of extraction, three-parameter three-level Box-Behnken design applied within response surface methodology. In the study, the calculated values of gallic acid equivalents of phenolics (Table 3) at respective conditions were entered into the Design-Expert 9.0 software. In the experiments the yield of extraction ranged from 1.45 to 3.30 mg GAE/g depending on the extraction conditions. The standard deviation of experimental results at the center points was 2.2%. All of the suggested functions were investigated by applying statistical analysis of the program, and the linear model was found to be the best function (Table 4) representing the extraction surface of the total polyphenols from *Capsicum annuum*. In this decision, the highest regression coefficient ($R^2=0.9834$), and the highest fitness in between the experimental data (actual) and their respective calculated values of the function (predicted) were considered (Figure 9). The symmetrical relationship between them (Figure 9) approved the applicability of the function chosen.

Generally, second order polynomials found the most appropriate functions when response surface methodology was applied to the systems [28-29]. This observation results from the interrelation of parameters on the process response.

In this study, the interactive effects between parameters were so low that the linear relations were found as enough for presentation of the extraction surface. This was approved by the statistical analysis of software function in which showing the model as “significant”, and lack of fit as “insignificant” (Table 4). The larger the F value and the smaller the p value, the higher the effect of the parameter on the extraction of the flavonoids of this plant. So, the dominant parameter was determined as temperature, whereas the least effective parameter was solid-to-liquid ratio. This result showed that at the extraction conditions, liquid had capable of dissolving all of the phenolic compounds in the solid.

At this point, three-dimensional response surfaces were constructed in this study by using software. The interactive effects of the parameters were shown in Figures 10-12. In those, red regions shows the highest amount of total flavonoids extracted, yellow and blue parts represent the lower and much lower extraction yields than those. As it can be seen from figures, extraction temperature must be in the coded range of [0.5;1] for the highest flavonoid extraction.

Fig. 10. Three-dimensional response surface of extraction yield depending on time and temperature

Fig. 12. Three-dimensional response surface of extraction yield depending on temperature and solid/liquid ratio

As a result, the empirical relation explaining the response surface was found as:

$$\begin{aligned} \text{Gallic acid (mg/100g)} &= +232,96487 + (73,42587) \cdot \text{temperature} + (16,48363) \cdot \text{time} \\ &+ (6,37150) \cdot (\text{solid/liquid}) \end{aligned} \quad (13)$$

Finally, the required extraction conditions were analyzed by using this equation and numerical analysis section of the software. In the analysis, restrictions of the parameters were selected as “in range” (has a meaning that they are in the experimental range), and the response criterion was determined as “max”. As a result of the multi-parameter optimization, the optimum conditions producing the highest yield (5.29 mg GAE/g) were determined as 70°C, 90 minutes, 1/50 g/mL.

V. CONCLUSION

This research investigated the extraction of gallic acid equivalents of total phenolics of red pepper. At the experimental conditions of the study, the yield and kinetics of solid-liquid extraction were influenced especially by temperature. The extracted total phenolics were in the range of 1.39-3.27 mg GAE/g. Mass transfer model found as the most suitable model for the extraction kinetics of phenolics from red pepper. Temperature increased the diffusion coefficients. The results of this work could contribute in the optimization of extraction of total phenolics from *Capsicum annuum* and in the design of drug-delivery systems including them in where the same value of diffusion coefficient may be more “natural” to the human body cells.

Abstract— In this study, a new non-enzymatic glucose sensor was developed based on Pd-Au nanoparticles were synthesized by using carbon support material. Synthesized nanoparticles were characterized and carried out glucose measurement by cyclic voltammetry method. The linear calibration graphs were obtained in the concentration range of 0.05-6.55 mM glucose.

Keywords— Glucose; Pd; Au; Nanocatalyst

I. INTRODUCTION

Glucose; it is a monosaccharide with 6 carbons which can be found in single chain or ring structure and high polar structure, easily broken off in water (1). Also is one of the most important carbohydrates for living organisms. For example, the concentration of glucose in a healthy person's blood should be 4.4-6.6 mM (2). The high level of glucose in the bloodstream leads to diabetes, which is a common disease nowadays (3).

At present, quantitative determination of glucose in the bloodstream is still one of the active research topics, and has received wide interest in determining the amount of glucose. Spectroscopic (4) and electrochemical (5) methods are used. The simplicity of electrochemical methods is very advantageous for the determination of glucose. Nanotechnology; today is an important discipline in science and technology (6). Nanomaterials have been interesting molecules in sensor applications due to some features such as small size, large surface area. In addition, nanoparticles are effective markers that increase signaling in the electrochemical determination of analytes. Conductivity properties of metal nanoparticles allow the design of material structures with controlled electrochemical functions (7). For example, gold nanoparticles (AuNp) are among the other metal nanoparticles are the most frequently used nanoparticles (8). In this study, a novel electrochemical sensor was developed that is glucose-sensitive and enzyme-free. The most serious problem of enzymatic sensors; It is easily affected by factors such as pH, temperature, substrate

concentration, and the disappearance of enzyme activity. In addition, enzymes have high cost.

II. EXPERIMENTAL PROCEDURE

Voltammetric measurements were carried out using CHI 660E Electrochemical Analysers with a three electrodes system consisted of a working electrode (bare GCE, Nafion/GCE, Pd-Au-NNGCE), a platinum wire counter electrode and an Ag/AgCl (sat.KCl) reference electrode, respectively. Cyclic voltammetry (CV), Chrono Amperometric (CA) were used throughout the electroanalytical studies. The pH measurements were made with Autolab analyzer meter pH. Magnetic stirrer model was Isolab.

GCE was activated by polishing with different grade of Al_2O_3 slurry (0.05-3 micron) on a synthetic cloth then rinsing with pure water and then ultrasonicated for 3 minutes in ethanol/ultrapure water (1:1 v/v) mixture. GCE was also electrochemically cleaned by keeping 10 minutes at constant potential at 1.0 V. For the electrode preparation, 5 mg of catalyst was dispersed in 1 mL of Aldrich 5% Nafion solution to obtain the catalyst ink. Then 5 μL of the ink was spread on the surface of the glassy carbon electrode. The electrode was dried at room temperature to remove the solvent.

Carbon supported PdAuNPs catalysts were prepared by polyol method. To investigate the effect of addition to glucose the carbon supported PdAuNPs catalysts were prepared at different Pd:Au (90:10, 80:20, 70:30, 50:50) atomic ratios. Then, the non-enzymatic glucose sensing activities of these catalysts were measured by electrochemical techniques.

III. CHARACTERIZATION

SEM images can effectively prove the morphological surface characterization of the modified electrodes. In the current study, the surface chemistry and morphologies of electrodes prepared using chemical reduction procedures were characterized by scanning electron microscopy, energy

dispersive X-ray spectroscopy (EDX) and X-ray photoelectron spectroscopy.

Scanning electron microscopy (SEM) and energy dispersive X-ray (EDX) measurements were carried out using a FEI QUANTA 250 FEG scanning electron microscope. X-ray diffraction (XRD) patterns were recorded by means of Rigaku RadB-DMAX II with an area detector that used a Cu K α source ($\lambda = 1.54056 \text{ \AA}$). Samples were obtained by depositing carbon-supported nanoparticles on a glass slide and then drying overnight under vacuum.

IV. RESULTS AND DISCUSSION

A. X-Ray Diffraction (XRD) characterization of the Pd-Au/C catalysts

Surface crystallographic information of Pd/C and Pd-Au/C catalysts were obtained from the XRD measurements. The diffraction patterns show that the structure can be indexed using Pd face centred-cubic (fcc) lattice, with (111), (200), (220) crystal planes. The diffraction peaks in the Pd-Au/C the catalysts are slowly shifting to higher heights. 2θ values refers to the formation of an alloy between Pd and Au relative to corresponding peaks in the Pd / C catalyst. (Figure 1).

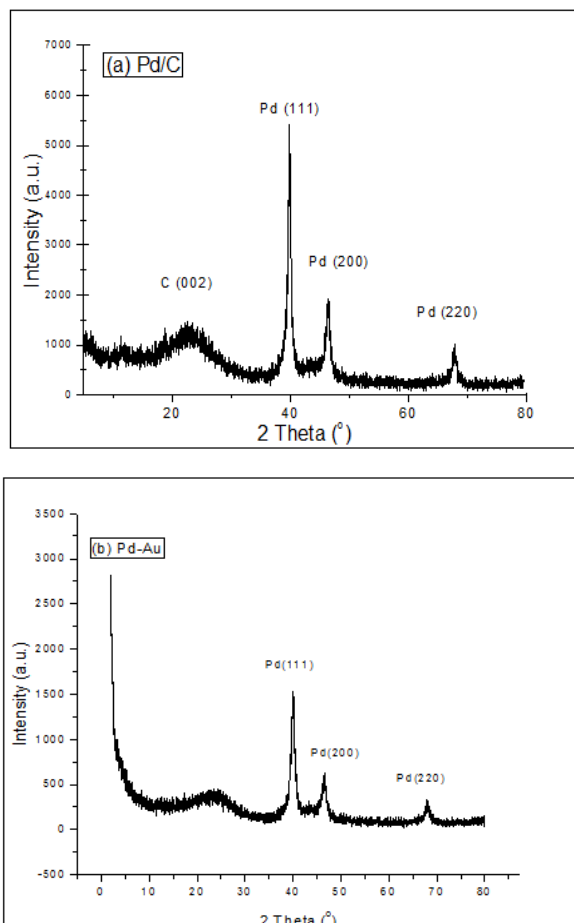

Figure 1. XRD patterns of (a) Pd/C, (b) Pd-Au/C catalysts.

B. SEM-EDX Measurements

SEM images of Pd-Au/C electrodes have presented in Figure 2a. and the EDX spectrum for Pd-Au/C is expressed at the same time 2b. For the Pd-Au/C catalyst, EDX analysis exhibited the presence of Pd and Au. With respect to EDX results, Pd-Au/C catalyst have 72.25: 27.75 Pd/Au atomic ratio, good agreement with the stoichiometric ratio 70:30 used in the preparation procedure.

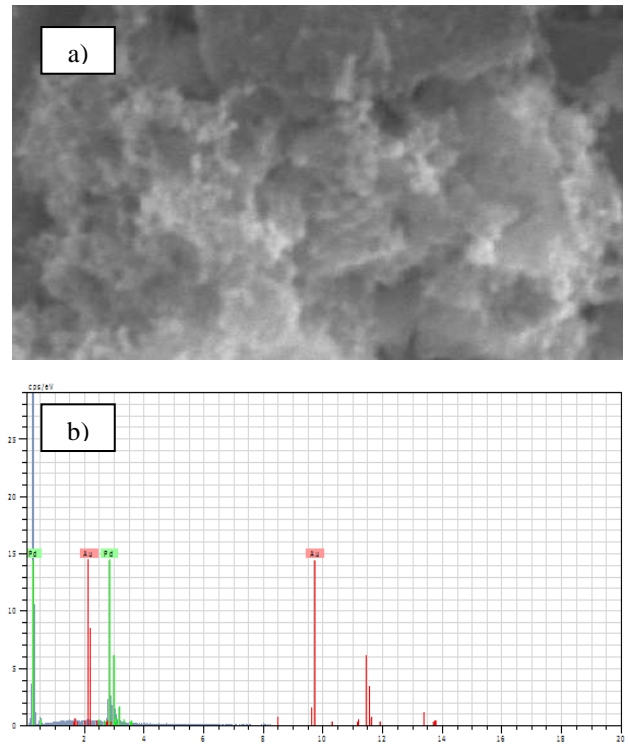

Figure 2. a) SEM images of Pd-Au/C and b) EDX spectra of Pd-Au/C catalysts.

C. Electrochemical characterization of Glucose over the Pd-Au/C

The voltammetric behavior of glucose at various atomic ratio (Pd₉₀:Au₁₀, Pd₈₀:Au₂₀, Pd₇₀:Au₃₀, Pd₅₀:Au₅₀) was investigated at 0.1 M phosphate buffer solution with a scan rate of 100 mV s⁻¹.

Firstly, glucose measurements were performed in the 6.55 mM concentration for the Pd₉₀:Au₁₀, Pd₈₀:Au₂₀, Pd₇₀:Au₃₀, Pd₅₀:Au₅₀ catalysts (Figure 3).

Figure 3. CV of the 4 synthesized catalysts with the highest current density in 0.1 M phosphate tested at a scanning rate of 100 mVs⁻¹.

Figure 5. Cyclic voltammograms at various scan rates 10, 20, 30, 40, 50, 60, 70, 80, 90, 100 mV s⁻¹

Figure 4. Effect of concentration of glucose in 0.1 M phosphate tested at a scanning rate of 100 mVs⁻¹.

The best current value was obtained at 6.55 mM. Scan rate experiments were carried out for 6.55 mM glucose concentration and atomic ratio Pd₇₀:Au₃₀. Under these conditions, the reaction mechanism is clarified with the scan rate studies. (Figure 5)

Cyclic voltammogram of Pd-AuNPs/C in 0.1 M PBS electrolyte shows one oxidation potential at -0.5 V and one reduction peak potential at -0.1 V. In addition to, observed peak potential shifted more positive potential by increasing scan rate (Figure. 5). This phenomenon could be attributed to irreversible electrode process.

Figure 6. The plot of the peak current (Ip) against the square root scan rates (v^{1/2})

The peak current increased with the square root of the scan rates (Figure 6). This result showed that Pd-AuNPs/C catalyst was controlled by diffusion of electrode surface.

V. CONCLUSION

The aim of this work was advisable a new non-enzymatic glucose sensor based on activated carbon, which was prepared in polyol method. Especially, experimental results showed that Pd-Au/NPs were able to catalyze the electro-reduction of glucose by modified electrode with Nafion solution and displayed a good catalytic activity to glucose.

Abstract -The increasing need for water in the world brought along the need to improve the processes of drinking water production from waste waters, sea, and lake waters. Bipolar membrane processes recently joined the ion exchange membrane processes as among the most effective separation processes. Three-compartment electrolysis comprises three separate membranes: anion exchange and cation exchange membranes, and a special membrane called a bipolar membrane. In these three separate ion exchange membranes and the compartments separated by these membranes, the cationic components of water are separated by the cation exchange membrane and transferred to the base compartment. The anionic components of water are separated by the anion exchange membrane and transferred to the acid compartment, and the water is simultaneously separated and cleansed of both its anionic and cationic components. This system enables simultaneous production of drinking water and of acids and bases.

In our previous study, we determined that this type of electrodialysis costs less than usual electrodialysis techniques. In regions, such as Turkey where seas have low salinity, and lakes and rivers contain heavy metals at low levels, it is easy to obtain drinking water using this method. Moreover, previous studies obtained very valuable acids at diluted concentrations, including HF and HBr.

Abstract—*In this study, ZSM catalysts were synthesized and the effects of synthesized zeolite in catalytic cracking were investigated. ZSM types were synthesized by varying synthesis time, synthesis method and calcination temperatures. The composition of the synthesis was kept constant and then compared with ultrasonic method and hydrothermal method.*

Two different ZSM derivative was synthesized with changing the synthesis method. Beta zeolite is obtained as a result of the synthesis with low temperature in 20 minutes with using of ultrasonic method. On the other hand, ZSM-5 zeolite is achieved at the end of the synthesis with high temperature in 72 hours with using of hidrothermal method.

The X-Ray Powder Diffraction (XRD) patterns and Scanning Electron Microscopy (SEM) images of ZSM-5 zeolites showed that the crystal structure and phase purity of ZSM-5 increased with increase in synthesis time and not affected by the calcination temperature. Otherwise, the crystal structure and phase purity of beta zeolite increased with increase in calcination temperature.

To determine the catalytic performances of the products, the catalytic cracking processes were performed. First of all, thermal cracking was realized without catalyst for comparison with the others. Then, catalytic cracking was carried out with CaO, Al₂O₃, SiO₂, natural zeolite, ZSM-5 and beta zeolite.

Comparing the results, the catalytic efficiency of the synthesized products were higher than the others. Yield of over 70 % was obtained with synthesized ZSM-5 and zeolite beta.

Abstract— Coumarin derivatives are an important group of compounds of synthetic and natural organic chemistry. The compounds with carbonyl group in the α -position of the benzopyrane ring are called coumarin (2H-1-benzopyrane-2-one). Coumarin analogues possess different physical properties [1]. In this study, 6,7-dihydroxy-3-(3-chlorophenyl)coumarin (CFHC) was obtained according to method in the literature [2]. We aimed to investigate the dielectric constant, dielectric loss and ac conductivity of CFHC at different mole ratios of Cu⁺² metal ions as a function of frequency.

Dielectric measurements for CFHC were carried out by means of an impedance analyzer as a function of frequency. Dielectric properties of samples prepared in a plate form were measured at room temperature over the frequency from 100 Hz to 20 kHz and given as compared with each other [3].

The dielectric measurements were realized by adding the increasing amounts of Cu²⁺ to a solution of CFHC, and remarkable decrease was detected.

Keywords— dielectric properties, Cu+2-doped, coumarin

A Holistic Analysis of Biogas Energy and Its Potential

Berrin KURŞUN
Marmara University Faculty of Engineering,
Istanbul, Turkey
berrin.kursun@marmara.edu.tr

Abstract— Lots of the heavy metals and their salts are widely used in the industrial applications. As a result of their widespread use, heavy metal pollution in waters is an important environmental problem encountered at industrial areas. Heavy metals are extremely toxic and their adverse effects can last for a long time in nature. Therefore, the wastewater containing heavy metals must be treated with an effective treatment method such as chemical precipitation, ion exchange, membrane processes and adsorption before the discharging [1]. Among these methods, adsorption is recognized as a promising method owing to the properties of high adsorption capacity, easy operation, low-cost and eco-friendly nature.

Usages of the low-cost adsorbents such as agricultural wastes and residuals, metallurgical slags, fly ashes and different minerals have been used or tested for heavy metal removal from the wastewaters recently [2-6]. Agricultural wastes or residues have become the subject of considerable interest due to their low cost, abundant and readily available. Starting from this information, in this study; effects of some parameters such as pH, adsorbent dosage, contact time, particle size, initial Pb(II) concentration and temperature on Pb(II) removal from aqueous solutions by agro-based adsorbent prepared from grape stalk were investigated. The data was analyzed with first and second-order kinetics models and Langmuir and Freundlich adsorption isotherms. It was found that the adsorption kinetics followed the second-order rate law and adsorption fitted to the Langmuir isotherm. The Pb(II) maximum adsorption capacity of the grape stalk was calculated to be 32.8947 mg/g at 25°C.

Abstract— *Biological weapon agents that manifest themselves by affecting human metabolism can spread in the form of outbreaks, leading to the death of hundreds, thousands or even millions of people in the world. However, some people think that the construction of such weapons is even chilling, these weapons are stockpiled in high quantities in some countries. Especially, yet bioterror agents are highly resistant to a variety of condition and can lead to serious diseases, when exposed to even the lowest dosages. With the decoding of the gene map, the production of more efficient microbiological weapons, which can be obtained at a lower cost instead of the present technological weapons, has gained importance. Today, bio-terrorism, whose impact limits are not yet known, uses toxins, which have many biological activities such as bacteria, viruses and sports. For this reason, there will also be a need for biosensors that will allow early identification of diseases that can be caused by toxins of this type which are potentially usable as weapons in future generations. Thanks to nanobiotechnology, which has developed in parallel with nanotechnology, many biochips can be designed with different techniques today. One of these techniques is polymeric brush-based biochips prepared on macroscopic surfaces (gold, glass, silicon, etc.) and exhibiting biological activity after appropriate functionalization at the nanoscale.*

In the present study, a novel hybrid biosensor composed of polymer brush coated magnetic nanoparticles and gold nanoparticle was prepared for detection of Botulinum toxin which is the most important bio-terror agent. Surface compositions and other characteristic features of the prepared polymer brushes was investigated by X-Ray Photoelectron Spectroscopy (XPS), Grazing Angle Fourier Transform Infrared Spectroscopy (FTIR). The characterization of the prepared nanoparticles was carried out by UV Spectrophotometry and Transmission Electron Microscope (TEM). The feasibility of the prepared hybrid systems as a SERS-based sensor was investigated by determining the limits of detection with various real samples (milk, product, juice, etc.).

Keywords— *Magnetic nanoparticle, polymer brush, Botulinum toxin, SERS*

Adsorption Effects of Clay, Treated With Acid at Different Concentrations

Tülay ARASAN

Abstract— The purpose of this study examining changes imposed by heat effects in adsorption capacity, structures of clay that used as natural adsorbent. The clay samples were synthesized by subjecting clay with acid at different concentration at 200 °C. Adsorption studies are done with obtained clay samples and adsorption capacities of them are found. The structure and surface properties of clay were examined by FTIR, XRD, SEM, TGA- DTA, Boehm titration, and adsorption of methylene blue and iodine.

In this study, a clay sample from Battalgazi / Malatya region selected as the material and after sample is broken with the aid of suitable breaker and grinding clay minerals were obtained under 200 by sieving with the help of molecular sieves. After the clay sample dried in the oven at 105 °C for 24 hours. Then effect of temperature examined with acid, H_3PO_4 in different concentrations (0.5N, 1N, 2N) was mixed with clay 1:3 ratio for 2 hours at 100 °C and 1 hour the product was processed in the furnace ash at 500 °C. Adsorption from aqueous solutions of copper is done with these samples. For this 500 ppm $CuSO_4 \cdot 5H_2O$ stock solution was prepared. 0,1 gram sample was stirred with solutions whom concentrations are 100, 200, 300, 400, 500 ppm 1 hour at 25 °C. Then quantity of Cu was recorded by measuring the filtrate obtained [1,2]. The structure and surface properties of obtained clays were examined by SEM, FT-IR, XRD, Boehm titration, and adsorption of methylene blue and iodine. One of the most widely used methods for the quantitative determination of the organic structural functionality of carbonaceous materials is the Boehm titration. With NaOH, Na_2CO_3 , $NaHCO_3$ compounds, various surface functional groups can be distinguished from each other. The carboxylic groups in the structure can be quantitatively determined by $NaHCO_3$ interaction, lactic groups Na_2CO_3 interaction and phenolic groups NaOH interaction [3,4]. The pH values were also found to be in the acidic zone. Another process with temperature was investigated using different concentrations of H_3PO_4 with SEM. Different constructions can be seen in which the amount of concentration can form within the structure. When the concentration is taken as 2N, a sedimented porous environment emerges from the whole SEM image. FTIR analysis of materials has an important place in terms of structure of a molecule, molecular bonds and functional groups. Decrease in the strength of the carbonates and OH groups in the structure resulting from the chemical treatment with phosphoric acid occurs. This change is supported by the decrease in the number of phenolic groups in the Boehm titration.

Adsorption from aqueous solutions of copper is done with each sample. Then amount of Cu was calculated and was observed that adsorption compliance with Freundlich isotherm. It has been found that the adsorption capacity increased with increasing concentration.

Abstract— Clay and clay minerals, has been one of the common workspace art, in many disciplines. Today, clays plasticity, moisture retention and strength besides organic or displacement with iodine all kinds of inorganic, high adsorption and other technological properties such as catalytic activity are used as industrial raw materials in the area of more than 100. Regarding the use of clay areas; from ceramics and cement production; paper, petrochemical and construction industries; vegetable oil, beer, wine and fruit juices of the bleached; radioactive waste and waste water to be cleaned; medicine, soap, detergent, diaphragm, electrodes, catalyst, rubber and plastic production can be listed a wide range of area [1, 2]. Adsorption properties of clay are due to wide surface area, surface functional groups and microporosity. Clay allowing them to use for different purposes in different areas, they have the common presence of clay minerals in nature are superior chemical and physical properties [3]. The purpose of this study examining changes imposed by heat effects in structures of clay that used as natural adsorbent. The clay samples were synthesized by subjecting clay with base at the same concentration, different temperature.

In this study, a clay sample from Battalgazi / Malatya region selected as the material and after sample is broken with the aid of suitable breaker and grinding clay minerals were obtained under 200 by sieving with the help of molecular sieves. After; the clay sample dried in the oven at 105 °C for 24 hours. Then NaOH particles added onto clay sample directly at 300 °C; 400 °C; 500 °C; 600 °C; 700°C [4, 5]. The structure and surface properties of obtained clays were examined by SEM, FT-IR, XRD, Boehm titration, and adsorption of methylene blue and iodine. The results of boehm titration shows that the presence of phenolic groups has little effect. According to SEM results, it is seen that the porosity distribution in the structure differs with the changing temperature. In XRD runs; as a result of the heat treatment with NaOH, a decrease in crystallinity is observed with increasing temperature. SEM images support this situation.

Decolorization of Jakofix Yellow Dye Solutions by Electrocoagulation

Zürriye Gündüz

Balıkesir University, Engineering Faculty

Balıkesir, Turkey

zyilmaz@balikesir.edu.tr

Abstract— The textile industry is regarded as a significant threat to groundwater resources due to both the large water demands and the production of effluent, containing significant concentrations of dyes, surfactants, suspended solids and organic matter. Between 1% and 15% of dye is lost during the dyeing process and is released into the wastewater with toxicity to microorganisms and humans. Most dyes are resistant to biodegradation due to their design requirements to withstand both oxidizing and reducing conditions, washing and light exposure. A pretreatment for removing toxic dyes and decolorization is therefore necessary before biological degradation processes can be employed. Much attention has been paid to methodologies for the removal of dyes from colored effluents; electrochemical oxidation, adsorption and coagulation, nanofiltration and reverse osmosis, enzymatic decolorization and ozone oxidation, some of which have been applied by industry.

In this study, treatment of synthetic wastewater containing Jakofix Yellow dye by electrocoagulation (EC) has been investigated in a batch process reactor with iron electrode. Effects of process parameters such as operating time (5, 10, 15, 20, 25, 30, 35, 40 and 45 minutes) and current for EC process are investigated on dye removal efficiency. After the electrocoagulation process, all samples are measured for pH, concentration, temperature and conductivity. Concentration determination is studied with spectrophotometric method at $\lambda=420$ nm wavenumber. The study revealed that at a neutral pH there was a colour removal efficiency of almost 100% with minimum electricity consumption. These performance characteristics indicate that the EC may be more promising in terms of practical application, as a cost-effective treatment for textile dye removals.

Synthesis and Characterization of Iron Nanoparticles Using *Eriobotrya japonica* Leaves Aqueous Extract for Effective Adsorption of Cr(VI)

Emel Simal ÖNAL, Tolga YATKIN, Tural ASLANOV, Memduha ERGÜT, Ayla ÖZER

Mersin University, Faculty of Engineering, Department of Chemical Engineering
Mersin, Turkey

memduha.ergut@gmail.com, ayozer@mersin.edu.tr

Abstract— In this study, Fe nanoparticles (FeNPs) were synthesized via a green method using loquat (*Eriobotrya japonica*) leaves aqueous extract as a renewable reducing agent. The synthesized FeNPs were characterized by DLS, XRD, FTIR, and SEM/EDX analysis and they were used as a sorbent for Cr(VI) removal from aqueous solutions. Batch adsorption experiments were carried out to investigate the optimum adsorption parameters such as the solution pH, temperature, initial Cr(VI) ion concentration and adsorbent concentration. The optimum adsorption conditions were determined as pH 3.0, temperature 45°C, initial Cr(VI) concentration 100 mg/L and adsorbent concentration 1 g/L. The biosynthesized FeNPs showed the high removal levels higher than 90% for Cr (VI) adsorption at a wide range of initial metal ion concentrations (50 - 500 mg/L) at optimum temperature. The experimental equilibrium data were modelled with Langmuir and Freundlich isotherm models and it was found that, experimental equilibrium data could be well described by Langmuir isotherm model. The maximum monolayer coverage capacity of FeNPs for Cr (VI) adsorption found to be 312.5 mg/g. The pseudo-first order and the pseudo-second order kinetic models were applied to the experimental adsorption data and it was concluded that the data were defined the best agreement with the pseudo-second order kinetic model. Weber Morris model was used to investigate the effect of mass transfer on the adsorption of Cr (VI) onto FeNPs, it was observed that both the film (boundary layer) and intra-particle diffusion affected the studied adsorption process. The thermodynamic studies suggested that Cr (VI) adsorption onto FeNPs was endothermic, non-spontaneous and the positive ΔS value indicated increased disorder at the solid-solution interface during the adsorption.

Keywords—adsorption; Cr(VI) removal; *Eriobotrya japonica*; iron nanoparticles.

I.

INTRODUCTION

Water pollution is one of the most important burning environmental issue among the various kinds of environmental pollution since water resources are contaminated by a variety of organic, inorganic and biological pollutants owing to day to day utilization and potential applications of water at domestic, industrial and agricultural areas all over the world [1, 2]. The

heavy metals (arsenic, zinc, copper, nickel, mercury, cadmium, lead and chromium, etc.) are the best known non-biodegradable water pollutants which are extremely toxic and dangerous for ecosystem, agriculture and human health [3].

The chromium ions exist in industrial wastewaters both trivalent and hexavalent forms. Cr(VI) ion exists in different forms in solutions as $\text{Cr}_2\text{O}_7^{2-}$, HCrO_4^- or CrO_4^{2-} depending on the pH and the Cr(VI) concentration. Otherwise, Cr (III) ion is relatively less toxic than Cr(VI) ion. The Cr(III) species in aqueous solutions present in the forms of Cr^{3+} , $\text{Cr}(\text{OH})^{2+}$, $\text{Cr}(\text{OH})_2^+$, $\text{Cr}(\text{OH})_3$, or $\text{Cr}(\text{OH})_4^-$ depending on the solution pH [4, 5]

Cr (VI) is widely used in paints and pigments, chrome chemicals, leather tanning, electroplating industries, cement and photography industries that lead to producing great quantities of effluents containing the toxic Cr (VI) metal ions [6]. Moreover, Cr(VI) is classified as the top 16 th hazardous substance by the Agency for Toxic Diseases Registry (ATSDR) due to its carcinogenic properties and toxicity degree [4]. It is quite harmful for the living organisms due to it has potential to pass through cell membranes and reduces to reactive intermediates. These reactive intermediates can attack DNA, proteins, and membrane lipids and cause damage to the cellular functions [7]. The acceptable discharge level for hexavalent chromium ion in industrial wastewaters is reported as 0.1 mg/L by United States Environmental Protection Agency (US EPA) and the permitted Cr(VI) ion limit in drinking water is 50 $\mu\text{g/L}$ according to the World Health Organization (WHO) data [4, 5]. Therefore, in order to reduce Cr(VI) ion to the standard level, effective, eco-friendly and economic treatment methods should be improved.

There are commonly used treatment methods for discharging chromium ions from wastewaters such as adsorption, biosorption, coagulation, chemical precipitation, reverse osmosis, ion exchange, extraction and membrane filtration techniques. Among them, adsorption offers good opportunity for the removal of chromium ion from the wastewaters because of its low cost, simple operation, capability of trace level pollutant removal and high efficiency [4, 6].

Recently, the usage of metal/metal oxide nanoparticles such as; Fe^0 , Fe_3O_4 , TiO_2 , ZnO and their composites as a sorbent, has attracted great attention in the treatment of various heavy metals like chromium. The advantage of these functional nanomaterials is high adsorption capacity that is associated with their large specific surface area and high reactivity in the adsorption processes [3].

Biosynthetic approaches are quite popular for synthesis of metal nanoparticles using microorganisms, enzyme and plant extracts; due to their predominant advantages compared to traditional chemical synthesis methods include toxic and expensive compounds such as NaBH_4 as reducing agent. Among biosynthetic procedures, the exploitation of plant extracts has a privileged position for nanoparticle preparing since plant leaves are inexpensive, natural, environmentally friendly, harmless, readily available and suitable for scale-up steps. Loquat (*Eriobotrya japonica*) is an Asian yellow fruit belonging to the Rosaceae family and its leaves are used widely for medicinal purpose against cough and asthma diseases in Turkey [8, 9]. Loquat leaves are very rich in terms of phenols, flavonoids, triterpene acids and polysaccharides and these special compounds act as a bioreduction agent for metallic ions. To the best of our knowledge, loquat leaves extract was used for synthesis of silver and gold nanoparticles [10, 11], but; this is the first study reported in literature about using of loquat leaves aqueous extract for the green synthesis of FeNPs. However biosynthesized zero-valent iron nanoparticles [12]; crystalline and amorphous Fe and Al-oxides such as; hematite [$\alpha\text{-Fe}_2\text{O}_3$], goethite [$\alpha\text{-FeOOH}$], alumina [$\alpha\text{-Al}_2\text{O}_3$] [4, 13] and composite materials include iron minerals such as; Fe_3O_4 magnetite graphene oxide encapsulated in calcium alginate beads [7], Fe-modified activated carbon [14] were reported as effective adsorbents for removal of Cr(VI) ions.

The aim of the present study was to synthesize of FeNPs using *Eriobotrya japonica* leaves aqueous extract as a reducing or capping agent and to investigate the Cr(VI) adsorption efficiency. For this purpose, a systematic characterization studies of the synthesized FeNPs were carried out by DLS, XRD, FTIR, and SEM/EDX analysis methods and then, the adsorbent properties of FeNPs for Cr(VI) ions and the adsorption mechanism for the studied adsorption process were investigated in a batch system.

II. EXPERIMENTAL PROCEDURE

A. Materials

All the chemicals used in experiments were of analytical grade and was used without further purification. $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ to be used in synthesis of FeNPs and 1,5-diphenylcarbazide were supplied from Carlo Erba and acetone (> 99.5%) and HCl (37%) were provided from Sigma-Aldrich. A stock solution of 1000 mg/L of Cr(VI) was prepared by dissolving appropriate amount of $\text{K}_2\text{Cr}_2\text{O}_7$ (Carlo Erba) in 1000 mL distilled water. The solution with desired Cr(VI) concentration was prepared

by appropriate dilutions from stock Cr(VI) solution. The pHs of the solutions were adjusted with 0.1 N hydrochloric acid and 0.1 N sodium hydroxide.

B. Biosynthesis of FeNPs

Loquat (*Eriobotrya japonica*) leaves were collected from loquat trees grown in Mersin, Turkey. Aqueous extract of *E. japonica* leaves was prepared by heating the certain amount of air-dried leaves as it's concentration will be 60 g/L, at 100°C , 500 ml of distilled water for 1 h. Subsequently, the filtered aqueous extract was added to 0.1 mol/L $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ solution in 1:1 volume ratio and the final mixture was kept under vigorous stirring for 3 h [15]. The immediate changing of the colour of the solution from clear to intense black indicated the formation of FeNPs. The formed nanoparticles were separated by evaporating water from solution on a hot plate and then collected nanoparticles, washed several times with deionized water and dried in an oven at 120°C overnight.

C. Characterization of FeNPs

The mean hydrodynamic particle size and size distribution of the green synthesized FeNPs was measured by dynamic light scattering (DLS) analysis with the Malvern Zetasizer. The functional groups of FeNPs before and after adsorption, were determined by Fourier transform infrared spectrometer (FT-IR) in the range of $4000\text{--}400\text{ cm}^{-1}$. Crystal structure was observed by XRD analysis, using nickel-filtered Cu K α radiation in a Philips XPert MPD apparatus operated at 40 kV and 30 mA, in the 2θ range of $10^\circ\text{--}80^\circ$. The morphology of the FeNPs was analyzed by Zeiss/Supra 55 SEM analysis and elemental identification and quantitative compositional information of the adsorbent was determined by Zeiss/Supra 55 energy dispersive X-ray analyzer (EDX) pre- and post adsorption. The pH at point of zero charge (pH_{PZC}) of prepared FeNPs was obtained by measuring ζ (zeta) potential at different ranges of pH (2.5 – 12) with Zeta-Sizer (Malvern Zetasizer Nano ZS model). The pH values of the FeNPs suspensions were adjusted from 2.5 to 12 by adding 0.1 M HCl and/or 0.1 M NaOH solutions as required.

D. Batch adsorption studies

The adsorption experiments were carried out in 250 mL Erlenmeyer flasks containing 100 mL of Cr (VI) adsorption solution. 0.1 g of FeNPs, except for adsorbent concentration experiments, was contacted with 100 mL of Cr (VI) solution at known initial Cr (VI) concentration and initial pH in an Erlenmeyer flask and then the flasks were agitated at a constant temperature and shaking rate for 480 min, which is more than ample time for adsorption equilibrium. Samples were taken before mixing the FeNPs and metal bearing solution and at pre-determined time intervals for the unadsorbed metal ion concentration in the solution. Samples were centrifuged at 3500 rpm for 5 min and the supernatant liquid was analysed.

The unadsorbed Cr (VI) concentration was analyzed in a spectrophotometer (Cheibos UV-vis model) according to

1151

green synthesized FeNPs indicated that the material was completely amorphous structure (figure not shown).

Fig.3. XRD pattern of FeNPs

The differences in the XRD patterns of FeNPs between before and after adsorption may be due to change the crystallinity and phase of the FeNPs during the chemisorption of Cr(VI).

FTIR study of crude extract and FeNPs before and adsorption was carried out to investigate the functional groups responsible for adsorption. The absorption bands were observed in all the samples, as presented in Fig. 4, Fig. 5 (a) and Fig.5 (b), respectively. The FT-IR spectrum of loquat leaves extract (Fig.4), the broad band at 3270.9 cm^{-1} may correspond to the surface O-H group related to the phenolic compounds. The 2928 and 2187 cm^{-1} bands are because of the C-H stretching vibration of the $-\text{CH}_2$ and CH_3 functional groups [12, 19]. The band at 1720 cm^{-1} is identified as carbonyl groups from dimerized saturated aliphatic acids [20], 1595.36 cm^{-1} and 1378.12 cm^{-1} are attributed to C=O, C-O and O-H groups and the presence of C-O stretching in carboxyl groups, respectively. The broad band in 1243 cm^{-1} corresponds to the C-O-C or C=O stretching vibration and 1036 cm^{-1} band may be assigned to C-O-C and O-H absorption [20]. The bands observed at 889.03 , 763.93 and 599.63 cm^{-1} are correspond to phenol groups and bending vibrations of aromatics, carboxylic acids and amides [12]. These peaks demonstrate the presence of phenolics could be probably responsible for the bioreduction of Fe^{2+} ions and formation of FeNPs.

According to the FT-IR spectrum of synthesized FeNPs (Fig. 5(a)), the bands at 3236.66 , 2155 cm^{-1} are attributed to O-H group related to the phenolic compounds and C-H stretching vibration of $-\text{CH}_2$ and CH_3 functional groups, the band at 1605 cm^{-1} corresponds to C=O, and the band at 1077 cm^{-1} due to C-O stretching [21]. Moreover, adsorption bands at 596 cm^{-1} and 458.88 cm^{-1} refer to Fe-O stretches of Fe_3O_4 and Fe_2O_3 [22], confirming the formation Fe NPs. After Cr(VI) adsorption, as seen from Fig. 5 (b) the FT-IR spectrum, a slight

change was observed in the peaks due to chemisorption of Cr(VI) ions. Based on the FT-IR results, the

Fig.4. FT-IR spectrum of loquat (*Eriobotrya japonica*) leaves aqueous extract

Fig 5. FT-IR spectrum of FeNPs a) before adsorption b) after adsorption

adsorption mechanism of the Cr(VI) ions onto FeNPs is due to the chemical interaction between $-\text{OH}$ and $-\text{C}=\text{O}$ functional groups on the FeNPs surface and Cr(VI) ions in the solution [2].

B. Effect of Environmental Conditions on the Cr(VI) Adsorption onto FeNPs

The solution pH is an important factor on the adsorption capacity due to its impact on the ionic forms of chromium in solutions and the surface properties of the adsorbent [7]. The effect of initial pH on the adsorption of Cr(VI) ions onto FeNPs was presented in Fig. 6.

According to Fig. 6, Cr(VI) removal by green synthesized FeNPs was a pH dependent adsorption system. The maximum equilibrium uptake value was found to be 99.28 mg/g at pH 3.0 and then started to gradually decrease while pH value increases up to 8.0. Cr(VI) ion exists in solution as $\text{Cr}_2\text{O}_7^{2-}$, HCrO_4^- or CrO_4^{2-} and their solubilities are strongly depend on the solution pH and the Cr(VI) concentration.

The logarithmic concentration diagram for the species distribution of Cr(VI) in an aqueous system was shown in

Fig. 6. The effect of initial pH (initial Cr(VI) concentration 100 mg/L, adsorbent concentration 1 g/L, temperature 25°C).

Fig. 7. The concentration diagram for Cr(VI) species depends of pH.

Fig. 8. The isoelectric point of the prepared FeNPs.

Fig. 7. [4]. According to this diagram, HCrO_4^- is dominant form of Cr(VI) at acidic medium in the range of pH 2.0 – 4.0; CrO_4^{2-} is the predominant form in an neutral and basic medium pH 7.0, [4, 7, 23]. HCrO_4^- ions occur as a result of the hydrolysis of dichromate ions and an increase in pH would ease of the formation of $\text{Cr}_2\text{O}_7^{2-}$ from HCrO_4^- [24].

The formation of different species of Cr(VI) in aqueous solutions are given by the equations (3) and (4):

In this study, the active form of Cr(VI) was chosen as HCrO_4^- because of obtaining high removal in acidic medium.

The attitude of the maximum adsorption capacity at pH 3, can be explained by isoelectric point of adsorbent. The isoelectric point of FeNPs (pH_{pzc}) was determined as 4.0 by the zeta (ζ) potential measurement was given in Fig.8.

The surface of adsorbent was charged positively at the lower pH values than isoelectric point of adsorbent and adsorption capacity increased due to strong electrostatic attraction between positively charged adsorbent surface and negatively charged HCrO_4^- ions. Conversely, at the higher pH values than isoelectric point of adsorbent, the number of negatively charged sites increases and the number of positively charged sites decreases, so; Cr(VI) adsorption capacity was decreased due to the electrostatic repulsion between surface and HCrO_4^- ions.

Metal ion adsorption onto hydrous solids such as metal oxides is a complex reaction between surface sites and adsorbent. The developed surface sites for a hydrated adsorbent are formulated in equations (5) and (6):

There S represents the FeNPs surface sites, S-OH_2^+ , S-OH and S-O^- refer to protonated, neutral and deprotonated surface hydroxyl functional groups, respectively. In this work, at pH value below pH_{pzc} , the positively charged adsorbent surface (S-OH_2^+) accelerates the uptake the anionic HCrO_4^- , adsorption whereupon the coulombic interaction forces can easily occurred [24].

Therefore, two possible reactions would be suggested as given below in equations (7) and (8), about adsorption mechanism depending on interaction between HCrO_4^- ions and the surface sites of adsorbent at pH value below pH_{pzc} [4].

where $=\text{SOH}_2^+(\text{HCrO}_4^-)$ and $=\text{SHCrO}_4$ are the bonding complexes.

The initial metal ion concentration is an important factor on the adsorption capacity in terms of providing higher driving force to overcome mass transfer resistances of the metal ions between the aqueous and solid phases. The effect of initial Cr(VI) concentration on adsorption was depicted in Fig.9. As can be seen from Fig.9, the adsorption capacities increased linearly ($q_e = 0.9453 \cdot C_o$, $R^2 = 0.997$) with the initial Cr(VI) concentration at optimum temperature 45°C, initial pH 3.0, 1.0 g/L adsorbent concentration and 480 min equilibrium time.

The adsorbent concentration effect on the percentage of adsorption and equilibrium uptake was presented in Fig. 10.

According to Fig. 10, the equilibrium uptakes of FeNPs for Cr(VI) ion concentrations decreased with increasing the

Fig. 9. The effect of initial Cr(VI) concentration (temperature 45°C, initial pH 3, adsorbent concentration 1 g/L)

Fig. 10. The effect of adsorbent concentration (temperature 45°C initial pH 3, contact time 90 min, initial Cr(VI) concentration 100 mg/L)

Fig.11. The effect of temperature (initial pH 3, initial Cr(VI) concentration 200 mg/L, adsorbent concentration 1 g/L)

adsorbent concentration from 0.5 g/L to 3 g/L, but; it was seen that the adsorption percentage increased up to 1.0 g/L of adsorbent concentration, and then slightly remained constant with further increase in adsorbent concentration. The decrease in uptake values with increasing adsorbent concentration may be arise from the interaction between adsorbent particles such

as aggregation, resulted from high adsorbent concentration. The agglomeration of the adsorbent particles would lead to decrease in active surface area of the adsorbent and an increase in diffusional path length, hence the lower adsorption capacities were observed at high adsorbent concentrations. As a result, the optimum adsorbent concentration was selected as 1.0 g/L for Cr (VI) ion adsorption onto FeNPs.

The effect of temperature on adsorption was investigated in the range of 25 – 55°C temperature values and results was presented in Fig. 11. According to Fig. 11, it was seen that high adsorption capacity was obtained with increase in temperature from 25°C to 45°C and then, moderately remained constant at 55°C. Therefore, the optimum temperature value for Cr(VI) ion adsorption was determined as 45°C. Based on the results, high operation temperature indicated that, the studied adsorption process was endothermic nature.

The thermodynamic parameters such as, Gibb's free energy change (ΔG), enthalpy change (ΔH) and entropy change (ΔS) which were calculated from Van't Hoff equation were supported the results of temperature effect. The equilibrium constant (K_c) values for the Cr(VI) adsorption on FeNPs were calculated from the $K_c = C_{Ae}/C_e$ equation [1]; where C_{Ae} and C_e are the adsorbed metal ion concentration (mg/L) and the unadsorbed metal ion concentration at equilibrium (mg/L), respectively. When the adsorbent concentration is 1.0 g/L, C_{Ae} is equal to q_e at studied temperature. ΔH and entropy change ΔS were calculated from the slope and intercept of the Van't Hoff's $[\ln K_c = (\Delta S/R) - (\Delta H/R)1/T]$ plot of $\ln K_c$ versus $1/T$ [25]. In this study, the linear form of Van't Hoff equation for the adsorption of Cr(VI) onto FeNPs was found as $\ln K_c = -8041*1/T + 23.03$ with the regression coefficient 0.999 (data not shown) and the thermodynamic parameters were calculated and were presented in Table II.

According to Table II, the positive enthalpy change indicated the endothermic nature of the studied adsorption process and also, this result confirmed the results of temperature effect for Cr(VI) ion onto FeNPs.

TABLE II. Thermodynamic parameters of adsorption system.

Metal ion	Thermodynamic parameters				
	T (K)	Kc	ΔH (kJ/mol)	ΔS (kJ/mol.K)	ΔG (kJ/mol)
Cr (VI)	298	0.01905	66.853	0.1915	9.813
	308	0.04703			7.828
	318	0.10389			5.986

The calculated ΔG [$\Delta G = -RT \ln K_c$] values had positive indicating that adsorption of Cr(VI) on FeNPs was non-spontaneous. The positive value of ΔS suggested that randomness of the adsorbed Cr(VI) species at the solid-solution interface during adsorption [5]. Moreover, the

calculated ΔH values higher than 42 kJ/mol indicated the process results from chemisorption of the Cr(VI) ions onto FeNPs [26].

C. Equilibrium, Kinetic and Mass Transfer Modelling

The Langmuir and Freundlich isotherm models are commonly used to describe the adsorption data so, get idea about the interactions of adsorbed materials with the adsorbent [27]. The Langmuir isotherm model suggests a monolayer adsorption occurring on a homogeneous surface comes from finite number of similar active sites and Freundlich isotherm model is valid for adsorption take place heterogeneous surface [26]. The well-known linearized forms of Langmuir and Freundlich isotherm models were given in equations 9 and 10:

$$\text{Langmuir: } 1/q_e = 1/Q^\circ b(1/C_e) + 1/Q^\circ \quad (9)$$

$$\text{Freundlich: } \ln q_e = \ln K_F + (1/n) \ln C_e \quad (10)$$

The linear forms of Langmuir and Freundlich isotherm models were applied to experimental equilibrium data at different temperatures and the isotherm constants calculated from the isotherm equations and regression coefficients were summarized in Table III. Also, the experimental and predicted isotherms for Cr(VI) adsorption at 45°C and initial pH 3 were given in Fig. 12. As seen from Table III and Fig.12, Langmuir isotherm model was better agreement with experimental equilibrium data.

TABLE IV. Comparison of results obtained in this study for the adsorption of Cr(VI) with those of other adsorbents

Fig.12. The comparison of the experimental and predicted isotherms for Cr (VI) adsorption (temperature 45°C, initial pH 3).

This result demonstrated that, the adsorption occurred at specific homogeneous sites within the adsorbent forming monolayer coverage of Cr (VI) at the surface of FeNPs.

The maximum monolayer coverage capacity of adsorbent was determined as 312.5 mg/g at 45°C which is the optimum temperature. As seen from Table III, the maximum monolayer coverage capacity values of FeNPs for Cr(VI) were increased by increasing temperature may be due to the endothermic nature of the studied adsorption process. The adsorption capacity of the green synthesized FeNPs in this study for the removal of Cr (VI) have been compared with those of other adsorbents reported in literature and their adsorption capacities have been presented in Table IV. According to Table IV, FeNPs in this study, has a good adsorption capacity in comparison with most of the other adsorbents.

However, the exactly comparison of adsorption capacity of sorbents is actually difficult due to the differences of optimum experimental conditions and physicochemical properties of adsorbents such as functional groups and specific surface areas.

The adsorption kinetics were elucidated by correlating the adsorption kinetic data of the Cr(VI) onto FeNPs using the linear forms of the pseudo-first-order [$\log(q_e - q_t) = \log(q_e) - k_1 t / 2.303$] and the pseudo-second order [$(1/(q_e - q_t)) = (1/q_e^2 k_2) + (t/q_e)$] kinetic models [31]. For the adsorption of Cr(VI) onto FeNPs, the parameters of the pseudo first-order and pseudo second-order kinetic models with regression coefficients were presented in Table V. From Table V, the adsorption kinetic of Cr (VI) onto FeNPs was better described by the pseudo second-order kinetic model due to consistency of the experimental and calculated q_e values and high regression coefficients than pseudo first-order model at all initial Cr(VI) concentrations. Based on the assumptions of the pseudo-second-order model, the chemisorption was the rate determining step in the adsorption of Cr(VI) on FeNPs.

In order to evaluate the boundary layer and intra-particle diffusion mechanism between Cr(VI) ions and FeNPs, Weber-Morris model [$q_e = K_i \cdot t^{0.5} + I$] was used and model parameters and regression coefficients were summarized at Table V.

TABLE V. Kinetic and intra-particle mass transfer model parameters.

Co (mg/L)	qe, exp (mg/g)	Pseudo-first-order			Pseudo-second-order			Weber-Morris Model		
		$k_1(\text{min}^{-1})$	$q_{e,cal1}$ (mg/g)	R^2	k_2 (g/mg.min)	$q_{e,cal2}$ (mg/g)	R^2	K_i (mg/g.min ^{0.5})	I	R^2
50	49.761	0.004145	5.2372	0.431	0.00904	50.237	0.999	0.3708	44.837	0.995

200	202.38	0.00460	119.922	0.748	0.000535	199.27	0.994	5.2275	84.077	0.991
300	297.85	0.00460	224.026	0.637	0.000879	302.62	0.996	5.8675	107.30	0.998
400	376.19	0.003915	361.826	0.799	0.001181	401.90	0.997	5.9466	107.34	0.992
500	458.809	0.003685	445.041	0.830	0.000629	496.94	0.991	7.8679	108.88	0.996

In Weber-Morris equation; I is the intercept related to the boundary layer effect and K_i is the intraparticle diffusion rate constant which can be evaluated from the slope of the linear plots of qt versus $t^{0.5}$. If Weber-Morris plot of qt versus $t^{0.5}$ is linear and pass through the origin, the intraparticle diffusion is the sole rate determining step but, when the plots in the figure are multi linear with three distinct regions, in that case there are three different kinetic mechanisms. The initial region corresponds to the external surface uptake, the second stage relates the gradual uptake indicating intraparticle diffusion as the rate limiting step and final plateau region represents equilibrium uptake [32]. Based on the results, it was observed a multilinear plot (figure not shown) indicated that both intraparticle and film diffusion were effective on the adsorption of Cr(VI) on FeNPs. Moreover, according to Table V; it was seen that the internal (K_i) and external diffusion constants (I) gradually increased with increasing initial Cr(VI) concentration.

IV. CONCLUSIONS

In summary, iron nanoparticles were biosynthesized by using a green reducing agent, loquat leaves aqueous extract and prepared FeNPs were tested as a adsorbent for Cr(VI) ions under our experimental conditions. The conclusions of this study can be summarize:

- The characterization studies confirmed the synthesis of FeNPs successfully. The synthesized FeNPs have irregular spherical morphology as well as they are relatively agglomerated. The XRD spectrum showed the diffraction peaks belong to mainly iron hydroxide and iron oxyhydroxide. According to FT-IR spectrums, the peaks refer to Fe-O stretches of Fe₃O₄ and Fe₂O₃.
- The optimum adsorption conditions were determined to be initial pH 3.0, temperature 45°C, initial Cr(VI) concentration 100 mg/L and adsorbent concentration 1.0 g/L.
- The adsorption equilibrium data best fitted to the Langmuir isotherm model. The monolayer coverage capacity calculated from Langmuir isotherm model was found to be 312.5 mg/g.

- The thermodynamic parameters; ΔG , ΔH , and ΔS were calculated as positive and results indicated that the studied adsorption process was endothermic and non-spontaneous.
- The adsorption kinetic data followed the pseudo-second-order kinetic model and both intraparticle and film diffusion were effective on the adsorption process.
- Based on the results, the biosynthesis method could be suggested for preparing iron nanoparticles in terms of ecofriendly, cost-effective and easy-to-handle synthesis process with large-scale, owing to abundance of loquat or other plant leaves.
- Consequently, green synthesized FeNPs can be a good candidate for Cr(VI) removal owing to their high adsorption capacity.

V. NOMENCLATURE

- b : A constant related to the affinity of the binding sites (L/mg)
 C_e : Unadsorbed Cr(VI) metal ion concentration at equilibrium (mg/L)
 C_o : Initial Cr(VI) metal ion concentration (mg/L)
 K_F : Freundlich constant indicating adsorption capacity ((mg/g)/(L/mg)^{1/n})
 K_i : Intraparticle diffusion rate constant (mg/g.min^{0.5})
 k_1 : Pseudo first order kinetic rate constant (1/min)
 k_2 : Pseudo second order kinetic rate constant (g/mg.min)
 q_e : Adsorbed amount per unit mass of adsorbent (mg/g)
 $q_{e,cal1}$: Calculated adsorbed amount per unit mass of adsorbent from pseudo first order kinetic model (mg/g)
 $q_{e,cal2}$: Calculated adsorbed amount per unit mass of adsorbent from pseudo second order kinetic model (mg/g)
 $q_{e,exp}$: Experimental adsorbed amount per unit mass of adsorbent (mg/g)
 q_t : Adsorbed amount per unit mass of adsorbent at any time (mg/g)
 Q_o : Maximum monolayer coverage capacity of adsorbent (mg/g)
 $1/n$: Freundlich constant indicating adsorption intensity

Abstract— In this study, alginate/ Fe_3O_4 nanoparticles (Alg/ Fe_3O_4 NPs) were synthesized by a fast and facile reduction (partial reduction of Fe^{3+} with sodium sulfite)-precipitation method (precipitation with ammonia) at room temperature. The characterization of Alg/ Fe_3O_4 NPs was performed by FT-IR, SEM, EDX, and XRD analysis methods. The adsorbent and catalysis properties of Alg/ Fe_3O_4 NPs for methylene blue dye were investigated in a batch system. The studies to determine effects of environmental conditions on the adsorption of methylene blue dye on Alg/ Fe_3O_4 NPs were done and the optimum experimental conditions were determined as follows: initial pH of 8.0, initial dye concentration of 300 mg/L, temperature of 308 K, and adsorbent concentration of 0.5 g/L. The adsorption equilibrium data of methylene blue on Alg/ Fe_3O_4 NPs fitted well to Langmuir isotherm model with the maximum monolayer coverage capacity of 393.39 mg/g. The studied adsorption process followed the pseudo second order kinetic model, and both intraparticle and film diffusion were effective on the adsorption system. Thermodynamic parameters such as Gibb's energy (ΔG) change, activation energy (E_a), enthalpy change (ΔH), and entropy change (ΔS) indicated that the adsorption was spontaneous, exothermic, physical, and decreasing in randomness of adsorbed species. The effect of H_2O_2 on catalytic degradation with Alg/ Fe_3O_4 NPs of methylene blue dye in the Fenton-like system was also investigated and the optimum H_2O_2 concentration was determined to be 5.0 % with 99 % of the degradation efficiency at the end of 40 minute.

Keywords—adsorption, alginate, degradation, Fe_3O_4 nanoparticles, Methylene blue

I. INTRODUCTION

Fe_3O_4 nanoparticles have been widely evaluated in many application areas like separation processes, biotechnology, sensors, optoelectronics, catalysts, medical diagnosis [1]. Especially due to the substantial properties of Fe_3O_4 nanoparticles like the advantages of strong catalytic activity, long-term stability, low toxicity, biocompatibility, and environment-friendly, they can be thought as ideal nanomaterials for the removal of various pollutants, including phenol species (2,4-dichlorophenol, p-nitrophenol), aniline, heavy metal, and dye pollutants. However, the aggregation of the nanoparticles is a significant problem causing decrease in the effective surface area of nanoparticles and thus reducing their removal capacities. The aggregation of nanoparticles could be overcome by the combine of the nanoparticles with organic, inorganic, and biological substances, such as

polyacrylic acid, activated carbon, multiwalled carbon nanotube, mesocellular carbon foam, thiol, cetyltrimethylammonium bromide, zeolite, poly(3,4-ethylenedioxythiophene), alginate, chitosan, gum, hydroxyapatite, yeast, and so on [2]. It is wanted that the substances must have high stability, environmental-friendliness, cost-efficiency, wide resource. Among these substances; natural polymers like alginate, chitosan, etc. are promising alternatives for the combining of the nanoparticles due to their low price, wide sources, and environmental friendliness [3]. In our study, sodium alginate, consisted of guluronic (G) and mannuronic (M) acid residues (linear copolymer of (1–4) linked β -D-mannuronic acid and α -L-guluronic acid units), was selected as the substance for combining of Fe_3O_4 nanoparticles. In the literature, there are some combination methods of Fe_3O_4 nanoparticles with the substances like co-precipitation, oxidation–precipitation, forced hydrolysis, and so on. However; since these methods generally required either the emulsifying agents, or protective gas, and high-temperature, the reduction–precipitation method with the advantages of being fast and simple, non-use of a protective/reactive gas and surfactant has been developed [4]. In this study, alginate/ Fe_3O_4 nanoparticles (Alg/ Fe_3O_4 NPs) were synthesized by the reduction–precipitation method and characterized by FT-IR, SEM, EDX, and XRD analysis. The adsorbent and catalysis properties of Alg/ Fe_3O_4 NPs for methylene blue dye were investigated in a batch system.

II. MATERIALS AND METHODS

A. Synthesis and Characterization of Alg/ Fe_3O_4 NPs

The synthesis of alginate/ Fe_3O_4 nanoparticles (Alg/ Fe_3O_4 NPs) was carried out via a reduction–precipitation process. Unlike the other synthesis methods; in this method, Fe^{3+} is partially reduced before the formation of Fe_3O_4 nanoparticles, that providing to prevent the aggregation. Firstly, 0.13 mole/L FeCl_3 and 20 mg/mL alginate solutions were separately prepared by solving the appropriate amounts of FeCl_3 and alginate in 1.0 % (v/v) solution of HCl, and then 35 mL of 0.13 mole/L FeCl_3 was added to 25 mL of 20 mg/mL alginate solution, the colloidal solution was in yellow color and it was stirred magnetically for 1 h. After that, 15 mL of 0.1 mole/L Na_2SO_3 solution in pure water was put into as-prepared

colloidal solution, and the color of the final solution changed from yellow to red immediately. As soon as the color altered from red to yellow again, 10 mL of 25 % (v/v) ammonia solution was added quickly to the final solution under vigorous stirring at room temperature and the black precipitates of Alg/Fe₃O₄ NPs occurred in a short time. In order to stabilization of Alg/Fe₃O₄ NPs, 2.5 mL of 1.0 % (w/v) starch solution was added to the black suspension and it was stirred magnetically at 60 °C for 3.0 h. Lastly, the resulting precipitates of Alg/Fe₃O₄ NPs were separated with centrifuge at 4000 rev/min for 5.0 min, washed with pure water, and then dried in an oven at 80 °C for 24 h. Alg/Fe₃O₄ NPs in closed vessels were stored in a refrigerator at +4 °C for the further studies [4]. The characterization studies of Alg/Fe₃O₄ NPs were performed by Fourier Transform Infrared Spectrometer (FT-IR- Perkin Elmer, Shelton), Scanning Electron Microscope (SEM- Zeiss/Supra 55, Germany), Energy Dispersive X-ray Spectroscopy (EDX- Zeiss/Supra 55, Germany), and X-ray Diffractometer (XRD- Philips XPert, Netherlands).

B. Adsorption Experiments

The experiments of Methylene Blue (MB; C₁₆H₁₈ClN₃S; M_w=319.852) adsorption onto Alg/Fe₃O₄ NPs were conducted in a single stage batch adsorption process. Firstly; a required amount of Alg/Fe₃O₄ NPs (0.1 g except for adsorbent concentration experiments) was put into 100 mL of the aqueous solution of MB at a known initial pH and initial dye concentration in conical flask, and then it was agitated in a water bath for a required period of adsorption to attain adsorption equilibrium. The samples were taken at predetermined time intervals and they were centrifuged at 3000 rev/min for 3.0 min to be separated from the adsorbent. The residual dye concentration in the supernatant was analyzed at 665 nm by UV-vis spectrophotometer (Chebios Optimum-One, Italy). Experiments were replicated for different initial pH, initial dye concentration, temperature, and adsorbent concentration values.

C. Degradation Experiments

The degradation studies were carried out as follows briefly; 0.1 g of Alg/Fe₃O₄ NPs were blended with 100 mL and 100 mg/L of MB solution at initial pH of 3.0 in conical flasks, and then the degradation was initiated by rapid adding of 10 mL H₂O₂ for different concentrations (1.0, 3.0, 5.0, and 10 %, v/v) to the reaction solution while they were being agitated in a water bath at 298 K. At given time intervals, 3.0 mL aliquots of MB solution were sampled, and immediately separated with centrifuge at 4000 rev/min for 30 second. After that, UV-vis spectrum scanning of the supernatant was done.

III. RESULTS AND DISCUSSION

Alg/Fe₃O₄ NPs were synthesized by the reduction-precipitation method and the predicted steps in this method were exhibited in Fig. 1. Accordingly, Fe³⁺ ions were firstly

chelated with COONa and OH groups of alginate, that providing homogenous dispersion of Fe³⁺ ions and thus prevention of agglomeration of the nanoparticles, and then they partially reduced to Fe²⁺ ions with the addition of Na₂SO₃ solution. Lastly, Alg/Fe₃O₄ NPs were formed in around 5.0 min with the aid of ammonia solution. Consequently, Alg/Fe₃O₄ NPs could be synthesized by a simple and fast method at mild conditions.

Fig. 1. The predicted steps of the reduction-precipitation process

The morphology of Alg/Fe₃O₄ NPs was characterized by SEM analysis and its image was presented in Fig. 2. It was observed from Fig. 2 that Alg/Fe₃O₄ NPs had porous and mostly spherical-like structures in nanoscale, and their growth were irregular. Also, the presence of the elements in Alg/Fe₃O₄ NPs such as basically iron, oxygen, carbon, sodium along with chlorine and sulfur in trace amounts was determined by EDX analysis. The elements of iron, oxygen, carbon, sodium arose from Fe₃O₄ and sodium alginate (Fe, Na, C, and O) structure while the others (S and Cl) were residual.

Fig. 2. SEM image with EDX spectrum of Alg/Fe₃O₄ NPs

FT-IR spectrums of alginate (Alg) and Alg/Fe₃O₄ NPs were recorded in order to determine the functional groups of Alg/Fe₃O₄ NPs and they were presented in Fig. 3. The broad peak placed at around 3200 cm⁻¹ was attributed to hydrogen bonded O-H stretching. The carbonyl group of Alg was into carboxylate anion form (O-C-O asymmetric stretching at 1600

cm^{-1}). The band at 1406 cm^{-1} was assigned to C–OH deformation vibration with contribution of O–C–O symmetric stretching vibration of carboxylate group. The weak bands at 1085 cm^{-1} and more intense at 1028 cm^{-1} represented C–O and C–C stretching vibrations of pyranose ring, respectively [5]. The strong peak at 615 cm^{-1} was attributed to Fe–O, confirming the presence of Fe_3O_4 NPs in Alg chains [6]. Moreover, the formation of new peaks at $3200\text{--}3000\text{ cm}^{-1}$ and the shifts of $1600, 1406, 1085,$ and 1028 cm^{-1} to $1594, 1404, 1102,$ and 1038 cm^{-1} , respectively showed that the carbonyl and hydroxyl groups of Alg were involved in complexation with Fe^{3+} ions [4].

Fig. 3. FT-IR spectrums of Alg/ Fe_3O_4 NPs and alginate

The crystal structure of Alg/ Fe_3O_4 NPs was determined by using XRD analysis method. The XRD pattern (Fig. 4) showed six characteristic diffraction peaks ($2\theta = 29.94, 35.54, 45.48, 53.50, 57.20,$ and 62.72°), corresponding to (220), (311), (400), (422), (511), and (440) crystal planes of inverse cubic spinel structure of Fe_3O_4 . It revealed that the crystal phase of Fe_3O_4 nanoparticles did not alter during the binding process [7].

Fig. 4. XRD pattern of Alg/ Fe_3O_4 NPs

The pH value of aqueous solution is a crucial factor affecting the adsorption processes. The plot of the adsorbed amounts at equilibrium (q_{eq}) versus initial pH values was presented in Fig. 5.a. It was indicated that high adsorption

capacities were obtained at the studied initial pH range. High adsorption capacities in the studied pH range can be explained with the point of zero charge (pH_{pzc}) of the adsorbent. In this study, the pH_{pzc} of the synthesized Alg/ Fe_3O_4 NPs was determined to be 5.7 by using experimental method in the previous work [8]. Mainly, the surface charge of adsorbent is positive at pH values lower than pH_{pzc} , zero at $\text{pH}=\text{pH}_{\text{pzc}}$, and negative at pH values higher than pH_{pzc} . At $\text{pH} > \text{pH}_{\text{pzc}}$, the surface of Alg/ Fe_3O_4 NPs were negatively charged which enhanced their interaction with MB cations through electrostatic force of attraction.

Fig. 5. a. Effect of initial pH ($T=298\text{ K}, C_0=100\text{ mg/L}, X_0=1.0\text{ g/L}$)

Fig. 5. b. Point of zero charge of Alg/ Fe_3O_4 NPs

The experiments in order to evaluate the influence of initial dye concentration on the adsorption were conducted at initial pH of 8.0, temperature of 308 K , and adsorbent concentration of 1.0 g/L in the initial dye concentration range of $25\text{--}500\text{ mg/L}$ and results were presented in Fig. 6. Fig. 6 indicated that q_{eq} values increased from 23.84 to 289.70 mg/g while the adsorption percentages decreased from 94.51 to 55.52% , as the experimental initial dye concentration increased from 25 to 504 mg/L . Also, the adsorption of MB onto Alg/ Fe_3O_4 NPs showed a saturation trend while the adsorption percentages diminished sharply at high initial dye concentrations since the adsorbent suggested a finite number of surface binding sites for dye cations. Hence, the optimum initial dye concentration was observed as 300 mg/L .

Fig. 6. Effect of initial dye concentration (initial pH=8.0, T=308 K, X₀=1.0 g/L)

The transfer of an adsorbate from the liquid phase to the solid phase takes place in the adsorption processes. In order to get information about this transfer mechanism, which is very crucial efficiency of the process, the kinetic and mass transfer models could be evaluated. For this purpose, the pseudo first order (PFOM) [$\log(q_{eq}-q_t)=\log(q_{eq})-(k_1 \cdot t/2.303)$] and the pseudo second order (PSOM) [$(t/q_t)=(1/(q_{eq}^2 \cdot k_2))+(t/q_{eq})$] order (PSOM) kinetic models along with Weber-Morris intraparticle diffusion model ($q_t=K_i \cdot t^{0.5}+C$) were tested for different initial dye concentrations at initial pH of 8.0, temperature of 308 K, and adsorbent concentration of 1.0 g/L.

The calculated rate constants and regression coefficients from the kinetic model plots ($\log(q_{eq}-q_t)$ vs. t for PFOM and t/q_t vs. t for PSOM; figures not shown) were summarized in Table I. The consistency between the experimental $q_{e,eq}$ values and the calculated $q_{cal,eq}$ values from the kinetic model plots was also presented in Fig. 7. The regression coefficients for the linear plots of PSOM were higher than PFOM and also the calculated $q_{eq,cal}$ values from PSOM showed an excellent agreement ($R^2 \approx 1$) with the experimental $q_{eq,exp}$ values, thus suggesting that the kinetics of the studied adsorption system could be described by the pseudo second order kinetic model.

TABLE V. THE ADSORPTION RATE CONSTANTS OF PFOM AND PSOM AT DIFFERENT INITIAL DYE CONCENTRATIONS (INITIAL PH=8.0, T=308 K, X₀=1.0 G/L)

C ₀ (mg/L)	k ₁ (1/min)	R ₂	k ₂ (g/mg.min)	R ₂
25	0.00806	0.7739	0.005879	0.9953
50	0.01635	0.7411	0.003311	0.9983
75	0.01251	0.8878	0.002416	0.9991
100	0.01474	0.8693	0.002081	0.9990

300	0.01313	0.7854	0.000704	0.9987
500	0.01612	0.9402	0.000781	0.9996

Fig. 7. The plots of the experimental adsorbed amount at equilibrium ($q_{eq,exp}$) vs. the calculated adsorbed amount at equilibrium from the kinetic models ($q_{eq,cal}$)

The adsorbate transport from the liquid phase to the surface of the adsorbent particles occurs in several steps, e.g. external diffusion, intraparticle diffusion, surface diffusion, and adsorption, or a combination of more than one step. Weber-Morris intraparticle diffusion model ($q_t=K_i \cdot t^{0.5}+C$) was applied to the experimental data for different initial dye concentrations in order to determine which steps were effective in the adsorption system. The slope and intercept value of the plot of q_t vs. $t^{0.5}$ give intraparticle diffusion rate constant (K_i) and C value attributed to external diffusion, respectively; K_i and C values along with regression coefficients were displayed in Table II. It showed that K_i and C values increased with increase in initial dye concentration. According to Weber-Morris intraparticle diffusion model, if the only intra-particle diffusion is effective in the adsorption process, then the plot of q_t vs. $t^{0.5}$ gives a linear line with intercept C equal to zero. However, if the plot of q_t vs. $t^{0.5}$ is multilinear, then adsorption is governed by more than one mechanism [9]. The plots of Weber-Morris model in Fig. 8 had three linear parts with different slopes, which indicated that the more than one mechanism took place in the process. The initial portion corresponded to the external diffusion, the second portion described the adsorption stage where intraparticle diffusion was effective on the process, and the third portion indicated the final equilibrium stage. Therefore, it was concluded that both external and intraparticle diffusion were effective on MB adsorption by Alg/Fe₃O₄ NPs.

TABLE VI. WEBER-MORRIS INTRAPARTICLE DIFFUSION MODEL PARAMETERS AT DIFFERENT INITIAL DYE CONCENTRATIONS (INITIAL PH=8.0, T=308 K, X₀=1.0 G/L)

C ₀ (mg/L)	K _i (mg/g.min ^{0.5})	C	R ₂
25	1.49	12.64	0.9903
75	9.36	18.14	0.9870
150	9.90	71.74	0.9938
500	11.81	160.78	0.9841

Fig. 8. The plots of Weber-Morris intraparticle diffusion model (initial pH=8.0, T=308 K, X₀=1.0 g/L)

The variation of the equilibrium uptake amounts (q_{eq}) with temperature values (298-328 K) was displayed in Fig. 9. It was observed that the adsorption capacity of Alg/Fe₃O₄ NPs for MB adsorption increased up to 308 K, and thereafter it was negatively affected by further increase in temperature. So, the optimum temperature was determined as 308 K for MB adsorption onto Alg/Fe₃O₄ NPs.

Fig. 9. Effect of temperature (initial pH=8.0, C₀=100 mg/L, X₀=1.0 g/L)

The effect of temperature on the studied adsorption process was also evaluated with thermodynamic studies by calculating the activation energy (E_a), entropy change (ΔS), enthalpy change (ΔH), and Gibbs energy change (ΔG). The activation energy could be determined by Arrhenius equation (Eq. 1) whereas Van't Hoff equation (Eq. 2) is used for the other thermodynamic parameters (Table III). These parameters were calculated by using following equations:

$$\ln(k_2) = \ln(k_0) - E_a/RT \quad (1)$$

$$\ln(K_c) = (\Delta S/R) - (\Delta H/RT) \quad (2)$$

$$\Delta G = -RT \ln(K_c) \quad (3)$$

where k_0 is the Arrhenius factor, k_2 is the pseudo second order rate constant (i.e. model that best described the adsorption kinetics), R is the gas constant (8.3145 J/mole.K), and K_c is the equilibrium constant at temperature T .

The values of ΔH and ΔS were calculated from the slope and intercept of the linear plot of $\ln(K_c = C_{ad,eq}/C_{eq})$ vs $1/T$, respectively, according to Eq. 2. The activation energy of MB adsorption on Alg/Fe₃O₄ NPs was determined from the slope of the linear plot of $\ln(k_2)$ vs $1/T$ by using Eq. 1. For the observation of the adsorption type, e.g. physisorption or chemisorption, the values of ΔH and E_a could be analyzed; accordingly, the ΔH value of physisorption system is lower than 84 kJ/mole whereas ΔH value of the chemisorption system is in the range of 84–420 kJ/mole [10]. Also, the activation energy of physisorption usually lies from 5 to 40 kJ/mole due to weak forces while higher activation energies offer chemisorption and its activation energy is usually in the range of 40–800 kJ/mole [11]. Hence it was concluded that the studied removal process proceeded through the physisorption with respect to the values of ΔH and E_a . Also, this result confirmed with FT-IR and XRD analysis that it was not observed any difference between before and after adsorption for FT-IR spectrum and XRD pattern of Alg/Fe₃O₄ NPs (figure not shown), which was indicating the physical adsorption in nature. Besides, the negative values of ΔS , ΔH , and ΔG showed that the adsorption system was decreasing in randomness of adsorbed species, exothermic, and spontaneous, respectively.

TABLE VII. THERMODYNAMIC PARAMETERS (INITIAL PH=8.0, T=308 K, C₀=100 MG/L, X₀=1.0 G/L)

T (K)	ΔG (J/mole)	ΔS (J/mole.K)	ΔH (kJ/mole)	E_a (kJ/mole)

The linear forms of Langmuir [$(1/q_{eq}) = (1/(Q_{max} \cdot b \cdot C_{eq})) + (1/Q_{max})$] and Freundlich [$\ln(q_{eq}) = \ln(K_F) + (1/n) \cdot \ln(C_{eq})$] isotherm models, the most frequently used adsorption isotherm models, were applied to the experimental equilibrium data at different temperature values and the calculated isotherm model parameters along with regression coefficients (R^2) were displayed in Table IV. It revealed that the experimental equilibrium data fitted well to Langmuir model due to the higher R^2 values rather than Freundlich model. Langmuir model suggested that the studied adsorption process was monolayer in nature meaning that only one MB cation adsorbed onto adsorbent surface and no further adsorption could take place at that site. Moreover, as it was expected from the results of temperature effect (Fig. 9) that Q_{max} values were close to each other and the maximum value of Q_{max} =393.39 mg/g was obtained at 308 K.

TABLE VIII. THE CONSTANTS OF THE ADSORPTION ISOTHERM MODELS ALONG WITH THE RELATED REGRESSION COEFFICIENTS (INITIAL PH=8.0, C₀=100 MG/L, X₀=1.0 G/L)

T	Langmuir isotherm model			Freundlich isotherm model		
	Q_{max}	b	R^2	K_F	$1/n$	R^2
298	376.3643	0.02119	0.9958	16.32	0.6286	0.9879
308	393.3910	0.03829	0.9998	17.21	0.7550	0.9826

328	380.3728	0.03038	0.9972	19.49	0.6505	0.9877

[T: K, Q_{max} : mg/g, b: L/mg, K_F : mg/g(L/mg)^{1/n}]

The comparison of Q_{max} values of various types of Fe_3O_4 nanoparticles for various dye molecules in the literature was shown in Table V. Accordingly, Alg/ Fe_3O_4 NPs used in this study had a relatively high adsorption capacity. The studies in the recent years shown that Fe_3O_4 nanoparticles have been supported with various substances in order to improve of the adsorption capacities.

TABLE IX. THE COMPARISON OF Q_{max} VALUES OF VARIOUS TYPES OF Fe_3O_4 NANOPARTICLES

Adsorbent	Dye	Q_{max} (mg/g)	Reference
Fe_3O_4 magnetic nanoparticles modified with sodium dodecyl sulfate	Safranin O	769.23	12
Fe_3O_4 nanoparticles loaded onto wheat straw	Basic Blue 9	627.10	13
Alginate/ Fe_3O_4 nanoparticles	Methylene Blue	393.39	This study
Humic acid (HA) modifying Fe_3O_4 nanoparticles	Rhodamine B	161.80	14
Fe_3O_4 nanoparticle produced with rice husk ash	Acid Red 114	111.00	15
Fe_3O_4 nanoparticles modified by polypyrrole	Reactive Red 195	99.00	16
Humic acid-coated Fe_3O_4 nanoparticles	Methylene Blue	93.08	17
Fe_3O_4 nanoparticles	New Coccine	35.50	18
Polyaniline/ Fe_3O_4 nanocomposite	Titan Yellow	34.00	19
Fe_3O_4 -loaded coffee waste hydrochar	Acid Red 17	16.30	20

The effect of adsorbent concentration on MB adsorption onto Alg/ Fe_3O_4 NPs was presented in Fig. 10 for initial pH of 8.0, initial dye concentration of 100 mg/L, and temperature of 298 K in the adsorbent concentration range of 0.5-3.0 g/L. As can be seen from Fig. 10, as increasing adsorbent concentration, the adsorption capacities decreased sharply while the adsorption percentages remained nearly constant. The reduction in adsorption capacities may be due to particle aggregation at higher than 0.5 g/L adsorbent concentration, that causing decrease in effective surface area of the adsorbent and an increase in diffusional path length. Therefore, the optimum adsorbent concentration was determined as 0.5 g/L.

Fig. 10. Effect of adsorbent concentration (initial pH=8.0, T=298 K, C_0 =100 mg/L)

The various iron oxide materials, such as magnetite (Fe_3O_4), hematite (α - Fe_2O_3), goethite (α - $FeOOH$), Fe^0/Fe_2O_3 , and Fe^0/Fe_3O_4 can be utilized as heterogeneous catalysts to activate H_2O_2 by generating hydroxyl radicals, which can degrade organic pollutants to H_2O , CO_2 , and inorganic salts. Hence, the effect of the presence of H_2O_2 on the degradation of MB in the Fenton-like process was also investigated in this study. In the Fenton-like process, it is known that the optimum pH is generally obtained as 3.0 for organic pollutant degradation [21]; so, the experiments of MB degradation in the presence of H_2O_2 were conducted at initial pH of 3.0, initial dye concentration of 100 mg/L, temperature of 298 K in the H_2O_2 concentration range of 1.0-10 %, and Fig. 11 exhibited the degradation of MB for different H_2O_2 concentrations. Accordingly, the degradation increased with an increase in H_2O_2 concentration. However, when H_2O_2 concentration was greater than 5.0 %, the degradation was not improved with further increase in H_2O_2 concentration. So, the optimum H_2O_2 concentration was observed as 5.0 % for MB degradation with 99 % decolorization efficiency. This case could be explained as follows; more H_2O_2 concentration at the beginning of the Fenton process provides more producing of hydroxyl radicals, that increasing the degradation efficiency. However, the excess of H_2O_2 concentration leads to scavenging effect for more hydroxyl radicals by generating perhydroxyl radicals, having lower oxidation capabilities, and eventually the degradation efficiency decreases at higher than optimum H_2O_2 concentration. Hence, the maximum degradation efficiency could be only attained when the concentration of H_2O_2 is optimal [22].

Fig. 11. Effect of H_2O_2 concentration (initial pH=3.0, $T=298\text{ K}$, $C_0=100\text{ mg/L}$, $X_0=1.0\text{ g/L}$)

Besides, the recorded UV-vis spectra during the Fenton-like degradation process was presented in Fig. 12. It showed that the solution of MB exhibited bands at 290, 610, and 665 nm that decreased rapidly and disappeared after 40 min, without the appearance of new absorption bands. Consequently, the complete degradation for decolorization of MB was achieved at the end of 40 min and the color of the MB solution altered from blue to colorless.

Fig. 12. UV-vis spectra of MB solution in the presence of 5.0 % H_2O_2 (initial pH=3.0, $T=298\text{ K}$, $C_0=100\text{ mg/L}$, $X_0=1.0\text{ g/L}$)

IV. CONCLUSION

In the present work, Alg/ Fe_3O_4 NPs were synthesized by using a simple and fast reduction-precipitation method and the synthesized Alg/ Fe_3O_4 NPs were characterized by FT-IR, XRD, SEM, and EDX analysis. The stretching and vibrations of O–H, O–C–O, C–O, C–C, and Fe–O were determined by FT-IR analysis. XRD analysis showed that Alg/ Fe_3O_4 NPs presented the characteristic pattern of cubic spinel structure of Fe_3O_4 . The porous structure and spherical-like structures in nanoscale of Alg/ Fe_3O_4 NPs were observed by SEM analysis. EDX analysis indicated that Alg/ Fe_3O_4 NPs had the elements of iron, oxygen, carbon, sodium, chlorine, and sulfur. Also, Alg/ Fe_3O_4 NPs were evaluated as potential adsorbents for removal of Methylene Blue from aqueous solutions in a single stage batch mode. The

adsorption studies were performed as a function of initial pH, initial dye concentration, temperature, and adsorbent concentration. The optimum conditions were obtained as follows: initial pH of 8.0, initial dye concentration of 300 mg/L, temperature of 308 K, and adsorbent concentration of 0.5 g/L. The pseudo second order kinetic model fitted quite well to the adsorption kinetic data, and both intraparticle and film diffusion were effective on the studied adsorption process. Thermodynamic parameters indicated that the adsorption was spontaneous ($\Delta G < 0$), exothermic ($\Delta H < 0$), physical ($E_a < 40\text{ kJ/mole}$), and decreasing in randomness of adsorbed species ($\Delta S < 0$). Moreover, the degradation of MB in the presence of H_2O_2 was also investigated; and it was found that the MB degradation efficiency of 99 % was achieved in 40 min. It was concluded that high removal capacities for MB with Alg/ Fe_3O_4 NPs could be achieved by both adsorption and degradation processes. Besides, Langmuir isotherm model was found as the best-described isotherm model for the adsorption equilibrium and the maximum monolayer capacity of 393.39 mg/g indicated the sufficient adsorption capability of Alg/ Fe_3O_4 NPs with respect to the other types of Fe_3O_4 nanoparticles in the literature.

Abstract- Volatile Organic Compounds (VOCs) are one of the main sources of the indoor air contaminants. VOCs including acetone, toluene and methanol in building materials such as adhesives, sealants, paints, solvents, stains, carpets, vinyl flooring, wallboard and engineered woods can act to indoor air quality due to their toxic effect. For this reason, these compounds emitted by building materials are considered as a rising problem for productiveness, comfortable and healthy life. On the other hand, gypsum plasters or boards are widely used to cover the interior walls or ceilings of the residential buildings because of their properties as aesthetics, easily workable, low density, and insulating behavior. One of the most properties of gypsum plasters is a highly porous material. The diffusion and adsorption of many compounds including moisture and low molecule weight vapors found in indoor environment can cause through this property. The effective diffusivity of the compounds is a key parameter to understand the transport and/or adsorption phenomena in porous media. This study aimed to investigate the diffusion and adsorption behavior of acetone, onto various gypsum plasters (perlite plaster, thermal isolation plate plaster and machine plaster) in the one-sided single pellet at different temperature and isobaric conditions.

The experimental setup includes (1) Carrier gas tube, (2) Rotameter, (3) Sample inlet, (4) Diffusion/adsorption pellet cell, (5) Soap bubble meter, (6) TCD detector, (7) Oven, (8) GC, and (9) Recorder. The experimental runs were performed under isobaric conditions were carried out at flow rates ranging from 50-175 ml/min and at different temperatures ranging from 25 to 60 °C. The pulses of the diffusing and adsorbing tracers were injected into the carrier gas stream by using a syringe, in order to flow past the upper face of the pellet. The response peaks obtained by GC were analyzed by the moment technique. The calculation of adsorption parameters and diffusion coefficient were obtained through the moments computed by using experimental data. The results showed that the adsorption of acetone on all gypsum plasters used was found to be reversible. The results indicated that the adsorption degree of acetone on the thermal insulation plaster was the lowest value. The acetone adsorption decreased with increasing temperature while the effective diffusivities of acetone increased with increasing temperature in the gypsum plasters. Moreover, the studies revealed that the adsorption process was physical adsorption process and exothermic. The study concluded that a considerable amount of VOC (acetone) was physically adsorbed onto the building material used in this study. In addition, the diffusion of VOC likely occurs in the building materials. Moreover, the reasons such as testing of different volatile organic compounds from acetone, moisture effect on VOC diffusion and adsorption in gypsum plaster samples and binary or multi-component diffusion and adsorption can be recommended for further investigation.

Abstract— The effect of ammonium persulfate (APS) concentration on electrochemical polymerization of catechol was investigated between 2-10 g/L at 6 g/L catechol concentration and 40°C reaction temperature in 120 min reaction time. Graphite working electrode, Ag/AgCl reference electrode and platinum auxiliary electrode were used in a batch electrochemical cell. Increasing APS concentration increased the catechol removal, amount of polymer obtained and the reaction selectivity. In the study, catechol removal, amount of polymer obtained and reaction selectivity were obtained between 65.2-77.6%, 4.8-117.7 mg, and 1.3-37.6%, respectively.

Keywords— catechol; electrochemical polymerization; wastewater treatment

I. INTRODUCTION

Catechol is a phenolic compound that can be found in various industrial wastewater (Zhang *et al.*, 2010) and must be treated due to its high toxicity and hazardous properties for humans and aquatic environment. The treatment methods include adsorption, solvent extraction, and advanced oxidation methods (Zhang *et al.*, 2010; Hou *et al.*, 2015; Aktaş and Tanyolaç, 2003; Liu *et al.*, 2017; Singh and Balomajumder, 2016; Kujawski *et al.*, 2004; Yang *et al.*, 2006).

In electrochemical polymerization, monomer dissolves in supporting electrolyte solution and a potential applies to working electrode for the formation of a radical cation. Polymer films and conductive polymers can produce by electrochemical polymerization (Bao *et al.*, 2010).

The aim of this study is to investigate the effect of ammonium persulfate (APS) concentration on the removal of catechol from aqueous solutions using electrochemical polymerization.

II. METHOD

The polymerization reaction was conducted in a batch electrochemical cell that consists graphite working electrode, Ag/AgCl reference electrode and platinum auxiliary electrode using VoltaLab 40 potentiostat. The volume of the electrochemical

reactor was 100 mL. Reaction medium was mixed with a magnetic stirrer at 400 rpm. Reaction temperature was controlled with circulating water recycled from a temperature controlled water bath using a peristaltic pump.

III. RESULTS AND DISCUSSIONS

The effect of ammonium persulfate (APS) concentration was investigated between 2-10 g/L at 6 g/L catechol concentration and 40°C reaction temperature in 120 min reaction time in a batch reactor. The increasing APS concentration increased the catechol removal, the amount of polymer obtained and the reaction selectivity as outlined in Table 1.

When the APS concentration was increased from 2 g/L to 10 g/L, the catechol removal increased from 65.2% to 77.6% while the reaction temperature and initial catechol concentration were held constant. Reaction selectivity increased from 1.3% to 37.6% that indicates the decrease of the amount of reaction by-products. Increasing APS concentration increased the polymer mass and as a result catechol removal was increased.

Table 1. Effect of initial APS concentration on electrochemical polymerization catechol.

APS (g/L)	Catechol removal (%)	Polymer (mg)	Reaction selectivity (%)
2	65.2	4.8	1.3
6	66.0	51.1	17.1
10	77.6	117.7	37.6

The FTIR spectrum and SEM images of the catechol polymer can be seen in Figures 1 and 2.

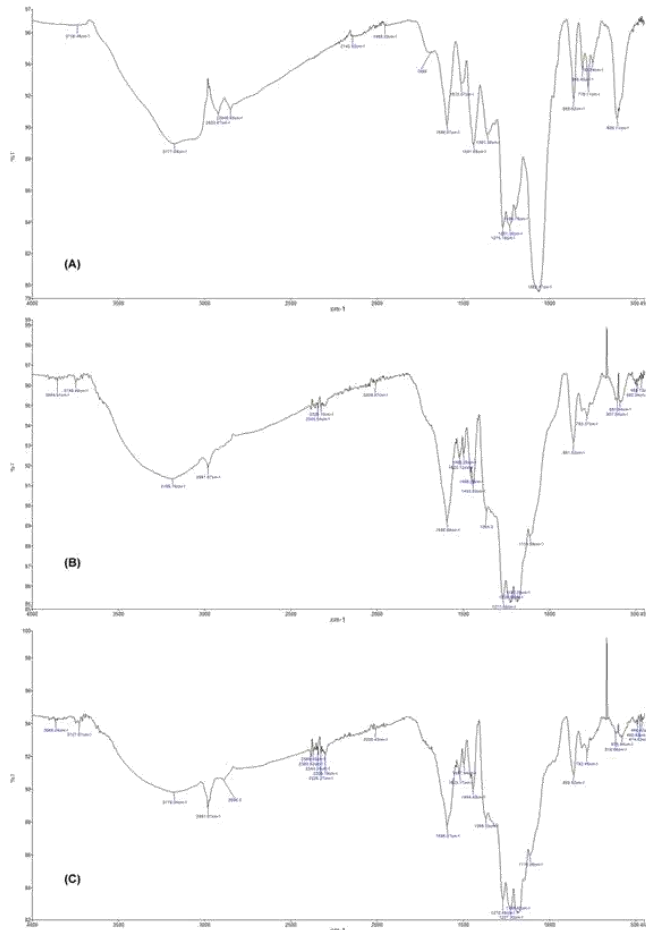

Figure 1. FTIR spectrum of catechol polymer. (A) APS=2 g/L, (B) APS=6 g/L, (C) APS=10 g/L.

In Figure 1, increasing APS concentration increased the OH stretching at 3700 cm^{-1} and the broad band at 3200 cm^{-1} was extended. A new peak was observed at 700 cm^{-1} with the increase of APS concentration and the peak at 1690 cm^{-1} was disappeared with increasing APS concentration to 10 g/L .

Aktaş and Tanyolaç (2003) produced catechol by oxidative polymerization using laccase enzyme. They reported 3370 cm^{-1} broad band phenolic -OH bond, aromatic $\text{C}=\text{C}$ bond peaks at 1400 cm^{-1} and 1600 cm^{-1} , C-O-C bond peaks at 1260 cm^{-1} and 1050 cm^{-1} , and $=\text{C-H}$ bond peaks at 810 cm^{-1} and 920 cm^{-1} . The obtained homogenous polymeric structures are seen in Figure 2B and 2C. The increase in the APS concentration showed positive effect on the formation of polymer chains whereas the aggregated polymeric structure can be seen in Figure 2A.

Figure 2. SEM images of catechol polymer (X25000). (A) APS=2 g/L, (B) APS=6 g/L, (C) APS=10 g/L.

IV. CONCLUSION

The effect of ammonium persulfate (APS) concentration on electrochemical polymerization of catechol in aqueous solutions was investigated in this study. The increasing APS concentration increased the catechol removal, the amount of polymer obtained and the reaction selectivity. In the study, catechol removal, amount of polymer obtained and reaction selectivity were obtained between 65.2-77.6%, 4.8-117.7 mg, and 1.3-37.6%, respectively. The results of this study indicated that ammonium persulfate (APS) could be used as an effective initiator for the electrochemical polymerization of catechol.

Abstract— In the world, many countries produce chemical materials such as dyes, hydrocarbons, phenolic compounds, rubber, plastics and pesticides. Dyes are one of the highest toxic, carcinogenic, hazardous and bulk produced compounds discharged into rivers, lakes and coastal areas, which are not degradable in its case [1]. Since the textile dye industry consumes large quantities of clean water and produces large volume of waste water from different steps in processing operations including dyeing, printing, pre-treatment and so on, environmental purification of dye has increasingly become a global concern calling for considerable attention. In recent decade, many researchers and strategists wanted to remove these pollutants by using traditional methods such as physical, biological and chemical and also advanced oxidation process (AOP) for degradation or a least to remove from the medium [2-4]. However, the traditional methods are often costly and can cause secondary pollution thus limiting large-scale using. Therefore, innovation efforts for creating a cost-effective and green solution have been passion for everyone in earth which provide us fresh water supply in an economic manner. That is why more efficient and economic methods such as AOP and the others need to be developed [5].

In this study, the photocatalytic degradation of C.I. Reactive Red (RR195) was studied using UV-C radiation in the presence of ZnO semiconductor (0.0-5.0 g/L; Figure 1.) as a function of initial dye concentration of RR195 (150-550 mg/L), air feed rate (0.0-1.0 L/min; Figure 2.) and temperature (283-323 K). It was found that the photodegradation efficiency was affected by the amount of ZnO, initial dye concentration, air feed rate and temperature of the solution. The color removal rate is faster in low initial dye concentration and also increased with increasing ZnO dosage, air feed rate and temperature increase.

Figure 1. Effect of ZnO amount (Conditions: 250 mg/L RR195; 0.5 L/min aeration rate; pH_{in} = 5.6 (natural pH of dye solution); 293 K reaction temperature; 1000 rpm mixing rate).

Figure 2. Effects of Aeration Rate (Conditions: 250 mg/L RR195; 4.0 g/L ZnO; pH_{in} = 5.6 (natural pH of dye solution); 293 K reaction temperature; 1000 rpm mixing rate).

The degradation of RR195 increase with the increasing ZnO, air feed rate and temperature but decrease with initial RR195 concentration. The efficiency values of photocatalytic degradation process of the RR195 dye at 30 minutes reaction time were 100, 94.8, 79.1, 57.3 and 46.2 % for the initial dye concentration values of 150, 250, 350, 450 and 550 mg/L respectively, at the conditions of 4.0 g/L ZnO; 0.5 L/min aeration rate; pH_{in} = 5.6 (natural pH of RR195 solution); 293 K reaction temperature; 1000 rpm mixing rate.

A comparison of the maximum photocatalytic activity of ZnO with other catalysts is shown in Table 1.

Table 1. Comparison of photocatalytic degradation of dyes using various photocatalysts.

Abstract— Torrefaction is a type of thermo-chemical pretreatment process to enhance energy density of lignocellulosic fuels. For a torrefaction process, a key challenge is to develop efficient thermal conversion technologies for torrefied fuels which can compete with fossil fuels. The calculation of chemical exergy is an essential step for designing efficient thermal conversion systems. However, there is a few correlation to predict the chemical exergy of solid fuels has been published so far. This study deals with a new method to characterize the chemical exergy of different kinds of torrefied lignocellulosic fuels by using Bayesian trained artificial neural network (ANN). The proposed model based on proximate analysis and higher heating values of torrefied fuels. Use of the artificial neural network method is encouraged to reduce variance in model results. The results indicate that the proposed model offers a high degree of correlation ($R^2=0.9999$) and its robustness and capability to compute the chemical exergy of any torrefied lignocellulosic fuels from its proximate analysis and heating value.

Keywords: Lignocellulosic fuels, chemical exergy, proximate analysis, neural networks.

I. INTRODUCTION

Environmental and economic concerns of fuel supply have been motivating the torrefied fuel for thermal conversion systems. Torrefaction is a thermochemical process in which raw biomass is heated under atmospheric pressure, at a temperature range of 200–300 °C, in the absence of oxygen or under low oxygen concentrations[1]. An efficient technology for torrefaction process which can produce torrefied fuel to substitute fossil fuels is a key challenge. Exergy analysis is commonly accepted as the most natural way to evaluate the performance of different processes and calculation of chemical exergy is the first step of exergy evolution [2] However, there is a few correlation to predict the chemical exergy of solid fuels have been published so far. These correlations are based on

ultimate analysis of fuels. However, the ultimate analysis requires very expensive equipment and highly trained analysts. The proximate analysis on the other hand only requires standard laboratory equipment and can be run by any competent scientist or engineer [3].

Artificial neural network is an effective alternative of linear and nonlinear correlations in that they can represent highly complex and nonlinear processes. Furthermore, they are quite flexible and robust against input noise and, once developed and their coefficients determined, they can provide a rapid response for a new input [4].

In this study, a new artificial neural network model was developed to evaluate the chemical exergy of torrefied biomass fuel, which is based on higher heating value and torrefied fuel content obtained by proximate analysis.

II. MATERIAL AND METHODS

A. Sample

The data of 116 torrefied biomass samples with their proximate and ultimate analysis were taken from the study of Daya Ram Nhuchhen [5], who acquired the data from previous studies in this field [6-16]. In order to develop a predictive model, the dataset used in this study was divided into two parts: the first part for training the model and the second for assessing the estimation capability of the obtained neural network architecture (called the “testing set”). All 116 torrefied biomass samples as well as a split of the samples into a training set with 97 samples and a testing set with 19 samples were randomly selected by using the MATLAB software. Description of torrefied biomass samples was given Table 1.

TABLE I. TORREFIED BIOMASS SAMPLES [5]

	Minimum (%)	Maximum (%)
Oxygen (% DAF*)	7.23	44.35
Nitrogen (%DAF)	0.00	2.65
Hydrogen (%DAF)	3.24	7.50
Carbon (%DAF)	49.25	88.50
Total sulfur (%DAF)	0.00	0.26
VM (%DAF)	15.71	87.37
FC (%DAF)	12.67	84.29
HHV (MJ/kg)	16.63	33.30

*DAF = Dry Ash free VM: Volatile Matter HHV: Higher Heating Value

In order to validate the artificial neural network model, untorrefied biomass samples from the study of Chun-Yang Yin[17] also were tested to measure the extensity of the proposed exergy model in this study. Description of biomass samples used in this study for 23 samples was given Table 2.

TABLE II. BIOMASS SAMPLES

	Minimum (%)	Maximum (%)
Oxygen (% DAF*)	33.02	48.99
Nitrogen (%DAF)	0.30	5.49
Hydrogen (%DAF)	4.49	7.34
Carbon (%DAF)	42.26	56.73
Total sulfur (%DAF)	0.02	0.85
VM (%DAF)	71.38	87.16
FC (%DAF)	12.84	28.57
HHV (MJ/kg)	15.09	21.95

*DAF = Dry Ash free VM: Volatile Matter HHV: Higher Heating Value

B. Artificial Neural Networks

An ANN is a massively parallel-distributed information processing system that simulates the functions of neurons using artificial neurons inspired from the studies of the brain and the nervous system[18]. An artificial neuron is the fundamental processing element of ANN and can be implemented in many different ways. The general architecture of an artificial neuron is shown in Fig. 1 [18, 19].

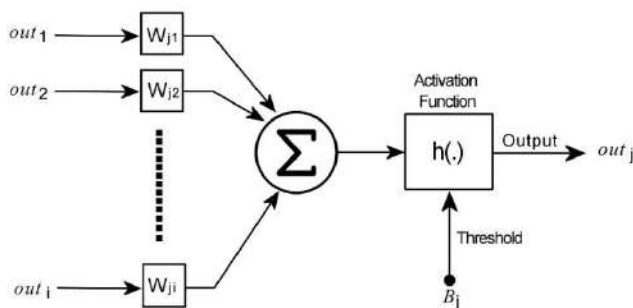

Fig. 1. Architecture of an artificial neuron

In this figure, input from the output (out_i) of the preceding layer neuron is multiplied by its weight value (W_{ji}). Then,

results of these multiplications are summed with bias value (B_j). The initial weights and biases are usually assigned randomly. The output of a neuron, which is in Fig. 1, can be described by Eq. (1).

$$out_j = h(\sum_{i=1}^N (W_{ji}X_i + B_j)), \quad (1)$$

where h is the activation (transfer) function. The activation function can be found in different forms, either linear or non-linear. In this work, logarithmic sigmoid, $h(x)$, function was used as an activation function which defines as:

$$h(x) = 1/(1+\exp(-2*x)) \quad (2)$$

Bayesian methods are the ideal methods for solving learning problems of neural network [20], which can automatically select the regularization parameters and integrate the properties of high convergence speed of traditional BP and prior information of Bayesian statistics [21]. The Bayesian Regularization method changes the error performance function by attaching a standard deviation of the weights and the thresholds [22] and can be expressed by [23]:

$$F = \beta E_D + \alpha E_w \quad (3)$$

where α and β are the regularization parameters.

Using (Eqn. 3) to minimize the performance error, enables the network to possess less weights and thresholds. This is equivalent to reducing the size of the network in such a way that it can respond smoothly, thus reducing overfitting [23].

C. ANN Model

The exergy value of a solid fuel is related to higher heating values and proximate analysis. Therefore, the correlation between the exergy values of torrefied fuels and their proximate analysis with higher heating values has been examined to develop an artificial neural network model. There are several classes of neural network architectures, classified according to a number of layers, neurons, and their interconnections. In this paper, we adopt a single-output three layered BP neural network with Bayesian regularization to predict the dry ash free based chemical exergy (e_{DAF}^{CH}) of the torrefied fuels. Fig. 2 presents the neural network structure of proposed model.

Fig.2. ANN Model

D. Validation of the correlations

In this study, Coefficient of determination (R^2) is employed to assess correlations for the chemical exergy of torrefied biomass, which is computed as follows:

$$R^2 = \left(\frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}} \right)^2 \quad (4)$$

Where y and x denote the estimated and calculated values, respectively. \bar{y} is the predicted average while, \bar{x} is the calculated average value. R^2 is used as a universal parameter to measure the accuracy of any model. A higher R^2 value means a better estimation and fitting.

III. RESULTS AND DISCUSSIONS

In order to use an artificial neural network model, one needs first to train the proposed model with training dataset. Fig.3 showed the quality of fit between the chemical exergy values and predicted chemical exergy values of torrefied fuels.

Fig.3. Training dataset

The artificial neural network model was tested for reliability using the testing dataset (Fig. 4).

Fig. 4. Test dataset

In this study, a high degree of correlation ($R^2 = 0.9999$) between actual and predicted chemical exergy was observed, as shown in Fig. 4, for test datasets of the torrefied lignocellulosic fuels. It can thus be apprehensible that the ANN model used in this study possesses chemical exergy prediction of good torrefied biomass accuracies and generalization performance.

To ensure the capability and predictive ability of the model, biomass fuel dataset also were used for the robustness of the proposed model. Fig. 5 shows the parity plots of the chemical exergy values and the corresponding ones estimated by the model in this study.

Fig. 5. Biomass Samples

IV. CONCLUSIONS

A model for chemical exergy prediction of lignocellulosic fuels was developed using artificial neural networks. The high R^2 values and the good fit in testing dataset lead to the conclusion that the artificial neural network model provides accurate predictions of the chemical exergy for a variety of torrefied lignocellulosic fuels. The major advantage of this model is its capability to compute chemical exergy of any torrefied fuels simply from its proximate analysis instead of ultimate analysis. Thereby provides a useful tool for exergy analysis of thermal conversion processes.

Abstract— *The architecture of scaffolds is important for tissue engineering applications. Because, scaffolds should have high porosity with interconnected pore structure to ensure cellular penetration and adequate diffusion of nutrients.*

In this study, chitosan was used to produce scaffolds in the form of hydrogel and cryogel. Hydrogels are mainly prepared by crosslinking polymerization of monomers at room temperature. On the other hand, the cryogelation technique is based on the crosslinking of polymers at sub zero temperatures. The aim of this study was to investigate the effect of system temperature on the final properties of the scaffold. Chitosan based scaffolds with a fixed polymer concentration of %1 (w/v) were prepared by adding the polymers in %6 (v/v) acetic acid solution. Three different temperatures (+25 °C, 0 °C and -25 °C) have been used to prepare scaffolds; chemical and physical structure of the scaffolds were analysed by FTIR and SEM; swelling and degradation profiles were followed. The results suggest that system temperature has significant effects on the characteristics of the chitosan gels.

Abstract—Chemical exergy is an influential parameter in the assessment of any fuel value as an indicator of the stored energy. Therefore, the determination of chemical exergy is the initial step in an application of any power plant. In this study, a model was developed to evaluate the chemical exergy of coal which was based on higher heating value and proximate analysis. The statistical validation shows that the proposed model in this study is reliable and accurate.

Keywords— Coal, chemical exergy, proximate analysis, nonlinear regression.

I. INTRODUCTION

Coal is a crucial energy source because of its low procurement costs attributed to a significant amount of recoverable reserves and stable supply [1].

The chemical exergy of coal is an important property in designing, operating and optimizing coal-based thermal processes. The exergy value can be utilized as a tool for the assessment of energy quantity as well as quality in thermolysis process using operational data at different conditions. There exist thermodynamics models based on the known homogeneous organic substances. Coal has unknown structure and chemical composition. Therefore, coal exergy value cannot be calculated directly [2].

Rant is one of the first researchers proposed the correlation of a semi-empirical formula to predict the exergy content of solid fuels [3, 4]. Szargut and Styrylska [5] improved Rant's equation and showed the ratio of exergy correlations depends significantly on the chemical composition of fuels. The correlation was commonly used for evaluation of chemical exergy of solid fuels in previous works. However, the states of some organic compounds had been mistaken in Szargut's source data, and the correlations do not involve the effect of sulfur on solid fuels [2]. Shieh and Fan [6] proposed a correlation to estimate the specific chemical exergy of a structurally complicate fuels. Stepanov modified Shieh and Fan model and applied the entropy model developed by Ikumi et al [7]. Bilgen and Kaygusuz [8] improved Stepanov's correlation for the estimation of the chemical exergy of coals by using the entropy model from the study of Eisermann et al [9].

In this study, we developed a new exergy correlation based on proximate analysis and higher heating value. The study aims to provide a simple model for the calculation of chemical exergy of coal.

II. METHOD

A. Sample

The coal data for this work is acquired from the study of Chelgani et. al [10]. A training set of 708 coal samples and a testing set of 177 coal samples were randomly selected by using the MATLAB software. The training dataset was employed for generation of the coal exergy model. Description of coal samples from the study was given in Table I [10].

Table 1. Coal samples [10]

	Minimum (%)	Maximum (%)
Oxygen (% DAF*)	0.43	14.74
Hydrogen (%DAF)	3.56	6.79
Carbon (%DAF)	72.28	88.6
Total sulfur (%DAF)	0.35	14.54
VM (%DAF)	27.72	54.95
HHV (MJ/kg)	26.43	36.92

*DAF = Dry Ash free VM: Volatile Matter HHV: Higher Heating Value

To choose the best suitable correlations, Turkish Lignites [11] also were tested to measure the accuracy of the proposed coal exergy model in this study. Description of Turkish Lignites data used in this study for 13 samples was given Table II.

Table 2. Turkish Lignites [11]

	Minimum (%)	Maximum (%)
Oxygen (% DAF*)	12.80	45.80
Hydrogen (%DAF)	4.20	7.30
Carbon (%DAF)	45.30	76.90
Total sulfur (%DAF)	0.10	7.20
VM (%DAF)	47.59	71.23
HHV (MJ/kg)	8.20	23.00

B. Chemical Exergy of Coal

Through a complete combustion at the reference state, the basis of 1 kg of DAF coal entering the control volume reacts with oxygen to produce carbon dioxide, water, nitrogen, and sulfur dioxide; that is,

where c, h, o, n, and s, each in kmol/kg (DAF), balancing the reaction equation, we have

$$\gamma_{CO_2} = c, \quad (2)$$

$$\gamma_{H_2O} = (1/2)h, \quad (3)$$

$$\gamma_{SO_2} = s, \quad (4)$$

$$\gamma_{N_2} = (1/2)n, \quad (5)$$

$$\gamma_{O_2} = c + (1/4)h + s - (1/2)o \quad (6)$$

For this case, chemical exergy equation takes the form [12]:

$$e_{DAF}^{CH} = (HHV)_{DAF} - T_0 [s_{DAF} + \gamma_{O_2} \bar{s}_{O_2} - \gamma_{CO_2} \bar{s}_{CO_2} - \gamma_{H_2O} \bar{s}_{H_2O} - \gamma_{SO_2} \bar{s}_{SO_2} - \gamma_{N_2} \bar{s}_{N_2}] + [\gamma_{CO_2} e_{CO_2}^{CH} + \gamma_{H_2O} e_{H_2O}^{CH} + \gamma_{SO_2} e_{SO_2}^{CH} + \gamma_{N_2} e_{N_2}^{CH} - \gamma_{O_2} e_{O_2}^{CH}] \quad (7)$$

The data of standard molar chemical exergy and absolute entropy of various pure substances at $T_0 = 298.15$ K and $p_0 = 1$ atm are presented in Table III [12].

Table 3. Standard molar chemical exergy and absolute entropy of pure substances [12]

Substances	$s^0/\text{kJ kmol}^{-1} \text{K}^{-1}$	$e^{\text{ch}}/\text{kJ kmol}^{-1}$
O ₂ (g)	205.15	3951
CO ₂ (g)	213.79	14176
SO ₂ (g)	284.09	301939
N ₂ (g)	191.61	639
H ₂ O (l)	69.95	45
H ₂ O (g)	188.82	8636

The absolute entropy for the dry and ash free coal can be estimated, in kJ/kgK, as follows [9]:

$$s_{DAF} = c[37.1653 - 31.4767 \exp(-0.564682 \frac{h}{c+n}) + 20.1145 \frac{o}{c+n} + 54.3111 \frac{n}{c+n} + 44.6712 \frac{s}{c+n}] \quad (8)$$

C. Validation of the correlations

In this study, three statistical parameters are employed to assess correlations for the chemical exergy of coal, which are computed as follows:

$$R^2 = \left(\frac{\sum_i^n (x_{cal,i} - \bar{x}_{cal})(x_{est,i} - \bar{x}_{est})}{\sqrt{\sum_i^n (x_{cal,i} - \bar{x}_{cal})^2} \sqrt{\sum_i^n (x_{est,i} - \bar{x}_{est})^2}} \right)^2 \quad (9)$$

$$\text{Average bias error (ABE)} = \frac{1}{n} \sum_{i=1}^n \frac{x_{est,i} - x_{cal,i}}{x_{cal,i}} \cdot 100 \quad (10)$$

$$\eta: \text{Relative Error} = \frac{|x_{est} - x_{cal}|}{x_{cal}} \quad (11)$$

where x_{est} and x_{cal} denote the estimated and calculated values, respectively. \bar{x}_{cal} is the calculated average value, while \bar{x}_{est} is the estimated average value. Statistical parameters are used as a universal parameter to measure the accuracy of the coal exergy model. A higher R^2 and lower ABE with η value means a better estimation and fitting.

III. RESULTS AND DISCUSSIONS

A. Predictive Model

The exergy value of a solid fuel is related to higher heating values and proximate analysis. Therefore, the correlation between the standard exergy values of coals and their proximate analyses with higher heating values has been examined to develop a new model. The correlation of the exergy values of coal can be represented as:

$$e_{DAF}^{CH} = \gamma_1 x_{HHV} + \gamma_2 x_{FC} + \gamma_3 x_{VM} \quad (12)$$

Where the coefficients from γ_1 to γ_3 denote the regression coefficients corresponding to the higher heating value (MJ/kg) and dry ash free components of coal proximate analyses: Fixed carbon and volatile matter, respectively. The model equation was solved in MATLAB using the fitlm function for the optimization of the values of the model coefficients. The fitted model was found as follows:

$$e_{DAF}^{CH} = 0.957420HHV + 0.034952FC + 0.010809VM \quad (13)$$

The specific chemical exergy of coal can be calculated by using the developed model (Eq. 14), in MJ/kg, as follows [12]:

$$e^{CH} = 0.791e_{DAF}^{CH} + \frac{0.1112}{18.015} e_{H_2O(l)}^{CH} \quad (14)$$

B. Validation of Proposed Model

To develop a generalized and unified exergy model, the training dataset was only utilized for the training of the nonlinear model. Fig.1 showed the quality of fit between the specific coal exergy values and predicted specific coal exergy values.

Fig.1. Training dataset

A high degree of correlation ($R^2 = 0.9991$) between actual and predicted coal exergy values was observed, as shown in Fig.1, for training datasets. The average bias error from estimating the training dataset for coal samples was only 0.29%.

To confirm the reliability of the proposed model, the testing datasets containing all 177 samples selected by using the MATLAB software were examined.

Fig. 2. Testing dataset

As shown in Fig. 2, the coefficient of determination (R^2) value was calculated as 0.9988. The average bias error from estimating the testing dataset for U.S. coals is only 0.32%. The results show that the equation provides a simple way to obtain a good prediction for the specific exergy values.

To ensure the robustness of the proposed correlation for calculating the exergy of any coal sample, Turkish Lignite datasets containing all 13 samples also were used for the predictive ability of the produced model. Fig. 3 shows the parity plots of the specific exergy values for Turkish Lignites and the corresponding ones predicted by the model in this study.

Fig. 3. Turkish Lignite dataset

Turkish Lignites is considered to be of poor quality because of its high ash and moisture content. The correlation coefficient

(R^2) for Turkish Lignites in Fig. 3 is 0.9994. Table IV shows the relative errors for Turkish Lignites between predicted specific chemical exergy versus calculated values.

Table 4. Comparison of specific chemical exergies of turkish lignites

e^{CH} (MJ/Kg)	Predicted e^{CH} (MJ/Kg)	η
10.2731	10.6354	0.0353
9.2240	9.6658	0.0479
12.8007	13.2940	0.0385
10.8916	11.1699	0.0256
9.2772	9.7054	0.0462
18.1617	18.6896	0.0291
8.1748	8.6461	0.0577
5.4063	5.5973	0.0353
6.1808	6.7235	0.0878
3.6039	3.8435	0.0665
4.4808	4.7250	0.0545
10.6934	11.1915	0.0466
13.9583	14.3215	0.0260

* η : Relative Error

The model is very sensitive to fixed carbon and volatile matter content with higher heating value. According to Table 4, it can thus be apprehensible that the model used in this study possesses excellent chemical exergy prediction accuracies and generalization performance.

IV. CONCLUSIONS

Some correlations are currently available to calculate chemical exergy of coal. Typical drawbacks of these equations are the determination of elemental analyses. The key merit of the proposed model in this study is an easy and robust method to predict the specific chemical exergy, when sophisticated measurement for ultimate analysis is not available. Furthermore, this approach can be easily applied via simple calculation.

Abstract— In the present work, the synthesis of silver nanoparticles (AgNPs) through a green synthesis method using avocado (*Persea americana*) leaf as a biological reductant and capping agent. The synthesized AgNPs were characterized by zetasizer, FTIR, UV-vis spectrophotometer, XRD, and SEM. Also, response surface methodology was used to understand and optimize the effect of the experimental parameters on the green synthesis of AgNPs. Three experimental parameters were chosen as independent variables: temperature, AgNO₃ concentration and aqueous leaf extract volume. A quadratic model was established as a functional relationship between three independent variables and the effective hydrodynamic diameter (nm) of AgNPs. The results of model fitting and statistical analysis demonstrated that only AgNO₃ concentration was statistically significant parameter. The optimum conditions for minimum effective hydrodynamic diameter (nm) of AgNPs (32.74 nm) were temperature of 25 °C, AgNO₃ concentration of 0.001 M, and aqueous leaf extract volume of 50 mL. Moreover, the antibacterial activities of AgNPs for *S. typhimurium*, *E. coli* O157:H7, *S. aureus*, and *L. monocytogenes* were tested and it was found that AgNPs had stronger inhibitory effects on growth of *L. monocytogenes* than the other bacteria.

Keywords—antibacterial activity, avocado leaf, optimization, response surface methodology, silver nanoparticles

I. INTRODUCTION

Silver nanoparticles (AgNPs) are amongst the crucial metallic nanomaterials that have become the focus of much investigation interest due to their unique optical, electrical, and biological properties which makes them to be used in various application areas such as catalysis, water treatment, electronics, biomedical, agriculture, food industry (packaging), accessories, animal husbandry, cosmetics, military, and textile industry. Besides, AgNPs are of significant interest in the area of especially biological systems, living organisms, and medicine because they are regarded safe and nontoxic inorganic antibacterial agents, which have been described as

“oligodynamic” due to its ability to exhibit bactericidal effect at even low concentrations [1]. There are various synthesis methods of metallic nanomaterials that include physical, chemical, and biological routes like sonochemical reduction,

microwave assisted process, hydrothermal synthesis, electrochemical method, reverse micelles/microemulsion method, green synthesis, and chemical reduction [2]. Among these methods, physical and chemical processes generally require to use of expensive and hazardous chemicals as well as high energy (high pressure and/or temperature). However, in the green synthesis method, environmental-friendly and biocompatible reagents are used in order to minimize the toxicity of the resulting nanomaterials and the environmental impact of the byproducts [3]. The basis of the green synthesis method is the reduction from the metal salt with the aid of the biological agents such as plant, algae, bacteria, and fungi. It is generally preferred to use plants, renewable sources, as reducing and capping agents for the nanoparticle synthesis because the green synthesis method using plants eliminates process of cell culturing and also it is a simple, efficient and low cost route [1]. Besides, the investigation of the effects of experimental conditions on the nanoparticle synthesis have become very important research area in order to understand and interpret the synthesis mechanisms. For this purpose, the optimization analysis could be evaluated by the traditional and statistical techniques. The optimization by the traditional ‘one-factor-at-a-time’ technique, where a single factor is varied while others are kept constant, requires a considerable amount of work and time; hence, an alternative statistical optimization techniques like response surface methodology (RSM) have been developed. The conventional optimization technique do not take into account the possible interaction of various

independent factors while RSM can be used to evaluate the relationship between a set of controllable experimental factors and observed results with limited number of experiments [4].

The aim of the present work is to synthesize of AgNPs by a fast, simple (one-step), environmental-friendly, and low-cost route using avocado (*Persea americana*) leaf, which acts as both reducing and stabilizing agent. Also, the effect of experimental conditions on the green synthesis of AgNPs was investigated with response surface methodology (RSM), the most widely used statistical technique for process optimization. Moreover, the antibacterial activity of AgNPs was tested against common foodborne pathogens such as *S. typhimurium*, *E. coli* O157:H7, *S. aureus*, and *L. monocytogenes*.

II. MATERIALS AND METHODS

A. Green Synthesis and Characterization of AgNPs

Extraction from avocado (*Persea americana*) leaves: The aqueous leaf extract, as a biological reducing and capping agent, was prepared for the green synthesis of AgNPs. For this purpose; 10 g of the purified and dried avocado (*Persea americana*) leaves were boiled in 500 mL of distilled water at 100 °C for 5.0 h. After cooling at room temperature, the brown aqueous leaf extract was filtered using by Whatman no. 1 filter paper and then it was stored in a refrigerator at +4 °C.

Synthesis and Characterization of AgNPs: The required volume of the aqueous leaf extract was added to 100 mL of AgNO₃ at the required concentration in the conical flasks. Then, they were shaken in an agitation vessel at constant temperature for 1 h. They were allowed to stand at the reaction temperature for 1.0 day to be accomplished the synthesis. After that, the resulting mixture was centrifuged at 4000 rev/min for 10 min and the precipitated AgNPs were washed with distilled water. They were dried at 110 °C in an oven for 24 h, and were stored at +4 °C in the refrigerator [5]. The characterization studies of AgNPs were performed by zetasizer (Malvern, UK) using Dynamic Light Scattering (DLS) technique, Fourier Transform Infrared Spectrometer (FTIR- Perkin Elmer, Shelton), X-ray Diffractometer (XRD- Philips XPert, Netherlands), and Scanning Electron Microscope (SEM- Zeiss/Supra 55, Germany).

B. Experimental Design and Optimization using Response Surface Methodology

The face centered central composite design (CCD) with free Minitab 17 software (Minitab Inc.) for the response surface methodology (RSM) was employed to optimize the experimental conditions such as temperature, AgNO₃ concentration, and aqueous leaf extract volume for green synthesis of AgNPs. The ranges and levels of the independent variables for the experimental design strategy were presented in Table I while the experimental design along with the responses for the effect of three independent variables in 20 sets of experiments was shown in Table II.

THE RANGES AND LEVELS OF THE INDEPENDENT VARIABLES

Symbol	Independent variable	Coded levels		
		Low (–1)	Center (0)	High (+1)
A	Temperature (°C)	25	45	65
B	AgNO ₃ concentration (M)	0.0010	0.0505	0.1000
C	Aqueous leaf extract volume (mL)	10	30	50

In the optimization process, the responses can be simply related to chosen factors by linear or quadratic models. A quadratic model, which also includes the linear model, is given as [6];

$$Y = b_0 + b_1A + b_2B + b_3C + b_{11}A^2 + b_{22}B^2 + b_{33}C^2 + b_{12}AB + b_{13}AC + b_{23}BC \quad (1)$$

where Y represents the response of the effective hydrodynamic diameter (nm) of AgNPs, where b₀ is intercept term, b₁, b₂, and b₃ are linear coefficients, b₁₁, b₂₂, and b₃₃ are quadratic coefficients, b₁₂, b₁₃, and b₂₃ are interactive coefficients, and the independent variables are coded A, B, and C. The interaction between the independent variables and the responses was tested by using ANOVA and the effect of the variables was also evaluated with response surface graphs.

THE EXPERIMENTAL DESIGN WITH THE OBTAINED RESPONSES

Run order	Independent variables			Response Y

15	65	0.1000	50	132.00
16	45	0.0505	30	62.77
17	45	0.0505	30	63.91
18	45	0.1000	30	96.10
19	25	0.1000	50	74.40
20	45	0.0505	30	61.68

C. Antibacterial Activity of AgNPs

Bacteria selection: In this study, *Escherichia coli* (O157:H7), *Listeria monocytogenes*, *Staphylococcus aureus* and *Salmonella typhimurium* bacteria species were selected for determining of antibacterial activities of AgNPs because they are common foodborne pathogens. Also they are used here as representative gram positive (*Listeria monocytogenes*, *Staphylococcus aureus*) and gram negative (*Escherichia coli* (O157:H7), *Salmonella typhimurium*) pathogens.

Culture and Inoculum Preparation: *Escherichia coli* (O157:H7), *Listeria monocytogenes*, *Staphylococcus aureus* and *Salmonella typhimurium* cultures were obtained from the Microbiology Laboratory of Food Engineering Department of Mersin University. The bacterial cultures were grown on TSA slants and kept at 4°C. Isolated colonies obtained from the TSA slants were inoculated into TSB medium. The broth culture was incubated at 37°C for 24 h. The optical density of the culture was adjusted between 0.08 to 0.1 at 625 nm to obtain inoculum size of 1×10^7 colony-forming unit (CFU)/mL.

Antibacterial Activity: Antimicrobial susceptibility was tested by the agar disk diffusion method on Mueller Hinton Agar. Surface of agar plate was inoculated by spreading of the test microorganism over entire surface. Then, antimicrobial discs with the diameter of 6 mm were treated with AgNPs solution and the excess solution was removed from discs. The Petri dishes are incubated at 37°C for 24 h. The test compound diffuses into the agar and inhibits the growth of the test microorganism. The diameters of inhibition growth zones are measured with a digital caliper.

III. RESULTS AND DISCUSSION

Optimization of Experimental Conditions of Green Synthesis of AgNPs

The effects of experimental conditions such as temperature, AgNO₃ concentration, and aqueous leaf extract volume on green synthesis of AgNPs were investigated by using RSM according to CCD. The experimental results were evaluated and the empirical relationship between the independent variables and the effective hydrodynamic diameter (nm) of AgNPs (Y) was given in Eq. 2:

$$Y = 78.6 - 0.79 A + 25 B - 1.475 C + 0.0046 A^2 + 5434 B^2 + 0.0103 C^2 + 7.32 AB + 0.01580 AC - 6.35 BC \quad (2)$$

The statistical significance of the quadratic model equation was evaluated by F-test for analysis of variance (ANOVA) and the results of ANOVA were presented in Table III. As can be seen from Table III, the model F-value of 31.36 and P-value<0.0001 indicated that the model was statistically significant. Besides, the independent variable B, AgNO₃ concentration, was the only significant term (P-value<0.0001) for the quadratic model. The R² of 0.9658 was in conceivable agreement with the R²_{adj} of 0.9350. Adequate precision measures the signal (response) to noise (deviation) ratio, and a ratio greater than 4 is required. The ratio of 7.7034 implied an adequate signal and the quadratic model can be used to navigate the design space [6]. Consequently, this quadratic model could be used for the purpose of predicting future responses successfully for the green synthesis of AgNPs.

ANOVA RESULTS OF THE QUADRATIC MODEL

Source	Degree of freedom	Sum of squares	Mean squares	F-value	P-value	Remarks
Model	9	16749.4	1861.0	31.36	<0.0001	Significant

Pure error	5	7.0	1.4			
Total	19	17342.8				

R²=0.9658; R²_{adj}=0.9350; Adequate precision=7.7034

The plot of the standardized residuals vs predicted effective hydrodynamic diameter (nm) of AgNPs was presented in Fig. 1. As can be seen from Fig. 1, it exhibited nearly a funnel-shaped pattern because the variance of the response depended on the mean level of Y, thus suggesting no need for transformation of the response variable [6].

Fig. 2 showed that the points of data were close to a straight line (R²=0.9658), which indicated a good correlation between the predicted and experimental responses. Also, it could be concluded that the chosen quadratic model was acceptable for the experimental data of the green synthesis of AgNPs [7].

Fig. 1. The standardized residual vs predicted effective hydrodynamic diameter (nm) of AgNPs plot

Fig. 2. The experimental and predicted plot for the green synthesis of AgNPs

The optimum effective hydrodynamic diameter (nm) of AgNPs was predicted as 32.7370 nm at temperature (A) of 25 °C, AgNO₃ concentration (B) of 0.001 M, and aqueous leaf extract volume (C) of 50 mL from the quadratic model. In order to investigate the interaction among the variables, 3D response surfaces were plotted on the basis of the model equation (Fig. 3. a-c). According to Fig. 3; as expected from ANOVA, only AgNO₃ concentration (B) significantly affected the effective hydrodynamic diameter of AgNPs. As B increased, the effective hydrodynamic diameter increased resulting from the substantially agglomeration of the AgNPs at high AgNO₃ concentrations. Also, temperature and aqueous leaf extract volume were not significant model parameters but it could be said that the effective hydrodynamic diameter slightly increased with increase in temperature while it decreased with increase in aqueous leaf extract volume. This could be explained as follows; the increase in the temperature raised the kinetic energy of the AgNPs, thereby resulting the collision frequency between the nanoparticles and this led to the increase in agglomeration [8]. Also, at high volumes of aqueous leaf extract, the biomolecules in the leaf extract acted as reducing agents and capped the nanoparticles protecting them from aggregation [9].

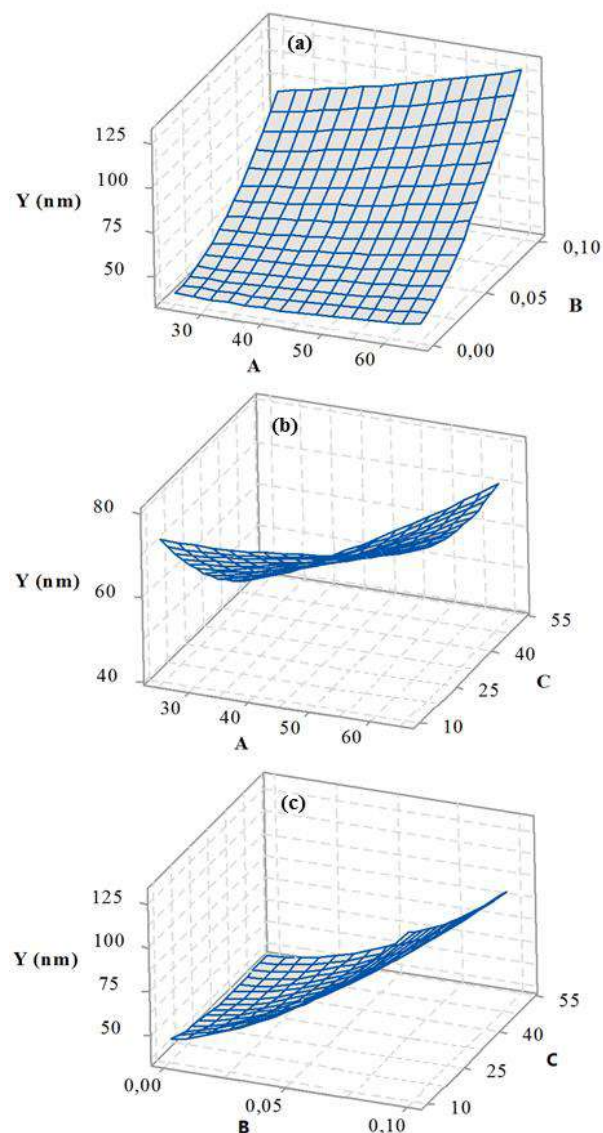

Fig. 3. Response surface plots of the model showing the effective hydrodynamic diameter (nm) of AgNPs as a function (in coded levels) of: a. temperature and AgNO₃ concentration, b. temperature and aqueous leaf extract volume, c. AgNO₃ concentration and aqueous leaf extract volume

Characterization of AgNPs

The formation of AgNPs was firstly noted by visual observation of the color of AgNO₃-aqueous leaf extract solution and then the UV-vis spectra of the solutions were performed against pure water with 1 mm optical path length quartz cuvette. Fig. 4 presented that the color of the solution altered from light brown to dark brown by the time of synthesis progress indicating silver nanoparticle formation due to the surface plasmon resonance (λ_{SPR} , nm) phenomenon. Also, as shown in Fig. 4, a characteristic and well-defined λ_{SPR} value for AgNPs was recorded at nearly 430 nm whereas AgNO₃ solution (for control) did not exhibit any characteristic peak.

Fig. 4. UV-vis spectra of AgNPs and AgNO₃ solutions along with the color change upon formation of silver nanoparticles

Besides, the values of λ_{SPR} were recorded for the run orders of 5 (A=25 °C, B=0.001 M, and C=10 mL), 7 (A=65 °C, B=0.001 M, and C=10 mL), 11 (A=25 °C, B=0.001 M, and C=50 mL), 15 (A=65 °C, B=0.1 M, and C=50 mL), and 19 (A=25 °C, B=0.1 M, and C=50 mL) and it was presented in Fig. 5.

Fig. 5. UV-vis spectra of AgNPs solution at different experimental conditions

As seen from Fig. 5, λ_{SPR} values were also observed at around 430 nm, which was the characteristic peak of AgNPs. Mainly, the sharp and narrow peak shows the stable and smaller formation of nanoparticles in the homogeneous distribution [9]. Hence, it can be seen from Fig. 5 that the maximum λ_{SPR} value, indicating the formation of smallest nanoparticles, was detected for the run order of 11, the optimum synthesis conditions. Consequently, the decrease in λ_{SPR} with increase in temperature and AgNO₃ concentration, and with decrease in aqueous leaf extract volume could be attributed to the decrease in the diameters of AgNPs. These observations confirmed the ANOVA results.

In the green synthesis method, +1 valent silver ion in AgNO₃ structure is reduced to zero valent silver, silver nanoparticles (AgNPs), with the aid of the various compounds in the aqueous leaf extract such as proteins, amino acids, organic acids, vitamins, flavonoids, alkaloids, polyphenols,

terpenoids, and polysaccharides. In order to determine the functional groups of AgNPs, FT-IR analysis was performed and it was presented in Fig. 6. O–H group in polyphenols or proteins/enzymes or polysaccharide (3400 cm⁻¹), =C–H alkenes (2980 cm⁻¹), –COOH carbonyl group (1630 cm⁻¹), –C–H alkane (1387 cm⁻¹), C–N stretch aliphatic amines (1091 cm⁻¹), C–N amines (1005 cm⁻¹), C–C bending (660 cm⁻¹) peaks were observed from FT-IR spectra of AgNPs. These FTIR peaks confirmed that the aforementioned compounds in the aqueous leaf extract played important roles in the reduction of Ag¹⁺ (AgNO₃) into Ag⁰ (AgNPs) [10, 11].

Fig. 6. FT-IR spectra of AgNPs

Fig. 7. The distribution of effective hydrodynamic diameters of AgNPs

At the optimum synthesis conditions (A=25 °C, B=0.001 M, and C=50 mL), the distribution of effective hydrodynamic diameters of AgNPs was measured by DLS technique and the results were represented in Fig. 7. The mean diameter of AgNPs was determined as 35.27 nm with low polydispersity index (PDI) of 0.377. The morphology of AgNPs was evaluated by SEM analysis for the optimum synthesis conditions (A=25 °C, B=0.001 M, and C=50 mL). As seen from Fig. 8., the nearly spherical-like nanoparticles were synthesized successfully and also it could be said that the mean diameter of AgNPs in SEM image was smaller than that observed with DLS technique. In DLS technique, the hydrodynamic diameters of materials dispersed in solvents are measured, that resulting in the bigger structures [12].

Fig. 8. SEM image of AgNPs

In order to investigate the crystal phase of AgNPs, XRD analysis was performed in 2θ value ranging from 30° to 90° for the optimum synthesis conditions ($A=25^\circ\text{C}$, $B=0.001\text{ M}$, and $C=50\text{ mL}$). XRD pattern of AgNPs (Fig. 9) exhibited peaks at 2θ angles of 38.10 , 44.28 , 64.41 , and 77.36° which corresponded to the $[1\ 1\ 1]$, $[2\ 0\ 0]$, $[2\ 2\ 0]$, and $[3\ 1\ 1]$, crystal planes of a cubic lattice structure of AgNPs. The unassigned peaks stemmed from the crystallization of bio-organic phase (as obtained in FT-IR spectra) on the surface of the silver nanoparticles due to the aqueous leaf extract [9].

Fig. 9. XRD pattern of AgNPs

Antibacterial Activity of AgNPs

The synthesized AgNPs at the optimum experimental conditions were effective against all selected bacteria, *S. typhimurium*, *E. coli* O157:H7, *S. aureus*, and *L. monocytogenes*, and the inhibition zone diameters of test compound for these bacteria were given in Table IV and Fig. 10. The results indicated that AgNPs had stronger inhibitory effected on growth of *L. monocytogenes* than the other bacteria. These results suggested that AgNPs could be successfully used as effective antimicrobial agents in food packaging to control the growth of pathogenic bacteria.

THE INHIBITION ZONE DIAMETERS

Bacteria	Inhibition zone diameter (mm)
<i>S. typhimurium</i>	10.00 ± 0.87
<i>E. coli</i> O157:H7	10.55 ± 0.68
<i>S. aureus</i>	10.72 ± 0.63
<i>L. monocytogenes</i>	12.26 ± 0.23

Fig. 10. Antibacterial activity of AgNPs

IV. CONCLUSION

In this work, an ecological method for synthesizing silver nanoparticles (AgNPs) was established by using avocado (*Persea americana*) leaf as a biological reductant and capping agent. The characterization studies of AgNPs were conducted by zetasizer (with DLS technique), FTIR, UV-vis spectrophotometer, XRD, and SEM. The size distribution obtained by DLS showed that the synthesized AgNPs had a relatively narrow size distribution (25–41 nm) and the mean effective hydrodynamic diameter of AgNPs was obtained as 35.27 nm. According to UV-vis spectra; AgNPs had characteristic surface plasmon resonance band at around 430 nm and it was a narrow and sharp band, which indicating the formation of homogeneous, stable, and small nanoparticles. XRD pattern exhibited the characteristic peaks of cubic lattice structure of AgNPs. The nearly spherical-like nanoparticles was found by SEM analysis. Moreover, response surface methodology (RSM) was practicable to optimize the effective hydrodynamic diameter (nm) of AgNPs for the green synthesis method. According to RSM, AgNO_3 concentration significantly influenced the size of AgNPs. Also, it was observed from response surface plots that the effective hydrodynamic diameter slightly decreased with decrease in temperature while it decreased with increase in aqueous leaf extract volume. The smallest particle size was obtained at the optimum synthesis conditions of temperature 25°C , AgNO_3 concentration 0.001 M, and aqueous leaf extract volume 50 mL. Besides, the

antibacterial activity of AgNPs was investigated and it was found that AgNPs synthesized at the optimum conditions were effective against *S. typhimurium*, *E. coli* O157:H7, *S. aureus*, and *L. monocytogenes*.

Abstract- The workers in a cement factory are exposed to many occupational hazards which contribute to work injuries, dies and allergic problems to cement components. Cement can cause ill health in workers through skin and eye contact or inhalation. The risk of injuries and occupational health problems for cement factory workers depends on the duration and level of exposure and individual sensitivity. Because of inevitable work-related diseases and accidents, occupational safety regulations are compulsive to prevent such risks through recognition, evaluation and control of the hazards in an ideal world. Safety management not only saves lives but also is a profit maker for the countries. Diverse studies for assessing the risks in cement plants have been previously investigated in various studies. This study aimed to identify risks and to assess the health risks may occur during cement production.

The case study is carried out in Elazığ-Altınova Cement Plant to determine safety risk scores by carrying out risk analysis within plant site according to the occupational health and safety risk managements in the cement production processes. The methodology used to determine occupational health risks scores in the Cement Plant is the 5x5 L type risk matrix. The plant site visit program covers the sections of raw material processing, storage and transportation, raw material milling, clinker production and cement milling. Data collection and assessment included listing of all possible risks, determination of likelihood and severity of the risks and calculation of risk scores by using these values. After determining the risks for the workers, the safety risk tables were prepared and the possible risks were classified as high, moderate and low risk degrees with respect to occupational and safety risk management system. The results showed that there were 413 risks in the Cement Plant. It was observed that the risk scores were cumulated between 20 and 6 risk scores, and there are no risks both at 25 risk score and under 6 risk score for the entire cement plant. It was also observed that among these risks, 76 of them were high risks (18,4 %), 333 of them moderate risks (80,6 %), and 4 of them were low risk (1 %). As a result of risk assessment, 128 risk scores of the total risk scores (31,0 %) are determined in the raw material milling section and these risks are encountered as the most dangerous risks. On the other hand, the highest risk score of 20 (only 1) was also seen in raw material milling section. The study concluded that the most dangerous risks which were determined in the raw material milling. On the other hand, the highest risk scores were also obtained in the raw material milling section. It was also observed that the crusher, raw material and cement mills and rotary kiln are the most dust, noise and vibration producing units. The study recommended that (1) work needed to improve occupational health and safety performance for workers, (2) periodic checkup needed for workers for early detection of occupational hazards, (3) periodic educational training are needed for all workers in cement factory about the occupational hazards, (3) emphasizing on the importance and usefulness of personal protective equipment are needed.

Keywords— cement Process, occupational health and safety, risk definition, risk analysis, risk assessment

Green Synthesis of Copper Oxide Nanoparticles (CuONPs) by Using *Myrtus Communis* Leaves Extract: Telon Blue AGLF Adsorption

Müjde HOCAOĞLU and Ayla ÖZER

E-mail address: hocaoglumujde@gmail.com and ayozer@mersin.edu.tr

Abstract— In this study, the green synthesis of copper oxide nanoparticles (CuONPs) was achieved by using *Myrtus communis* leaves extract as reducing agent. The biosynthesized CuONPs were characterized by various physicochemical characterization techniques such as X-Ray Diffraction (XRD), UV-Vis Spectroscopy, Scanning Electron Microscopy (SEM), Fourier Transform Infrared Spectroscopy (FT-IR) and Energy Dispersive X-Ray Spectroscopy (EDX). Thereafter, the biosynthesized CuONPs were used as an adsorbent for batch adsorption of Telon Blue AGLF (TB AGLF) dye. The optimum adsorption conditions were determined to be initial pH 7.0–8.0, temperature 25 °C and adsorbent dose 1.0 g/L. The adsorption equilibrium was described well by the Langmuir isotherm model with maximum adsorption capacity of 3225.8 mg/g at 25 °C. The intraparticle diffusion and the pseudo-second order kinetic models were applied to the experimental data in order to describe the removal mechanism of TB AGLF by CuONPs. The pseudo-second order kinetic model described very well the adsorption kinetics of TB AGLF dye.

Keywords— Adsorption, biosynthesis, *Myrtus communis*, copper oxide nanoparticles, isotherm.

I. INTRODUCTION

The use of nanotechnology in environmental applications for wastewater treatment has attracted considerable attention in recent years. Nanomaterials in water treatment have revealed enormous performances that might be based on their unique characteristics such as large surface area to volume ratio, smaller particle sizes, presence of a large numbers of active sites, and a high capacity for regeneration [1,2]. The improving of influential green chemistry methods for synthesis of metal nanoparticles has become a great focus of researchers [3]. Especially, metal oxide nanoparticles are drawing increasing attention in great numbers of applications. Various studies have centered on metal oxide nanoparticles (NPs) due to their electronic, specific optical and catalytic properties [4]. The metal nanoparticles are usually synthesized by diverse physical, chemical and biological methods. Among them chemical synthesis is widely prevailed which uses many inorganic and organic reducing agents. But, this method has

many disadvantages like toxic, expensive, high pressure and energy requirement, hard to separation and extremely dangerous. Therefore, improving of clean, nontoxic and eco-friendly green methods for synthesis of metal oxide nanoparticles have been arisen as best alternatives which has been reported current research [5]. In this study, the green synthesis of copper oxide nanoparticles (CuONPs) and characterisation were achieved by using *Myrtus communis* leaves extract as reducing agent and then they were used as an adsorbent for the removal of TB AGLF dye from aqueous solution.

II. MATERIAL AND METHODS

A. Preparation of *Myrtus Communis* Leaf Extract

Myrtus communis leaves collecting from Yenişehir Campus of Mersin University were twice with tap water in order to remove dirties, soil, etc. It was dried at room temperature and then in an oven at 105°C for 24 h until all the moisture was evaporated. The extract was prepared by boiling 100 g of dried *Myrtus communis* leaves in 500 mL of distilled water at 100 °C for 1 h, thereafter the extract was filtered and stored at +4 °C to use in the biosynthesis of CuONPs.

B. Biosynthesis of Copper Oxide Nanoparticles

For green synthesis of the CuONPs, 100 mL of 0.1 M CuSO₄ aqueous solution was added dropwise to 50 mL of *Myrtus communis* leaf extract (MCLE) and then the obtained solution was mixed at constant stirring rate and 130 °C temperature for 7h. As soon as the MCLE comes in to contact with the copper ions spontaneous, the blue color of copper ions changes to green color. After 15 min, the green mixture started changing to a brown suspended mixture, indicating the formation of copper oxide nanoparticles. The synthesized CuONPs precipitate was filtered out, washed with distilled water and dried at 130 °C for 6 h. Finally, CuONPs were stored in refrigerator at +4 °C for adsorption.

C. Batch Adsorption Studies

The adsorption experiments were conducted in 250 mL Erlenmeyer flasks in a thermostated water bath at constant temperature for 180 min. The dye solutions were prepared with deionized water. The solution pH values were adjusted by using 0.1 M HCl or 0.1 M NaOH solutions. The known amount of CuONPs was mixed with 100 mL of TB AGLF solution at the desired initial pH and TB AGLF concentration. The flasks were shaken in an agitation vessel at constant temperature for 180 min to achieve adsorption equilibrium. The samples at predetermined time intervals were taken and centrifuged at 3000 rev/min for 5.0 min. The residual dye concentration in the supernatant was analyzed at 610 nm by Chebios brand spectrophotometer.

D. Characterization Of Copper Oxide Nanoparticles

The characterization studies of the biosynthesized CuONPs were done by using X-ray diffractometry (XRD), Fourier transform infrared (FT-IR), Scanning electron microscopy (SEM) and EDX analysis methods.

III. RESULTS AND DISCUSSION

A. The Characterization of Biosynthesized CuONPs

Scanning electron microscopy (SEM) images of CuONPs before and after adsorption were presented in Figure 1a-b and the size and shape of CuONPs were analysed by using SEM images. The SEM images of CuONPs before adsorption showed that their surface were porous and spherical structure. It was observed that the pores of CuONPs after adsorption covered with dyestuff molecules. In addition, the average particle size from SEM images was observed in the range of 40-60 nm.

Figure 1. The SEM images of CuONPs a) before b) after adsorption

The EDX spectrums of CuONPs before and after adsorption were recorded to determine the elemental composition of the nanoparticle samples and were presented in Figure 2a-b. EDX analysis results indicated that CuONPs before adsorption have 36.34% Cu, 32.33% O, 30.15% C, 0.8% Cl, 0.32% Fe and 0.06% Mg. According to the results of elemental analysis; C, O, Fe and Mg elements was resulted from the plant extract. The elemental composition of CuONPs after adsorption was determine as 24.48% Cu, 24.72% O, 34.62% C, 7.46% S, 6.88% N and 3.9% Na. As a result, N, Na and S elements in CuONPs can be explained by the presence of the adsorbed dye molecules on CuONPs.

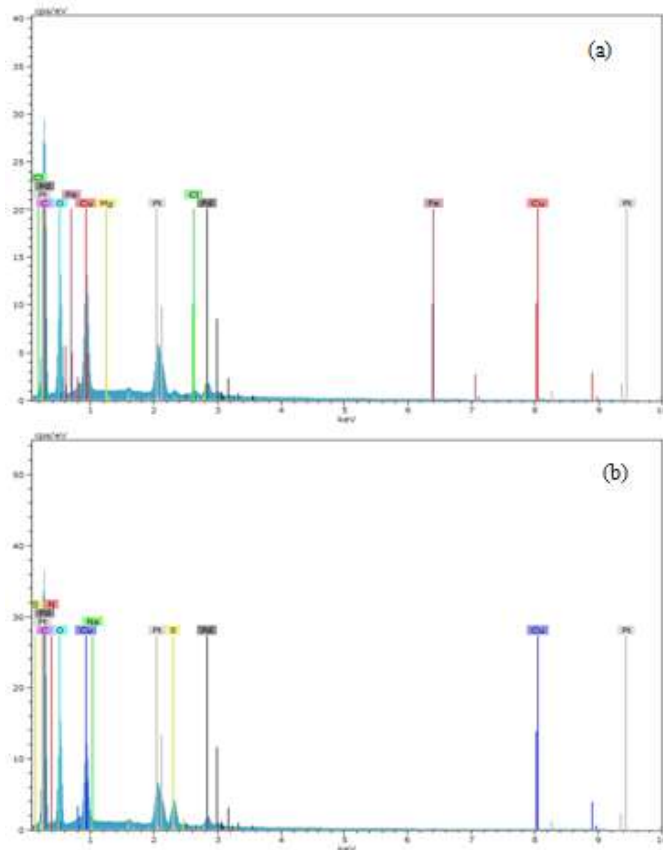

Figure 2. EDX analysis of CuONPs a) before b) after adsorption

The XRD analysis of CuONPs before and after adsorption were indicated in Figure 3a-b. XRD pattern of CuONPs was recorded peaks at 2θ angles of 35.46° , 38.63° , 53.50° , 58.20° , 66.11° , 68.30° and 75.24° which corresponded to the (0 0 2), (1 1 1), (0 2 0), (2 0 2), (1 1 3) and (0 0 4) crystal planes of a cubic lattice structure of CuONPs [6]. It can be said that the adsorption of TB AGLF dye on CuONPs was by physical adsorption. Because any differences from XRD patterns before and after adsorption for CuONPs were not observed.

Figure 3. XRD patterns of CuONPs a) before b) after adsorption

The various absorption peaks were observed from FT-IR spectra of CuONPs before and after the adsorption, as can be seen from Figure 4a-b. From FT-IR spectra before adsorption, it was determined that the peaks in the 1075 cm^{-1} and 1230 cm^{-1} bands caused by the C = C aromatic ring and the C - H or C - O stretching vibrations of methyl, methylene and methoxy groups, respectively. These peaks show the presence of phenolic compounds in the leaf extract, which leads to the reduction of metal ions and the formation of nanoparticles. The observed peak at 803.1 cm^{-1} was originated from the M-O (M = Cu) stretching vibration of the CuO nanoparticles. In addition, the observed peaks at 616 cm^{-1} , 595 cm^{-1} and 474 cm^{-1} showed the presence of the stretching vibration of the Cu - O bond in the monoclinic CuO structure. The observed peaks at 1012 cm^{-1} and 1039 cm^{-1} in the FT-IR spectra after adsorption were determined to belong to C - O stretching of alcohols and the observed peaks at 1571 cm^{-1} and 931 cm^{-1} were indicated that they originated from the C = O stretching vibrations of the alcohol.

Figure 4. FT-IR spectra of CuONPs a) before b) after adsorption

B. The Effect of Environmental Conditions on the TB AGLF Adsorption onto CuONPs

The initial pH is one of the most important parameters influencing the removal process of dyes for water treatment as the charge of surface on adsorbent and dye molecules can be influenced by pH values in aqueous solution. The effect of initial pH on TB AGLF adsorption was examined by varying the pH from 5.0 to 10.0 at the initial TB AGLF concentration 100 mg/L , CuONPs dose 1.0 g/L , temperature 25°C and contact time 180 min . The effect of initial pH on TB AGLF adsorption is shown in Figure 5-a. From Figure 5-a, it was observed that the amounts of adsorbed TB AGLF per unit adsorbent mass at equilibrium did not change with the studied initial pH values. The wide range of pH was an advantage for the waste water treatment because the excess reagent was not use in the purification process. The optimum initial pH for the adsorption of TB AGLF on CuONPs was chosen as 7.0-8.0 which is the original pH value of the dye solution.

The effect of temperature on TB AGLF adsorption onto CuONPs was studied in the range of $25\text{--}55^\circ\text{C}$ at 100 mg/L initial TB AGLF concentration, 7.0- 8.0 initial pH, 1.0 g/L CuONPs concentration and 180 min contact time. The relationship between temperature and TB AGLF adsorption capacity of CuONPs was shown in Figure 5-b. For the TB AGLF dye, the adsorption capacity of CuONPs decrease slightly with increasing temperature, implying the exothermic nature of the adsorption process. This exothermic nature is beneficial to the practical application such as the river or other natural systems. The excess energy did not add to adsorption process to reach the desired purification. Therefore, the optimum temperature value was determined as 25°C for TB AGLF adsorption onto CuONPs.

The adsorbent dose and dye removal rate are economically very important parameters for industrial effluent treatment process. The effect of adsorbent concentration on TB AGLF adsorption onto CuONPs was studied for 0.5, 1.0, 2.0, and 3.0 g/L at initial pH value 7.0-8.0, 100 mg/L initial TB AGLF concentration, and 25°C temperature for 180 min contact time and the results was shown in Figure 5-c. As can be seen from Figure 5-c, the uptake capacity of CuONPs decreased from 173.3 to 32.6 mg/L whereas, the percentage removal increased from 88.13% to 94.62% with increasing from 0.5 g/L to 3.0 g/L of the CuONPs concentration. The aggregation of CuONPs at high adsorbent concentrations may result in a decrease in the active surface area and an increase in the diffusional path length, and so the lower adsorption capacities were observed at high adsorbent concentrations. As a consequence, the optimum adsorbent concentration for TBAGLF adsorption was determined to be 1.0 g/L .

In order to investigate the effect of initial TB AGLF concentration on percentage removal of TB AGLF and uptake capacity of CuONPs, the experiments were conducted by varying TB AGLF concentration from 50 mg/L to 3000 mg/L at initial pH 7.0– 8.0, CuONPs dose 1.0 g/L and temperature 25°C

for 180 min contact time. The obtained results are reported in Fig. 5-d.

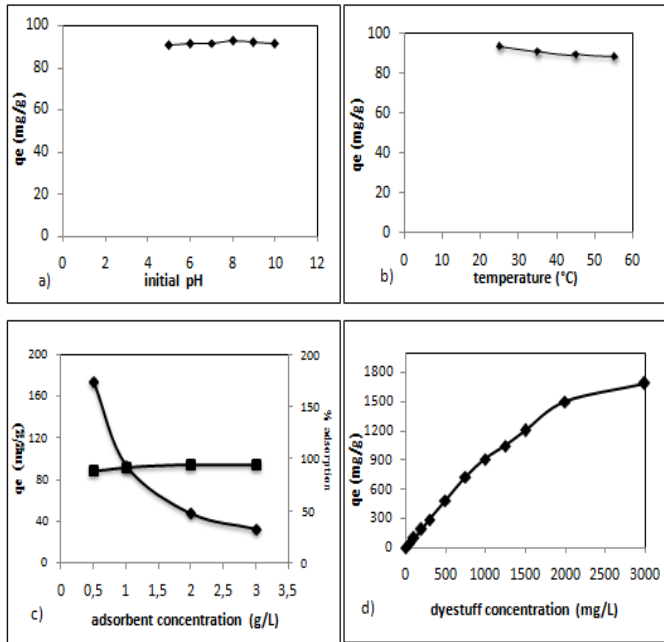

Figure 5. Effect of the environmental conditions on the adsorption of TBAGLF onto CuONPs

C. Equilibrium, Kinetic and Mass Transfer Modelling

Two isotherm models such as Langmuir isotherms and Freundlich isotherm were used to analyze the adsorption equilibrium of TB AGLF onto CuONPs. The Langmuir model showed the good linearity with high values of R^2 (Table I) which indicated that the adsorption was monolayer and adsorption energy was uniformly distributed over CuONPs surface. The R^2 values indicate that the Langmuir isotherm fitted the experimental data better than that of the Freundlich isotherm model at 25 °C. As a result, the adsorption of TB AGLF dye onto CuONPs was the monolayer uniform adsorption type. Langmuir and Freundlich isotherm models were given in equations (1) and (2):

$$\begin{aligned} \text{Langmuir isotherm} & ; 1/q_e = 1/Q^\circ b(1/C_e) + 1/Q^\circ \\ \text{Freundlich isotherm} & ; \ln q_e = \ln K_F + (1/n) \ln C_e \end{aligned} \quad (2)$$

Table 1. The isotherm model constants and regression coefficients (initial pH 7.0-8.0, CuONPs concentration 1.0 g/L, temperature 25 °C and contact time 180 min)

T (K)	Langmuir isotherm model			Freundlich isotherm model		
	Q°	b	R^2	K_F	$1/n$	R^2
298	3225.8	0.00145	0.999	9.94	1.3004	0.980

Q° (mg/g), b (L/mg), K_F [(mg/g)/(L/mg)^{1/n}]

Adsorption kinetics describe the residence time of adsorbate at the solution adsorbent interface which controls the rate of removal. Thus, the kinetic studies are essential to design a continuous system for the adsorption. In this study, the experimental adsorption data determined at different initial TB AGLF concentrations were used to evaluate the kinetics of TB AGLF adsorption on CuONPs. Both the linear forms of the pseudo-first order and the pseudo-second order kinetic models were employed and evaluated to define the kinetic behavior of the adsorption system. The calculated kinetic parameters and correlation coefficients (R^2) for these two models are given in Table 2. The pseudo-second order kinetic model showed better fit for TB AGLF adsorption on the CuONPs in the terms of correlation coefficient. Pseudo-first order and the pseudo-second order kinetic models were given in equations (3) and (4):

$$\text{Pseudo-first order; } [\log (q_e - q_t) = \log (q_e) - k_1 t / 2.303] \quad (3)$$

$$\text{Pseudo-second order; } [(t/q_t) = (1/q_e^2 \cdot k_2) + (t/q_e)] \quad (4)$$

The Weber-Morris model was used to evaluate the mass transfer effects in this adsorption process. To evaluate the diffusion mechanism between TB AGLF and CuONPs, an intraparticle diffusion model proposed by Weber-Morris ($q_t = K_i \cdot t^{0.5} + I$) was used and the calculated parameters were presented in Table 3. If Weber-Morris plot of q_t versus $t^{0.5}$ gives a straight line and pass through the origin, this means that only intraparticle diffusion controlled the adsorption process. On the other hand, the Weber-Morris plot can be linear and also has intercept value if the adsorption system follows both intraparticle and film diffusion. As understood from Table 3, both intraparticle and film diffusion were effective on TB AGLF-CuONPs adsorption process.

IV. CONCLUSION

The green synthesis of CuONPs was achieved by using MCLE as reducing agent. The physiochemical properties of green synthesized CuONPs were characterized by SEM, EDX, XRD and FTIR. The average particle size of the synthesized CuONPs by using MCLE was found in the range of 40-60 nm. The biosynthesized CuONPs were used as an adsorbent for batch adsorption of TB AGLF dye. The optimum adsorption conditions were determined to be initial pH 7.0–8.0, temperature 25 °C and adsorbent concentration 1.0 g/L. The adsorption equilibrium was described well by the Langmuir isotherm model with maximum adsorption capacity of 3225.8 mg/g at 25 °C. The intraparticle diffusion model and the pseudo-second order kinetic model were applied to the experimental data in order to describe the removal mechanism of TB AGLF by CuONPs. The pseudo-second order kinetic model described very well the

adsorption kinetics of TB AGLF dye. It was concluded that both intraparticle and film diffusion were effective on TB AGLF-CuONPs adsorption process. As a result, the biosynthesized CuONPs by using the leaf extract, as a known cheap source, can be used as an adsorbent with high capacity for the purification of the waste water involving dyes.

Abstract— Advanced Oxidation Process (AOP), one of most efficient method for the degradation of dyes is the photocatalytic process. AOP including fenton, photo-fenton, UV/semiconductors and UV/O₃ have been recently studied extensively and seen as a promising technology to clean the toxic dye effluents [1]. Therefore, AOPs represent potential alternative methods able to decolorize and reduce to final products such as CO₂ and H₂O. Photo-catalysis using semiconductor zinc oxide (ZnO) is an alternative method and extensively provided itself to be the significantly better material for the purification because of its properties such as highly stable, cheap and capable of oxidation of a wide range of organic compounds into harmless compounds [2, 3]. A significant advantage of using heterogeneous photocatalysis, ZnO and TiO₂ which are based on the generation of very reactive species such as hydroxyl radicals (OH•) and others, is the total mineralization of organic dyes and organic compounds which results in CO₂, H₂O and mineral acids. ZnO as semiconductor used for the degradation of dyes is considered to proceed via the following general mechanism [4];

where, $h\nu$ is photon energy required to excite the semiconductor electron from valance band (VB) to conduction band (CB) region.

The photo-generated holes are capable of oxidizing the dye either directly (2) or indirectly by the production of adsorbed OH• radicals and via reactions (3) and (4). The photo-generated electrons on the surface of ZnO are able to reduce oxygen which is absorbed into the media with the feeding air to superoxide radical (5), which consequently react with the dye and then acting as a source of OH• radical to oxidize the dye. The dye is also directly reduced by the photo-generated electrons (7).

To increase the k_{la}, in the solution of dye in order to increase oxygen level in solution, the air is introduced to the reactor in a good manner. The introducing air into reactor improve degradation rate in many ways as diluting and decreasing the color intensity which increase penetration debt to enhance degradation rate with increasing OH• radicals.

In this study, the photocatalytic degradation of reactive dye, C.I. Reactive Black 5 (RB5), was investigated by using zinc oxide (ZnO) in aqueous solution under UV-C lamb in a batch aerated annular Photoreactor (Figure 1.). The effect of key operation parameters including photocatalyst loading (0-10.0 g/L), initial dye concentration (150-550 mg/L) and aeration rate (0.0-3.0 L/min) were determined on color removal in aqueous solution. The efficiency values of photocatalytic degradation process of the RB5 dye at 45 minutes reaction time were 100, 77.0, 62.4, 44.0 and 31.5 % for the initial dye

Figure 1. Illustration of annular photoreactor (1- Annular Reactor; 2- UV-C Lamb; 3- Air Feed; 4- Sampling Port; 5- Cooling Water In; 6- Cooling Water Out; 7- Magnetic Rod; 8- Cooling Jacket; 9- Lamp Shield; 10- Power Supply).

concentration values of 150, 250, 350, 450 and 550 mg/L respectively, at the conditions of 7.5 g/L ZnO; 2.0 L/min aeration rate; $\text{pH}_{\text{in}} = 5.6$ (natural pH of dye solution); 293 K reaction temperature; 1000 rpm mixing rate.

The result showed that the degradation of RB5 dye depended on initial dye concentration, catalyst loading and aeration rate as well. The further increase of catalyst loading, observed from the experiment started decreasing the color removal yield because of the decreasing of light intensity and thereby decreasing OH^\bullet radicals. The increasing of initial dye concentration decreased the color removal yield whereas increasing of aeration rate increased the color removal yield.

Synthesis of Silver Particles Using Aloe Vera Extract and Their Characterization

Didem DEMİR, Gülşah Gül, Nimet Bölgen Karagülle
Chemical Engineering Department, Faculty of Engineering, University of Mersin,
Mersin, Turkey
nimetbolgen@yahoo.com

Abstract— *In recent years, there is a worldwide interest in developing a cost effective and environmental friendly process for synthesis of metal particles. The use of plant extracts for this purpose is potentially advantageous due to the ease of improvement, less biohazard and very short reaction time. Aloe vera (Aloe Barbadensis) is a shrubby, perennial succulent plant characterized by stemless large, thick, fleshy leaves having a sharp apex and a spiny margin. Since early times, Aloe vera has been traditionally used for the treatment of several skin cuts and burn abnormalities, because of its anti inflammatory, antiviral, antifungal and antibacterial properties.*

In the present study, young fresh aloe vera leafs were collected and their green extract was used for the synthesis of silver particles. 50 mL of aqueous extract was added to 500 mL of 0.001 M silver nitrate solution. The solution was allowed to react at room temperature and incubated in dark condition for 24hrs. The color of solution changed from yellow to dark Brown. The extract was analysed by Ultraviolet-Visible spectrophotometer (UV-Vis). The synthesized silver particles were characterized by Fourier Infra Red Spectroscopy (FTIR) and Dynamic Light Scattering (DLS). In DLS analysis, the size of the silver particles was found to be 169 nm. Since silver particles are known to have antibacterial properties, the submicron sized silver particles produced in this study can be potential candidates to be used in biomedical applications.

Abstract— Hydroxyapatite has a biocompatible, biodegradable and natural apatite characteristic to be used in biomedical applications such as bone tissue engineering. The objectives of this study were to synthesize hydroxyapatite from domestic waste eggshells which is utilized as pure calcium source; compare the properties of biosynthesized hydroxyapatite with commercially purchased hydroxyapatite; and produce biosynthesized hydroxyapatite reinforced chitosan cryogels for possible tissue engineering applications. Calcium oxide powders obtained after calcination of waste eggshells showed different particle sizes depending on calcination temperature. It was found that increased temperature of calcination led to the powders of smaller particle sizes. Structural changes at carbonate groups of calcined eggshell were determined by FTIR analysis. The effect of the biosynthesized hydroxyapatite on the morphology of chitosan cryogel biocomposites were determined. The changes in the chemical bond structure of the cryogels were analysed by FTIR and swelling behavior of produced chitosan cryogels was determined by swelling ratio tests.

Keywords— biosynthesis; eggshell; hydroxyapatite; chitosan; biocomposite scaffold; cryogel; tissue engineering.

I. INTRODUCTION

Hydroxyapatite (HAp, $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$) exhibits excellent biocompatibility, biodegradability, osteoconductive and bioactive properties due to its chemically similar composition to the inorganic component of natural bone minerals [1]. HAp can be produced by chemical synthesis such as sol-gel method, hydrothermal method, sono-chemical synthesis, co-precipitation and mechanochemical method or by extraction from natural sources such as corals, sea shells, animal bones and eggshells [2]. The worldwide availability, unlimited supply, low cost, simple, inexpensive, economical, and efficient production are the advantages of obtaining HAp from natural

biological sources [3]. Eggshell is one of the major waste product of food industry, and it becomes useless after the use of egg contents and its derivatives [4]. Eggshell is composed of calcium carbonate (94%), organic matter (4%), calcium phosphate (1%) and magnesium carbonate (1%) [5]. In recent years, the combination of a polymeric matrice (especially made of a natural polymer) with a biocompatible, reinforcing and bioactive component like HAp has shown significant improvements as biomaterials for clinical applications [6]. In this study, we aimed to obtain biosynthesized HAp (bio-HAp) from waste egg shells and combine it with chitosan cryogel scaffolds. The chitosan used in this study was extracted from the blue crab, as demonstrated in our previous study [7]. The present study firstly demonstrates producing calcium oxide (CaO) powder from domestic waste eggshells (a cheap and widely available biological source in worldwide) by using a simple heat treatment process at different calcination temperatures. Then, describes the synthesis and characterization of nanometer scale bio-HAp from this CaO powder by co-precipitation method. The properties of synthesized CaO powders and bio-HAp was characterized by fourier transform infrared spectroscopy (FTIR) and dynamic light scattering (DLS) analysis. Finally, we combined bio-HAp with chitosan cryogels. The chemical structure and swelling behaviour of chitosan-HAp cryogels were demonstrated for possible tissue engineering applications.

II. MATERIALS AND METHODS

A. Material

In this study, eggshells which were collected from domestic wastes were used as starting material for the synthesis of biosynthesized HAp (bio-HAp). Phosphoric acid was obtained from Merck, Germany. The commercial HAp (com-HAp) used for the comparison of the properties of bio-HAp was purchased from Sigma Aldrich, USA. Chitosan from blue crab shells were used for the production of cryogel scaffolds. Glutaraldehyde (25%, v/v) as the crosslinker was obtained from Merck, Germany. All solution preparations and washing steps were performed by using distilled water.

B. Preparation of Waste Eggshells and Synthesis of CaO

Waste eggshells were first washed with tap water to remove contaminants. The cleaned eggshells were washed with distilled water and dried at 105 °C for 4 hours. The pretreated eggshells were crushed, milled and sieved to a standart powder (500 µm sieve). For CaO synthesis, powder of eggshells were calcined in an ash furnace (Protherm, Plf 130/45, Turkey) at different temperatures (400, 600, 800 and 1000 °C) for 2 hours with a heating rate of 10 °C/min. During calcination, the eggshells were converted to calcium oxide by releasing carbon dioxide (CO₂) according to following reaction:

The CaO samples obtained from the eggshells were stored in an oven at 40 °C for further analysis.

C. Synthesis of Bio-HAP

Bio-HAP were prepared from CaO powders by co-precipitation method according to Kunjalukkal et al, 2015 [6]. The calcination temperature of 800 °C was selected in order to prepare CaO powders for certainty of the complete transformation of CaCO₃ to CaO based on TGA results. A stoichiometric amount of CaO powder (2 grams) were weighed and hydrolysed in 250 mL of distilled water to obtain calcium hydroxide (Ca(OH)₂) solution as follows:

Under continuous stirring at 1400 rpm, 1350 µL phosphoric acid solution was added drop by drop to the Ca(OH)₂ solution at 100 °C by using a magnetic stirrer. The expected reaction is as follow:

After the bubbling was finished, the mixed solution was kept on the same conditions for 2 h. The resulting solution was allowed to cool down to room temperature and the resulting precipitate was filtered out using filter paper. Wet sample was put in an oven at 40 °C for 24 h. The dried precipitate was then collected and stored.

D. Characterization of Synthesized CaO and Bio-HAP

Thermogravimetric analysis, TGA/DTG of waste eggshell was carried out using Perkin Elmer Pyris 1 TGA, ABD. A total of 7.5 mg of the sample was used and TGA curve was obtained from 40 °C to 1000 °C in nitrogen atmosphere with a heating rate of 10 °C/min. FTIR (Perkin Elmer, FTIR/FIR/NIR Spectrometer Frontier ATR, USA) was used to determine the functional groups and chemical compositions of the CaO powders synthesized by the calcination of waste eggshells at different temperatures and synthesized bio-HAP at selected calcination temperature. FTIR analysis were performed at a resolution of 4 cm⁻¹ in the wavelength range of 450-4000 cm⁻¹. For the characterization of particle size, the dynamic light scattering (DLS) (Malvern, Nano ZS90, England) was used to measure powder particle size distribution of synthesized CaO and bio-HAP samples. The samples were dispersed in acetic acid (100% purity, Glacial).

E. Production of Chitosan-HAP Cryogel Biocomposites

The chitosan-HAP cryogels were synthesized at different amounts of synthesized HAP by cryogelation method. Chitosan solution (3%, w/v) was prepared in acetic acid solution (6%, v/v) and mixed on a magnetic stirrer until solution was homogenous and clear. At the end of mixing, three different ratio of synthesized HAP (1:1, 1:2, 1:3, ratio of chitosan to HAP) was added to prepared chitosan solutions. 1 mL of GA solution (3%, v/v) was added to 2 mL of prepared chitosan-HAP solution. The whole solution was immediately poured into a 2 mL plastic syringe and transferred into the cryostat. The reaction mixture was incubated in the cryostat at -16 °C for 2 h. After this period the cryogels were stored in the fridge at same conditions for 24 h. After the reaction was completed, the frozen samples in the syringe molds were thawed to room temperature and washed several times to remove the unreacted reagents. The samples were lyophilized before characterization.

F. Characterization of Produced Chitosan-HAP Cryogel Biocomposites

The obtained cryogels' chemical structure was analysed by FTIR in the range of 450-4000 cm⁻¹, with automatic signal gain collected in 20 scans at a resolution of 4 cm⁻¹. To determine the swelling behavior of chitosan-HAP cryogels, the samples were dried at room temperature to a constant weight (W_D). Then, dried samples were immersed in distilled water to obtain swollen cryogels. The excess water on the surface of the cryogels was removed and the samples were weighed (W_S). Swelling ratio was calculated by the following equation:

$$\text{SR\%} = [(W_S - W_D) / (W_D)] * 100 \quad (4)$$

III. RESULTS AND DISCUSSION

A. Characterization of Synthesized CaO and Bio-HAP

FTIR analysis was carried out to determine the chemical composition of the waste eggshell and CaO powders synthesized after calcination of eggshells at different temperatures. Fig. 1 shows the FTIR spectra of the waste eggshell and CaO powders. The bands at between 873 and 1413 cm⁻¹ were attributed to C-O bond of carbonate (CO₃) groups of eggshell. However, the CO₃ ions disappeared from the structure at high temperatures (800 and 1000 °C) during heat treatment. The intensity of the O-H stretching band observed at 3642 cm⁻¹ wavelength is due to the O-H bond in Ca(OH)₂, which is formed during the adsorption of water by CaO [8]. The peak at 2981 cm⁻¹ is characteristics of free CO₂ due to the background of the measurement system or reaction process [9]. Presence of these characteristic bands is a proof of the CaO powder formed.

Fig. 1. FTIR analysis of waste eggshell and CaO powders synthesized at 400, 600, 800 and 1000 °C.

CaCO_3 , the main component of the eggshell, can completely decompose in CaO and CO_2 with the increase in calcination temperature [10]. In this study, eggshells were calcined in an ash furnace at 400, 600, 800 and 1000 °C, respectively to evaluate the effect of calcination temperature on formation of CaO. Thermal analysis of the waste eggshell was performed to determine the optimum calcination temperature (Fig. 2). The weight decrement during the heating process was determined by TGA. The CaO content in the eggshells were determined as about 49% (w/w). With the increase in temperature from 600 to 800 °C, a significant weight loss has occurred because of the CO_2 molecules moving up from the structure of eggshell. The CaCO_3 decomposes completely into CaO at a maximum temperature of 760 °C.

Beside the thermal analysis of waste eggshell, DLS analyser measurements were made to observe the effect of the calcination temperature on the particle size of the synthesized CaO. Fig. 3 shows the variation of CaO powder size as a function of calcination temperature of eggshells. It reveals that increasing the calcination temperature results in smaller size of CaO powder which was in close agreement with the [11]. At the calcination temperature of 800 the particle size was 103,5496 nm. The calcination temperature was chosen as 800 °C for the synthesis of bio-HAp.

Fig. 1. TGA and DTG curves of waste eggshell

Fig. 2. Particle size distribution of CaO powders synthesized at 400, 600, 800 and 1000 °C.

B. Characterization of Bio-HAp

FTIR analysis was performed to compare the functional groups of bio-HAp and commercially purchased hydroxyapatite (com-HAp). The FTIR spectrum of the bio-HAp was chemically in good agreement with the spectrum of com-HAp and the FTIR spectrum reported by another study that demonstrated HAp powder synthesized from hen eggshells [12]. The band at 1027 cm^{-1} is the characteristic band of phosphate (PO_4) stretching vibration whereas the bands at 562 and 501 cm^{-1} are due to phosphate bending vibration [13]. According to spectral data, the absorption peak at 1412 cm^{-1} corresponds to the asymmetric stretching of carbonate ion substitution. FTIR spectra indicated that bio-HAp was successfully derived from CaO calcined at 800 °C.

The particle size distribution of bio-HAp and com-HAp samples was analysed (Fig. 5). The average size of bio-HAp was 33.08 nm while the size of com-HAp was 115.98 nm. The polydispersive index (PDI) of samples were 0.462 and 0.722, respectively. This PDI value showed that the synthesized sample was homogeneous and uniform in size [14]. Moreover, DLS analysis showed that the synthesized bio-HAp was in the nanometer size.

Fig. 3. FTIR analysis of com-HAp and bio-HAp

Fig. 4. Particle size distribution of com-HAp and bio-HAp

C. Characterization of Chitosan-HAp Cryogels

The ratio of bio-HAp to chitosan solution was varied in this study. The amount of bio-HAp affected the chemical, physical, mechanical, morphological and porous structure of cryogels.

Fig. 6 shows the photograph of chitosan-HAp cryogels after cryogelation reaction is completed (in wet form) and after lyophilization (in dry form). The colour of cryogels including bio-HAp were more opaque than the plain chitosan cryogel. Also with increasing the amount of bio-HAp in the chitosan cryogels, a more smooth and elastic surface was reached.

Furthermore, FTIR analysis demonstrated the functional groups of bio-HAp, interactions between bio-HAp and chitosan, crosslinking bonds between glutaraldehyde and chitosan. The FTIR spectra of the cryogels, as shown in Fig. 7, demonstrated bands corresponding to hydroxyl, phosphate and amine groups. The major absorbance bands of the spectra correspond to hydroxyapatite. Width of bands decreases with increasing bio-HAp content of cryogels [15]. With the increase in the amount of bio-HAp a sharp peak was observed at near by 1050 cm^{-1} . This peak shows the interaction of chitosan with the phosphate groups of bio-HAp [16]. The bands between $1550\text{--}1700\text{ cm}^{-1}$ are attributed to mode superposition of the hydroxyl group of bio-HAp and amide groups of chitosan [15]. The hydroxyapatite phosphate bending bands are at 562 cm^{-1} . The broad peak started at 3480 cm^{-1} , gradually decreased and became narrower with the increase in the amount of bio-HAp.

At the cryogelation step, chitosan-HAp cryogels with interconnected pores were obtained. Swelling ability of a cryogel is related with the highly porous and spongy morphology of the cryogels [7]. The swelling ratio results of the plain chitosan and chitosan-HAp cryogels are demonstrated in Fig. 8. Plain chitosan and all chitosan-HAp cryogels showed a swelling ratio higher than 3000% in the first 5 min. It was observed that as the amount of bio-HAp in the cryogels increased the swelling ratio decreased. The decrease may be due to the decrease in the pore size of the cryogels. As the amount of bio-HAp increased the pore walls of the cryogels were filled with more bio-HAp. Plain chitosan cryogel showed the highest swelling ratio (8660.43%) after 60 minutes of swelling time.

Fig. 6. Photograph of blank chitosan and chitosan-HAp cryogels in wet and dry form [CH0= plain chitosan. CH1=1:1, CH2= 1:2, CH3= 1:3 (chitosan:HAp)]

Fig. 7. FTIR analysis of plain chitosan and chitosan:bio-HAp cryogels

Fig. 8. Swelling ratio analysis of plain chitosan and chitosan-HAp cryogels

IV. CONCLUSION

CaO powder was produced by using domestic waste eggshells through a calcination process at different temperatures. Pure bio-HAp was synthesized by co-precipitation method using the CaO powder which was calcined at 800 °C. The particle size of the synthesized bio-HAp was measured as in nano scale. FTIR analysis showed the purity of bio-HAp. This process can lead to the development of a cost

effective biomaterial and can improve waste management in future. Chitosan cryogel scaffolds reinforced with bio-HAp were successfully produced for possible tissue engineering applications. Hence, from the results, it can be concluded that the synthesized bio-HAp can be economically produced from waste eggshells by a simple calcination and co-precipitation method for wide range of biomedical applications especially for tissue engineering. The bioHAp reinforced chitosan cryogel biocomposites can be potential scaffold candidates to be used in possible tissue regeneration.

Abstract— *In this study; removal of Cr(VI) from aqueous solution by using activated carbon prepared from apricot, peach stones and almond shell mixture was investigated in a fixed-bed column as a function of pH, initial Cr(VI) concentration and flow rate.*

In order to prepare the solutions used in the experiments, the stock solution of Cr(VI) (1000 mg/L) was prepared by dissolving K₂CrO₄ in distilled water. All working solutions of varying Cr(VI) concentrations (10, 20 and 40 mg/L) were obtained by diluting the stock solution with distilled water. pH adjustments were performed by using HNO₃ and NaOH solutions in different concentrations. All the reagents used in this study were of analytical grade. The fixed-bed column experiments were carried out in a glass column designed with an internal diameter of 0.8 and 22 cm in length having a cooling jacket. Activated carbon was placed into the column supported with glass wool from the top and bottom. Liquid samples were collected from the top of the column at 15 minute intervals until $C/C_0 \geq 0.95$. Cr(VI) concentration was then measured by using a spectrophotometer depending on diphenyl carbazide method. The performance of fixed-bed column adsorption is usually described through the concept of the breakthrough curve. The time for breakthrough appearance and the shape of the breakthrough curve are very important characteristics for determining the operation and the dynamic response of an adsorption column. The breakthrough curve is defined as the ratio of effluent metal concentration to inlet metal concentration (C/C_0) as a function of time or volume of effluent for a given bed height. It has been determined that the adsorption of Cr(VI) onto activated carbon is pH dependent. Although Cr(VI) adsorption yields increased with the decreasing pH, Cr(VI) began to reduce to Cr(III) oxidation stage under pH 3. Cr(VI) concentration decreased with this reduction but total chromium concentration began to increase. Therefore, pH of 3 was selected as most suitable pH for the adsorption of Cr(VI). The maximum bed capacities for the investigated flow rates of 2, 3 and 4 mL/min were found to be 9.95, 6.67 and 6.16 mg/g, respectively. When the initial Cr(VI) concentration was increased from 10 to 40 mg/L, the adsorption bed capacities increased from 6.67 to 11.77 mg/g.

The adsorption capacity was decreased with increasing the pH and flow rate but increased with the increasing influent Cr(VI) concentration. As the flow rate and initial Cr(VI) concentration increased, the breakthrough curve became steeper, the breakthrough time and adsorbed ion concentration decreased. The results indicates that the activated carbon prepared from triple mixture can be used as an effective and environmentally friendly adsorbent for the treatment of Cr(VI) ions in aqueous solutions.

Abstract—ZnO thin films deposited on glass substrate were prepared by dip-coating and studied different coating time for structural characterization and photo catalytic activity. The films were prepared by depositing different numbers of layers. The morphology, structure and resistivity of the thin films were measured by scanning electron microscopy, X-ray diffraction, and UV Spectrophotometer. The best photocatalytic activity obtained when the multilayer was 3.

Keywords— zinc oxide; photocatalyst; sol gel; dip-coating

I. INTRODUCTION

In recent years, nanomaterials have attracted much attention because of their excellent physical and chemical properties, large surface area and ability to interact with other materials. [1,2]. Zinc oxide (ZnO) semiconductors have properties such as easy availability, chemical stability, and strong oxidative capacity. Also the processing performance, crystallographic compatibility is high [3,4]. These properties make ZnO catalysts a simple and attractive solution to water pollution.

ZnO as a special photocatalyst has been achieve mineralization of a lot of organic dyes leading to the investigated in recent years also. Many kinds of nanostructured such as nanoparticle, nanotube, nonorod and thin film ZnO structures have been used for the photocatalytic degradation of pollutants such as textile dyes, organic waste and pesticides in water[5–6]. Some studies show that ZnO is a better catalyst than TiO₂ [7,8] because ZnO has a wide band gap (3.37 eV) and thus electron holes efficiency and mobility is higher. The most important feature of these catalysts is that visible light activities can be enhanced [9].

ZnO photocatalysts can be used in diffused forms immobilized on a substrate or powders [10]. Although more efficient results are obtained in slurry reactors there are two important restrictions [11] on its use. First, small particles can agglomerate to form large particles lead to reduce catalyst performance. Secondly, the separation and recovery of catalyst

from slurry is a difficult and costly process. Thus, many researchers have been prefer immobilized catalysts on a suitable support.

When a semiconductor irradiated with UV light, an electron in the valence band is excited into the conduction band. So that electrons are formed in conduction band and holes are formed in conduction band. These electron-hole pairs become radicals after various redox reactions. These radicals also effect the oxidation of organic substances and pollutants, the destruction of bacteria and viruses [12,13]

In the present work, ZnO thin films were prepared by the sol–gel technic and immobilized on surface by dip-coating method. Five different coatings were selected and thus thin films were obtained in different layers, 1 2 3 4 and 5. After each coating the samples were subjected to heat treatment for 10 minutes at 200 ° C. So that the layers are strengthened and the final film thickness is obtained.

II. METHOD

A. Preparation of sol-gel

Zinc acetate dihydrate) was used as the precursor and dissolved in the isopropanol with the molar ratio of zinc acetate is 0.4. DEA was also added dropwise with molar ratios ZnAc: DEA = 1: 1. DEA was used as a stabilizer. Solutions stirred at room temperature for 2 hours until a homogenous solution was formed.

B. Preparation of thin film

This solution was immobilized on glass substrates by applying several times the dip-coating technique. After each coating the samples were subjected to heat treatment for 10 minutes at 200 ° C. For 5 samples coating times choosen 10, 20, 30, 45 and 60 minute. Thin films consisting of 1 2 3 4 and 5 layers were obtained with this procedure. Finally, For the removal of organic residues and for the provision of crystallisation the multilayer films were annealed during 2,5 h at 500°C.

C. Characterization

Prepared samples were characterized by using X-ray diffraction (XRD) (Rigaku D/Max-2200). For surface structures and morphology analysis, scanning electron microscope (SEM) was used (FEI, Inspect S50). UV spectrophotometer (Shimadzu UV-2200, Japan) was used to test the photocatalytic activity of thin films. And also the transmittance of the film was analyzed by this spectrophotometer.

D. Photocatalytic degradation experiment

The photocatalytic efficiency of the prepared thin film photocatalyst were tested in batch reactor under UV lamb (Cole-Parmer 254 nm 44W/m²) irradiation source using Acid Red 27 as the pollutant. O₂ in the reaction was provided by sending air at a constant flow rate by a pump. The dye solution was prepared at 20 mg/l and filled in the 400 ml batch reactor. Samples were taken from the reactor every 15 minutes and analyzed.

III.RESULTS AND DISCUSSIONS

Effect of the coating time on ZnO layers on transmittance for photocatalytic activity. The transmittances of the thin films photocatalyst from 1 layer to 5 layers are shown in Fig1 Fig. 2 shows XRD patterns results for ZnO thin films at different thicknesses. 1 2 3 4 and 5 layers of samples are named from A to E in Fig. 2. As a result of the analysis, characteristic peaks of (100), (002) and (101) (102), (110) (103) and (004) planes were obtained. The result are in accordance with the standard XRD patterns of JCPDS 36-1451 data.

Fig. 3 shows the SEM images of the ZnO thin films prepared at different coating time. SEM images show that, thin films of ZnO is in network structure. According the results when the dip coating layer was 3, it gives the best transmittence. As shown in Fig. 3b, when the dip coating layer was 3 thin films have smooth and uniform surface and polycrystalline structure. The layers for this coating time do not clog the pores, thus obtained light trapping structure on surface. With this surface property, both sunlight reflections and photocatalytic efficiency can be increased. As shown in Fig. 3a, The ZnO crystals, when dip coating at 1 layer, combine on the surface like a island structure. As shown in Figure 3b, when the 3-layer coating is applied, the layer structure is formed to the layer by layer growth. So that the light trapping structure is formed. As shown in Figure 3c, when the 5 and over layers are coated, the granules are collected and maintained in one direction to reduce surface energy, then many dendritic crystals are formed and interconnected.

Effects of Storage Time on Some Properties of Yogurt Cheeses

Çağla Özbek, Nuray Güzeler

Çukurova University, Agricultural Faculty, Food Engineering Department
Adana, Turkey
cglaayldrm@gmail.com

Abstract— In this research Yogurt cheeses which were produced by coagulation of milk by adding yogurt with different ratios (20%, 30%, 40%, 50%) were stored at $4\pm 1^\circ\text{C}$ for 90 days. Some physical, chemical and sensory properties of cheeses were analyzed while storage and the effects of storage on these properties were evaluated. For this reason pH, titration acidity, dry matter amount, fat content, protein content, salt content, curd firmness, water soluble nitrogen, ripening degree, 12% TCA soluble nitrogen, 5% PTA soluble nitrogen, casein nitrogen, proteose-peptone nitrogen, total free amino acid values, color and sensory analysis were performed. Titration acidity, dry matter content, fat content, salt content, water soluble nitrogen, ripening degree, 12% TCA soluble nitrogen, 5% PTA soluble nitrogen, proteose-peptone nitrogen, total free amino acids, a^* and b^* values of cheeses increased while pH, protein content, curd firmness, casein nitrogen, L^* values and sensory points of cheeses decreased during storage. The effects of storage time on titration acidity, protein content, salt content, water soluble nitrogen, ripening degree, 12% TCA soluble nitrogen, 5% PTA soluble nitrogen, casein nitrogen, proteose-peptone nitrogen, total free amino acids, a^* values, curd firmness, appearance, odor and taste properties of cheeses were significant ($p<0.05$). As a result of sensory analysis, the most desirable cheese was selected as cheese that contained 30% yogurt.

Keywords— Yogurt cheese; acid coagulation; storage effects

I. INTRODUCTION

Yogurt cheese is produced by adding yogurt to boiling milk, filtering the whey, keeping the curd in brine or grating of curd, mixing with salt and black cumin, pressing into pots and lastly keeping at cool places. The milk-yogurt ratio changes with production places and producers [1], [2], [3], [4]. This cheese type is not produced by industrially; it is generally produced in small scaled plants or domestically and is sold in local markets. The origin of Yogurt cheese which is generally produced in Hatay and Mersin (Tarsus) provinces is considered as Arabic countries such as Syria and Lebanon [5]. It is known that Yogurt cheeses are used in making of desserts such as “Künefe”, “Cheese Halva” and “Semolina Dessert with cheese” in Hatay province [6].

The cheeses which are similar with Yogurt cheeses are generally in the form of “Tulum” cheeses. “Ayaş Ovma” cheese which is produced by adding black cumin to “Cokelek” and pressing into the pots, “Antalya Çoban” cheese which is produced by boiling and filtering of buttermilk that is obtained

by butter production, adding salt and black cumin to it and pressing into the pots, “Erzincan Tulum” cheese which is produced by coagulating of milk by enzyme, pressing the curd, mixing with black cumin and pressing into the pots, “Hatay Carra” cheese which is produced by mixing with cokelek with black cumin and crushed cheese with black cumin and pressing them into the pots, “Mersin Köy” cheese which is produced by adding rennet and some yogurt to cow and ewe milks, boiling of them, pressing the curd and pressing into the drums, “Çerkez” cheese which is produced by coagulation of milk by using whey can be shown as examples to these cheeses [7], [8], [9], [10], [11], [12]. It is possible to obtain cheese which is similar with Yogurt cheese can be produced by coagulating milk by lemon juice or vinegar [3], [11].

II. MATERIAL AND METHOD

Milk was obtained from Cukurova University Faculty of Agriculture, Research and Application Farm Animal Husbandry Branch. Yogurt was produced from obtained milk. Black cumin and salt were supplied from markets. Plastic cans were supplied from Konya Şah Plastik plant.

The first step is yogurt production for the production of Yogurt cheese. For this purpose, raw cow milk was heat treated (at 95°C for 5 min) and it is cooled to inoculation temperature ($44\pm 1^\circ\text{C}$). 3% yogurt (w/w) was inoculated to milk and it was incubated at $44\pm 1^\circ\text{C}$ up to pH 4.7. When the pH reached to 4.7, obtained yogurt was stored at $4\pm 1^\circ\text{C}$ for one night. After yogurt production, raw cow milk was boiled for producing of cheese. 20%, 30%, 40% and 50% (w/w) yogurt additions were performed to boiling milk. Yogurt and milk were boiled together for 10 minutes and they were cooled to room temperature. The curd was taken to cloth bags and they were pressed for removing the whey. After 2-3 hours pressing, cheeses were grated and kneading with 2% salt (w/w) and 1.25% black cumin (w/w). Obtained cheese was pressed into plastic drums and some cloth pieces were placed on the mouth of the drums. They were kept at $4\pm 1^\circ\text{C}$ for 90 days.

The chemical, physical and sensory analyses were performed at Çukurova University Food Engineering Department Dairy Technology Laboratory. pH values and titration acidities were measured according to [13]. Dry matter amounts were determined according to [14], Fat amounts were determined according to [15], protein contents were measured according

to [16], salt amounts were determined according to [17]. Water soluble nitrogen (WSN) and ripening degrees of cheeses were determined according to [16]. 12% Trichloroacetic acid (TCA) soluble nitrogen values were determined according to [18]. 5% Phosphotungstic acid (PTA) soluble nitrogen values were measured according to [16]. Casein nitrogen and proteose-peptone nitrogen values were determined according to [19]. Total free amino acid values were measured according to [20], [21]. Color measurement was performed by using Minolta CR-400 color meter. Curd firmness of cheeses was

determined according to [22]. Sensory properties were evaluated according to [13].

III. RESULTS

Some chemical properties of Yogurt cheeses which were obtained by adding yogurt in different ratios are shown in Table 1. In the table, the cheese that contains 20% yogurt is called as A, 30% yogurt is called as B, 40% yogurt is called as C, 50% yogurt is called as D.

Table 1. Some chemical properties of Yogurt cheeses while storage

Properties	Storage time (day)	Cheeses

K, L: Values that are shown in the same column with different exponential letters are different in terms of $p < 0.05$ level of significance.

When the table is examined, it is possible to see that the effects of storage time on pH, dry matter content and fat content of cheeses were not found significant ($p > 0.05$). Titration acidity

of cheeses increased during storage and the effects of storage time were found significant on titration acidity values of B cheese ($p < 0.05$). The increase of the titration acidity of

cheeses during storage was reported by many researchers [23], [24], [25], [26], [27], [28], [29], [30], [31]. The protein contents of cheeses decreased during storage and these changes on D cheese were found significant ($p<0.05$). In many research it is reported that the protein content of cheeses decreased while storage [32], [33], [34], [35], [36].

Salt content of cheeses increased during storage and the effects of storage time were found statistically significant on salt contents of B cheese ($p<0.05$). The increase of the salt contents of cheeses during storage was reported by many researchers [37], [38], [39], [40], [41].

K, L: Values that are shown in the same column with different exponential letters are different in terms of $p<0.05$ level of significance.

Water soluble nitrogen value is accepted as an indicator of proteolysis and ripening of cheeses. Low molecular weight fractions of nitrogen levels which are occurred by casein

hydrolysis may be expressed by water soluble nitrogen value [42]. In this research, water soluble nitrogen values of Yogurt cheeses continuously increased during storage and the effects

of storage time on these values of B and D cheeses were found statistically significant ($p<0.05$). Similarly in another research, it is reported that water soluble nitrogen value increased with time [43]. The changes of ripening degrees of cheeses with storage time were also found significant on B, C and D cheeses.

12% TCA soluble nitrogen values of cheeses increased during storage and the effects of storage time were found statistically significant ($p<0.05$) on 12% TCA soluble nitrogen values of B and C cheeses. Similar results were reported in many other researches [44], [45], [46], [47].

5% PTA soluble nitrogen values of cheeses increased during storage similar with 12% TCA soluble nitrogen values. These increases were statistically significant ($p<0.05$) on 5% PTA soluble nitrogen values of A, C and D cheeses. In some other researches it was reported that 5% PTA soluble nitrogen values of cheeses increased during storage, too [48], [49], [50], [51].

Casein nitrogen values of cheeses decreased during storage and the changes on casein nitrogen values of B cheese were found statistically significant ($p<0.05$). Many researchers reported that while storage casein nitrogen values of cheeses decreased [52], [27], [33].

Protease-peptone nitrogen values of cheeses increased during storage and the effects of storage time were found statistically significant ($p<0.05$) on protease-peptone nitrogen values of B and D cheeses. Similar results were reported in many other researches [53], [54], [55], [56].

Total free amino acid content of cheeses increased during storage and the effects of storage time were found statistically significant on total free amino acid contents of all cheeses ($p<0.05$). The increase of the total free amino acid contents of cheeses during storage were reported by many researchers [57], [58], [59], [60].

	45	13.20±1.75 ^K	13.90±1.37 ^K	12.96±1.18 ^K	12.00±1.20 ^K
	90	14.05±2.31 ^K	15.68±2.05 ^K	13.69±1.92 ^K	15.57±1.56 ^K

K, L: Values that are shown in the same column with different exponential letters are different in terms of $p<0.05$ level of significance.

In the colorimetric analysis, L* value is expressed brightness (0-100), a* value is expressed from green to redness (-120-120), b* value is expressed from blue to yellow (-120-120) [61], [62]. According to the statistical analyses, the storage time had no significant effects on L* and b* values of cheeses. a* values of cheeses increased during storage and these changes were found significant ($p<0.05$). In the other researches, it was reported that a* values of cheeses increased during storage [63], [33].

K, L: Values that are shown in the same column with different exponential letters are different in terms of $p < 0.05$ level of significance.

Curd firmness of cheeses increased during storage and the effects of storage time were found statistically significant on curd firmness of A and C cheeses ($p < 0.05$). The increase of the curd firmness of cheeses during storage was reported by many researchers [64], [65], [66], [67].

When the sensory properties of cheeses were evaluated, it was seen that the texture and structural properties of cheeses were not affected by storage time significantly ($p > 0.05$). Appearance properties of B and D cheeses, odor properties of B cheese and taste properties of A and B cheeses were affected significantly by storage time ($p < 0.05$). D cheese which contained the highest yogurt amount was selected as the least desired cheese. The most desired one was chosen as B cheese with 80.13 points and C (76.11), A (75.75) and D(69.16) cheeses followed it respectively.

IV. CONCLUSION

Yogurt cheese is a traditional cheese type which is produced by directly using of yogurt instead of common coagulators. It could not be found any scientific research about Yogurt cheese which is produced by this method and it could not be reached enough information about cheeses that are obtained by using yogurt. It is considered that they are important to determine the properties of traditional cheeses and to record them. For this reason, further researches are required in these subjects.

As a result of the research, the effects of storage time on titration acidity, protein content, salt content, water soluble nitrogen, ripening degree, 12% TCA soluble nitrogen, 5% PTA soluble nitrogen, casein nitrogen, protease-peptone nitrogen, total free amino acids, a^* values, curd firmness, appearance, odor and taste properties of cheeses were significant ($p < 0.05$) and according to the sensory analysis, the most desirable cheese was selected as cheese that contained 30% yogurt.

The Effects of Storage Time on the Properties of Soft Cheeses That Was Produced By Sodium Caseinate Addition to Fat Enriched Milk

Nuray Güzeler, Fazaleh Mesgari, Çağla Özbek

Çukurova University, Agricultural Faculty, Food Engineering Department

Adana, Turkey

nsahan@cu.edu.tr

Abstract— In this research, cheeses which were produced by adding sodium caseinate to milk for condensation in 1.5%, 2.5% and 3.5% ratios were stored for 90 days at $4\pm1^{\circ}\text{C}$. The effects of storage time on cheese yields, pH, titration acidity, dry matter, fat in dry matter, total nitrogen, protein, protein in dry matter, salt, salt in dry matter, curd firmness, water soluble nitrogen, ripening degree, 12% TCA soluble nitrogen, 5% PTA soluble nitrogen, casein nitrogen, proteose-peptone nitrogen, total free amino acids, color and sensory properties were determined. According to the statistical analyses that were performed it was determined that the storage time had significant effects ($p<0.05$) on pH, titration acidity, dry matter content, protein content, salt content, water soluble nitrogen, ripening degree, 5% PTA soluble nitrogen, casein nitrogen, proteose-peptone nitrogen, total free amino acid values, curd firmness, L^* , a^* and b^* values of Soft cheeses. There was no significant effects of storage time on fat content and 12% TCA soluble nitrogen values of Soft cheeses ($p>0.05$). As a result of sensory analysis; the most liked cheese were selected as cheese with 3.5% sodium caseinate and cheeses with 2.5% and 1.5% sodium caseinate were followed it respectively.

Key words— Condensed milk; Cottage White cheese; sodium caseinat; storage period

I. INTRODUCTION

Sodium caseinate is defined as milk protein and it is generally used as emulsifier and stabilizer. It binds water and fat molecules and it makes fat globules smaller for making foods have good appearances [1]. It is commonly used in making of yogurt and cheese for increasing protein content, in preparing light products, in protein and lysine enrichment of breads and in sticking sauces and meat products together [2],[3]. It is possible to elongate the shelf life of the foods by using sodium caseinate [4]. The advantages of increasing dry matter amount of milk may be remarked as;

- The production method is industrially profitable,
- The cheeses that are produced by this method have higher yield than other cheese types,

- The obtained cheeses are more hygienic because of the simplicity of the production method,
- The obtained cheeses have more nutritional values because there is no loss of serum protein and minerals with whey removing by this method [5], [6].

II. MATERIAL AND METHOD

For the production of Soft cheeses that were produced by using sodium caseinate ratio in different ratios, raw cow milk was obtained by Kültürova plant. Danisco MA19LYO starter culture was supplied from Danisco. Microbial cheese yeast (*Rhizomucor miehei*) that was used as coagulating enzyme was obtained from DSM Food Specialties. Cheese powder that was used in production of Soft cheese was supplied from Enka Milk plant. Sodium caseinate was supplied from MBH Food plant and salt was provided from Unvertuz Ind. Plant. For packaging, 500 grams of plastic cheese bowls were supplied from IML Çağrı Packaging.

The production procedure of Soft cheese was started with fat standardization of raw cow milk to 18% fat content. After standardization, milk was pre-heated to $35-45^{\circ}\text{C}$ and dry matter standardization was performed. For this reason, sodium caseinate with different ratios (1.5%, 2.5%, 3.5%), 1.5% cheese powder and 2% salt were added to milk. It was homogenized at 65°C at 180 bar. Then it was pasteurized at 75°C for 10 minutes. It was cooled to inoculation temperature (42°C) and 1% starter culture and 0.15g/100kg rennet additions were performed. It was packaged and incubated at 42°C for 9-11 hours until pH reached to 4.7. After incubation, cheeses were stored at $4-8^{\circ}\text{C}$ for 90 days.

The chemical, physical and sensory analyses were performed at Çukurova University Food Engineering Department Dairy Technology Laboratory. pH values and titration acidities were measured according to [7]. Dry matter amounts were determined according to [8], Fat amounts were determined according to [9], protein contents were measured according to [10], salt amounts were determined according to

[11]. Water soluble nitrogen (WSN) and ripening degrees of cheeses were determined according to [10]. 12% Trichloroacetic acid (TCA) soluble nitrogen values were determined according to [12]. 5% Phosphotungstic acid (PTA) soluble nitrogen values were measured according to [10]. Casein nitrogen and proteose-peptone nitrogen values were determined according to [13]. Total free amino acid values were measured according to [14], [15]. Color measurement was performed by using Minolta CR-400 color meter. Curd firmness of cheeses were determined according to [16]. Sensory properties were evaluated according to [7].

Some chemical properties of soft cheeses which were obtained by adding sodium caseinate in different ratios are shown in Table I. In the table, the cheese that contains 1.5% sodium caseinate is called as A, 2.5% sodium caseinate is called as B, 3.5% sodium caseinate is called as C.

When the chemical properties of Soft cheeses were evaluated, it could be seen that pH values of cheeses decreased during storage. The effects of storage time were found statistically significant on pH values of all Soft cheeses ($p < 0.05$). It was reported that pH values of cheeses decreased with time in many researches [17],[18],[19],[20],[21],[22].

III. RESULTS

Table 1. Some chemical properties of Soft cheeses while storage

K, L, M: Values that are shown in the same column with different exponential letters are different in terms of $p < 0.05$ level of significance.

Titration acidities of Soft cheeses increased unlike pH values during storage and the similar results were reported in some other researches in terms of increasing titration acidities of

cheeses [23], [24], [25], [26], [27], [28], [29], [30]. Storage time had statistically significant effects on titration acidities of all Soft cheeses ($p < 0.05$).

K, L, M: Values that are shown in the same column with different exponential letters are different in terms of $p < 0.05$ level of significance.

Dry matter amounts of Soft cheeses increased during storage and this increase was found statistically significant on all cheese types ($p < 0.05$). Increasing of dry matter amounts of

different cheeses by time was reported by many researchers [31], [32], [33], [34], [35], [36], [37], [38], [39]. The storage

time had no significant effect on fat contents of cheeses ($p>0.05$).

Soft cheeses' protein contents decreased during storage and similar decreases were reported by many researchers [40], [41], [42], [43]. The effects of storage time were found statistically significant on protein contents of all Soft cheeses ($p<0.05$).

Salt content of cheeses increased during storage and the effects of storage time were found statistically significant on salt contents of A, B and C cheeses ($p<0.05$). The increase of the salt contents of cheeses during storage was reported by many researchers [44], [18], [45], [2], [46], [47]. Nitrogen fractions and total free amino acid values of Soft cheeses during storage are given in Table II.

Water soluble nitrogen and ripening degrees of Soft cheeses increased during storage. These increases were reported by some researchers [2], [46]. The effects of storage time were found statistically significant on water soluble nitrogen values of all Soft cheeses and ripening degrees of B and C cheeses ($p<0.05$). There was no statistically significant effect on 12% TCA soluble nitrogen values of cheeses ($p>0.05$).

5% PTA soluble nitrogen values and proteose-peptone nitrogen values of cheeses increased during storage and the effects of storage time were found statistically significant on 5% PTA soluble nitrogen values and proteose-peptone nitrogen values of A, B and C cheeses ($p<0.05$). The increase of the 5% PTA soluble nitrogen values of cheeses during storage was reported by many researchers [48], [46], [49], [50]. Otherwise casein nitrogen values of cheeses decreased with time and this decrease was found statistically important ($p<0.05$). It was reported that casein nitrogen values increased during storage in many researches [51], [52], [2], [41]. Additionally the increase of the proteose-peptone nitrogen values of cheeses during storage was reported by many researchers [53], [52], [54], [55].

There were increases on total free amino acid values of Soft cheeses during storage and storage time affects total free amino acid values of all cheeses significantly ($p<0.05$). In some researches, it was reported that total free amino acid values of different cheeses increased while storage [54], [56]. The results of the color measurements are shown at the Table III.

K, L, M: Values that are shown in the same column with different exponential letters are different in terms of $p<0.05$ level of significance.

L* values of cheeses decreased during storage and the effects of storage time were found significant on L* values of all cheeses ($p<0.05$). Some other researchers reported that L* values of cheeses decreased with [57], [58], [59].

a* values of Soft cheeses increased while storage. Storage time had statistically significant ($p<0.05$) effects on a* values of all cheeses. It was reported that increasing of a* values was occurred with time [41], [58].

There were increases on b* values of Soft cheeses during storage and storage time affects b* values of C cheeses significantly ($p<0.05$). In a research, it was reported that b* values of different cheeses increased while storage [57]. The curd firmness and sensory properties of Soft cheeses are shown at Table IV.

Curd firmness of cheeses increased during storage and the effects of storage time were found statistically significant on

curd firmness of A, B and C cheeses ($p<0.05$). The increase of the curd firmness of cheeses during storage was reported by many researchers [2], [60], [61].

Table 4. Curd firmness and sensory properties of Soft cheeses while storage

	Storage time (day)	Cheeses		
		A	B	C

	90	-	-	-

K, L, M: Values that are shown in the same column with different exponential letters are different in terms of $p<0.05$ level of significance.

Sensory analyses were performed on Soft cheeses at 1st, 15th and 45th days of the storage. It could not been performed at 90th day of the storage because of molding on the surface of the cheeses. When the sensory properties of cheeses were generally evaluated, it was determined that the most desired cheese was C cheese which contained the highest sodium caseinate ratio (3.5%) and B and A cheeses followed it respectively. According to obtained results, it was concluded that Soft cheeses should be consumed as fresh and sodium caseinate addition improved the sensory properties of Soft cheeses.

IV. CONCLUSION

It was determined that sodium caseinate addition affected the sensory properties of cheeses in a positive way. According to the results of the sensory analyses it was determined that the most desired cheese was cheese contained 3.5% sodium caseinate and the least desired one was cheese contained 1.5% sodium caseinate. The negativities that were happened on the taste and odor properties of Soft cheeses at the 45th days of the storage showed that the Soft cheeses should

be consumed as fresh. Molds and off-flavors were occurred on the surface of the cheeses at the 90th day of the storage.

As a result of the research it was determined that the storage time had significant effects ($p<0.05$) on pH, titration acidity, dry matter content, protein content, salt content, water soluble nitrogen, ripening degree, 5% PTA soluble nitrogen, casein nitrogen, proteose-peptone nitrogen, total free amino acid values, curd firmness, L*, a* and b* values of Soft cheeses.

Abstract— To enhance consumer comfort, many of today's food products are pre-prepared so they can be quickly reheated, for example in a microwave. There has been an important increase in the number of household microwave ovens in recent years. Microwave food processes offer many advantages such as short start up time, faster heating, high energy efficiency, space savings, precise process control, selective heating and foods with high nutritional quality. One of the industrial pre-inspection methods is air-convection cooking. During this cooking procedure moisture content of food products are changed. The moisture concentration in patty is also modified by COMSOL Multiphysics simulation. In terms of product quality, it is interesting to minimize the loss of moisture in the cooking line. In this context, cooking yield is the percentage of moisture in the patty after the cooking process. Moreover, the moisture concentration affects the temperature field by the loss of heat due to evaporation and also by changing the thermal conductivity of the patty [1].

Keywords— Heat change, Comsol multiphysics, Food processes modeling.

Abstract— *In the poultry sector, fully-cooked products are a rapidly growing part of total product sales, with pre-cooked, refrigerated products projected to account for 80% of the industry growth. Today many of food are precooked so they can be quickly reheated, for example in a microwave. One of the industrial pre-cooking methods is air-convection cooking method. For this reason, thermal processes for determining the safety, quality and safety of retail products are becoming increasingly important. The design and operation of these processes also affect the total cooking yield, which is an important economic parameter for the industry. In order to analyze and improve these processes, considerable previous study has focused on simulation of heat penetration in meat products under different thermal conditions. To predict heat penetration during thermal processing, heat transfer models have been widely employed for meat products. In these models COMSOL Multiphysics program can be used for this purpose. This model forms a time dependent model of convection cooking for a chicken patty and shows the increase in temperature within the patty relative to time [1].*

Abstract— In Turkey, Erzincan Tulum (Şavak) cheese which is one of the most important cheese and in third place in terms of amount of production is produced from sheep's milk as original and traditional and ripened in the goat's skin bags. The cheese is our first cheese taken out a patent with the geographical sign. The economic significance and production of this cheese increases for the reasons of its originality having very high nutritional value, winning the appreciation of every segment of the consumers and being more expensive than butter.

In this research, ripened in goat's skin bags (Tulum) originally but nowadays in the cheese replaced by plastic barrels, were investigated the effect on some quality characteristics of packaging difference. Therefore, the Tulum cheeses produced traditionally from raw sheep's milk Dumlu (Erzurum) plateaus were ripened at $4\pm1^{\circ}\text{C}$ for 90 days pressed in the tulum and plastic barrels.

The cheeses pressed into the Tulum the dry matter, fat, fat in dry matter, total protein, total nitrogen, salt, salt in dry matter contents were found higher statistically significant according to the cheeses pressed into the plastic barrels at 90 d of ripening ($P<0.01$). Also, the value of ripening index in the Erzincan Tulum (Şavak) cheese samples pressed into the plastic barrels was found higher statistically significant according to the samples pressed into the Tulum ($P<0.01$). According to these results, it is more appropriate ripening in the Tulum in terms of nutritional value. In this study, will be make to contribute some results have been obtained for branding of this cheese as offered on behalf of the Tulum Cheese Festival and Elazığ Cheese Panel arrangement in Tulum Cheese Workshop by us.

Abstract— As an aromatic plant, *aşotu* (*Coriandrum sativum* L.) is an annual herb in the family of Apiaceae. All parts of the plant are edible, but the fresh leaves and dried seeds are the parts most traditionally used in cooking. The use of *Coriandrum sativum* L. in Erzurum is very common and it is used especially with ayran soup. In this study, the possibility of using *Coriandrum sativum* L. as an ingredient in white cheese was investigated.

Coriandrum sativum L was added to cheese by the rate of 2%, and microbiological analysis were made on the 1, 5, 10 and 14 days of ripening period at 4°C. According to the results, 2% level of *Coriandrum sativum* L. and storage time had a significant effects on the total viable count (TVC), lactic acid bacteria, *Streptococcus* counts and yeast-mould and Enterobacteriaceae counts ($p < 0.05$). Acidity, pH, analysis of the cheese samples were investigated on days 1, 5, 10, and 14 during storage at 4°C.

Keywords— White Cheese, *Coriandrum sativum* L, TVC, storage period

I. INTRODUCTION

Cultured dairy products especially cheeses are an important part of the diet of many societies. These dairy products, initially developed as a means to preserve milk also have desirable sensory characteristics [1]. More than 1000 varieties of cheese are produced around the world. In Turkey, 40–50 cheese varieties are known, but only three of them have national and economic value: Turkish White (its original name is Beyaz peynir), Kasar and Tulum cheeses [2]. In Turkey, although there are many traditional cheese varieties, their production is largely based in small-scale dairies and family farms. Recently, the industrial production of herby cheese has been introduced, and today this variety has gained nationwide popularity as well as being exported to Middle Eastern countries [3,4]. For thousands of years the cradle of diverse civilizations, and with a geography which lends itself to animal raising, Anatolia is

well endowed in terms of the variety of its cheeses. If at first impression it appears that Turkey does not possess a rich cheese culture, there are in fact more than 130 varieties of cheese to be found in Anatolia. The data in hand shows that, alongside several types of cheese such as White Cheese, Kaşar, Tulum, Lor and Çökelek which dominate the Turkish marketplace at large, there are to be found numerous varieties of cheese able to meet society's every requirement. Some of these are still produced in response to local preferences and needs, while others are now known and sold in many regions of the country [5].

Nonconventional oilseeds are being considered because their constituents have unique chemical properties and may augment the supply of edible oils. Interest in newer sources of edible oils has recently grown. Among the various seed oils, black cumin (*Nigella sativa* L.), coriander (*Coriandrum sativum* L.), and Niger (*Guizotia abyssinica* Cass.) are of particular interest because they may be utilized for the production of formulations containing phytochemicals with significant antioxidant properties and health benefits [6]. The aromatic proprieties of the fruits of coriander (*Coriandrum sativum* L.) and wild fennel [*Foeniculum vulgare* Miller var. *Vulgare* (Miller)], plants belonging to the family Apiaceae typical of the Mediterranean region, are exploited by the pharmaceutical industry to correct the flavor of medicines and, above all, of some laxatives of plant origin. In the case of fennel oil, an effect on the digestive processes has been ascertained; hence, it may exert an additive effect [7].

The objective of this study was to introduce the production of coriander herb cheese and reveal its microbiological properties and chemical composition.

II. MATERIAL AND METHODS

A. Milk and manufacture:

Milk used in the manufacture of cheese samples was obtained from the Atatürk University, Pilot Dairy Factory of Food Engineering, Erzurum, Turkey. The leaves used to manufacture cheese were obtained from Coriander plants in Erzurum, Turkey in the autumn. Rennet was obtained from the Mayasan, İstanbul, Turkey.

Cheeses were manufactured according to the standard procedure with a different modification [8]. Turkish white cheese, used as a control, and Turkish white cheese made using 2 % Coriandrum leaf were manufactured in the pilot dairy plant (Department of Food Engineering, Erzurum, Turkey).

All samples were stored at 4 ± 1 °C for up to 14 days. Analysis were conducted on the 1th, 5 th, 10th, and 14th days of the storage.

B. Microbiological analysis:

Total aerobic mesophilic bacteria, Lactic acid bacteria, Streptococcus count and Enterobacteriaceae counts were determined on the 1th, 5 th, 10th, and 14th days of the storage. Samples of cheese (10 g) were serially diluted (w/v) with saline solution (NaCl 0.85%) and homogenized for 1 min. Serial dilutions of the homogenates were prepared up to 10⁻⁵, then spread-plated (0.1 mL) in duplicate onto plates of MRS agar (de Man Rogosa Sharpe Agar, Merck) for the enumeration of Lactic acid bacteria (LAB) and M17 Agar (Merck) for Streptococcus. Inoculated plates were incubated anaerobically (Anaerocult C; Merck) at 30°C for 72 h for Lactobacilli and aerobically for Streptococcus at 30°C for 48 h. The counts of Lactobacilli were enumerated according to the method of Dave and Shah [9]. The counts of Streptococcus were enumerated according to the method of Harrigan [10]. For total viable bacteria (TVC), Plate Count Agar (PCA, Merck) was used and plates were aerobically incubated at 30 °C for 48 h. VRBD Agar (violet red bile dextrose, Merck) was used for Enterobacteriaceae and plates were anaerobically incubated at 30 °C for 48 h. Yeast and mould count were enumerated on PDA (Merck) after incubation at 23 °C for 5 days. [11]. Plates containing 25 to 250 colonies were enumerated and the colony forming units per gram (CFU/g) of the product was calculated.

C. Chemical analysis

Cheese samples were analyzed for salt according to the IDF standard method [12], fat content by Gerber method [13], moisture content [14]. The pH values of the yoghurt samples were determined by direct measurement with a digital microprocessor pH meter (Hanna Instruments 211, Romania) after calibration with pH 4.0 and 7.0 standard buffer. Titratable acidity (lactic acid, %) was determined by the titrating with 0.1 N NaOH using phenolphthalein indicator previously described by Kurt et al. [15] and expressed as a percentage of lactic acid. All analyses were performed in duplicate.

III. RESULTS AND DISCUSSION

Adding Coriandrum sativum L. had a few effect on pH and titratable values of samples. The results of mean values are presented in Table 1

	pH	Titrateable acidity (%)	TVC (log cfu/g)	LAB (log cfu/g)	Streptococcus counts (log cfu/g)
Storage time (days)					
1	6.15	0.21	5.17	4.844	5.04
5	6.20	0.24	5.21	4.837	4.967
10	6.19	0.27	5.27	4.948	5.497
14	6.21	0.25	5.26	4.891	5.518
Chesee samples					
C	6.18	0.24	5.26	5.102	5.74
2%	6.19	0.26	5.17	4.612	5.14

The pH value of the chesee samples was not significantly affected by adding of Coriandrum sativum L. The initial mean pH values of the control and containing C. sativum L. chesee were 6.22, and 6.265 respectively. At the end of 14 d, the values were 6.232, and 6.194. This results may have been due to the lack of starter cultures. Treatment also affected the titratable acidity of the chesee samples. During the storage period, titratable acidity of the samples increased slowly.

Coriandrum sativum L. treatment had a significant on TVC numbers. The highest average TVC count was in the control chesee samples while the lowest counts were in the Coriandrum sativum L. added samples. These results indicate that Coriandrum sativum L. may has an antimicrobial effect. But since the storage time is very short, telling a definite conclusion is difficult at this situation. Storage time also had effects on TVC number. (Table 1). TVC counts did not differ between the 10th and 14th days of storage. However, TVC counts increased slowly in samples during storage.

Coriandrum sativum L application affected viable counts of LAB and Streptococcus counts. Changes in the counts of number in during storage are presented in Table I. LAB numbers in control samples showed a more marked increase than treatment group during the storage period. The counts of LAB counts increased in regularly during the storage time.

IV. CONCLUSION

Adding Coriandrum sativum L application significantly affected the pH and acidity of cheese samples. Through this research, At this point, a step will be taken towards the

introduction of a new cheese to our regional cheese varieties and transfer to future generations.

Abstract–The aim of present study is to analyse the effect of osmotic dehydration pretreatment applied to the banana of Grand Nain type (*Musa Parasidiaca*) on the textural parameters and ultrastructural changes of this fruit. For this purpose, at the end of time periods as 0, 60, 120, 240, 360 and 480 minutes of 8 hours immersion time, the effect of 25%, 45%, 55% and 65% sucrose solution concentrations and 25°C, 35°C and 45°C immersion temperatures on banana slices has been studied. The samples have been examined by analyzing on scanning electron microscope with the aim of determining cellular structure and changes. Also the fruit slices have been evaluated by using Texture Analyzer instrument with the aim of detecting the texture profile analyse (TPA). During the osmotic dehydration process as associated with water loss and solid gain parameters, the increase in cohesiveness and elasticity values has been determined while there has been the decrease in textural values such as hardness, adhesiveness, chewiness and gumminess in TPA of fruit samples. While the effect of process time and temperature with solution concentration has found statically significant ($p<0.01$) on the values of hardness, gumminess and elasticity, it has been stood out that the effect of process temperature only has found statistically insignificant ($p>0.01$) on the values of cohesiveness and springiness of banana samples. It has been determined that there are ultrastructural changes generally such as collapse in the cells, dilatation in the intracellular spaces, deterioration in the cell segmentations and deformation in the cell's walls of the banana sample tissues. Unlike fresh control samples which are not subjected to any treatment, it has been stood out that starch molecules which are found largely in structure have gelatinized by swelling with increasing process temperature in these samples dried by the osmotic method. In conclusion, it has been determined that osmotic dehydration pretreatment is not sufficiently a effective method for the banana fruit.

Key Words– *Osmotic dehydration, texture, microscopic structure, banana.*

Various Animal Species Milk: Nutritional Value and Technological Properties

Songül Çakmakçı

Food Engineering Department, Atatürk University
Erzurum, Türkiye

Engin Gündoğdu

²Food Engineering Department, Gümüşhane University,
Gümüşhane, Türkiye

Abstract— According to FAO databases, the total World milk production accounted for 696 million tons of which approximately 83% was cow milk. Throughout the centuries, milk became a desirable and valuable food source. Different regions around the world have adapted the particular species common to their area for the purpose of producing milk. In many regions of the world buffalo milk is often used. The latest nutritional discovery is donkey milk, which is exceptionally similar to human milk in terms of protein composition. The majority of milk produced in the world undergoes processing, during which a variety of technological procedures occur. It is not only mainly related to cow milk, but also sheep, buffalo, goat, and camel milk. The most universal is cow milk and technological suitability of milk from other species is very diverse. The concentration of protein, mainly including casein, determines the technological suitability of milk. Currently, global milk production is dominated by 5 animal species: dairy cattle, buffalo, goats, sheep, and camels. The impact of factors altering the milk composition, such as breed, feeding system, stage of lactation and seasons. Cow milk is the most universal raw material for processing, which is reflected in the broadest spectrum of manufactured products. Sheep and buffalo milk, regarding their high content of protein, including casein, and fat, make a very good raw material for processing, especially cheesemaking. Camel milk also has valuable nutritional properties as it contains a high proportion of antibacterial substances and higher concentration of vitamin C in comparison to cow milk. The composition of goat milk allows using it as the raw material for dairy processing and also to some extent as a therapeutic product. The energy value of milk from various animal species is closely related to the concentration of certain compounds in dry matter, especially content of fat. The highest energy value is characteristic of sheep milk. In this review, this subject has been discussed.

Keywords— various animal species milk; nutritional properties; technological properties

I. INTRODUCTION

The milk of different ruminant species, which is consumed directly or as dairy products, has a profound importance for humans throughout their lives as being a source of macro- and micronutrients, and has a number of

active compounds having a significant role in both nutrition and health protection [1]. Because of being nutritionally essential food for humans and contains nearly all nutrients milk and milk products are recommended to consume an adequate amount for healthy lifestyle. In terms of fluid milk consumption, developed countries have changed the habits due to health concerns, aging of the population, increased education and income level factors [2]. Today, world milk production is provided from 5 animal species including dairy cattle, buffalo, goats, sheep, and camels. The major cow milk producers worldwide are The European Union (148.1million kg3), The United States of America (85.9million kg3), India (45.1million kg3), and Russia (32.3 million kg3) [3]. Milk consumption is fairly different between consumers as they prefer fluid, pasteurized, reconstituted for daily fresh milk requirement especially for the people living in big cities [4].

II. METHOD

1. NUTRITIONAL VALUE OF MILK

Milk composition of mammalian species varies widely with reference to genetic, physiological and nutritional factors and environmental conditions [5]. Milk from different species varies most notably regarding protein quality and concentration but also in the content of electrolytes, various carbohydrates and lipids [6]. Basic milk components are protein, fat, and lactose, breed, feeding system, stage of lactation, or time of year alter the composition of milk. Milk is a valuable source of vitamins, both water-soluble and fat-soluble ones [3]. The energy value of milk from various animal species is closely related to the concentration of certain compounds in dry matter, especially the amount of fat. The highest energy value is characteristic of sheep milk, cow milk, buffalo milk, camel milk, goat milk, donkey milk, and horse milk as respectively. The main component of milk, which has a major impact on its nutritional value and technological suitability, is protein. Milk proteins are a heterogeneous group consisting of casein complexes and whey protein fractions which have different from composition and properties [3]. Lipids are the most important components of milk in terms of cost, nutrition, physical and

sensory characteristics that impart to dairy products [7]. Fat which is the major substance for milk's energetic value makes a major contribution to the nutritional properties of milk, as well as to its technological suitability [8]. Milk is a considerable resource of products whose composition varies. Four components are dominant in quantitative terms: water, fat, protein and lactose; while the minor components are minerals, enzymes, vitamins, and dissolved gases [9]. Raw milk and raw milk products can lead to food-borne illness in humans. If these products are not pasteurized, alternative safety controls are required to ensure that they do not a public health risk.

2. VARIOUS ANIMAL SPECIES MILK

A. Cow Milk

The term "milk" being almost synonymous with cow milk in most people's minds. The literature mainly deals with cow milk, followed by goat and sheep milk. More than 80% of World milk production is cow's milk [10]. Cow's milk is the most used raw material in the variety of dairy products. Casein is the most important protein in milk, while the proportion of whey proteins is low. Content of whey proteins in cow milk is in the range of 0.55 to 0.70 [11]. Some studies have found that the majority of children with cow milk protein allergy synthesize antibodies predominantly against α -casein and β -lactoglobulin [12]. In cow milk the casein content is 86.01% of total protein [13]. The average diameter of milk fat globules in cow milk is 3.51 μm for cow milk (range of 0.92 to 15.75 μm) [14].

Cow milk accounted for 83 % of global milk production in 2010 [15]. Cow milk contains more protein and minerals, especially calcium and phosphorus, than human milk. This is because a young calf grows faster than a child. The protein in cow milk is of high-quality, containing a good balance of all the essential amino acids, including lysine. Many human diets are deficient in certain essential amino acids [10, 16]. Cow milk contains more protein than does human milk, but human milk contains more lactose, resulting in comparable energy contents. Cow milk and human milk differ in the amounts of various proteins they contain. Human milk does not contain β -lactoglobulin, one of the main proteins associated with cow milk allergy. Caseins can form leathery curds in the stomach and be difficult to digest. The casein content of cow milk varies between breeds and cheese makers often use milk from breeds with a higher κ -casein content in their milk [17]. Cow milk generally contains between 3 and 4 g of fat/100 g. Most milks consumed now contain a standardized fat content of around 3.5 g/100 g. Cow milk contains a higher proportion of saturated FA (SFA) than does human milk: 65–75 g/100 g total FAs, of which about 40 percent are C12:0–C16:0. Cow milk also has a high content of C18:0. The monounsaturated FA that is present in highest concentration in cow milk is C18:1 (oleic acid). The conjugated linoleic acid (CLA) content in cow milk is generally reported to vary from 0.1 to 2.2 g/100 g total FA depending on season, region, farming system and feeding,

and animal and breed [18]. Cow milk is mostly used in the production of drinking milk. Basic chemical composition of milk from various animal species was given in Table 1.

B. Goat Milk

Goats play an important role in livestock industry because of having adaptability to harsh climates which make them suitable for landless and marginal farmers. The contribution of goats for milk and milk products is high and contribute to rural economy and health. Goat milk has high amount of calcium, magnesium and phosphorus when compared cow and human milk [19]. Goat milk is a good source of vitamin A, niacin, thiamin, riboflavin, and pantothenic acid. However, it contains 5 times less vitamin B₁₂ and folic acid than cow milk does [3]. Goat milk is rich in terms of medium chain triglycerides (MCT) and proteins, and these MCT and proteins have unique health benefits. Goat milk having a soft curd may be an advantage for adult humans suffering from gastrointestinal disturbances and ulcers. Goat milk is important for prevention of cardiovascular disease, cancer, allergy and microorganism and used for stimulation of immunity. Goat milk is recommended for infants, old and convalescent people. Despite this fact, goat has remained neglected in research and development [19]. Goat milk production as commercially is more expensive due to lower productivity, seasonal variations and the need of bigger animal herds. Goat milk which is better digestibility alkalinity, buffering capacity and certain therapeutic values in medicine and human nutrition is different from cow milk [7]. The excellent digestibility of goat milk, the favorable composition of fatty acids and its content of bioactive compounds make suitable food in treating or preventing certain medical conditions [19]. The average diameter of milk fat globules in goat milk is 2.76 μm (range of 0.73 to 8.58 μm) [14]. Goat milk has a stronger flavor due to the liberation of short-chain fatty acids during rough handling, which give off a goaty smell. Goat milk is alkaline in nature because of higher protein content and, which is very useful for people with acidity problems, when compared with cow milk which is acidic. This alkalinity is due to the higher protein content and a different arrangement of phosphates [20]. Goat milk is mostly used in drinking milk and ice cream technology.

C. Sheep Milk

The sheep milk, regarding its high content of protein, including casein, and fat, make a very good raw material in the world is used for cheese manufacture [3, 16, 21]. While yoghurt is also produced in Turkey, fresh sheep milk is rarely consumed and in Greece [22]. Sheep milk is the richest in whey proteins (1.02 g/100 g), and also contains the highest concentration of casein (4.18 g/100 g) [23]. The main use for sheep in cheese making and is usually conducted 30 at farm level or in small local dairies, in particular in Mediterranean

and South-East European countries, although some big cheese factories can also be found, mainly in Western Europe. Over the past few years, the sheep milk dairy industry, along with the other agro food sectors, has considerably developed its production capacity by increasing the industrialization and automation of the processes. These changes are because of the definition of hygienic and sanitary standards at international level Codex Alimentarius and European Union Directives [24]. Dairy sheep farming comprise a crucial part of the national economy in many countries, especially in the Mediterranean and Middle East region [25], and are particularly well organized in France, Italy, Spain, and Greece [26]. The Mediterranean region produces 66% of the world's sheep milk and 18% of the world's goat milk. Of all the milk around the world produced by all species, sheep milk makes up about 1.5% and goat milk 2.0% in official statistics, although the actual usage is much higher due to the non-reporting of home consumption to the IDF (1996) [27]. Sheep's milk is mostly used in cheese and yoghurt technology.

Table 1. Proximate composition of cow, sheep, goat, buffalo milks (per 100 g of milk) [10].

Energy and component	Cow milk	Sheep milk	Goat milk	Buffalo milk
Energy (kcal)	62	100	66	99
Water (g)	87.8	82.1	87.7	83.2
Total protein (g)	3.3	5.6	3.4	4.0
Total fat (g)	3.3	6.4	3.9	7.5
Lactose (g)	4.7	5.1	4.4	4.4
Ash (g)	0.7	0.9	0.8	0.8
Minerals				
Calcium (mg)	112	190	118	191
Iron (mg)	0.1	0.1	0.3	0.2
Magnesium (mg)	11	18	14	12
Phosphorus (mg)	91	144	100.4	185
Zinc (mg)	0.4	0.6	0.3	0.5
Vitamins				
Retinol (µg)	35	64	45	69
Carotene (µg)	16	-	13	-
Vitamin A (µg)	37	64	48	69
Vitamin E (mg)	0.08	0.11	0.05	0.19
Riboflavin (mg)	0.20	0.34	0.13	0.11

D. Buffalo Milk

Buffalo milk which is produced 82 billion litres each year (12.5% of milk produced in the world), is the second most

produced milk in the world after cow's milk (84% with 551 billion litres) [28]. More than 91% of buffalo milk is produced in India (60%) and Pakistan (31%).

Buffalo milk has a rich compositional point of view between other milks. Especially fat constitutes the main fraction of buffalo milk and gives it a highly energetic and nutritive value. For example, the production of 1 kg of butter requires 14 kg of cow milk against 10 kg of buffalo milk. In many countries, buffalo milk is used for making traditional cheeses, such as mozzarella and ricotta in Italy, gemir in Iraq, paneer in India, domiati in Egypt, pecorino in Bulgaria, and pickled cheeses from the Middle- Eastern countries. Thus, buffalo milk is important due to its nutritional value for the countries that breed buffaloes. From this point, if the the knowledge of the specific physicochemical properties of buffalo milk fat globules are known these will give permit for dairy plants to improve their technological processes and to produce high quality products [29]. While buffalo milk over 50% is used for drinking milk in certain developing countries including India, Pakistan, Egypt and Nepal, it is almost exclusively used for mozzarella cheese production in italy [30]. There is an increasing research interest and investment in various countries for Buffalo milk because of its attractive nutrient content. Buffalo milk has a higher content of fat, crude protein, lactose, total solids, vitamins and minerals, which impart a rich flavour and taste, and make it a highly suitable ingredient for the manufacture of a wide variety of milk products, such as cheese, butter fat, ice cream, and yoghurt when compared with cow milk [30]. In Turkey, buffalo milk is widely used in making fat-rich milk products called "kaymak" [31].

E. Camel Milk

There are approximately 18 million camels in the world, 14 million of which are located in Africa and 4 million in Asia according to the FAO data (2008) [32]. In arid and semi-arid areas camels play a major role in supplying the population with milk [10]. One of the main components of the human diet in many parts of the world [33]. It contains all essential nutrients and a high biological value because of having the higher contents of antimicrobial factors such as lysozyme, lactoferrin and immunoglobulins [33]. Camels are well adapted to the harsh desert climate and can survive without drinking water for up to forty days and can produce a volume of milk well beyond the capacity of other domestic animals. A camel can yield 3,500 or more liters of milk during a lactation period which can extend for 18 months [4]. Camel milk is an important source of proteins for the people living in the arid lands of the world and is known for its medicinal properties as in several countries from the ex-Soviet Union and developing countries [34]. It is much more nutritious than that from cow milk due to its low fat and lactose contents, and higher in potassium, iron and vitamin C [35]. Camel milk contains 81.4-87% water, 1.2-6.4% milk fat, 2.15-4.90% protein, 1.63-2.76% casein, 0.65-0.80% whey protein, 2.90-5.80% lactose and 0.60-0.90% ash [32].

F. Donkey Milk

In the last decade, donkey's milk has a considerable scientific interest in Europe, especially because of its nutritional and functional ingredients. Because it is a suitable milk substitute for the infants who are not accessible of giving of human milk or in allergic reactions to cow's milk during the first months of life infants show [36]. The properties of milk differ from that one of other mammals in many ways that include important differences in nutritional value; moreover, its composition does not permit the production of cheese due to the high content of whey proteins that represent 35-50% of the nitrogen fractions [37]. The average milk production found 172.12 mL per milking with the average fat percentage of 0.33%, milk protein 1.55%, and lactose 6.28% [36]. Donkey's milk composition and its organoleptic characteristics are similar to human milk, especially with respect to the composition of proteins and lipids. It has low amounts of casein and β -lactoglobulin, and high concentrations of lysozyme which is essential to protect digestive system of children from various infections [36]. Enzymes in donkey milk have unique characteristics such as bactericidal property which makes donkey milk different from other mammals' milks and lysozym concentration in ass's milk is 4000 mg/L when compared to bovine milk [38]. Donkey milk has gained popularity due to its beneficial components.

G. Mare Milk

Mare's milk, is not only the most important nutritional resource for foals during the first months of life, but also the most important basic foodstuffs for the human populations in those areas of central Asia, where a lactic-alcoholic beverage called Koumiss is traditionally produced through fermentation [5]. Around 30 million people consume mare milk regularly throughout the world especially in areas of central Asia steppes: Turks, Bashkirs, Kazakhs, Kyrgyz, Mongols, Yakuts and Uzbeks. It is also one of the most important basic foodstuffs for the human populations [39]. Composition of mare milk is between human and cow milk and is suitable especially for the elderly, convalescents, and infants due to its nutritional characteristics. It is rich with whey protein, polyunsaturated fatty acids, vitamin C content, optimal Ca/P ratio and bioactive components [40, 41]. Also, It is sensitive for preservation and transformation processes. On the other hand the lactose content of mare's milk is similar to that of human milk and higher than that of cow's milk [40, 41]. From the early 20th century it was popular in Germany where it was delivered door to door. Now it is also back fashion in France, Belgium, Austria, and Holland. Mare milk contains high levels of vitamins and minerals, better digestibility and lower fat content than cow milk and that is why it is preferred by consumers who are conscious about health. Different breeds of dairy horses are used for mare milk production in the world and the composition of mare milk

are: dry matter: 9.3-11.6; protein: 1.5-2.8; fat: 0.5-2; laktoz: 5.8-7.0 g/100 g milk [42].

CONCLUSION

Milk is a valuable source of dietary energy, high-quality protein and fat. Bioavailability of some nutrients in milk, for example calcium, is high compared with that in other foods. Cow milk is the rawest material for processing in the World. Sheep and buffalo milk, regarding the high content of protein, especially casein, and also fat, make a very good raw material for processing, cheese and yogurt making. Goat milk was used for a wide range, such as consumption milk, and therapeutical product. Goat milk is mostly used in drinking milk and ice cream technology. Camel milk also has valuable nutritional properties as it contains a high proportion of antibacterial substances and higher concentration of vitamin C. Donkey milk has the most comparable protein composition with human milk. It is consumed predominantly in a nonprocessed form. Composition of mare milk is between human and cow milk and is suitable especially Koumiss making.

Abstract - Traditionally microbiological assessment for quality and safety of demands the foodstuffs enumeration and specific detection of pathogenic and spoilage microorganisms. Known testing methods consist of growth media and cultivation to enumerate and isolate cells of microorganisms from food samples. However, testing methods rely on cultivation are usually slow and give results after a few days. Also a lot of material and labour are used for this method. In recent decades, some non-traditional techniques named as molecular methods have been developed. Molecular techniques are applied for the detection and characterization of microorganisms in food products due to increasing demand for rapid results. Especially the polymerase chain reaction (PCR), detecting specific DNA or RNA for amplification processes constitutes based on method. Real time PCR, RFLP, DNA microarray assay, immunological techniques like ELISA are different molecular methods used for this purpose.

Key words: Molecular methods, PCR, food microbiology, food safety.

Recent advances in ultrasound and microwave assisted extraction of bioactive compounds from plant food processing by-products

Abstract—The food industry generate considerably huge amount of byproducts such as pomace, hull, peel, shells, seeds, stems, bran, etc., from a variety of sources which potentially lead environmental pollution. Therefore, there has been growing interest in valorization of byproducts through the extraction of bioactive compounds such as proteins, polysaccharides, fibres, flavor compounds, and phytochemicals, and using them in health promoting functional food and/or pharmaceutical formulations. Emerging “green” techniques, such as ultrasound-assisted extraction (UAE), microwave-assisted extraction (MAE), pressurized solvent extraction, supercritical fluid extraction, pulsed electric field extraction, and enzyme-assisted extraction has been considered as fast and efficient methods applicable for bioactive recovery from natural byproducts.

Novel techniques or the combination with conventional techniques might be employed as a pretreatment to increase the efficiency of extraction by improving cell-membrane permeability. UAE is simple and easy to scale up to the industrial level and MAE offers good recovery yields, and extractions are usually performed particularly fast. The principal objective of any extraction process is to obtain materials in higher yields while retaining the desired levels of bioactivity. However, the application of emerging techniques in industrial level still require further investigation and optimization researches, and represents a major step regarding the valorization of food processing byproducts. This presentation will cover an up-to-date review on the use of ultrasound and microwave assisted extraction processes to obtain functional bioactive compounds from plant based food byproducts.

Keywords— Ultrasound assisted extraction, microwave assisted extraction, bioactives, food byproducts

Abstract— In this study, it was aimed to determine the presence of *Staphylococcus aureus* (*S. aureus*) and the ability to enterotoxin production by molecular methods in meat samples (beef and chicken) obtained from different local markets in Erzurum. *Staphylococci* isolated from 54 different meat samples were identified as presumptive *S. aureus* using classical microbiological and biochemical methods. In the molecular evaluation of isolates, the presence of *S. aureus* was confirmed by detecting the *nuc* gene region and their toxigenic properties were revealed by detecting the enterotoxin A, B, C and D gene regions. *S. aureus* positive isolates were obtained in 15 (24%) of the analyzed meat samples. When evaluated according to the meat origin, *S. aureus* was detected in 6 (32%), 2 (13%) and 7 (63%) samples in drumstick, wing and beef, respectively. *S. aureus* strains which can produce the enterotoxin A were detected for all three meat types based on the multiplex PCR application for the determination of enterotoxigenic properties in the isolates.

Keywords— PCR; meat; *S. aureus* Introduction

I. INTRODUCTION

Staphylococcus genus are ubiquitous microorganisms which contain at least 40 species. They are Gram positive, non-spore, non-motile, facultative anaerobic and catalase positive microorganisms. They also form the part of the normal flora by living on the skin and mucous membranes of humans and animals. Bacteria in the *Staphylococcus* genus can cause to many diseases in humans, *Staphylococcus aureus* (*S. aureus*), which is included in this group, is known as an agent that causes more staff infections such as pneumonia, dermatitis, toxic shock syndrome, septicemia and food poisoning. *S. aureus*, resistant to high salt concentrations, has the ability to produce lecithinase, coagulase and thermonuclease [1]. Especially

enterotoxemia, which is caused by ingestion of enterotoxins produced by *S. aureus* which has enterotoxigenic properties, is a serious concern for public health. The data on outbreaks caused by this microorganism are very limited. As a result, toxication has a short duration and moderate symptoms. Despite the fact that this bacterium is susceptible to methods of control the growth of microorganisms on foods, especially high heat treatment applications, the toxins are resistant to heat treatments. Although many enterotoxin types that can be produced by *S. aureus* have been identified to date, toxemia is known to be caused mainly by types Enterotoxin A, B, C, D and E, which are classical enterotoxins. The enterotoxin production occurs in foods contaminated (i.e., poultry, meats, salads, eggs and products, pudding and pie) with *S. aureus* [2]. Nonspecific poisoning symptoms such as nausea, vomiting, stomach cramps, sweating, exhaustion and sometimes a decrease in body temperature occur with the consumption of these foods that contain enterotoxins. In addition, the presence of this microorganism in the food is considered as a sign of weak personnel hygiene.

Meat and meat products have a highly capacity of production and consumption in the world. These foods have a potential for outbreaks due to production under inappropriate conditions and contamination by food workers. Meat and meat products cause outbreaks a contaminant with pathogenic microorganisms such as *S. aureus*, mainly *Salmonella*, *Listeria*, *Escherichia*, *Campylobacter*, *Shigella*. *S. aureus* can proliferate and produce the toxins in contaminated meats that are kept on inappropriate conditions by food workers or self-contaminated [3]. There are many studies that were conducted in different countries in order to reveal the presence of *S. aureus* which can

produce enterotoxin. The aim of this study is to reveal the presence of *S. aureus* and ability of enterotoxin production of isolates by molecular methods in cattle and poultry meat offered for sale in Erzurum.

II. MATERIAL AND METHODS

A. Sampling and Analysis:

The samples were taken at local markets in Erzurum, Turkey and brought to laboratory under cold chain. Microbiological analyzes were conducted on the same day. The presence of *S. aureus* was studied on 54 different meat samples (drumstick, wing, beef). 10 g of meat sample was weighed into a stomacher bag and 90 ml of ¼ Ringer solution was added. Homogenization was then carried out for 2 min using a masticator. One mL was taken to make serial dilutions (100,10-1,10-2) from the homogenized sample.

B. Isolation and identification of *S. aureus*

0.1 mL of the homogenate from prepared each dilutions were planted onto mannitol-salt agar by spreading techniques. The plates were incubated for 24 hours at 37 °C. At the end of the incubation, yellow colonies with yellow zone were evaluated as presumptive staphylococcus. Presumptive colonies were subcultured on blood agar and then gram positive, catalase positive, oxidase negative and coagulase positive colonies were identified as presumptive *S. aureus* colonies. Subsequently, presumptive *S. aureus* was confirmed by PCR targeting the nuc gene region. *S. aureus* ATCC 29213 strain was used in this study as reference strain.

C. Extraction of DNA

For DNA extraction, the isolates were subcultured in tubes containing Brain Heart Infusion Broth (Oxoid, CM0225) and incubated at 37 °C for 18-24 hours in aerobic conditions. 0.1 mL of broth culture was taken into eppendorf tubes and centrifuged (Hettich Rottina 35R) for 30 secs at 16.000 g. Thereafter, the pellet was suspended in 50 µl of lysostaphin (Sigma-Aldrich, L7386) (100 µg/mL) and the suspension was allowed to incubate at 37 °C for 10 min. 50 µl proteinase K (Sigma-Aldrich, P2308) (100 µg/mL) and 150 µl buffer solution (10 mM Tris-HCl pH 8.3) were added to the cell suspension and incubated again at 37 °C for 10 min. Then, it was kept in boiling water bath for 5 minutes and at the end of this process it was immediately taken on ice and it was maintained at -20 °C until used for PCR.

D. PCR Protocol&Condition

PCR reactions were performed using a mixture (25 µl final volume) containing 1 µl of genomic DNA, 0.25 µl of each primer (nuc1a (5'-CCTGAAGCAAGTGCATTTACGA-3'); nuc1b (5'-CTTTAGCCAAGCCTTGACGAAGT-3')), 1.25 µl of dNTPs, 2.5 µl 10x PCR buffer, 1.5 µl of MgCl₂ and 0.2 µl of Taq DNA polymerase (Thermo Fisher Scientific) in a Biomeriux thermal cycler. Amplification conditions were given Table I. The presence of Enterotoxin A, B, C and D (SEA, SEB, SEC and SED) were performed according to Mehrotra et al.[4] by multiplex PCR method.

DNA amplification was carried out with the following protocol: initial denaturation at 95°C for 15 min, 35 cycles of amplification (denaturation at 91°C for 1 min, annealing at 60°C for 1 min, extension at 72 °C for 1 min) and final extension at 72 °C for 10 min in a (Bio-Rad Gel Doc XR System) system. PCR products were analysed on a 1% Agarose (Bio Basic Inc.) with 1 x Tris-acetate-EDTA buffer to see PCR products with 166 bp length [5].

E. Statistical analysis

One way ANOVA was used in the evaluation of the data by SPSS statistic programme.

III. RESULTS AND DISCUSSION

A total of 54 samples were examined. Presumptive *S. aureus* was isolated from 40 of the 54 samples. Isolates confirmed by species specific PCR (nuc gene) and 15 (27.8%) of them were determined as *S. aureus*. The results showed Table I. The PCR image of the analyzed samples was shown in Fig. 1.

Table 1 Number of meat samples positive for *S. aureus* and enterotoxigenic strain

Meat origin	Number of samples	N (%) of samples positive for <i>S.aureus</i>	N (%) of samples positive for enterotoxigenic strains of <i>S. aureus</i>
Drumstick	19	6 (32%)	1 (17%)
Wing	17	2 (13%)	1 (50%)
Beef	18	7 (63%)	1 (14%)

The contamination rate of beef with *S. aureus* was higher than chicken meats. Of the four different types of enterotoxins tested, only Enterotoxin A was detected in one drumstick, wing and beef sample.

Figure 1 : Gel electrophoresis of PCR products, using primer for *nuc* gen: *S. aureus* ATCC 29213 (lanes 10), negative control (lanes 11), positive (lanes 5, 10, 12, 13 and 15) samples, and 100 bp DNA ladder (lanes M)

S. aureus, located in the natural habitat, contaminates the meats due to poor hygienic conditions during the processing, storage or sale of the meat. It was reported by Gündoğan and Ataol [6] that 10.7% of the minced meat samples were positive for *S. aureus*, however, they could not isolate from chicken samples. In another study, Gündoğan et al. [7] demonstrated that *S. aureus* was isolated from 80 (53.3%) of 150 meat and chicken samples. In this study, the presence of *S. aureus* was determined in chicken meats and beef at a rate 22.2%, 38.8%, respectively. Cıtaç and Duman [8] identified 195 isolates of staphylococci from a total of 105 chicken samples in Ankara and identified 92 (47%) of them as *S. aureus*. The results obtained from these studies are higher than our findings. Guven et al. [9] reported that they isolated the *S. aureus* at a rate of 68.4% in beef cattle and 55% in poultry meat samples. The reason for the emergence of this difference between the data, the meats served in the Erzurum region indicate that the contamination during transportation and sales are low. It is also believed that the sample numbers are different, which may cause these data to be different

All strains were analysed for the presence of several known staphylococcal enterotoxin (SE) genes (SEA, SEB, SEC and SED) determinants by PCR. Staphylococcal enterotoxin A (SEA) were detected in 3 out of 15 *S. aureus*. When *S. aureus* finds the appropriate conditions, it rapidly growth and can form one or several of the toxins A, B, C, D, E, G, H. Guven et al. [9] reported that they found the presence of enterotoxigenic *S. aureus* in 2 and 7, respectively, of isolates from beef and poultry by ELISA-based method. Gencay et al. [10] found that two chicken meat isolate out of 70 *S. aureus* strain were carried out

SEA gene. Omoe et al. [11] determined that 36 (11.7%) out of 146 *S. aureus* isolates had SEA genes. SEA in 77.8% and SEB in 10% of the food poisoning cases in the US have been reported [2]. Enterotoxin A is the most toxic of *S. aureus* enterotoxins. Enterotoxin B (SEB), on the other hand, is the most resistant to heat and is also used as a biological weapon [12]. It has been reported that SEA is produced mostly by human strains, and SEC and SED are produced by strains isolated from mammals [13]. Rosec and Gigaud [14] determined that the rate of the strains carrying SEG, SEH, SEI and SEJ genes was very higher (57%) than that of the strains classical enterotoxin genes (SEA, SEB, SEC, SED, and SEE). Aydin et al. [15] reported that they isolated enterotoxigenic *S. aureus* at 13 of a total of 115 meat samples. Of the isolated enterotoxigenic strains, four SEH (30.7%), one SEA (7.7%), SEL (7.7%) and SEP (7.7%) were found. In this study the data of SEA gene was similar to those found by Gencay et al. [10] and Omoe et al. [11], but differ from those found by Aydin et al. [15] and Rosec and Gigaud [14]. Different result may be due to the low number of samples. Also only classical enterotoxin genes have been determined in this study. These isolates are thought to be investigated for other enterotoxin genes in subsequent studies.

CONCLUSION

The presence of *S. aureus* in the meat samples presented on sale at the Erzurum local markets shows that this bacterium can easily be contaminating directly or indirectly at any stages of food production. Moreover, the isolation of strains capable of producing enterotoxin suggests that these foods may be a source of public health risk. Although the data on toxemia caused by *S. aureus* in Turkey is little, it is an important fact that higher value-added studies are needed.

Abstract—In this study, it was aimed to product of fish crackers *Oncorhynchus mykiss*. For the purpose of adding groups into the paste mixture, two different groups of crackers were occurred as A and B by adding fish meat at the rates of % 20 and % 30. Nutrient composition (moisture, raw protein, raw oil, raw ash, carbohydrate) and sensory quality of the samples that were acquired in the study were determined and the analyses were repeated for 3 times. Evaluating the data acquired as a result of chemical analyses in the study statistically; it was determined that the difference between these two groups was significant in terms of food composition ($p<0,05$). Additionally, energy values of the products were determined respectively as 349,12—348,41 Cal/100 g in the groups A and B. As a result of sensorial analyses which were conducted in this study; samples in the group A received the highest number of likes from the panelists among the products that were prepared experimentally.

Keywords—Fish cracker; *Oncorhynchus mykiss*; Food composition; Energy value, Sensory quality.

I. INTRODUCTION

In our contemporary world, in parallel to evolving life style, changes in eating habit have increased consumption of foods easy to carry and ready to eat. Food products such as crackers, treats, biscuits and chips are considered as low nutritious and imbalanced because they lack of some nutrition elements although their energy values are high (1; 2; 3; 4). Therefore, if snack foods are consumed frequently between meals this might result in excessive energy intake. It is considered that it would be worth to enrich these products with fish meat since they are consumed in large volumes today (1; 2; 3; 5; 6; 7).

The present study aims to investigate the effect of fish meat on chemical composition, energy values and sensorial characteristics of crackers in order to supply an alternative food, crackers containing meat of trout aquacultured in Turkey.

II. MATERIAL AND METHODS

Within this study, *Oncorhynchus mykiss* fishes with certain economic value were procured from fisheries in Pertek territory in the Keban Dam Lake. Fishes were transferred in insulated polyurethane carriage boxes with ice in them to the laboratory set in the Pertek Vocational College. Then, they were processed in the very same day. After fish fillets were prepared, they were rinsed with fresh water. Then, they were boiled in water for 10 minutes before grounding in blender.

A. Creation of Fish Crackers

Figure 1 exhibits flow chart of fish cracker process and Fish crackers are seen in Figure 2. As a result of these operations, 2 distinct groups were prepared and each operation was repeated for three times.

B. Chemical Analyzes

Moisture content was determined by drying the sample at 100 °C until constant weight was obtained. (8). Crude Protein was determined according to AOAC procedure with N-Protein analysis (9). In analysis of fat content, Soxhlet (Extraction) method was employed (10). The percentage of ash content was determined by means of crude ash burning method (9). Carbohydrate value was determined by subtracting total moisture, ash, protein and fat amount percentages found during analysis from 100 (11). Energy values were obtained by adding up energy values supplied by individual nutrition elements (11).

C. Sensory Analysis

Sensory analyses on samples were conducted by a group of panelist (n=40) aged 18-65. Each panelist sensorial examined cracker samples in terms of their colour, odour, flavour appearance and general acceptability (5—Very Good to 1—Very Bad) (12).

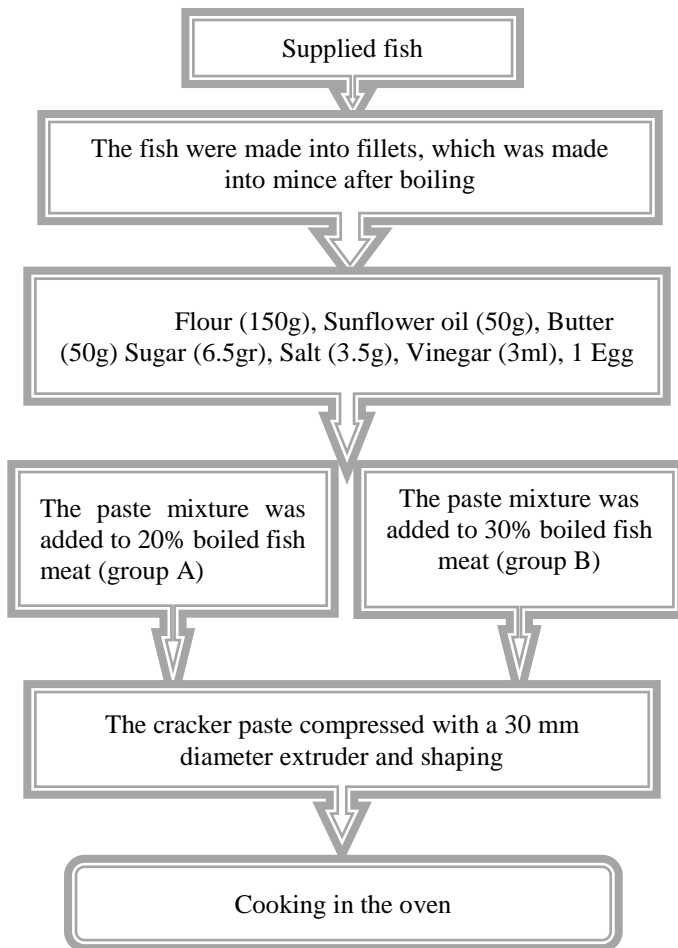

Figure 1. Flow chart of fish cracker process

Figure 2. Cracker Samples

III. RESULTS AND DISCUSSIONS

Table 1 exhibits chemical compositions of prepared samples. According to the Table 1, average moisture, protein, fat, ash, carbohydrate contents of fish meat ingredient of cracker samples were determined as follows $71 \pm 1.00\%$, $21.00 \pm 1.00\%$, $4.75 \pm 0.25\%$, $0.85 \pm 0.05\%$ and $2.25 \pm 0.15\%$, respectively. Table 1 exhibits moisture %, protein %, fat %, ash % and carbohydrate % amount of prepared cracker paste as they were containing fish meat in various proportions. Across these samples, statistically significant difference wasn't determined among groups in terms of moisture ($p > 0.05$). In parallel to these findings, Karaton Kuzgun (15) reported in their study conducted on *Luciobarbus esocinus* fillet that moisture, protein, fat and ash percentages were 71.27 ± 1.20 , 19.21 ± 1.78 , 7.75 ± 1.20 and 1.19 ± 0.28 , respectively. These values are also similar to our findings.

Of considered samples, whereas the highest protein amount was determined with the group B cracker and paste at 20.50 ± 0.50 and 13.50 ± 0.50 , respectively; the lowest amount was determined with group a cracker at 9.76 ± 0.23 (Table 1). Statistically significant difference was determined between samples in terms of protein amount ($p < 0.05$). Two groups displayed similarity in terms of fat amounts in cracker samples, others wasn't exhibited notable statistically significant difference among groups ($p > 0.05$) (Table 1). Whereas the highest ash percentage measured with crackers enriched with fish meat was estimated with group A at 2.80 ± 0.20 ; the lowest percentage was estimated with group B at 1.60 ± 0.10 . In terms of percentage of carbohydrate content of prepared fish cracker samples, it was estimated with group A and B at 40.90 ± 0.50 and 37.21 ± 0.05 , respectively. For paste samples, the same Carbohydrate value was estimated with group A and B at 11.50 ± 1.70 and 13.05 ± 0.15 , respectively (Table 1). In terms of ask content of samples, statistically significant difference wasn't determined among groups ($p > 0.05$). In the statistical analysis of cracker samples enriched with fish meat with respect to their carbohydrate content, the differences among groups were found significant ($p < 0.05$). In another study on cake paste, moisture, ash, fat and protein content percentages of mixture were

D. Statistical Analysis

In statistical analysis of acquired data within the scope of the present study, IBM SPSS®22 (SPSS Inc., Chicago, IL, USA) statistical package software was employed. The statistical significance of the difference among groups was investigated by means of variance analysis (ANOVA) ($p < 0.05$) (13).

reported as 58.32 ± 0.70 , 0.45 ± 0.02 , 2.58 ± 0.37 and 4.23 ± 0.50 , respectively. These findings are similar to our findings. However, fat and protein amounts were found to be lower than the values found in our study (16). This situation could be associated with the different proportions in paste mixture. As it could be seen from Table 1, sample crackers' moisture%, protein%, fat%, ash% and carbohydrate% values were measured at high levels as follows $7.50 \pm 0.50\%$ (B), $20.50 \pm 0.50\%$ (B), $32.31 \pm 0.31\%$ (A), $2.80 \pm 0.20\%$ (A) and $40.90 \pm 0.50\%$ (A), respectively. According to another study in the literature, amounts of constituents in per 100 g of substance were determined measured; and ash%, moisture%, protein%, fat% and carbohydrate% percentages were reported as 2.55, 10.00, 11.68, 6.74 and 69.08, respectively (4). In the same line, Yağmur et al. (2005)(17), measured nutrition values of biscuits and similar wheat products found available in the market. In these products, average moisture, protein fat, carbohydrate and

ash were determined as 5.54%, 6.48%, 18.49%, 68.43% and 1.08%, respectively. These findings displayed similarity with our findings.

As it was exhibited by Table 1, when 100 g. of each sample was analyzed on the basis of their energy values, group A and B samples were measured as 349.12 Cal/100 g and 348.41 Cal/100 g, respectively. The difference between groups was then found statistically significant in terms of energy value ($p < 0.05$). According to another study, the respective value was reported as 466 Cal/100 g for prepared biscuit and similar wheat products (17).

Table1. Food Composition of Cracker Samples

(%)	Fish Meat	Paste A	Paste B	A	B
Moisture	71.00 ± 1.00^d	45.00 ± 1.00^c	41.00 ± 1.00^b	6.50 ± 0.50^a	7.50 ± 0.50^a
Protein	21.00 ± 1.00^a	9.76 ± 0.23^d	13.50 ± 0.50^c	17.43 ± 0.43^b	20.50 ± 0.50^a
Fat	4.75 ± 0.25^a	31.81 ± 0.81^b	30.50 ± 0.50^b	32.31 ± 0.31^b	32.30 ± 0.30^b
Ash	0.85 ± 0.05^a	1.90 ± 0.10^{bc}	1.60 ± 0.10^b	2.80 ± 0.20^d	2.41 ± 0.19^{cd}
Carbohydrate	2.25 ± 0.15^a	11.50 ± 1.70^b	13.05 ± 0.15^b	40.90 ± 0.50^c	37.21 ± 0.05^d
Energy value	-	-	-	349,12	348,41

a,b,c,d: The difference between average values with different letters on the same column

Sample crackers were also evaluated by participants in terms of color, smell, taste, appearance and general like (Figure 2). Sample crackers were scored the same in two groups in terms of their color (5.00 ± 0.00) (Figure 3). When colors of samples were analyzed statistically, the differences among groups weren't found to be significant ($p > 0.05$). When cracker samples were evaluated by participants in terms of their smell, the highest score was given to samples from group A (4.50 ± 0.50), the lowest score was given to the samples from group B (3.25 ± 0.43) (Figure 3). In statistical analysis of samples for sensorial perception regarding their smells, it was revealed that differences among groups were found to be statistically significant ($p < 0.05$). As it was seen from Figure 3, in sensorial analysis of cracker samples for their tastes, whereas group A samples were given 4.50 ± 0.70 score, group B samples were given 4.00 ± 0.00 . It was also determined that the differences among groups weren't statistically significant in terms of taste sense ($p < 0.05$). As it was exhibited in Figure 3, when sample groups were evaluated by respondents for their appearance, the difference among groups weren't found to be statistically significant in terms of their appearance ($p > 0.05$). According to Figure 3, when samples were evaluated by respondents in terms of general acceptability, it was seen that the highest score

(4.75 ± 0.43) was given to group A; and the lowest score (4.00 ± 0.00) was given to group B. In statistical analysis of samples in terms of sensorial general acceptability, the differences among groups were found significant ($p < 0.05$). İzci ve Bilgin, (2015) (18), determined in their study conducted on cracker that general acceptability score of the cracker as 8.09 ± 0.25 . This value coincides with our findings.

Figure 3. Sensory Change in Cracker Samples

IV. CONCLUSION

Finally, it was concluded that crackers could be added meat of fish species studied in this research so that nutritious values of crackers could be enhanced and variety of products could be enriched, which eventually makes significant contribution into country economy.

Abstract— Spray-drying, which has been used for commercial production of functional ingredients from several fruits and vegetables, has not yet been studied for grape juice processing. Pekmez, known also as evaporated grape juice, was spray dried in the laboratory type pilot drying unit to obtain pekmez powder. Because fruit juices could not be spray-dried in the drying unit without filler or carrier, maltodextrin which is frequently used as a filler and carrier, was used for this purpose. Therefore, pilot experiment was carried out with the mixture of grape pekmez and maltodextrin (as a carrier, 40-60% v/w).

Keywords— *Pekmez powder; spray drying; maltodextrin*

I. INTRODUCTION

Pekmez is one of the traditional food products in Turkey and it is commonly produced from grape and mulberry by concentration of juices up to 70–80 soluble dry matter content. Pekmez, consumed generally for breakfast [1], can also be produced from fruits containing high amounts of sugar like apple, carnob, plum, watermelon, apricot, sugar beet and fig [2, 3].

Pekmez is a concentrated and shelf-life extended form of grape juice formed by boiling without the addition of sugar or other food additives [4, 5, 6]. Therefore, it can be assumed as a natural food containing natural sugars such as glucose, galactose and minerals. The purpose of concentration is to extend the shelf-life by reducing the water content and to pasteurize the grape juice [5, 7, 8, 9, 10].

Pekmez is nutritious food. Average energy value is 280 kcal/100g (11). Specially, pekmez is rich in iron, phosphor, calcium, and potassium minerals (12). Pekmez is a natural source of energy due to its high carbohydrate content (65-68%). It contains valuable minerals such as calcium (0.084-0.086%) and iron (0.005-0.01%). The high iron content makes the product a recommended treat for anemia [13]. In addition, B1 and B2 vitamins add extra value to the product. This is of nutritional importance, especially for babies, children,

sportsmen and in situations demanding immediate energy [14, 15].

Pekmez is produced in low heat evaporation steps, commercially sold and commonly consumed in viscous liquid and solid forms. The color of the pekmez changes from dark brown to white depending on the processing conditions, concentration, types of bleaching agents, heat and mixing rate. The viscosity of pekmez increases with increasing solids concentration and decreasing temperature [16].

However, prolonged storage of pekmez causes problems related with some quality characteristics. Hydroxymethyl furfural (HMF) development is one of the most significant problems occurring during the pekmez storage. Tosun and Ustun [15] reported that HMF content of pekmez increased during prolonged storage period. In addition, the color of pekmez darkens during this period, because of maillard reaction. When excessive maillard browning is undesirable in food systems, it can be inhibited by drying process in which the moisture is decreased to very low levels [17]. HMF is one of the most widely used indices in nonenzymic browning studies on juices and fruit derivatives. Therefore, storage of pekmez as a dried form may be one of the useful ways to inhibit or delay excessive maillard browning, consequently decrease HMF development during the storage period. Another purpose of drying is to extend the shelf-life by reducing water content. In addition, storage of pekmez as a dried form will help to reduce storage costs. Spray drying is ideal for heat sensitive products such as maltodextrine, soup mixes and sugar-based foods. However, pekmez powder production by spray-drying technology is new and has not been applied yet in Turkey so far. Fig. 1 shows a flow diagram of pekmez powder processing operation. Pekmez powder is produced from pekmez by using spray drying, which is the most widely used industrial technology involving particle formation and drying. Like other heat sensitive liquid foods, pekmez can also be dried by the spray drying technology.

II. MATERIAL AND METHODS

A. Spray Drying

Spray drying involves the atomization of a liquid feedstock containing solids in solution, suspension or emulsion, and directing the resulting spray of droplets into a flow of hot drying air. Liquid feedstocks are not only just dried, but are also converted into powders having specific properties as determined by the atomization and drying conditions adopted, and also the drying chamber and plant layout selected. One of the most important reasons why spray drying has been adopted for producing powdered products is the ability of the technology to produce an end product continuously to a precise quality specification. The most commonly quoted specifications involve moisture content, solubility, bulk density, and hygroscopicity. The temperatures and drying conditions experienced by a droplet during drying have an important influence on the above powder properties [18, 19]. In the early stages of drying, the droplet has a free liquid surface and evaporation from this surface is rapid. The depletion of liquid will cause the solute to be more concentrated at the surface - this will depend on the speed of evaporation and the rate at which the liquid can be replenished from the interior of the droplet. Because of this increased concentration, solids will come out of solution at the surface of the droplet first, leading to the formation of a crust or skin around a hollow particle. The thickness of the crust will depend on the drying rate - high initial drying rates will lead to larger particles with thin shells and low density, whereas, low initial drying rates will lead to smaller particles with thick shells and high density. The presence of occluded or absorbed gases in the liquid feed is another possible mechanism for the formation of hollow, high porosity particles. In addition to the above particle formation processes, conditions should also be tailored to physical and chemical changes within the material itself [18, 19]. Spray drying of sugar-rich foods is difficult due to the presence of high content of sugars and organic acids. These compounds exhibit sticky behavior during spray drying. Stickiness is a term used to describe the phenomena of particle-particle cohesion and particle-wall adhesion in the spray drying process. Stickiness depends not only on the properties of materials but also on the inlet variables applied in a spray drying system. Deposition is another phenomenon in spray drying. It relates to the stickiness and the design of a dryer system. Theoretically, there should no deposition problem if the size of the dryer chamber is large enough. Because of the economic factors, the size of the dryer needs to be limited to a suitable range. Therefore, stickiness and deposition need to be solved by other methods rather than by using a very large dryer chamber.

Additives such as glucose syrups or maltodextrin have been used to produce physical changes in the product, consequently reducing the stickiness and wall deposition in spray drying. Glucose syrups have been used for blackcurrant [20] and

orange juice [21] and maltodextrin has been used for different sugar-rich foods such as orange [22], blackcurrant [23], honey [24] and tamarind [25]. The addition of these carriers into the feed improved the powder recovery. The fraction of additives in juices is normally in the range of 40–60% but higher fraction can also be used [26]. However, the required sensory quality of final products limits the amount of additives.

B. Pekmez Powder Production

To produce pekmez powder, pekmez produced from fresh grapes according to the traditional method was spray-dried by Niro atomizer laboratory type pilot drying unit in the plant of ENKA Dairy and Food Products Co., Konya, TURKEY, as in the process flow scheme diagrammed in the Fig. 1.

Pilot scale test was performed in Niro Atomizer pilot spray-drying unit with the capacity of 1-7 kg water evaporative per hour. The sprays were produced by rotary (wheel) energy (Fig. 2.). Evaporation of moisture from the pekmez droplets and formation of particles were performed under controlled temperature and airflow conditions. Pilot experiment was carried out with the mixture of grape pekmez and maltodextrin (as a carrier, 40-60% v/w).

Because fruit juices could not be spray dried in the drying unit without filler or carrier, maltodextrin which is frequently used as a filler and carrier, was used for this purpose. Maltodextrin addition prevents pekmez from becoming thicker and more adhesive to the processing equipment due to maillard reaction, which may also result in pumping problems. The drying step took 60 min. The temperature of inlet air was 200 °C and outlet air temperature did not exceed 70 °C. The air flow direction and particle trajectories were the same. At the end of processing, the pekmez powder having 96-97% of dry matter was packed with triple layered kraft paper pouches and stored in this way until analyses. To analyze physical and chemical properties of the pekmez powder properly, it was diluted with 30 % of distilled water.

C. Determination of Chemical and Physical Characteristics

Total and soluble dry matter, ash and pH values were determined according to the standard method of AOAC [27]. The pH was measured with a pH meter (pH 315i/SET WTW, Weilheim, Germany). Soluble dry matter was determined with an Abbe-Zeis refractometer at 21 °C and expressed as °Brix. Water activity measurements were performed with an AQUALAB apparatus (DECAGON Devices Inc., Model Series 3TE, USA). Pure water (1.000±0.003%) was used as standard for equipment calibration. Color measurement was performed using a Minolta Chroma Meter CR-400 (Minolta, Osaka, Japan).

The L*, a* and b* color measurements were determined according to the CIELab color space system, where L*

corresponds to light/dark chromaticity (changing from 0% dark to 100% light), a^* to green/red chromaticity (changing from -60% green to 60% red) and b^* to blue/yellow chromaticity (changing from -60% blue to 60% yellow). The instrument was calibrated with a white reference tile ($L^*=97.10$, $a^*=-4.88$, $b^*=7.04$) before the measurements. Color measurements were made 4 times, 1 on the middle and 3 on the different parts of the solutions.

III. RESULTS AND DISCUSSION

As shown in Table 1, diluted pekmez powder (DPP) produced from fresh grape contained similar total and soluble dry matter, ash content and pH value to those reported for mulberry and white grape pekmez [28, 29]. L^* , a^* and b^* values of DPP were measured as 50.68, +4.44 and +10.19, respectively. A high redness (a^*) value is not desired because it occurs as a result of excessive caramelization of sugars. A low redness (a^*) and high brightness (L^*) values indicate a good quality pekmez parameters [30]. In this study, DPP, which was regarded to be equivalent to pekmez showed high L^* values and low a^* values, being an indicative of good quality DPP product. Therefore, pekmez powder production process and obtained pekmez from DPP product could be regarded as a valid production method and product, which was free of problems with respect to the pekmez's physical and chemical quality parameters, mentioned above.

IV. CONCLUSION

Pilot-scale experiment proved the possibility of production of dried product, called pekmez powder whose diluted form (diluted pekmez powder, DPP) showed the similar physical and rheological characteristics to those reported for the pekmez in the literature. Therefore, process of pekmez powder production from pekmez by pilot type atomizer drying unit can be regarded as an acceptable production method, without modifying the fundamental pekmez's physical and quality parameters studied in this study, by this way, processing and storage of pekmez powder may be an alternative way to the processing of pekmez in the liquid form.

TABLE 1 The chemical and physical characteristics of DPP

Properties		DPP
Total dry matter		74.09 %
Soluble dry matter		69.43 °Brix
Ash		2.01 %

a_w		0.852
Color	L^*	50.68
	a^*	+4.44
	b^*	+10.19

DPP, diluted pekmez powder.

Rotary atomizer, located in the center of the chamber roof. An air turbine drive operating from a six-bar compressed air source, supplies power to the atomizer wheel. A vaned atomizer wheel is used for non-abrasive feeds and an atomizer wheel with carbide bushings for atomizing abrasive feeds. Particles in the range 5-25 μ m are created.

Co-current two-fluid nozzle, located also in the center of the chamber roof. The atomization is created by compressed air at a pressure of 0.5-2.0 bar. The feed and atomizing gas are passed separately to the nozzle head where the atomization takes place. Two-fluid nozzles have the advantage of handling more viscous feeds. The co-current mode is selected for drying heat sensitive products to fine particles in the range 5-25 μ m.

Fountain two-fluid nozzle, located in the cone of the drying chamber, spraying upwards. The fountain mode is selected to meet a more coarse and free-flowing powder specification. Often used for fine ceramics and other non-heat-sensitive products. The counter-current flow offers a dryer performance with excellent heat utilization and provides the longer powder residence time in the drying chamber required to complete the drying to larger particles in the range 15-80 μ m.

Abstract— The study area is located in the Derindere drill hole, around Bismil, Diyarbakır, southeast of Turkey. Investigated Early Silurian-Early Devonian organic rich Dadas Formation is one of the main source rocks for oil. Formation consists of grayish-green, organic-matter rich dark colored shales, limestones, mudstones and sandstones. Samples were collected from the Derindere drill hole. Element analysis of 20 representative samples were carried out, using ICP-AES for the determination of major and trace elements. 20 total organic carbon (TOC) analysis was performed by the pyrolysis method using the Rock-Eval 6 analyzer. Al_2O_3 , Fe_2O_3 , Na_2O , TiO_2 and Cr_2O_3 , Sc, Ba, Co, Cs, Ga, Hf, Rb, Nb, Ta, Th decrease at the between 3000-3020 m. showing lower detritic contribution at these levels. On the other hand CaO is higher at these levels show carbonate occurrences. Cu, Pb, Zn, As sulphophile elements are lower at the 3060. meter (Table 2), showing lower sulphide minerals at these level. TOC values increase between 2890–3070 meters. These variations in elements and TOC concentrations reflect changes in paleoclimate, paleoredox and paleoproductivity in Paleozoic sedimentation. The positive correlations between SiO_2 , Al_2O_3 , Cs, Ga, Nb, Rb, Ta, Th, Sc reflect silicates and, positive correlations between Cu, Pb, Zn, Ni show sulphide occurrences. Negative correlations of TOC and SiO_2 , Al_2O_3 , Fe_2O_3 reflect that these elements depend on silicates than organic materials. The correlations between Ga, Rb, Ta, Th and TOC show detritic silicate- organic material discriminations.

Keywords—organic matter; major element, trace element, Dadaş , Eastern Turkey

1. INTRODUCTION

In comparison to shales, black shales are enriched in both organic matter and some trace elements [1]. Element enrichment in shale is associated with the accumulation of

elements together with organic matter under anoxic conditions [2].

Paleozoic Dadaş Shales are exposed around Diyarbakır – Bismil in southeast Anatolia, and are deposited in the foreland area of south-east of Turkey [3]. Dadaş Shale is the Turkish equivalent of Silurian hot shales in the Middle East. and have been continued since 2011 by the Turkish National Petroleum Company (TPAO) and several international companies.

Geology and organic geochemical characteristics of the Dadaş Shales were investigated by [4], [5], [6], [7],[8]. However, the major and trace element geochemistry of these shales were not study. In this study, the concentrations of both major, trace elements and the organic matter element relations have been investigated in Derindere drill hole samples from Dadaş Formation.

I. GEOLOGICAL SETTING

The study area is located in the Derindere drill hole area around Bismil, Diyarbakır, southeast of Turkey (Fig. 1). The Formation around area is shown in Fig. 2. In the area, Miocene Şelmo Formation overlies the Early Silurian-Early Devonian Dadaş Shales.

The Dadaş Formation consists chiefly of shale, mudstone and sandstone starts with a grayish, green colored transgressive sequence deposited in a shelf environment and ends up with a regressive sequence [3], and divided into three members; with organic rich clastic rocks restricted to the lowermost part as Dadaş I and Dadaş II and uppermost part of Dadaş III (Fig.3). Dadaş-I member is comprised by carbonate-interlayered dark shales, Dadaş-II member is composed of sandstone-interbedded, banded, organic-matter rich dark shales and Dadaş-III member is comprised by shale, sandstone, dolomite and marl lithologies [6]. Derindere drill hole cut the Dadaş-I member.

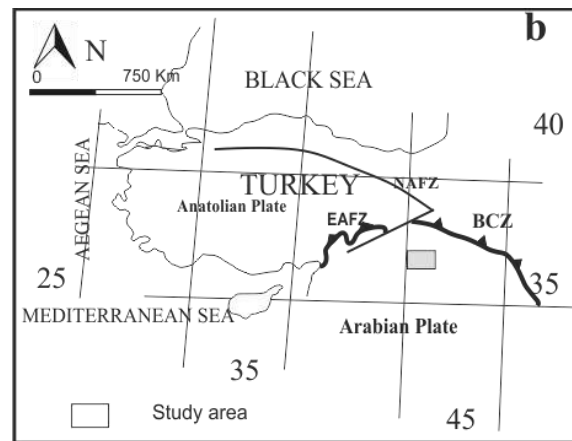

Figure 1. Location map of the study area

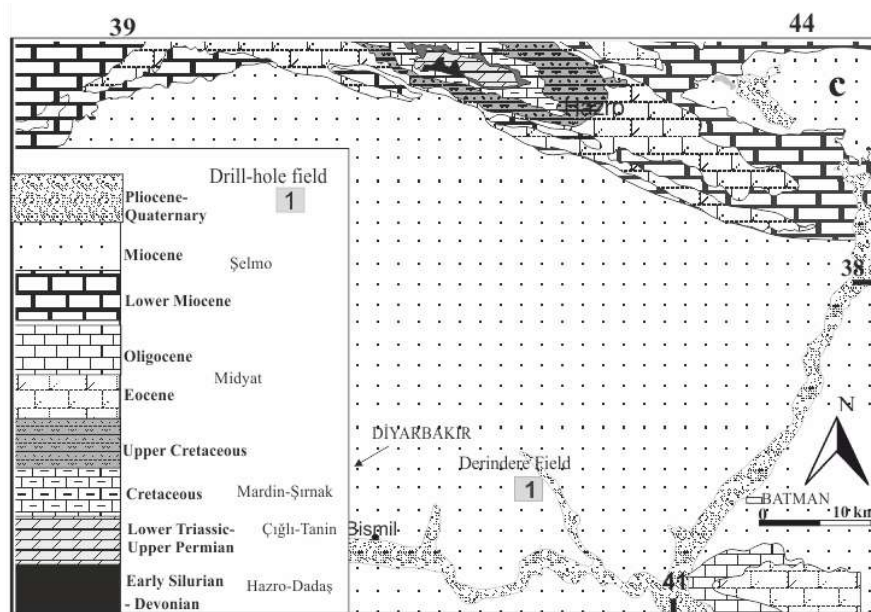

Figure 2. Geological map of the study area showing the locations of Derindere drill hole. Simplified from 1/500.000 scale geological map.

II. SAMPLING AND ANALYTICAL METHODS

Samples were collected from the Derindere drill hole (DDH). Element analysis of 20 representative samples were carried out at Acme Analytical Laboratories Ltd. (Canada), using ICP-AES for the determination of major and trace elements. Major elements are expressed as oxide percents (i.e. SiO_2 , Al_2O_3 , CaO , Cr_2O_3 , total Fe_2O_3 , K_2O , MgO , MnO , Na_2O , P_2O_5 and TiO_2). Other element concentrations are given in ppm. Loss on ignition was determined by weight difference after ignition at 1000 °C. In order to determine the relation between the elements and organic material, total organic carbon (TOC) analysis was performed. TOC (%) analysis was conducted at Geochemistry Laboratories of Turkish Petroleum Corporation (TPAO) by the pyrolysis method using the Rock-Eval 6 analyzer.

III. RESULTS and DISCUSSIONS

A. Geochemistry

Concentrations and average of major and trace elements of the Derindere drill hole samples are shown in Table 1. Al_2O_3 , Fe_2O_3 , Na_2O , TiO_2 and Cr_2O_3 elements depend on the detritic silicates [9]. In drill hole, these elements decrease at the between 3000-3020 m. levels. This shows that detritic contribution is lower at these levels. Sc, Ba, Co, Cs, Ga, Hf, Rb, Nb, Ta, Th are lower at levels also suggest this phenomena. CaO element is higher at the these levels show carbonate sedimentation (Table 1). On the other hand, Cu, Pb, Zn, As elements (sulphophile elements) are lower at the 3060. meter (Table 2)., showing lower sulphide minerals.

Formation	Member	Lithology	Explanations
Hazro			Shale Sandstone
Dadaş	III		Shale Siltstone Limestone
	II		Limestone band and gray shale
	I		Limestone Shale
Bedinan			Shale Sandstone Siltstone

Figure 3. Lithographic section of Dadaş Formation [3].

The Dadaş Shales were deposited in a shelf environment. These variations in element concentrations reflect deposition conditions and paleoclimate [10]. Detritic contribution shows mainly drier climatic conditions prevailed between 3000-3020 levels. There is a significant positive correlation with LOI and CaO ($r=0.96$) in all samples suggesting that carbonates play an important role on the LOI of the shale samples (Fig. 4). With the exception of MgO, CaO, P_2O_5 the major oxides show significant positive correlation with Al_2O_3 demonstrating that Al, K, Na and Ti sources are mainly from feldspar and clay minerals. However, CaO shows a negative correlation with SiO_2 , Al_2O_3 , K_2O and TiO_2 .

Ca is attached to carbonates and these negative correlations reflect the separation of carbonates and silicates. The positive correlations between SiO_2 , Al_2O_3 , Cs, Ga, Nb, Rb, Ta, Th, Sc reflect silicates (Table 4) and, positive correlation between Cu, Pb, Zn, Ni show sulphide occurrences (Fig. 5).

B. Organic Matter Content

The concentration of organic matter in a rock is typically evaluated by measurement of the TOC content. TOC values of the Dadaş Shales are shown in Table 5. TOC values increase between 2890–3070. meters. In generally, TOC content increase with the deep of Derindere drill-hole (Table 5, Fig. 6).

C. Elements -TOC Relationships in Derindere Drill-hole

Table 6 and Fig. 7 show correlations between TOC and some important elements. Negative correlations of TOC and SiO_2 , Al_2O_3 , Fe_2O_3 , show that these elements depend on silicates than organic elements. These elements are detritic in origin [11]. It is not present correlation between TOC and MgO, CaO, show that these elements depend on carbonates than organic materials.

There are no significant correlation present between TOC and Ga, Rb, Ta, Th which are detritic elements, also suggest detritic silicate - organic material discriminations. Mangan is an element sensitive to redox changes [2]. It is not present correlation between Mn and TOC can be explained by consumption in anoxic conditions. The association of P with the organic matter in coals has been established. P is associated with the organic material [12]. A positive correlation between TOC and P indicates the dependence of this element on the organic matter.

Figure 4. Some major oxide elements correlations ($P>0.05$)

V, Ni, Cu, Pb, Zn, As are enriched in organic matter-rich rocks [13], [2], [14]. This explains the positive correlation of these elements with TOC (Table 6). U, Mo, also have positive

correlations with TOC, indicate that these elements are grouped with TOC. U and Mo is one of the most common and

highly enriched elements in black shales [11]. The positive correlation is present between Ba and TOC. Ba is often assumed to be an indicator for paleo-production [15]

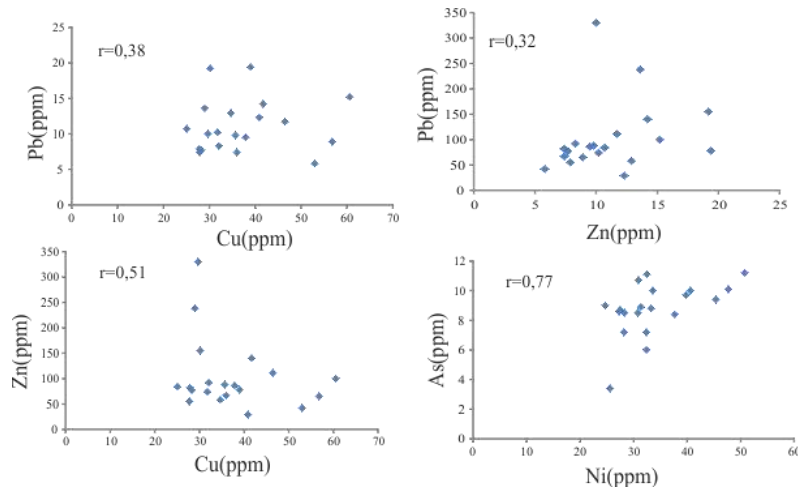

Figure 5. Some trace elements correlations ($P>0.05$)

Figure 6. Total organic carbon (TOC) contents of samples in Derindere drill-hole

IV. CONCLUSION

Chemical compositions of analyzed samples of Derindere drill hole from Dadaş Formation have been used to deduce the following.

- 1) In study area, Miocene Şelmo Formation overlies the Early Silurian-Early Devonian Dadaş Shales. The Dadaş Formation is divided into three members; Dadaş I and Dadaş II and uppermost part of Dadaş III. Derindere drill hole cut the Dadaş-I member. The formation that consists chiefly of shale, mudstone and sandstone starts with a dark grayish, green colored
- 2) Transgressive sequence deposited in a shelf environment and ends up with a regressive sequence.
- 3) Detritic silicate contribution is lower, carbonate contribution is lower between 3000-3020, and sulphide minerals are lower at the 3060 meter.
- 4) TOC values increase between 2890–3070 meters and in generally, TOC content increase with the deep of Derindere drill-hole
- 5) The variations in detritic element concentrations and TOC contents reflect deposition conditions and paleoclimate. Lower detritic contribution shows drier climatic conditions prevailed in 3000-3020 levels than the other levels of drillhole.
- 6) The correlation analysis show the silicate, carbonate , sulphide discriminations.
- 7) It was shown that U, V, Ni, Cu, Pb, Zn, As , Ba show the enrichment with organic material content in Derindere drill-hole.
