INTRODUCTION

Dear Distinguished Delegate,

International Conference on Advances and Innovations in Engineering (ICAIE) is held at Firat University, Faculty of Engineering in Elazığ, Turkey during May 10-12, 2017 in honor of the 50th anniversary of the establishment of the faculty.

International Conference on Advances and Innovations in Engineering is an international scientific forum of distinguished scholars engaged in scientific, engineering and technological research, dedicated to the furtherance of science, engineering and technology. The academic research conference since its inception is at the cutting edge of international nonprofit scientific, engineering and technological progress to promoting excellence in science.

The conference plays an influential role in science and promotes developments in science, engineering and technology in a wide range of ways. The conference aims to foster research in the area of science and technology and its impact to mainstream human activities. Specifically, it serves as a venue for discussions and exchange of ideas in current issues in science and technology.

All full paper and abstract submissions to the conference are peer reviewed and refereed and evaluated based on originality, research content and correctness, relevance to contributions, and readability. In this content the full paper and abstract submissions are chosen based on technical merit, interest, applicability and how well they fit a coherent and balanced technical program. The accepted papers after rigorous peer reviewing process have been published in the refereed international conference proceedings

Chair of ICAIE Committee
Prof. Hasan KÜRÜM

Performance of Some Soil Bacteria on Ethalfluralin Biodegradation

Gökhan Önder ERGÜVEN

Department of Environmental Engineering,
Faculty of Engineering,
Munzur University,
Tunceli, Turkey
gokhanondererguven@gmail.com

Abstract— *The aim of this study is investigate the efficiency of *Bacillus thuringiensis* and *Fusarium fujikuroi* soil bacteria on ethalfluralin biodegradation with chemical oxygen demand (COD) and reveal the population dynamics of these bacteria during biodegradation process under agitated culture conditions with turbidity. Bacteria samples were firstly isolated from agricultural soil in agar media taken from Thrace region of Turkey and these bacteria were stocked. These stocked cultures were used in experimental studies. COD experiments were done according to standard methods 5220C closed reflux titrimetric method and turbidity experiments were performed by Photolab 6600 UV-VIS Spectrophotometer. All experiments were performed triplicate. As a result; COD removal efficiency of *Bacillus thuringiensis* was determined as 83% and *Fusarium fujikuroi* as 53%, at the end of the 120th hour. According to the results; COD removal efficiency showed some differences depend on the bacteria species. It was also observed that *Bacillus thuringiensis* had more removal efficiency on COD and it was a suitable bacteria species for bioremediation contaminated waters by ethalfluralin against *Fusarium fujikuroi*.*

Keywords— *bacteria; ethalfluralin; biodegradation; chemical oxygen demand; removal efficiency.*

Abstract— Wood is a natural material that can be deteriorated and decomposed by both biotic (fungi, insects, bacteria, etc.) and abiotic factors (UV radiation, fire, chemicals, mechanical effects, etc.). Impregnation by various chemical agents is a common application to protect and extend service life of wood and wood products against such factors. High permeability of wood is a required feature for successful impregnation process in terms of better penetration and high retention level of preservative chemical. For refractory wood species, various attempts to increase permeability and treatability i.e. immersion in water, steaming, solvent application, enzyme treatment, mechanical incising and incubation with fungi or bacteria are available. Among those applications, bio-incising by organisms is a process that aims at increasing the permeability of wood without affecting its desired properties in a negative way. *Physisporinus vitreus* is a fungal species having an ability to penetrate the sealed pits of wood microstructure that are important cell elements for fluid flow. This species is a well-know fungal species for bio-incising attempts in refractory woods. In this study, we evaluated various practices for applicability of *P. vitreus* to *Picea orientalis* wood (spruce), which is difficult to impregnate and less durable. The main goal of this study is to increase the service life of wood from *P. orientalis*, one of the refractory wood species in Turkey by improving its ability to impregnate by bio-incising procedures. Within the scope of the study, ten different strains of *P. vitreus* were obtained from various research laboratories and augmented in laboratory conditions in Petri dishes containing 4% of malt-agar nutrient medium.

The Petri plates inoculated with the strains were periodically observed and the strain that showed the fastest development was preferred as a basic test strain. Three different growth media were used during the experiments and the EN 113 standard test method was used for each test medium. Only glass jars were used during the tests as they provided larger usage volume for wood specimens rather than standard Kolle flasks. In the first set of the experiments, wood specimens previously dipped into 2% malt extract emulsion were inoculated by *P. vitreus* strains. Wood specimens were dipped into glucose-pepton malt extract emulsion in the second set. Wood specimens in the third experiments were directly placed into glass jars containing 4% malt extract agar nutrient medium previously inoculated with the fungal strains. The methods were evaluated according to the ability of the fungal mycelium to envelop the entire wood surfaces. The key point is the necessity of ensuring the homogeneous penetration of fungal hyphae into the wood structure. As a result of macroscopic and microscopic evaluations, the best development was provided by the third test set, which is simpler than the other methods followed. The best fungal growth in the third test set was provided at the conditions of $24\pm 2^{\circ}\text{C}$ and $70\pm 5\%$ relative humidity and by using a growth medium where wet vermiculite was added under sterile conditions.

Keywords— *Physisporinus vitreus*, bio-incising, permeability, impregnation, wood, optimum growth conditions.

Abstract— *In this study, Bacillus subtilis 4NK isolated from Bingöl Binkap hot spring in Turkey. The isolate was identified based on different by morphological, physiological, biochemical and 16S rRNA gene sequencing. The strain 4NK was found to be an aerobic, Gram-positive and rod shaped. The optimum temperature, pH and incubation period for bacterial growth were 40 oC, 6.0-7.0 and 24 h, respectively. The result of 16S rRNA gene sequence analysis showed that, the strain 4NK related to the Bacillus subtilis (98% similarity). This strain was found to produce biotechnologically important enzymes for industrial application.*

Keywords— *16S rRNA, hot spring, isolation, enzyme.*

Investigation of α -Amylase Production in Novel Rotating Drum Bioreactor

Abstract— Alpha amylase are extracellular endo enzymes that randomly cleave the 1,4- α linkage between adjacent glucose units in the linear amylose chain and ultimately generate glucose, maltose and maltotriose units. Amylases are one of the most important industrial enzymes and their annual production volume is 25-30% of the total manufacturing of enzyme production [1]. Solid substrate fermentation (SSF) that is a good alternative to produce cheaper enzyme was known as a fermentation process in which microorganism grown in the absence of free water media. Solid particles distributed in a liquid phase are defined as slurry state fermentation (SLSF) [2]. SLSF merges advantages of other fermentation modes that SSF (higher yield, lower cost) and submerged fermentation (easy control and measurement of fermentation conditions). Rotating drum bioreactor (RDB) that is one of main solid state bioreactors types has gained great attention from researchers. Although conventional RDB is an important microbial production system in terms of preventing heat accumulation and having less severe shear stress on microorganisms, it isn't completely adequate in larger-scale RDB due to high levels in temperature gradient.

In this study, RDB was designed by adapting for SLSF and the effects of bioreactor operating parameters on α -amylase production was screened by experimental design with enzyme production system (Fig. 1). Ceramic micro diffuser was used to increase oxygen transfer efficiency in the RDB design. *Bacillus amyloliquefaciens* NRRL B-645 that is a commercial bacterial α -amylase producer was used. In the α -amylase production studies was used optimum conditions (25 g/l corn bran, 10 g/l yeast extract and 1 g/l KH_2PO_4) that determined earlier obtained α -amylase production studies in erlenmeyer flasks. Dissolved oxygen, pH, temperature, oxygen and carbon dioxide at gas outlet were followed online during fermentation. Dinitrosalicylic acid method [3] was used for determination of α -amylase activity.

Effects of operating parameters, rotation speed, aeration rate, working volume, diffuser's pore diameter, baffle size, temperature and inoculum size, on the α -amylase production in the RDB were determined with Plackett-Burman design. According to ANOVA results, Model is significant as it is seen Model F value (17,46) and very low probability value (0,0075). The enzyme production in erlenmeyer scale was applied to laboratory scale RDB and an important step was taken for production on commercial scale.

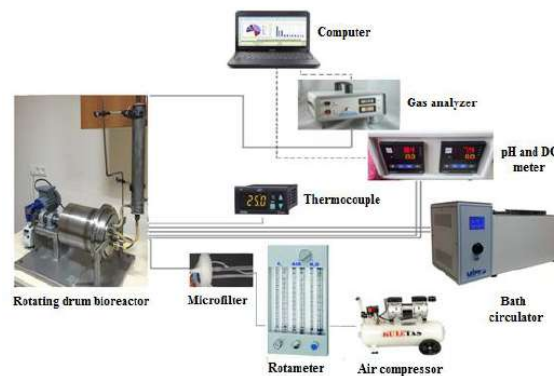

Figure 2. Enzyme production system.

When the results are compared, the enzyme production in RDB was about 2-fold higher specific productivity (50,86 U/g corn bran.h), with higher activity and shorter time, according to the erlenmayer scale production (25,36 U/g corn bran.h) and a cheaper enzyme production system by using agricultural wastes has been created.

Abstract— In the present study, α -amylase production and microbial growth by SmF was investigated in the novel rotating drum bioreactor that has micro air diffuser. Ceramic micro air diffuser was used for minimization of mass transfer limitations by increasing oxygen transfer efficiency in addition to the conventional RDB design. *Bacillus amyloliquefaciens* NRRL B-645 was used as α -amylase producer. In rotating drum bioreactor studies, optimum conditions (15 g/l starch, 2,5 g/l peptone, 1 g/l yeast extract, 1 g/l $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 1 g/l KH_2PO_4 and 0,1 g/l CaCl_2) that determined from earlier erlenmayer flasks was used. Dissolved oxygen, pH, temperature, oxygen and carbon dioxide at gas outlet, starch concentration, growth and total weight of bacteria was followed during fermentation. Dinitrosalicylic acid method [3] was used for determination of α -amylase activity. The highest enzyme activity (24,84 U/ml) was measured for the incubation time (14 h) in the conditions that are rotation speed (18 rpm), aeration rate (1 lpm) and baffle size (4 cm).

Keywords— Rotating drum bioreactor, Ceramic micro diffuser, α -Amylase, Submerged fermentation.

I. INTRODUCTION

Enzyme production has grown rapidly and is a vital sector. According to Grand View Research report, the global industrial enzyme market was \$8.18 billion in 2015 and it is forecasted that the market will reach \$17.50 billion by 2024 [1]. Amylases are one of the most important industrial enzymes and their annual production volume is 25-30% of the total manufacturing of enzyme production [2]. Alpha-amylases catalyze the hydrolysis of the 1,4- α -linkage between adjacent glucose units in the amylose chain of starch.

Submerged fermentation (SmF) has important advantages and it has commonly been preferred thanks to greater control of process parameters that has great significance about yield such as pH, dissolved oxygen and temperature and easier sterilization. Despite of its high cost, approximately 90% of fermentation products has been produced by SmF.

Rotating drum bioreactor (RDB) is an important microbial production system in terms of having less severe shear stress and researchers have explored applications of RDB in a plant cell culture, solid substrate fermentation, bioleaching and bioremediation. Although conventional RDB is an important microbial production system in terms of preventing heat accumulation [3,4] and having less severe shear stress on microorganisms [5], it is not completely adequate in terms of heat and mass transfer due to the absence of an effective air diffuser and free water. Therefore, biomass or enzyme production yield decreases in larger-scale RDB due to high levels in temperature and concentration gradient [6]. In addition to, on account of liquid-gas mass transfer, a drum reactor should be operated in lower working volumes ($\leq 50\%$) to keep a thinner film to provide the effective gas-liquid contact [7].

Studies have shown that the size of the air bubbles is effective on the cells and air bubbles in large diameters are damaged by the shear stress of the cell, on the other hand the bubbles in micron size cause less damage to the cell [8, 9, 10]. Michaels et al. (1996) have shown that the clustering and dispersion problems of bubbles can be minimized by microbubbles supplied to the system at low rotational speeds [11]. Nehring et al. (2004) compared a ceramic micro air diffuser producing bubbles with a diameter of 100-500 μm and a stainless steel air diffuser producing bubbles with a diameter of 800-3000 μm in a cell culture bioreactor [12]. Ceramic micro air diffuser has proven to 3 times more high oxygen transfer. Czermark et al. (2005) compared ceramic, stainless steel and silicone air diffusers in another study of cell culture and reported that the ceramic micro-air diffuser has a distinct advantage over other air diffusers in terms of oxygen transfer, ease of design and operating parameters at large scales [13].

Problems of RDB are mainly the lack of free water and the efficiency of mixing, especially for large scale production. For minimization of the problems in RDB,

ceramic micro air diffuser with proven effectiveness [12, 13, 14] can be used in addition to the conventional RDB design in liquid phase.

In the present study, α -amylase production and microbial growth by SmF was investigated in the novel rotating drum bioreactor that has micro air diffuser.

II. MATERIALS AND METHODS

A. Microorganism and Inoculation

For α -amylase production, *Bacillus amyloliquefaciens* NRRL B-645 (kindly provided by ARS Culture Collection) that is a commercial strain was preferred. The strain was maintained on an agar slant at 4°C. Inoculum culture was produced by using medium that contains (g/l) glucose 10, CaCl₂ 0.1, MgSO₄ 0.5, KH₂PO₄ 0.5, NaCl 1.5, yeast extract 2.0 and peptone 2.5. Inoculum was cultivated in 50 ml liquid medium at 150 rpm and 37°C for 18. All enzyme production studies were done with the production medium that was determined as optimum conditions in earlier studies [15].

B. Rotating drum bioreactor and fermentation

The enzyme production experiments were conducted in a RDB, which is a stainless steel tank of 5 mm thickness, 205 mm diameter, and 225 mm length. The technical drawing of the designed RDB is given in Fig. 1.

Figure 1. The technical drawing of the designed DTB. A gas outlet; B condenser; C Buffer; D dissolved oxygen probe; E pH probe; F heat exchanger; G thermocouple; H ceramic micro air diffuser; K stationary shaft.

The total volume of the bioreactor is 7 L. The bioreactor and its condenser, which is designed to prevent water losses, are shown in Fig. 2. The bioreactor is equipped with a 0.5 hp motor and inverter with adjustable rotation rate of 3-18 rpm. The bioreactor top cap can be demountable for loading substrate and installation of equipments. A micro air diffuser, a heat exchanger tube, a thermocouple, a DO probe (Hamilton, Visiform Arc 120) and a pH probe (Hamilton, Easyform Plus Arc 120) were attached to the stationary surface on the cap. The static top cap was mounted with autoclavable sealed bearings while the drum rotates around its axis.

Four straight baffles were placed to the bioreactor's inner surface for increasing mixing efficiency. For improving the

gas-liquid mass transfer efficiency of the RDB, a 200-mm ceramic micro air diffuser (Refractron, USA) with a pore size about 6-25 μ m was used as a sparger. An air compressor equipped with a rotameter was used to adjust the inlet air velocity and a water bath with external circulation was used to control the reactor temperature with heat exchange tube. After substrate loading and equipped with ceramic micro air diffuser, DO and pH probes and gas inlet and outlet line, the RDB was sterilized in an autoclave (Lab Companion, ST-65G) at 121°C for 30 min. Gas analyzer (Quantek, Model 902P) was used to determine concentration of O₂ and CO₂ at gas outlet. When the foaming in fermentation is observed, a simethicone based antifoam was added. Enzyme production system is shown in Fig. 2.

Figure 2. Enzyme production system.

C. α -Amylase Assay

Sampling was conducted at regular intervals and supernatant was obtained by centrifuge at 4100 rpm for 10 min. The supernatant was used as crude enzyme extract for activity assay. 0.5 ml enzyme was added to 1 ml soluble starch (1% (w/v)) in phosphate buffer (0.02 M, pH=6.9) and incubation was carried out at 37°C for 3 min. The reaction was stopped by using 3,5-dinitrosalicylic acid and reducing sugar was determined by Bernfeld method [16].

D. Bacterial Growth and Starch Analysis

Bacterial growth during fermentation was measured by turbidity meter followed by measurement of absorbance at 600 nm wavelength. For starch analysis, 0.1 ml of cell-free fermentation medium, was added to the tube containing 1 ml of KI-I₂-HCl solution and 10 ml of distilled water were added. This solution is read at 600 nm wavelength against the blind sample which does not contain the fermentation medium. The starch concentration is determined in g/l by calibration graph.

III. RESULTS AND DISCUSSION

The highest enzyme activity (24,84 U/ml) was measured for the incubation time (14 h) in the conditions that are rotation speed (18 rpm), aeration rate (1 lpm) and baffle size (4 cm). The change of investigated physical parameters with time in the validation experiment is shown in Figure 3 and 4. The maximum enzyme activity (24.84 U / mL) were reached in 14 h. The maximum activity was reached in the end of the logarithmic phase can be interpreted according to analysis of DO and CO₂ value at gas outlet.

Figure 3. The change of α -amylase activity, DO and pH with time.

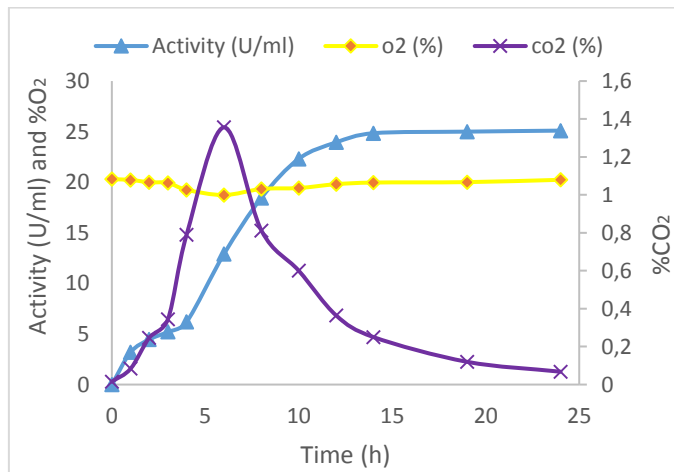

Figure 4. The change of α -amylase activity, O₂% and CO₂% with time.

The change of bacterial growth, amylase production and starch concentration with time is shown in Fig 5. The enzyme production started from mid-log phase and continued in the stationary phase. After starch is completely consumed, there is a noticeable increase in enzyme production. This increase can be explained by the induction of enzyme production by hydrolysis products formed by the catalysis of starch by the enzyme. It is seen that the enzyme production reaching

maximum in the stationary phase has remained constant after this period.

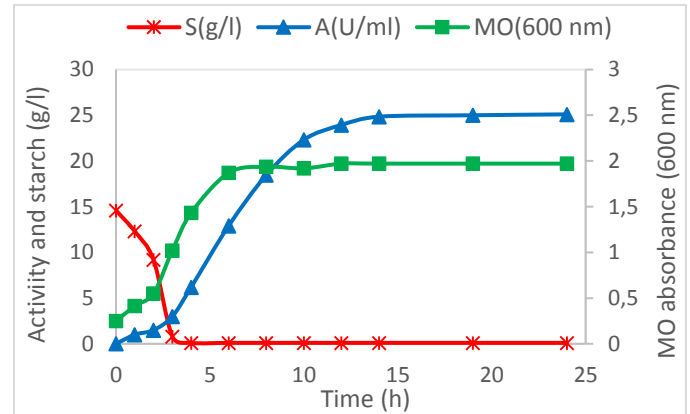

Figure 5. The change of starch and mo absorbance with time.

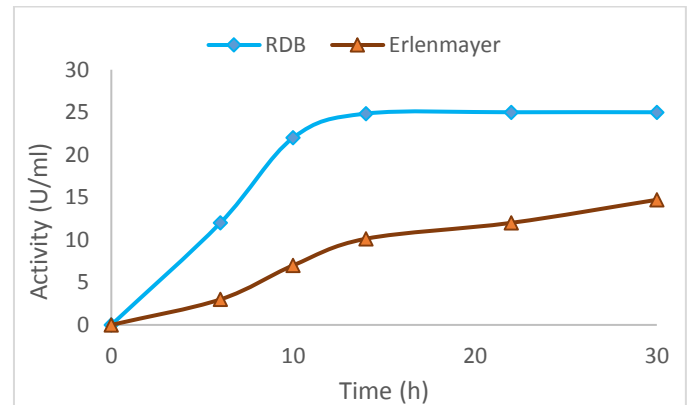

Figure 6. The change of enzyme production in RDB and erlenmeyer with time.

When results compared, enzyme production in RDB (24,84) was performed with approximately 2-fold higher enzyme activity than erlenmeyer scale study (14,72 U/ml) in shorter time as shown in Fig. 6.

As a result, enzyme production by SmF was successfully applied to novel RDB that can be operated at higher working volumes and an alternative bioprocess has been created to produce enzyme efficiently without dissolved oxygen limitation thanks to ceramic micro diffuser.

Rozelin AYDIN
Bioengineering Department,
Adana Science and Technology University,
Adana, Turkey

Abstract— Caves are formed by rocks such as gypsum, granite, quartzite, and talus but most commonly by calcareous rocks such as limestone and defined as a type of natural, rocky cavity under the ground that receives little to no light and also accessible to humans. Especially deep of the caves are usually considered to be extremely nutrient poor environments because of the absence of photosynthetic activity due to the lack of sunlight; nevertheless the cave environment presents variety of other potential energy sources for microbial growth. Firmicutes, Actinobacteria and α - β - and γ - Proteobacteria stated as three dominant phyla that can be found in such environments.[1] Furthermore, recent studies suggest bacteria may also have a role in cave formations such as carbonate precipitation in speleothem formations or moonmilk depositions. [2,3] In addition to that, the number of cave studies increase rapidly due to its potential to host microorganisms that can secrete secondary metabolites that may be of value to humans eg. enzyme, antibiotic and biofuel production. [4]

In this study bacterial load of a Cave located in Mersin was investigated by using culture dependent and culture independent methods. Samples were taken by sterile swaps and submersed in distilled and stored in +4°C degrees until culturing. For culturing the water that samples were submersed in was diluted 103 fold before plating. First, the bacteria were cultured on R2A media which is widely used for cave microbiology research and distinct looking colonies were picked from the petri dishes and isolated. After isolation, 16S rRNA PCR analysis was performed and PCR products were sent to a company for identification. As a result of this study, the bacterial load of the related cave is unveiled. The further results will be discussed in the oral presentation.

Abstract—Crystal structure of myofibril resembles a graphene like structure, which looks interesting, moreover it can be useful in myofibril modeling.

Solid state physics deals with the electrical behavior of the solids. The conductive properties depend on the properties of electron and on the arrangement of the atoms [1]. It is well known that crystals are built with a periodic array of single atom or groups of atoms. An ideal crystal can be defined as the infinite repetition of the identical groups of atoms called a lattice. Lattice, atomic planes and atomic directions determine not only the mechanical properties of crystals, such as ductility and strength but also its electrical properties [2].

The micrograph of a cross section of the myofibril, can be found in any undergraduate level physiology book, is given in figure 1. Hexagonal arrangements of the thick and thin filament can be seen in a myofibril, in which six thin filaments surround each thick filament whereas three thick filaments surround each thin filament [3]. Flexibility of the myofibril can be related to the graphene like structure of it, moreover the nearest neighbors of the crystal structure determine the mechanical properties, thus the flexibility of the myofibril can be written as a function of the lattice space.

In such crystal structures packing efficiency is also important parameter, which characterizes the structure. It is well known that hexagonal close-packed structure has the highest packing fraction (0.74). In nature, it is impossible to find a structure –regular or not- with a packing fraction higher than 0.74.

Most of the solids can be found in crystal form and the property of it is known in detail. This knowledge can be used to understand myofibril structure better and may connect two unrelated disciplines: solid state physics and biology.

Keywords— crystal structure; hexagonal lattice; myofibril

Abstract—Nanotechnology is effective in almost every area of concern to human and animal health. Nanomedicines against various pathogens in veterinary medicine could be developed. Antimicrobials are being placed into polymer-coated crystalline nanoparticles, cholesterol-conjugated amphiphilic peptide self-assembled particles, homogenized particulate suspensions, liposomes, composite hydrogel/glass particles, poly lactic-co-glycolic acid, cationic and pDNA coated gold nanoparticles. Liposome-based therapeutics have been accepted by the FDA for fungal infections, for instance, liposomal amphotericin B. Probiotics, prebiotics and immunomodulators can be used as growing promoter in animals. Recently, natural products which have antibacterial effects are preferred. Because, the use of antibiotics as growing promoter in animals brings out problems associated with microbial resistance and antibiotic residue. These nanostructures have indicated perfect results, particularly in life-threatening. In recent years for this aim, the alternative solution including natural antibacteria as propolis. It was reported that propolis has an efficacy against the inhibitory effects of free radicals and as an antibacterial (Hasan et al., 2014; Kothai and Jayanthi, 2014; Schmidt et al., 2014). Barud et al. (2013) determined that the ethanol extract of propolis is 70% effective at inhibiting the growth of microorganisms.

Epecially, natural nano antimicrobials such as nanopropolis are useful to veterinary medicine in terms of health, performance, and reliable food production. Propolis does not have a good solubility in water. Nanopropolis expected to supply a better antibacterial activity compared to propolis. Nanopropolis would raise the ability to dissolve a substance achieving better solubility compared to propolis. Nanopropolis can more easily enter through the outer membrane of bacteria in order that the active antibacterial compounds can harm bacterial cell walls. (Hasan et al., 2014). Also, the antimicrobial activity of nanopropolis was determined to be more effective against gram-positive bacteria than yeast. It is assumed that the causes for being more effective in antibacterial activity from antifungal activity of nanopropolis can be due to the characteristic of cell walls, differences present in membranes of bacteria and yeast, the antibacterial activity, and the thickness of the peptidoglycan layer (Afrouzan et al., 2012). As a result, nanomedicines against various pathogens in veterinary medicine could be developed. Especially, natural nano antimicrobials such as nanopropolis are useful to veterinary medicine in terms of health, performance, and reliable food production. But, there is a need to increase research because of the paucity of research currently being done on this topic.

Abstract— 6-Phosphogluconate dehydrogenase (6PGD; E.C.1.1.1.44) is an enzyme in the pentose phosphate pathway. It is a well-known oxidative carboxylase that catalyses conversion of 6-phosphogluconate into ribulose 5-phosphate [1]. It was reported that suppression of 6PGD decreased lipogenesis and RNA biosynthesis and increased reactive oxygen levels in cancer cells, lessening cell proliferation and tumour growth implying that 6PGD could be an anticancer target [2]. The aim of this study was to investigate whether biologically active organic indole derivatives alters the enzymatic activity 6PGD of rat erythrocytes in vitro. In order to do that, the 3,3'-bisindole derivatives 1 and 2 were synthesized, the enzyme was purified from rat blood and its activity was spectrophotometrically measured. The studies of the effect of these compounds on the activity of rat 6PGD revealed that while the 3,3'-bisindole derivatives 1 inhibited the activity with an IC₅₀ of 115.8 μ M, the activity was increased in the presence of 3,3'-bisindole derivative 2. To understand the mechanism of inhibition/activation, in silico docking experiments were performed.

Keywords— erythrocyte, docking, indole.

Abstract— Glucose 6-phosphate dehydrogenase (G6PD, E.C. 1.1.1.49) is one of the key enzymes that involves in the catalysis of a rate-limiting reaction in the pentose phosphate pathway (PPP), providing reducing power to all cells in the form of NADPH and ribose 5 phosphate [1,2]. Recently, the corresponding enzyme, G6PD, has been revealed to be involved in apoptosis, and the efficacy to anti-cancer therapy, making it as a important target in cancer treatment as one of the final products of the PPP, ribose-5-phosphate, is necessary for nucleic acid synthesis and tumour progression[3]. In this study we reported the synthesis of some biologically active indomethacin derivatives and studied their effects on the activity of corresponding enzyme obtained from rat erythrocytes. Among ten heterocyclic compound we found that the inhibition was most potent in the presence of 5 and 6 with an IC₅₀ of 3.85 μ M and 3.39 μ M respectively while compound 2 and 10 did not alter the activity. In silico docking studies of 5 and 6 were also carried out to understand binding mechanism in detail.

Abstract— The pentose phosphate pathway (PPP) is an anabolic pathway that utilizes glucose to generate molecular building blocks of nucleic acids and reducing equivalents in the form of NADPH through 6-phosphogluconolactone dehydrogenase (6PGD). Recently, it was reported that 6PGD is implicated in cancer disease which makes designing 6PGD inhibitors in cancer treatment a necessity [1- 3]. Herein we reported the synthesis of 3,3'-bisindole derivatives and studied their effects on the corresponding enzyme. The studies demonstrated that o bisindole derivative 1 inhibited the activity of 6PGD with an IC50 of 115.8 μ M, while the activity was increased in the presence of 2. In silico docking studies were also performed to clarify the mechanism of inhibition/activation.

Keywords—component; Glucose-6-phosphate dehydrogenase (G6PD) indole, indole derivatives, in silico docking

Abstract—*Thermophilic bacteria are well known to be of great importance, since they are the source of industrially used enzymes. Therefore a novel amylolytic enzyme producing thermophilic bacterial strain FMB2 from the Sorgun hot spring water in Yozgat, Turkey, was isolated in the present study. Phylogenetic analysis based on the partial 16S rRNA gene, biochemical and physiological tests revealed that the strain FMB1 belongs to the genus Bacillus licheniformis. Optimal growth was obtained at pH 9.0–10.0 and 55-60 °C. The optimum pH and temperature for the enzyme activity were determined. Out of six variables in the α -amylase production medium, pH and temperature were screened and optimized through response surface methodology (RSM) for higher α -amylase production. These methods have proven suitable to optimize α -amylase production by a thermophilic Bacillus licheniformis.*

Keywords—*component; Bacillus licheniformis, α -amylase, optimization, response surface methodology*

Abstract— Glucose-6-phosphate Dehydrogenase (G6PD) is the rate-limiting enzyme of the pentose phosphate pathway. It catalyses the irreversible conversion of glucose 6-phosphate to 6-phosphoglucono- δ -lactone in the presence of NADP⁺ [1]. 6-phosphogluconolacton Dehydrogenase (6PGD) is the third enzyme in the pentose phosphate pathway. It is a well-known oxidative carboxylase that catalyses conversion of 6-phosphogluconate into ribulose 5-phosphate. In the absence of these enzymes the erythrocyte is susceptible to oxidative damage. G6PD is associated with some human diseases including cancer, metabolic disorders and cardiovascular diseases. It was also reported that suppression of 6PGD decreased lipogenesis and RNA biosynthesis and increased reactive oxygen levels in cancer cells, lessening cell proliferation and tumour growth suggesting that 6PGD could be an anticancer target. Therefore one aim of the work described in this paper is to investigate the effect of some biologically active indole derivatives on the activity of corresponding enzymes. The studies revealed that while the bisindole derivatives 1, 2 and 3 inhibited the activity of G6PD with an IC₅₀ of 138 μ M, 231 μ M and 304 μ M respectively, the studies of rat erythrocyte 6PGD indicated that the activity was increased in the presence of 1 and 2 and was inhibited in the presence of 3. Molecular docking studies were also carried out to understand the mechanism of inhibition/activation.

Keywords— carboxylase, heterocyclic, inhibition.

Abstract— Glucose-6-phosphate dehydrogenase (G6PD) is an enzyme participates in the pentose phosphate pathway, a metabolic pathway that supplies reducing energy to cells (such as erythrocytes). G6PD reduces NADP⁺ to NADPH while oxidizing glucose-6-phosphate [1]. In last decade, the role of G6PD in apoptosis and the efficacy to anti-cancer therapy has been reported which makes it a promising target for cancer treatment. The aim of the work described in this study was to synthesise potent inhibitors of G6PD and investigate their effects on the enzyme along with in silico molecular docking studies. Among two derivatives tested we found that the compounds 1 and 2 inhibited the activity with an IC₅₀ of 3.39 and 3.89 μ M respectively. In silico docking studies of 1 and 2 were also carried out to understand binding mechanism in detail.

Keywords—component; Glucose-6-phosphate dehydro-genase (G6PD) indole, indole derivatives, in silico docking

Abstract—Glucose-6-phosphate dehydrogenase (G6PD) and 6-phosphogluconate dehydrogenase (6PGD) are the two important enzymes of the pentose phosphate pathway which provides reducing power to the cell. G6PD, the rate-limiting enzyme of the pentose phosphate pathway, catalyzes the irreversible conversion of glucose 6-phosphate to 6-phosphoglucono- δ -lactone in the presence of NADP [1]. 6PGD is the third enzyme in the pentose phosphate pathway. G6PD is associated with some human diseases including cancer [2]. It was also reported that suppression of 6PGD decreased lipogenesis and RNA biosynthesis and increased reactive oxygen levels in cancer cells, lessening cell proliferation and tumor growth suggesting that 6PGD could be an anticancer target. In this study, G6PD and 6PGD were purified with 2'5' ADP-sepharose 4B affinity chromatography in single step. Following purification, we investigated the in vitro effects furosemide, cefazolin, gentamicin and cefuroxime on the activity of rat erythrocyte G6PD and 6PGD. It was determined that gentamicin and furosemide inhibited 6PGD with an IC₅₀ of 13.86 mM and 0.775 mM respectively while cefuroxime and cefazolin increased the activity of the enzyme. On the other hand, gentamicin and furosemide inhibited the activity of the G6PD with an IC₅₀ of 1.75 mM, 0.526 mM respectively whereas cefuroxime and cefazolin increased the activity of the enzyme.

Keywords— G6PD, 6PGD, Antibiotics, Inhibitors, Activators, Rat Erythrocyte

Does Hypovolemia Effect Contraction Kinetics?

Nilüfer AKGÜN

Selçuk University Faculty of Medicine Department of
Biophysics
Konya, Turkey

Abstract— An inadequate volume condition that develops with any loss of volume in the body is called hypovolemia. This loss of volume is wrong to evaluate as a blood loss only. Hypovolemia can be caused by blood loss due to external and internal blood vessels in the body, extracellular fluid loss, vomiting and dehydration. Hypovolaemia is a serious problem with electrolyte impairments due to both direct effects of loss of fluid and loss of dense electrolyte. Hypovolemic disorders occur when these reduced circulating fluid volume. Even though at hypovolemia is reduced the volume of extracellular fluid, actually plasma sodium concentration is reduced. This study aims to reveal the effects of hypovolemia on the cardiac contraction with computer simulation of a rabbit ventricular cardiomyocyte. As a result of maximum reduction was seen in contraction kinetics (CT50) period with 8.3%.

The disturbance of water-electrolyte balance may cause hypovolemia, is the most common fluid disorder, especially seen in postoperative and elderly patients in which the findings are all related to the reduction of tissue perfusion [1]. In such cases, restoration of the water-electrolyte balance is vitally important [2,3]. Since sodium ions have an important role in the water balance of the extracellular fluid, regulation must be done via sodium-rich fluids [4]. The amount and the rate of fluid administration are adjusted according to the clinical response of the patient in the treatment of hypovolemia [5].

Simulation programs are an extremely powerful aid in the solution of the biological problems that's why they are widely used. Indeed, following the construction of the simulation of the biological system it is so easy to produce data that has been similar to biological systems. It also removes the experiments that have been used by the animals. Indeed the cost of the experiments decreased dramatically when we use the simulations. Besides their advantages due to the nature of the calculation mistakes the results of the simulation should be double checked. [6]. For the production of the data we used the modified version of the non-commercial software program of Lab Heart 5.3. The contraction parameters were analyzed by the home made excel program. The physiological parameters were established by the ionic concentrations of mM: extracellular; Na:142, K:4 intracellular; Na:10, K:120. For the simulations of the hypovolumetric situation Na:110 mM were used and comparison to physiological case was done.

There is a connection between action potential and muscle contraction, which known as excitation contraction coupling. This study aims to investigate the effects of hypovolemia on the rabbit ventricular cardiomyocyte contractions. It is well known that heart works as a pump, which sends deoxygenated blood to the lung and oxygenated blood to the body, thus the troubles in the contraction of it is a key parameter in several pathophysiology. It was shown that hypovolemia (110 mM) results in a 12.66% decrease in the maximum contraction value. Furthermore both the contraction and the relaxation kinetic values of contraction were also affected. To reveal the effects of it on the kinetics 50% of the contraction time, 50% and 90% of the relaxation time are measured and a reduction of 8.3%, 3.2% and 0.3% is observed respectively, maximum reduction was seen in CT50 period with 8.3%. Our simulation results show that the modifications observed in excitation-contraction coupling are serious effects on hypovolemic conditions.

Keywords— Contraction kinetics; excitation-contraction coupling; hypovolaemia; water-electrolyte balance

The Role of Alkali Metals on Nerve Action Potential

Murat AYAZ

Selcuk University, Medical Faculty,
Departments of Biophysics Selcuklu,
Konya 42130 Turkey
ayaz72@yahoo.com

Abstract— Sodium and potassium are the major ions of the extracellular matrix, moreover they have key role in nerve excitability. It is found that changes in the extracellular ion concentration (Na^+ and K^+) affect not only axonal action potential parameters but also conductance of the ion channels.

Since 1700s scientists have been trying to understand the electricity in living organisms. As far as we know today, similar to electrical wire information is delivered through the body in the form of electricity. Living organism produce electrical energy from the ion concentration gradient across the membrane, and the measured current is the flow of the ions, both inside and outside of the excitable cell and controlled by the ion channels in the membrane, thus transmission is tightly dependent on the ionic concentrations. Unlike pH or temperature there is not a tight control mechanism for the extracellular sodium and potassium concentration, thus, dysnatremia and dyskalemia are frequently seen in the clinic especially in hospitalized, postoperative and elderly patients [1].

Sodium ions abundant in the blood and extracellular fluid, and it have a key role in osmotic pressure regulation and excitation of the nerve and muscle cells. Sodium is obtained through nutrients and excreted via sweat and urine. If the intake and excretion are not in balance dysnatremia occurs. Potassium is the major ion of the intracellular matrix. Like sodium intake is done by nutrients, excretion is seen through the digestive tract and in sweat, urine; moreover imbalance causes dyskalemia. It is vital to keep extracellular potassium concentration in a tight range otherwise it may have serious consequences such as abnormal heart rhythm or cardiac arrest. Ionic changes in the plasma level can be seen, but if the change is dramatic and persistent it may have many effects on the body, for instance, it may affect prognosis and even the survival rates of the patients with cancer, brain trauma and in many pathophysiology [2,3]. Macroscopic effects of the ionic changes, are well known, however the research on the molecular level is still missing.

In a microscopic point of view, the change in the ionic content affects the conductivity of the extracellular and intracellular matrix, so the transmission is very much dependent on the ions around their membranes. In this research, the effect of change in extracellular ion concentration on the single nerve fiber action potential is studied by using action potential simulation. The experimental conditions are built to simulate hypo/hyperkalemic and hypo/hyponatremic conditions and, it is found that the sodium ion channel conductivity is much more susceptible to the changes in the extracellular ion concentrations. Due to the susceptibility of the sodium channel conductivity, hypo/hyperkalemic conditions are much more dangerous for patients at least for neuronal conduction.

Keywords—axonal action potential; ion channel; ion concentration; simulation.

A Biological Example of Avalanche Multiplication: Hodgkin Cycle

Murat AYAZ

Selcuk University, Medical Faculty, Departments of Biophysics

Abstract— Voltage gated Na⁺ channels, has a key role in the excitable cells, is one of the few examples of positive feedback mechanism, and opening of it exhibits an avalanche-like multiplication which can be used to understand nature and the kinetics of the voltage –gated sodium channels.

In a manner of excitation sodium is the most important ion, and it is abundant in the extracellular matrix. In comparison with the extracellular matrix, intracellular matrix is characterized with lower sodium concentration. Since sodium is roughly 15-fold larger than inside, with the opening of voltage gated sodium ions a large current is measured across the membrane, it is usually high enough to saturate the electronic equipment, so ion replacement is necessary [1].

The cell membrane is composed of lipids, proteins and carbon hydrates, which houses organelles. Lipid bilayer is a perfect insulator for the ions, thus ion movement is only observed through, protein component of the membrane, ion channels [2].

Modeling of the biological mechanism is used in educational purposes and helps us to reveal the unknown phenomena, to develop new therapeutic approaches.

Axonal membranes can be modeled as a p-n junction, in which the application of reverse or forward bias results in an electron flow from p to n or vice versa. In its resting state the extracellular matrix is p-doped (has an excessive positive charge) whereas the intracellular matrix is n-doped (has an excessive negative charge), and the lipid bilayer, the depletion region, is lack of free charges in the absence of an applied external electric field [3].

Voltage-gated Na⁺ channels, has a key role in the excitable cells, and is one of the few examples of positive feedback mechanism in living organisms. The opening of sodium channel triggers the rest, which is called as Hodgkin circle. The avalanche-like opening can be modeled with avalanche multiplication seen in p-n junctions. In the presence of a large electric field an electron entering from the p side may be accelerated high enough kinetic energy, and the interaction of with the lattice creates carrier multiplication. By using the probability of carrier to create carrier multiplication P, total multiplication can be calculated as follows. For n_{in} entering from the p side will create Pn_{in} electron hole pairs (secondary carriers) for each collision. Likewise the collision of secondary carriers will create P²n_{in} electron hole pairs and summation gives

$$\begin{aligned}n_{out} &= n_{in} (1 + P + P^2 + P^3 + \dots) \\n_{out}/n_{in} &= 1 + P + P^2 + P^3 + \dots \\M &= n_{out}/n_{in} = 1/(1-P).\end{aligned}$$

It should be noted that the ionization probability depends on the reverse bias. The empirical relation near breakdown voltage is given in the following formula

$$M = 1/(1 - V/V_{br})^n$$

where M is the carrier multiplication, V_{br} is the breakdown voltage, and n is the exponent varies from 3 to 6 which depends on the material [3].

Keywords— avalanche multiplication; p-n junction; voltage-gated sodium channel

Abstract—Nanotechnology has a significant potency to solve the problems in the animal health field, since likely applications of the technology to veterinary practices are almost mind-boggling. Lately, studies related to nanotechnology have been on the agenda. In particular, they have focused on drugs used in human health. To develop improvements in techniques of animal production, it is necessary to enforce this knowledge for animal health. Nanotechnology can solve lots of mysteries related to animal health, reproduction, production, good hygienic practices during rearing and maintaining of food animals. Nanotechnologies can be used for constitute nanostructures of food ingredients that can improve taste, texture and stiffness or provide the formation of emulsions. Also, nanotechnology has been utilized to improve finding of a range of chemical and microbial contaminants in feeds. Nanotechnology offers scientific advantage with its rapid and specific moves, besides high bioavailability, and biodegradability properties. All these advantages have significant effects on both fewer production and economic losses in livestock animals and more healthy food and feed production. The technology application is usable especially with livestock. But, much more research and company development are needed before this research can be used widely in veterinary medicine and the animal science field of nanotechnology.

Abstract—Liquid loss is not just water loss also electrolytes are lost. Depending on the severity of fluid loss hypovolemia creates different clinical signs. Cardiovascular manifestations involve reduction of central venous pressure and it varies from resting tachycardia to hypotension. The aim of this study is to reveal the effects of extracellular sodium concentration on the duration of action potential with computer simulation of a rabbit ventricular cardiomyocyte. As it is expected, sodium concentration is effective on these measured currents. As a result, it shows that the potassium ion channels which are the major responsible for APD 90 is also associated with the concentration of extracellular sodium.

Hypovolemia is a serious problem with electrolyte impairments due to the direct effects of fluid and dense electrolyte loss [1,2,3]. Since sodium is the major extracellular cation, when the volume of extracellular fluid is reduced, the plasma sodium concentration is reduced as well. Depending on the severity of fluid loss, hypovolemia shows different clinical symptoms [4,5]. Cardiovascular manifestations involve reduction of central venous pressure and it varies from resting tachycardia to hypotension [6].

Simulation is the process of creating a model that represents a real system. Simulation studies are extremely effective in problem solving issue [7].

For the production of the data we used the modified version of the non-commercial software program of Lab Heart 5.3. The contraction parameters were analyzed by the home made excel program. The physiological parameters were established by the ionic concentrations of mM: extracellular; Na:142, K:4 intracellular; Na:10, K:120. For the simulations of the hypovolumetric situation Na:110 mM were used and comparison to physiological case was done.

The aim of this study is to reveal the effects of hypovolemia on the duration of action potential and ionic currents with a simulation program of a rabbit ventricular cardiomyocyte. In its physiological range, plasma sodium concentration varies between 138-145 mM. When this value is lowered to 110 mM, the action potential duration at 25%, 50%, 75% and 90% repolarization is decreased 18.5%, 39.2%, 30.5% and 29.2% respectively; furthermore, the decrease is more significant APD 90 values. As a result, it shows that the potassium ion channels which are the major responsible for APD 90 is also associated with the concentration of extracellular sodium. Moreover the results of simulations are use to investigate the ionic mechanism underlying these changes in action potential. In comparison with the physiological value, the decrease of extracellular sodium concentration results in a 6.6% decrease in the peak value of the sodium current, thus decline in the external sodium ion concentration generates less current. As it is expected, sodium concentration is effective on these measured currents. Our simulation results show that hypovolemic conditions caused significant changes in the APD 90 of the simulated action potentials. In addition, the peak sodium current was found to be depressed.

As a result, treatment should be performed with liquids containing sodium, which are the most important elements of the extracellular fluid space. To have a successful outcome in cardiac arrest it is necessary to evaluate the causes of it such as hypovolemia, underestimation of may cause serious results such as death.

Keywords— action potential; hypovolemia; ionic currents; plasma sodium concentration; simulation

Abstract— *In cardiac tissue action potential not only initiates the contraction but also, with its presence along the contraction, it regulates contraction, thus it is more sophisticated than nerve action potential. This study aims to reveal the effects of potassium channel conductivity on the action potential and contraction parameters.*

Since Galvani and Volta, electricity in the living tissue is one of the hottest subjects of science; furthermore, generation, conduction and creation of it still have some blanks and many scientists tries to fill them. One fact we are sure of is that, living system generates electrical energy from the ion gradient present across the cell membrane, which can be visualized in excitable cells as action potential, membrane potential change that is the result of the flow of the ions through channels. The molecular mechanism of action potential must be studied in detail to cure any pathophysiology, which results in alterations in action potential parameters.

In comparison with the other excitable tissues cardiac action potential is more complex, and since in every cycle it pumps deoxygenated blood to the lung and oxygenated blood to the body alterations in cardiac action potential is vitally important. It is well known that in cardiac tissue action potential not only initiates the contraction but also, with its presence along the contraction, it regulates contraction [1].

Although there are a group of ion channels which all together make the pumping function more controllable, this work contains the effect of the conductivity changes of the I_{to} s, I_{to} f and IK_1 , which are the well marked ion channels in the literature [2,3]. As expected the conductivity changes affected the action potential parameters, but surprisingly degree of change in increase and in decrease are not same, somehow channels resembles a rectification-like behavior. Likewise, in contraction parameters a rectification-like behavior is observed too.

It has been shown that I_{to} , which is the responsible for the early repolarization, has two types in which the slow type is more dominant, whereas at the determination of the maximum depolarization of the action potential IK_1 is more prominent. Additionally, this channel has an important role in the regulation of intracellular free calcium concentration mechanism.

Abstract— HA demonstrates greater hydrophobic property, and possesses lower resorption rate than TCP. There have been advantageous in pairing HA with TCP, as some designed parameters such as degradability and surface characteristics of the engineered scaffold have been improved [1]. By using a simple chemical method, it is possible to synthesize such biphasic nanoceramics from natural marine shells [2,3]. Marine sourced hydroxyapatite (HA) is a natural ceramic and is used as the most preferred implant material in orthopedics and dentistry due to their chemical similarity to bone scaffold. A relatively new process known as “electrospinning” has received considerable attention in the production of porous scaffolds [4]. In the present study, biocomposites having different compositions were prepared from bioceramics and biocompatible, biodegradable polymers. Solution of Poly(lactic acid) (PLA), a Polyurethane (PU), HA with different concentrations were used for electrospinning technique to prepare nanofiber based biocomposite. Physical measurements such as viscosity, electrical conductivity and density were conducted to optimize the system. Structural analysis were performed with fourier transform infrared spectroscopy (FTIR) and the crystalline structure were analyzed with x-ray diffraction (XRD) measurements. Morphological properties of the formed nanotopographic fibrous mat were investigated in terms of fiber structure, size and diameter range. by scanning electron microscopy (SEM). Mechanical tests were carried out after production of nanobiocomposites.

Abstract—Pneumatic wearable walking support device (PWWS) is especially designed to increase performance in repetitive gaiters such as factory workers. The support of the device in the lower extremities was measured by evaluating myoelectric signals obtained from the EMG measurement on leg muscles during the gait cycle swing phase. Twelve male volunteers were measured three times from right side of the body on the treadmill, at the speed of 2.5 km/h for 2 minutes, without/with device, device-off and device-on. When the device was running – in device-on mode- , there was a decrease in Rectus Femoris (RF) muscle mean amplitude of 3 volunteers as a result of superficial EMG, an increase in mean amplitude in the remaining 9 volunteers, a decrease in 7 volunteers in the mean amplitude of Vastus lateralis (VL) muscle, and an increase in 5 volunteers. In 2 volunteers, the mean amplitudes of both muscles measured were reduced during instrument use (device-on mode). It was seen that the PWWS supported these two muscles, which play a key role in movement the thighs and legs, in the swing phase of the gait cycle during device-on mode. In conclusion, the performance can be maintained constantly by adjusting such as thigh-leg size, person weight, and thigh-leg thickness parameters or considering walking habits of the person in the design of such devices and providing the necessary ergonomics by using a flexible and light material in the structure of the device.

Keywords—Wearable walking helper; Pneumatic system; EMG measurement)

I. INTRODUCTION

Nowadays, auxiliary mechanisms are gaining importance due to the increase of the elderly population and the current working conditions. Especially, gait ability is the most necessary functional movement during life. For this reason, except for wheeled systems, systems which will make it easier to step are needed. Many researchers have invented and developed walker-type support system. In this study, A PWWS is specially designed to increase efficiency for the factory walkers during the swing phase of walking and measured the efficiency of PWWS on the subjects. The main aim of this study is to evaluate the myoelectric signals obtained by superficial EMG measurement during walking and to have knowledge about the support of PWWS to the lower extremity muscles, to create the groundwork for new studies to be done in this topic.

II. MATERIAL AND METHODS

A pneumatic cylinder and its valves were mounted on a post-op knee brace with aluminum bar. Then the device was fitted to the subjects. Three measurements from the volunteers were performed from VL and RF muscles in the right thigh region for 2 minutes on the treadmill. In all measurements, the walking speed was set at 2.5 km/h to provide pneumatic piston activation of the PWWS. The first measurement was performed without the PWWS, while the second measurement was performed with device attached, but pneumatic piston was inactive in device-off mode in order to observe the effect of the weight of the apparatus and the adjustment points of the volunteer. The third measurement was made while the device was active in device-on mode. Superficial EMG measurements were performed by a 4-channel Biopac MP36R instrument and the results obtained by comparing the mean amplitudes of the myoelectric signals produced by the muscles using the Biopac Student Lab 4.0 software were evaluated.

III. RESULTS AND DISCUSSION

The myoelectric signals of RF and VL muscles of the 3 volunteers resulted in a reduction in the mean amplitude of RF and an increase in mean amplitude of the remaining 9 volunteers. In the mean amplitude of VL, a decrease was seen in 7 volunteers and an increase was seen in 5 volunteers. During the use of the PWWS in 2 volunteers, the mean amplitudes measured in both muscles decreased together. The PWWS supports the RF in 4 volunteers and the VL in 5 volunteers in device-off mode. That means the average amplitudes of the muscles decreased in both muscles of these 4 volunteers. In device-on mode, RF muscle of 2 volunteers and VL muscle of 5 volunteers were supported by the PWWS. It was seen that there was no device support in the remaining measurements. The severity of PWWS is thought to result in different outcomes in different volunteers due to restricting hip-knee movements during the walking cycle. So, it is considered that the necessary ergonomics should be provided.

Abstract— Tissue engineering focuses on clinical applications in regenerative medicine. Tissue engineering scaffolds can be used as matrices for three dimensional (3D) cancer cell cultures to imitate the tumors and better understand tumor development and metastasis. The purpose of this study was to reveal the effects of Etoposide (chemotherapy drug) on the two dimensional (2D) and 3D culture models. In this study, PVA/Starch cryogel scaffolds were produced with different ratios (90:10;70:30;50:50) and prepared scaffolds were analysed by FTIR and SEM. Swelling ratio and degradation profile of the scaffolds were also determined. 3D culture was established by culturing Human U-87 MG glioma cancer cells within highly porous PVA/Starch cryogel scaffolds. MTT assay and SEM was used to investigate the biocompatibility of the scaffolds and cell morphology. To investigate the drug resistance, cytotoxic effects of Etoposide were compared in 2D and 3D cell culture models. Results show that, in addition to tissue engineering applications, scaffolds can be potentially used as 3D model systems to better simulate the in vivo tumor microenvironment.

Abstract—The World Health Organization (WHO) has indicated breast cancer as the second most lethal leading cause of cancer in women. In the advanced computerized era, computer aided diagnosis (CAD) systems framework are generally developed to detect and characterize the breast cancer in light of screening mammography test. Various techniques have been developed for mammogram screening examination to get high accuracy, robustness and exactness. The three class classification is still an open research area because the tumor can be benign, malignant or normal. In this paper, a novel scheme for three class classification study is presented. Mammogram patches are filtered by the Columnwise neighborhood operations filter (COLFILT). Discrete Wavelet Transform (DWT) is used to decompose the enhanced patches into sub-band images. Six rotation and scale invariant features are extracted by using the Dense Scale Invariant Feature Transform (DSIFT). In last step a features matrix is generated that is used as input to Multi Layer Perceptron (MLP). Image Retrieval in Medical Application (IRMA) database is used to test the proposed scheme. Simulation results have verified the importance of the proposed idea in comparison to the existing schemes in the literature

Keywords—Mammography, Detection, cancer, Multi-Layer Perceptron

I. INTRODUCTION

According to breast cancer care, United Kingdom (UK) facts and statistic for year 2015 shows that the breast cancer is the second most regular reason for death from disease in ladies in the UK. Consistently around 55,000 are analysed for the breast cancer in UK, which is like one individual in every 600 seconds interval. In UK one women out of eight in her life time have a chance to be diagnosed as a patient of breast cancer [1]. Breast cancer usually takes time to develop and symptoms are shown very late. As there is no effective way to cure later stage breast cancer, many lives can be saved if it can be detect at early stage. Therefore for the early detection of breast cancer it is recommended by America Cancer Society (ACS) that every women who have risk factor of breast cancer should take screening test once in a year [2].

In modern technological era, CAD system widely use mammogram screening method to classify the breast tumour. CAD system typically rely on machine learning classifier (MLC) to classify the tumour. It needs discriminant descriptive feature that can help MLC to classify the image into multiple classes. In past decade various schemes have been proposed for mammogram screen methods to get high characterization precision, robustness and efficiency. However it is still an open area of research.

Many researchers have studied mammogram images for two class classification and achieved significant results. Mazurowski et al. [3] proposed a template based a recognition algorithm for breast masses. Their data set is based on 1,852 Digital Database for Screening Mammography (DDSM) images and it achieved accuracy up to 83%. Lesniak et al. [4] compared the performance of Support vector machine (SVM) based classification with nearest neighbor algorithms. They have used a private data set of mammography patches containing 10,397 images. The accuracy of their model is up to 67%. Wei et al. [5] present relevance feedback learning method and performed classification using SVM radial kernel with a data set of 2,563 DDSM images. Tao et al. [16] has compared the performance of two classifier named curvature scale space, and local linear embedded matric using a database of 476 and 415, and the accuracy of the two classifiers are 75% and 80% respectively. Bovis & Sing [6] and in [9] Elter & Hasslmer performed classification using Artificial Neural Network (ANN) and Euclidean metric classifier respectively and achieved a performance over 85 %. All of the above mentioned researchers have used two class classification but two class classification is not enough to avoid unnecessary biopsy because the tumour can be either benign or malignant. Vani et al. [12] proposed Extreme Learning Machine (ELM) method to classify mammograms of the Mammographic Images Analysis Society (MIAS) [13] database. Performance results of the algorithm out performed other techniques with same database. Jasmine et al. [14] performed two class classification with his proposed method based on wavelet analysis using ANN. This experiment is performed using MIAS database of 322 images and has achieved accuracy up to 87%. In [15] Xu, et al. compared the performance of three NN and has suggested that improved performance through

Figure 1: Sample images of mammogram patches

From literature, it can be seen that significant results have been achieved for two-class classification. However, for three-class classification, either data set is small or it has not achieved very promising results. ANN have been widely used for the classification of biomedical images. ANN is capable of precision for classification particularly for biomedical problems [11]. Standard MLP use back propagation methods techniques, which train feed forward ANN. They are supervised networks so they also need training. In this work, a novel classification technique is proposed for large dataset of mammograms using feed forward MLP. At first, a two-class classification is carried out. The features regarding scale invariant and rotation are extracted by using DSIFT descriptor. Then same procedure is followed for the three-class classification study for the malignant, benign and normal. The patches of mammogram are filtered by the column wise filter. DWT is used to decompose the enhanced patches into four sub- band images. Six scale invariant and rotation features are extracted by using the DSIFT descriptor. In the end a features matrix is generated that process as input to MLP. Results have verified the importance of the proposed scheme in comparison to the existing schemes in the literature. A flow diagram of the proposed scheme is given in Figure 2. The rest of the paper is sorted out as follows: Section 2 explain the feature extraction and representation. Section 3 describes the MLP. Section 4 and 5 comprises the simulation / results and conclusion respectively.

IV. FEATURE EXTRACTION AND REPRESENTATION

Enhancement technique is used to enhance the possibly degraded contrast in some of mammogram images; therefore as pre-processing step we have applied a contrast enhancement technique i.e.

$$I \leftarrow \text{COLFILT} (E, 3) \quad (1)$$

Where column wise filter enhances the image E depending upon the global mean and global variance of the image [29].

A. Two - Dimensional Discrete Wavelet Transform

In the next step enhanced mammogram patch I is decomposed into four sub groups by utilizing DWT. It is the combination of digital filter banks and down-samplers. It consist of high-pass (h) and low-pass (l). The quantity of banks is set according to the desired resolution of the architect [27]. As the mammogram image is a 2D signal, separable wavelet functions are used to compute the DWT. The columns and rows of the image are independently process through the 1D WT to obtain the 2D-DWT. In frequency domain, the mammogram patch I is subdivided into four sub-band images at resolution 2^{j+1} . B^a is the approximation image. B^h , B^v and B^d are three detailed sub-band images in horizontal, vertical, and diagonal directions respectively at resolution 2^{j+1} .

As the result of wavelet decomposition the enhanced image I decomposed into four sub-band components like igh - High (HH), High - Low (HL), Low - High (LH) and Low - Low (LL), that correspond to sub images are B^a , B^d , B^v and B^h , respectively.

B. Dense Scale Invariant Feature Transform

Next, DSIFT descriptor is applied to all the sub-bands components. DSIFT used Difference-of-Gaussian (DOG) function to distinguish potential interest focuses points [25], which were invariant to orientation and scale.

$$D(x, y, \sigma) = (G(x, y, \alpha\sigma) - G(x, y, \sigma)) * I(x, y) \quad (2)$$

Where α a constant multiplier and variable scale is is Gaussian, which is represented by $G(x, y, \sigma)$ i.e.

$$G(x, y, \sigma) = \frac{1}{2\pi\sigma^2} e^{-\left(x^2+y^2/2\sigma^2\right)} \quad (3)$$

Figure 1: Block Diagram

$$D(x, y, \sigma) = G(x, y, \alpha\sigma) * I(x, y) - G(x, y, \sigma) * I(x, y) \quad (4)$$

$$= L(x, y, \alpha\sigma) - L(x, y, \sigma)$$

Where scale space of an image $L(x, y, \alpha\sigma)$ is the convolution of G with an input image $I(x, y)$. DOG was utilized here rather than gaussian to enhance the computation speed.

In keypoint localization stage, hessian matrix is utilized to compute key curvatures that eliminate the edges by rejecting the low contrast point [25]. Keypoint descriptors were found out by using a three dimensional histogram. Here the first two dimensions correspond to image spatial dimensions and the third dimension corresponds to the image gradient direction and it is computed centred at the keypoints.

The DSIFT descriptor is applied to all the sub-bands with step size 4 and radius size 5; while feature matrix having dimension (128 x 400) are extracted for all the sub bands.

From the columns of this matrix, six statistical features (kurtosis, mean, skewness, energy, maximum and standard deviation) are extracted for each sub-band. The resultant feature matrix is of the shape of (128 x 6), which is reshaped into a vector form of (1 x 768). Coefficient weights are apply to the sub band images according to the equation 5.

$$Feature\ vector = (3 * LL + 2 * LH + 2 * HL) \quad (5)$$

Equal zero padding is performed on start and end columns such that feature vector as (1 x 784). Enhancement and feature extraction steps are performed on all the data set so that we have a data matrix Y of the shape (2796 x 785), where 2796 are the sample images and 784 features of the each sample. Every sample has a last column label, which belongs to its receptive patch class

V. MULTI LAYER PERCEPTRON

In the last step, the features set Y is used as input to ANN. ANN are mostly used in classification due to significant success in nonlinear mapping among the input features and

desired output [26]. MLP is an ANN consist of an input layer, hidden layer and an output layer. The number of hidden layers depend upon the designer and application. Each node in MLP

performs two function. At first step, it computes the weighted sum of the input along with the bias.

$$s_j = \sum_{i=1}^n (W_{ij} X_i) - \theta_j, \quad j = a, a1, a2, \dots, z \quad (6)$$

Where X_i shows the i^{th} input, W_{ij} indicates the connection weight from input i to j^{th} hidden layer, θ_j is bias of j^{th} hidden layer and n is number of input neuron.

Activated function is used to generate the output of each neuron, i.e.

$$S_j = f(s_j) \quad (7)$$

$f(s_j) = \text{sigmoid}(s_j)$ and is defined as:

$$\text{sigmoid}(s_j) = \frac{1}{1 + \exp(-s_j)}, \quad j = a, a1, a2, \dots, z \quad (8)$$

The final output are defined as:

$$o_l = \sum_{j=1}^z (W_{jl} S_j) - \tilde{\theta}_l, \quad l = a, a1, a2, \dots, m \quad (9)$$

Where W_{jl} indicates the connection weight from j^{th} hidden layer to output l , $\tilde{\theta}_l$ is bias of l^{th} hidden layer and l is the output neuron. In output layer each neuron use activated function to generate the output, i.e.

Figure 3: Multi layer perceptron model

$$O_l = f(o_l) \quad (10)$$

Where $f(o_l) = \text{sigmoid}(o_l)$ and is defined as:

$$\text{sigmoid}(o_l) = \frac{1}{1 + \exp(-o_l)}, \quad l = a, a1, a2, \dots, n1$$

In this experiment, we use MLP to classify this data set into three classes. To train the MLP optimal values of weights and bias are required for desirable output. In our experiment, we have used MLP with 500 hidden units and one hidden layer. Figure 3 presents the basic concept of MLP.

VI. SIMULATION / RESULTS

A. Database

We have used IRMA dataset [28] for this study. Total 2796 patches of original mammogram images are used for this experiment. Selected IRMA patches consist of four different sources including 2,576 images from DDSM. 150 images from MIAS, Lawrence Livermore National Laboratory (LLNL) and Rheinisch-Westfälische Technische Hochschule (RWTH) contribute 1 and 69 images respectively. The selected images are further divided into two classes (normal and cancerous) and three Classes (malignant, benign and normal) as prescribed in IRMA dataset. The final size of mammogram images patches are 128 x 128.

Initially a two-class classification is done by using DSIFT, Local Configuration Pattern (LCP) and Histogram Oriented Gradient (HOG) methods. Figure 4 shows the result of two-class classification. It can be observed that in two-class classification HOG method performs better with accuracy rate 83.2 %. The other two schemes LCP and DSIFT have accuracy rates of 82.26% and 74.6% respectively. Then three-class classification is performed by using the same methods. In three-class classification with large dataset of mammogram images, results from all three state of the art techniques are not very promising so we proposed our scheme. We initially train our model with MLP and then used the output of MLP as input for the classifier. In this research, SVM with linear kernel is used for classification.

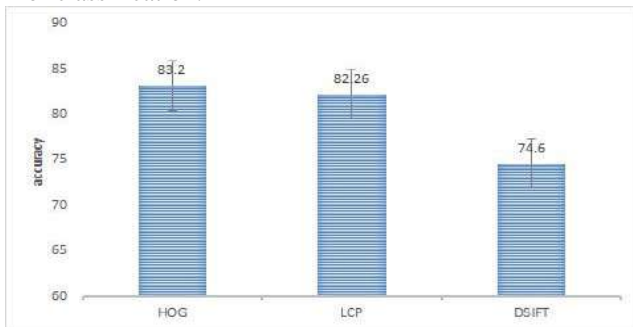

Figure 4: Two class classification accuracy rate for different methods

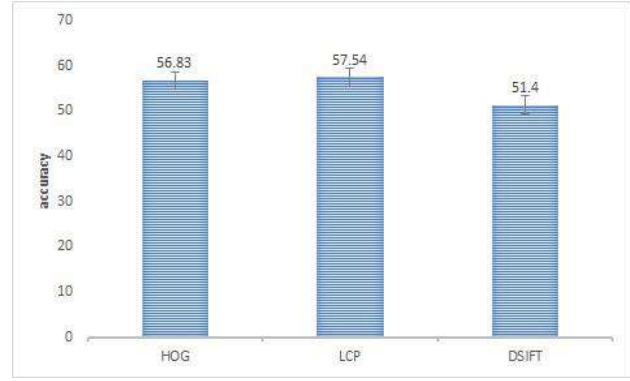

Figure 5: Three class classification accuracy rate for different methods

Figure 5 shows the result of three-class classification. Here LCP method performs better than the other two schemes but the results is not so promising, with the best result accuracy of 57.54%.

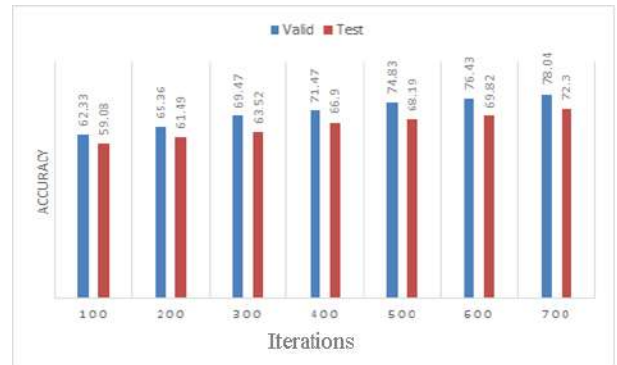

Figure 6: Accuracy rate of proposed method for test and validation data set

Figure 6 shows the results of proposed method. Note that the classification results for three-class category obtained by proposed scheme is more pleasing as compared to the existing schemes in Figure 5. Proposed method achieved the accuracy of 72.3% and 78.04% on test data set and validation dataset respectively.

VII. CONCLUSION

Novel mammograms classification method for breast cancer detection based on MLP is proposed. Result shows the significance of our proposed method for large amount of mammogram data as compared to other state of art techniques. In future, this method can be used with the combination of deep neural networks techniques for more accuracy.

ACKNOWLEDGMENT

Abstract— Segmentation of any region of interest in three-dimensional structural MR images is a difficult and laborious process. Manual segmentation of these regions is relative to user dependence and experience. Electronic brain atlases, which have been accepted by international standards and have proven to be reliable, are used in the literature to address these challenges. There are very few studies on how to use the brain atlas as a pipeline. In this study, a pipeline was developed to measure the volume of the brain limbic system using the atlas based segmentation technique. Calculated volumes were statistically compared between Alzheimer's and Normal images from the Open Access Series of Imaging Studies database. Statistical analysis revealed that the limbic system volume was significantly different between Alzheimer's Patient and Normal Control, and decreased in average. At the same time, the ratio of limbic system volume to total brain volume was discussed in terms of its effect on the analysis result. SPM8 and MRICro programs were used in the study.

Keywords— Brain Atlas, Alzheimer, MRI, Volume Measure

I. INTRODUCTION

The human brain is divided into three main parts: gray matter (GM), white matter (WM), cerebrospinal fluid (CSF). The GM forms the cortex layer that surrounds the outside of brain, and subcortical regions are also present in the brain's inner parts. The CSF is a fluid that protects the brain from impulses and the BM is a kind of communication cables that provide communication between GM and body functions. If any of the body functions have lost their function because of the brain, this is a problem caused by the degeneration of the relevant functional center on GM. This problem is caused by the occurrence of volumetric losses or textural defects [1].

Alzheimer's Disease (AD) is a neurodegenerative disease that usually starts with age and is not reversible. As the AD phases begin with mild forgetfulness, it makes it impossible for the person to do daily work. The degeneration that begin in the hippocampus and amygdala regions, which are memory centers in the brain, then spread to other regions, especially the limbic system. In addition to volumetric loss, the neurofibrillary tangles and senile plaques wrap around the brain structures on

a micro basis. The alteration of the amount of some proteins in CSF is another biomarker in AD [2]. Rapid and accurate segmentation of brain regions in AD and volume analysis are important in terms of diagnosis of the disease. If the volumes of biomarkers in AD are adequate and are followed up gradually over time in a strong population, the stages of newcomers can be statistically determined. The delaying medication needed to prolong the interval of the phase can be given in time. Volume studies done for this purpose are divided into manual and automatic methods. Manual methods are volume calculations by peripheral drawings of areas of interest by a specialist radiologist, neurologist or anatomist. This method can give relative results in terms of user dependency and inexperience. Auto-based methods are computer programs based on brain atlases [3]. In this study, a brain atlas based volume measurement pipeline of the limbic system, one of the basic lobes is initiated by AD, was developed and statistical analysis of volume differences between AD and Normal Control (NC) was performed.

II. ATLAS BASED VOLUME MEASUREMENT

Atlas based approach is the mapping of the MR image to the corresponding regions by overlapping a predefined template image. Brain labeling studies are based on very ancient histories. One of the first studies to be used today was made by German scientist Korbanian Broadmann in 1909. Korbanian Broadmann labeled the brains in 52 different regions and defined "Broadmann Fields", which are still used in his own name [4]. In 1988, scientists named Talairach and Tourneux identified the Anterior Commissure (AC) as $x, y, z = 0$ and designated the brain center. With reference to this point, the line leading to the front and the back of the brain is accepted as y -axis, the line leading to the ears is accepted as x -axis, and the line leading to the head and neck is accepted as the z -axis. These axes have made it practical to assign coordinates to the brain regions according to a reference system. Talairach did this work at the age of 60 a right-handed dominant French female cadaveric brain. The brain is parceled with images showing the sagittal, axial and coronal axes with high resolution [5]. Three dimensional stereotactic space was created from the parceled

regions and a brain mask database named "Volume Occupancy Talairach Labels" consisting of 148 regions was produced [6]. This study has been criticized because it does not represent the general population, mapping from a single individual. To overcome this shortcoming, the Montreal Neurological Institute (MNI) has continued to work for the general population, again referring to the axis of the Talairach. The template, which is formed by taking 305 healthy MR averages and developed by MNI, is often used in normalization processes because it is a representative image of all brains. The MNI and Talairach coordinate systems differ from the points they represent, even though the AC point is centralized. Therefore, a point in the Talairach coordinate system may not compatible with the same point in MNI. To avoid this incompatibility, MATLAB code scripts such as "mni2tal" and "tal2mni" are used [7]. Developed by Wake Forest University, the WFU Pick Atlas is a collection of different atlases and provides the masks of the respective regions in a practical way. The program maps the Talairach Deamon (TD) tags (TD Broadmnn areas, TD Lobes, TD Hemipheres, TD Labels, TD Type), Automated Anatomical Labeling (AAL), IBASPM116, IBASPM71 atlas. The mask of a selected region can be obtained as converted into MNI space. These generated masks can be easily used in MNI space-aligned structural MR images [8].

III. MATERIAL AND METHODS

The data used in the application consist of structural MR images labeled with the Clinical Dementia Rating (CDR) from the Open Access Series of Imaging Studies (OASIS) database. CDR is a psychological test used to measure the degree of illness in AD. CDR0: Normal CDR0.5: Mild Cognitive Impairment CDR1: mild stage, CDR2: modarete stage, CDR3: severe stage. Dementia and normal over 60 years of age were obtained from the database and only CDR labeled data were taken [11]. 99 AD and 97 NC MR images were taken in three dimensional .* nii format. 030 and 031 MR images were removed from the work because they failed in the MRIcro program. The imaging protocol of the structural MR images are 1.25 mm slice thickness, pixel resolution 1x1 mm without any gap between the cross sections, the imaging protocol of TR = 9.7 ms, TE = 4.0 ms, Flip angle = 10, TI = 20 ms, T1-weighted MP-RAGE (Magnetization-Prepared Rapid Gradient Echo) with a 256x256 matrix sized 1.5 T Siemens device. The demographic structure of the population set used is given in Table 1.

Table 1. Demographic features of the data used

	NC	AD
Mean Age	76.03	76.64
M/F	26/71	40/59
CDR	0	0.5(70)/1(27)/2(2)

From the database, raw MR images with image size of 256*256*160, voxel size of 1*1*1, prefixed with "OAS1_xxxx_MRy_mpr_ni_anon_sbj_111" were taken. Since the

limbic system is a part of GM, it must be segmented into MNI space by preserving the GM's volume from the raw MR images. For this, Voxel Based Morphometry toolbox (VBM8) (<http://www.neuro.uni-jena.de/Vbm/>) [9], working under Statistical Parametric Mapping (SPM8) [10] (<http://www.fil.ion.ucl.ac.uk/spm/>) library was used. VBM8 offers a practical application since it performs noise reduction, normalization and segmentation in one interface in one operation. The DARTEL method, which has proven to be better than many methods for registration, has been chosen [12]. In the study, modulated normalized GM used the "affine + nonlinear" option, which preserves the volume after normalization. Although the VBM8 normalizes to the MNI space, the coordinate shift originates because of the default Tissue Probability Map (TPM) in VBM8. This shift is corrected by performing "Coregister" operation on the TPM with the AC point (x,y,z)=0 so that the modulated GMs exactly register with the AC point (x,y,z)=0. There is no interpolation during this process, only the image is shifted axially. The limbic system mask created with Wfu Pick Atlas was produced in the MNI space, with AC points (x,y,z)=0. However, since the voxel size is incompatible with GM, the masks are resliced using the "coregister" operation and the "nearest neighbor" interpolation method. As a result of this process, the GM and the mask were placed on the same coordinate plane with the same voxel size. The volume calculator was implemented with the "get_totals.m" script developed by Ged Ridgway (http://www.cs.ucl.ac.uk/staff/g.ridgway/vbm/get_totals.m). This script offers practical use in the volume calculation of the GM images that have been specially Jacobian determinants and the masks overlapping under GM. The preprocessing and volume calculations performed in Figure 1 are shown on the patient flow diagram with OASIS 028. Significance of Limbic system volume difference between AD and NC was analyzed by using MATLAB statistical tool.

IV. EVALUATION

All images taken from the OASIS database were processed through the operations shown in Figure 1 one by one. The total brain volume was summing up by calculating the volumes of GM, BM, BOS images modulated by VBM8 library with "get_totals.m" script. Differences between the two groups were examined by t-test in MATLAB. The statistical results and some descriptive statistics obtained in Table 2 are given.

Table 2. Statistical results and some descriptive statistics

	AD		NC		Stats
	Mean	Std	Mean	Std	
Limbic Lobe(ml)	53.148	6.092	56.087	5.443	5E-04
Limbic Lobe/TIV	0.0391	0.003	0.0416	0.002	2E-11

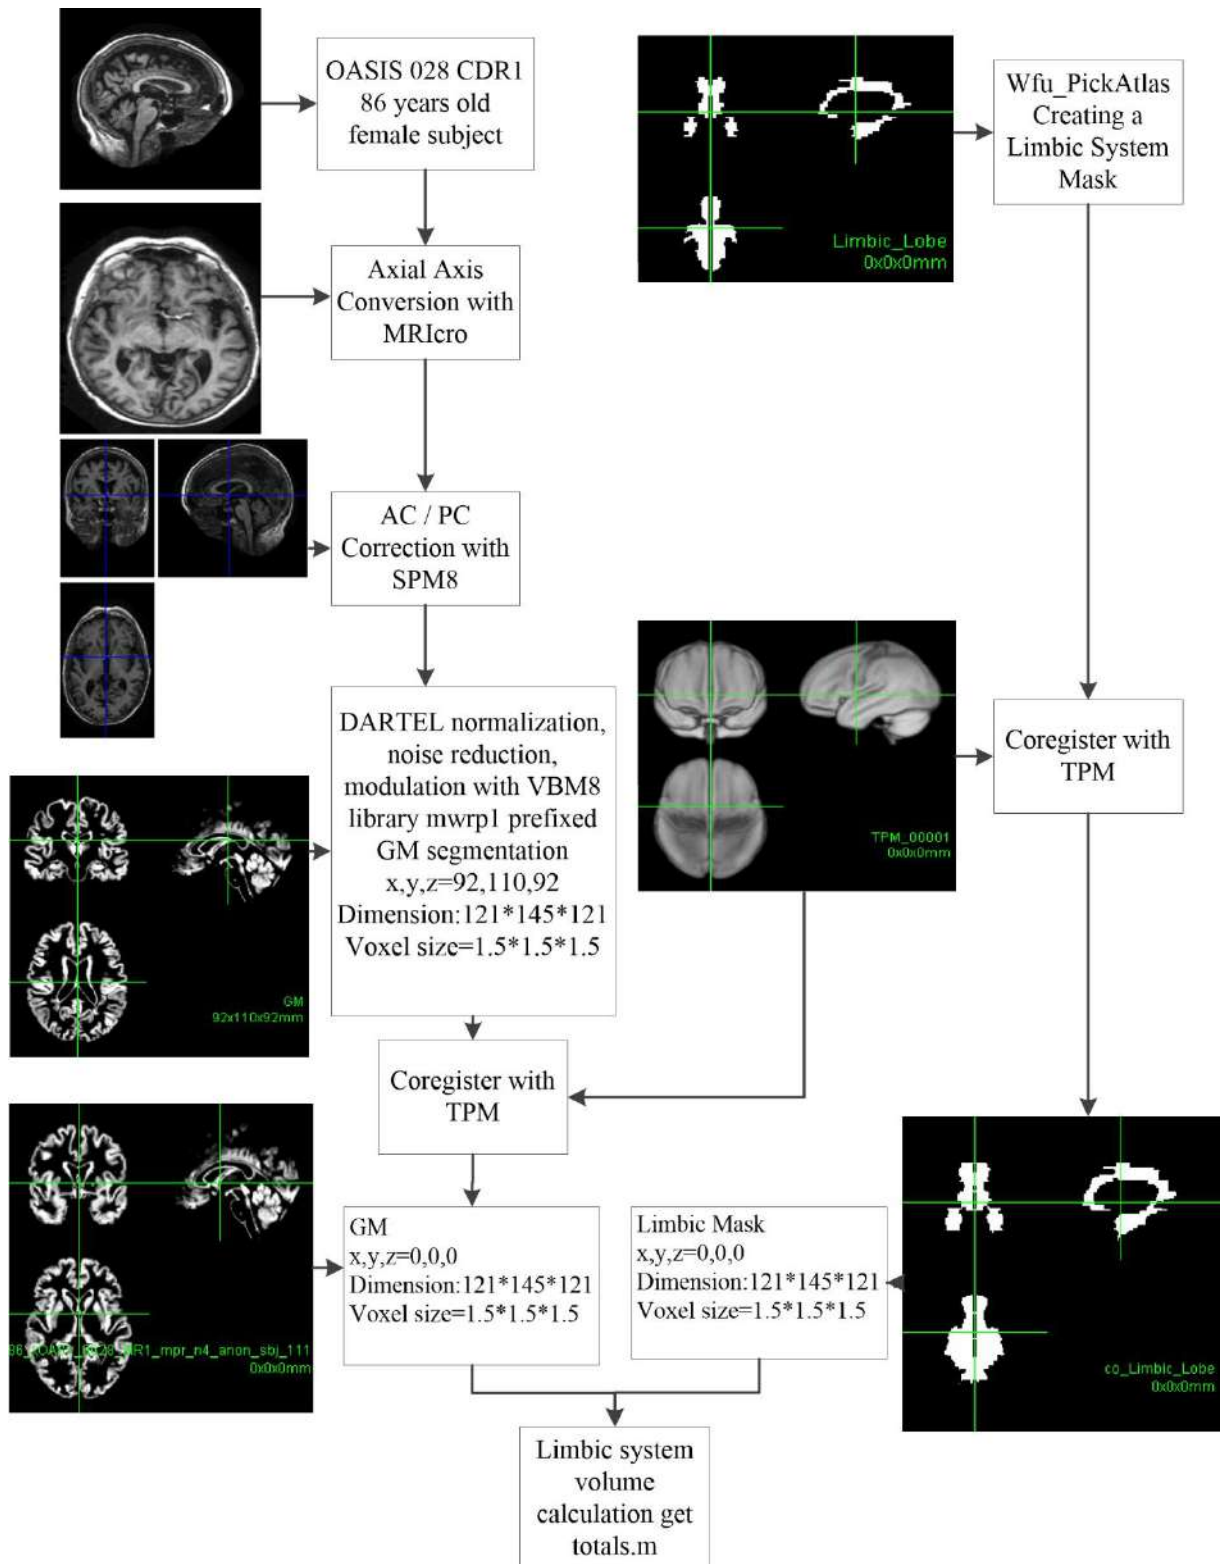

Fig 1. Atlas Based Volume Measurement Pipeline

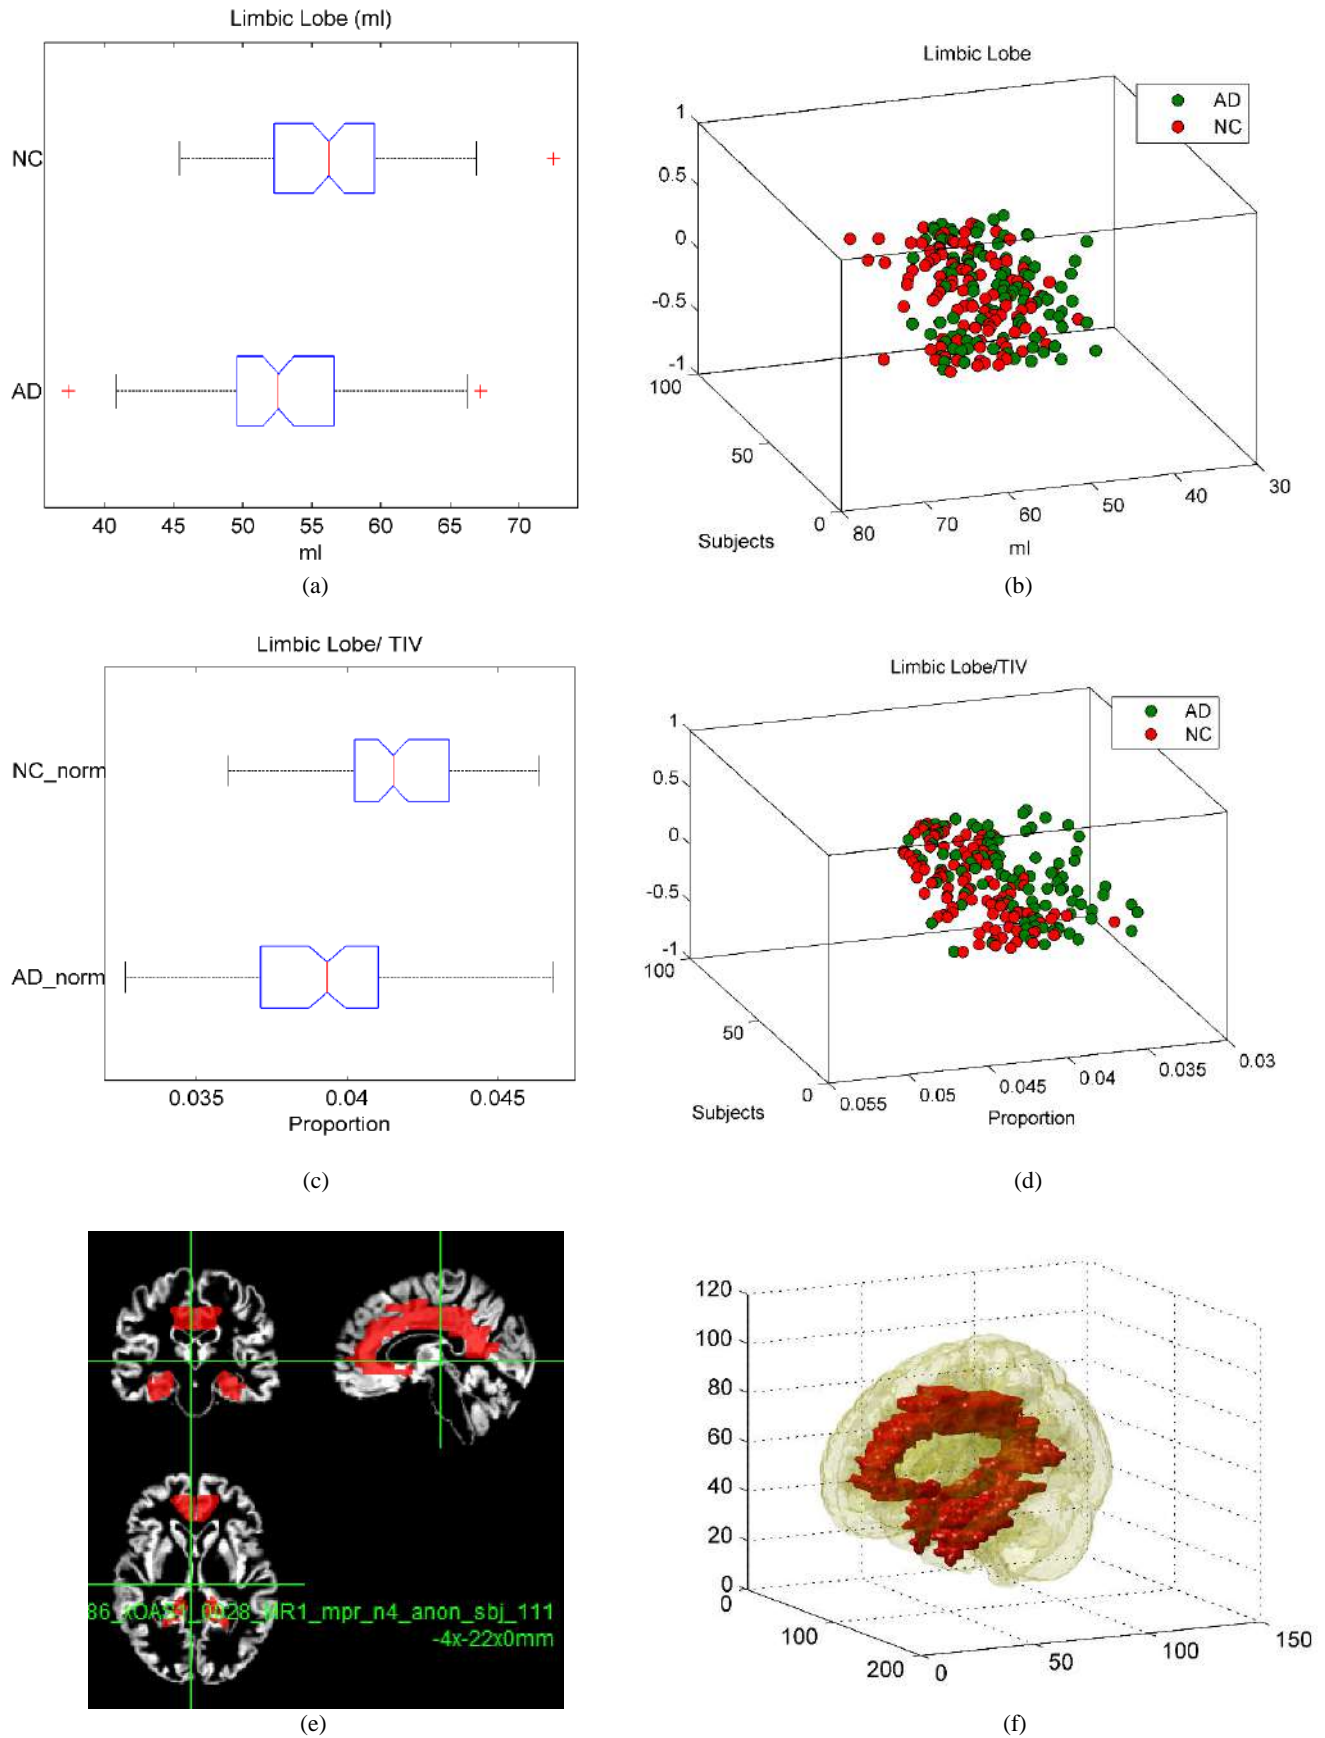

Fig. 2. (a) Box-plot for AD and NC Limbic Lobe Volume (b) Scatter diagram AD and NC Limbic Lobe Volume (c) Box-plot for AD and NC TIV normalized Limbic Lobe Volume (d) Scatter diagram AD and NC TIV normalized Limbic Lobe Volume (e) Superimposing Limbic Lobe mask and normalized segmented modulated image (f) 3D model Limbic Lobe inside brain

As shown in Table 2, the Limbic system volumes were higher in NC than in all brain normalization and non-normalization measurements with respect to AD. The limbic lobe volume and TIV ratio between AD and NC were statistically significant ($p < 0.05$). However, the ratio of the limbic system to the TIV was statistically more significant. Because each person's brain size is different, volume measurements differ from person to person. However, this bias can be corrected by normalizing any region volume to TIV as proven in this study.

When looked at the box-plot graph shown in Fig 2a, it shows outliers. This discrepancy is due to the fact that the total brain volume of each person is different. Even if the disease progresses, the total brain volume does not change, but the ratio of the functional regions in the brain to the total brain volume changes. Because of this, the brain regions measured in the literature are often normalized to the total brain volume. In Fig 2c, the outliers are moved together with the other outputs due to this normalization. In both box-plot charts, the median volume of the limbic system of NC is higher than the AD as expected. Fig 2b and 2d show the distribution of raw limbic lobe volume and TIV normalized limbic lobe, respectively. Fig 2d shows the normalized segmented modulated GM image with the superimpose of the limbic lobe mask and Fig 2e shows the three-dimensional shape of the limbic system mask in the brain. The limbic systems shown in both figures are very similar to the limbic system in the real brain.

V. CONCLUSION

In three-dimensional MR images, segmentation and volume calculation of the corresponding region is a difficult and laborious process. Since the boundaries of the corresponding regions are not clear in the MR images, it is almost impossible to find the transition regions by image processing methods. GM, WM and CSF volumes can be easily calculated after the segmentation process. However, brain atlases must be used to calculate the subcortical zone volumes of the gray matter. There are programs such as FSL [13] and Freesurfer [14] that calculate automatic volume in the literature. However, since analysis with Freesurfer takes a lot of time for an MR image and FSL may not offer practical use because it only calculates certain subcortical regions.

In this study, a practical pipeline for atlas based volume calculation of three dimensional MR images was proposed. The volume calculation for the limbic system in which the most volume loss occurred in AD was realized. A statistically significant difference was found when the limbic system volume was analyzed statistically between AD and NC. This significant difference is consistent with the literature. The masks and borders produced are discussed with an anatomist. The size inconsistency between the MR image and the atlas generated mask has been removed with some preprocessing. With this pipeline, statistical differences can be analyzed by calculating brain volume not only for limbic system but other lobe volumes. At the same time, subregions belonging to the lobe regions can be calculated with the pipeline developed by creating masks with Wfu Pick Atlas. These values will be calculated in other neurodegenerative diseases such as Parkinson, Frontotemporal dementia and used in future studies for pattern recognition and artificial intelligence.

Abstract—*In situations such as congenital spinal defects, degenerations, tumors, spinal trauma, it is often necessary to use an implant to re-establish stability and bring the vertebrae in line. Any operation with a higher degree of difficulty contributes to the development of next generation equipment. It has become compulsory to work on modifying or completely replacing old systems due to the difficulties or deficiencies identified by the surgeon.*

Studies on modern biomechanics have made considerable progress in terms of understanding the mechanism of musculoskeletal movement. Innovative spinal implants have begun to offer a variety of internal fixation concepts for spinal stabilization. In this context new types of materials and designs have emerged, more successful surgical interventions and treatment methods have been developed. Nowadays, many similar principles are presented in pedicle screw / rod systems in different designs. The advantages and disadvantages of these systems, especially in terms of biomechanics, are the subject of this extensive work.

Spinal systems are implants commonly used in vertebral injuries and spinal injuries that require surgical intervention. It is very important that spinal systems are implanted correctly in diseases such as scoliosis, which makes the daily activities of people difficult. Thus, the so-called rod, which directly affects the spinal curve in the implant system, is an important part of this system. The geometric changes in the rods directly affect the biomechanical performance of the spinal implant. At the same time, less rigid rods increase patient comfort and this geometry improves the mechanical performance of the system. In this context, the literature includes rod designs with different geometric properties.

In this study, rods with three different geometries were designed and their effects on the dynamic rod structure were investigated. Solid models of parts were obtained using SolidWorks 2014 software. The mechanical tests of the obtained models were analyzed by ANSYS Workbench 17.0 software. These analyzes consist of tensile, compression, bending, torsion and fatigue tests. In this study, it was aimed to increase the fatigue life and strain value of the models subjected to biomechanical tests. Models that designed under the same load are expected to be less rigid than standard models and therefore they are more suitable for dynamic rod construction.

Abstract— Saffron is one of the highly prized spices known since ancient times for its color, taste and disease treatment. Saffron spices obtain from stigma of Saffron plant (*Crocus sativus*). This plant is a sterile geophyte. The natural propagation rate of most geophytes including saffron is relatively low. The aim of this study determination of corm forming capacity of saffron sprout. The saffron corms obtained from a farmer from Safranbolu in Karabük province of Turkey. The corms were descaled and thoroughly washed under running tap water for 1h and then cleaned with the detergent Tween-20. These corms were then surface-disinfected with PPM. Murashige Skoog media [1] supplemented with 3% sucrose, 0.8% agar and different concentration and combination of PGR (BAP, NAA, 2,4D) used for in vitro corm regeneration from saffron sprout.

The cultures were incubated at 24 °C under 16/8 h (light/darkness) photoperiod with a light intensity approximately 3000 lux. 1 0.5 mg l⁻¹ BAP + 0.5 0.5 mg l⁻¹ NAA resulted in maximum corm regeneration [2].

Keywords: Saffron, corm regeneration, sprout

Abstract— Glioblastoma multiforme (GBM) is the IV grade of glioma which is the most aggressive and the most frequent of the primary brain tumor. This highly invasive tumor has very poor prognosis and the lifespan of the patients generally couldn't be more than 15 months after the diagnosis. In many cases, the tumor can gain resistance against the treatment. Therefore, developing new therapy strategies, finding new approaches and combining them with the existing methods have importance to be able to prolong the lifespan of patients and fighting with this lethal tumor. In this study it was aimed to investigate the cytotoxic effect of *Lavandula dentata*, an aromatic Mediterranean plant in the glioblastoma and fibroblast cell cultures. Inspired by the traditional medicine, the plant was prepared as an infusion solution. Studies were carried out with the Glioblastoma (GBM) (U87 MG) and Mouse Embryonic Fibroblast (MEF) cell lines. Cytotoxic effects were determined by the neutral red cell viability assay

Keywords— Glioblastoma multiforme; U87MG; *Lavandula dentata*; Lavender

[5] Introduction

Glioblastoma multiforme (GBM) is an aggressive and invasive type of primary brain tumor [1–3]. GBM is a vascular tumor with very poor prognosis [4]. The usual treatment of the GBM is surgical resection, radio- and chemotherapy. Despite the important advances in treatment strategies, the lifespan of the patients generally couldn't be more than 15 months after diagnosis [5–9]. There are so many molecular alterations which involve in the development of GBM and cause to gain resistance to radio- and chemotherapies [10].

Lavender (*Lavandula*) is an aromatic, evergreen Mediterranean plant belongs to Lamiaceae family [11]. Like many plants belonging to the Lamiaceae family, lavender has served traditional medicine for hundreds of years. Nowadays it is greatly used in aromatherapy as a relaxant and widely used in cosmetic and food industries [11], [12]. In addition to that, many studies have shown that the various species of lavender including *Lavandula angustifolia*, *Lavandula stoeches* and *Lavandula dentata*, possess antibacterial, anti-inflammatory and anticancer properties [13]–[15]. One of the lavender species used in traditional medicine for various purposes is *Lavandula dentata* [16]. *Lavandula dentata* also has cytotoxic and antioxidant activity [17]. Besides, it was observed that *Lavandula dentata* had the highest anticancer

potential among different plants against human breast adenocarcinoma (MCF7) cells [18].

[6] METHOD

A. Cells and Culture Conditions

The study was constructed using Glioblastoma (GBM, U87 MG (ATCC® HTB-14™)) and Mouse Embryonic Fibroblast (MEF, (CF-1) (ATCC® SCRC-1040™)) cell lines. The GBM cells were provided by Asst. Prof. Tuba Bağcı Önder (Koç University, Faculty of Medicine, Bağcı Onder Laboratory) and the MEF cells were provided by Assoc. Prof. Devrim Gözüaçık (Sabancı University, Gozuacık Laboratory). The cells were seeded into 24 well plates (40000 GBM cells and 10000 MEF cells/well), and cultured with Dulbecco's Modified Eagle's medium (DMEM, Lonza, Belgium) which was supplemented with 10% fetal bovine serum (FBS, South America) in a humidified incubator at 37 °C in which the CO₂ level was kept constant at 5%.

B. Preparation of the *Lavandula dentata* Infusion

Lavandula dentata was collected from Adana, Turkey and the infusion solution was prepared as indicated below;

1,5 grams of the herbal were added to 50 ml of double distilled hot water (90°C). After ten minutes it was sterilized by a 22 µm pore sized filter.

C. Cytotoxic Effect of *Lavandula dentata* on GBM and MEF cells

On the second day of the culture, *Lavandula dentata* infusion solutions were given to cell cultures, except the control group, in the proportions equivalent to 1/25, 1/15, 1/10 (v/v) and only ddH₂O was given to the control group in the equivalent volume of infusion solutions. GBM cells have exposed the infusion solution 3 and 5 days. MEF cells have exposed the infusion solution for 5 days. Each day the culture mediums were refreshed. At the end of the incubation periods, cytotoxic effects were measured by the neutral red cell viability assay.

D. Cytotoxicity Assay

Cell viabilities were tested by neutral red assay. As regards the neutral red assay, firstly the growth medium was removed after the incubation period, and 500 µL of neutral red solution was added to each well. Cells were incubated for nearly 2

hours until the red precipitates became visible. Following the growth of visible red precipitates, 1000 μ L of neutral red solubilization solution (50% absolute ethanol, %1 acetic acid and % 49 ddH₂O mixtures) was added to each well. Plates were incubated for nearly 1 hour until the red precipitate completely dissolved. Absorbance values of each well were measured at 540 nm using a spectrophotometer (Shimadzu UV-VIS, UVmini-1240, Japan). All tests were performed in triplicate. Cell viability percentages were calculated with respect to control groups.

[7] RESULTS AND DISCUSSIONS

Neutral red assay results indicated that increased quantities of *Lavandula dentata* inhibited the survival of GBM cells (Figure 1). However, the most significant result was observed in the fifth day of the GBM culture with 1/10 (v/v) *Lavandula dentata*. The viability of GBM cells was reduced by nearly 46%. The results showed that *Lavandula dentata* has cytotoxic and antiproliferative activity for the GBM cells.

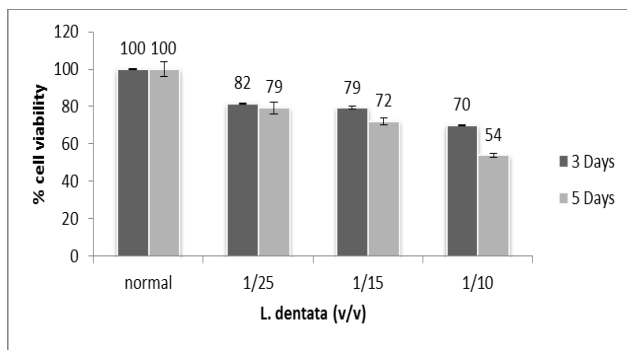

Fig. 1. The neutral red cell viability assay results of 3 and 5 days cultured U87MG cells.

According to neutral red assays, it was also observed that the viability of MEF cells were reduced in the *Lavandula dentata* added cultures (Figure 2). But the antiproliferative effects in the MEF cell cultures were less than that of the GBM cell cultures.

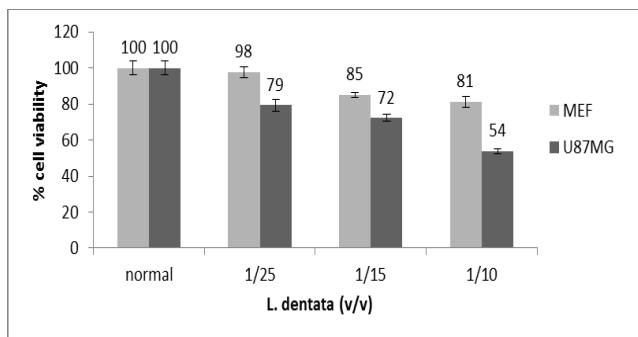

Fig. 2. The neutral red cell viability assay results of 5 days cultured U87MG and MEF cells.

[8] CONCLUSION

This study indicated that *Lavandula dentata* has cytotoxic effect for the GBM cells. It may contribute to researches that aim to develop new strategies for the treatment of GBM.

Moreover in the future as the continuation of this study, it is planning to investigate the effect of *Lavandula dentata* in combination with the several chemotherapeutic agents in different cell lines to be able to develop new approaches.

Abstract— *Fritillaria* is represented World wide by 7 subgenera, 2 sections, and 165 taxa. In Turkey is showing a wide distribution area there are 45 taxa *Fritillaria* genus is that 19 of them endemic to Turkey [1]. *Fritillaria minuta* which is an endangered species shows distribution in Eastern Anatolia and South East Anatolia. The plant has very showy red and brown-orange flowers [2].

This study was carried out with aim to determine in vitro micropropagation potential of *F. minuta* bulbs of the plant that were cultivated at the Department of Bioengineering, Firat University, Elazığ, Turkey, at 2015. For in vitro tissue culture, the bulbs were carefully selected from disease free material without any injury on the them. At tissue culture studies, parts of bulb scales which is obtained *Fritillaria minuta*, petals of not open flowers and stems of flowers were used as the explant source. Murashige and Skoog medium as the primary food (MS) was used [3]. Murashige and Skoog was used as the primary nutrient medium. As plant growth regulators, different combinations of 6-Benzyl amino purine (BAP), indole acetic acid (IAA) and α -naphthalene acetic acid (NAA) was added to nutrient medium. At sterilization of surface process, to ensure the best sterilization, considering literature, it was prepared preliminary various protocols.

The best results in carried out the preliminary experiments for sterilization were taken from treated explants in Tween 20 was added dropwise 30% sodium hypochlorite (20 min), 70% ethyl alcohol (1 min) and sterile distilled water. At two different concentrations of sucrose (30% and 60%); Plant growth regulator (PGR Plant Growth Regulator = PRG) free, 1 mg / l BAP + 0.6 mg / L NAA + 0.4 mg / L IAA containing, 0.1 mg / L BAP + 0.6 mg / L NAA + 0.4 mg / L containing media were prepared. Plates completely wrapped with stretch film are incubated at $20 \pm 1^\circ \text{C}$ under 16 hours white fluorescent light ($30 \mu\text{mol m}^{-2}\text{s}^{-1}$) and 8-hour dark photoperiod. The most effective culture medium was containing %30 sukroz, 1 mg / l BAP + 0.6 mg / l NAA + 0.4 mg / l IAA. It was observed that the cultures induced excessive somatic embryos were formed from bulbs of *F. minuta* at culture medium. In this study was obtained direct organogenesis, callus and indirect organogenesis from pieces of bulb scales. The results showed that *F. minuta* could be successfully propagated using in vitro techniques.

Keywords— *Fritillaria minuta*, in vitro micropropagation, bulblet

Abstract— Accessing to clean water is very important in order to protect human health. Realization of minor changes in parameters such as smell, color or taste or misdirected news on the visual/written media led public to use bottled water or residential water filtration systems in the cases of crowded households for economical reasons to clean the tap water instead of buying bottled water. The aim of this study was to investigate public awareness on the residential water filtration systems.

A total of 5139 people participated the survey according to simple random sampling method. The survey was completed by using face to face interview and computer aided telephone interview (CATI) methods. The collected data were analyzed by using SPSS V11.5.

For the research, a total of 5139 people were surveyed. 29% of the respondents stated that they prefer not to use municipal water as drinking water while 53,9% stated they do not prefer drinking municipal water as drinking water because they do not believe it is clean enough to drink. It is determined that of all the respondents 13,4% were using residential water filtration systems(WFS) while the main purpose of the usage was to clean the water from pathogenic microorganisms.

The respondents (82%) stated that they knew the proper frequency to replace water filter cartridges. When definition of the WFS were asked 34,4% of them said “a sanitation process to remove all of the harmful substances and impurities as well as living microorganisms, or decrease them in number”.

The behavior of the use of WFS showed statistically significant relationships with the variables age ($\chi^2= 30,75$; $P<0,05$), education level ($\chi^2= 6,17$; $P<0,05$) and income ($\chi^2= 6,17$; $P<0,05$). Also profession of the household head ($\chi^2= 24,29$; $P<0,05$) variable showed statistically significant relationship with the behavior of the use of WFS. Similar findings were observed that consumption of municipal water was decrease, when age-earnings profile and education level were increase.

One of the most important outcome of the research is that the tendency to use WFS increase with age. Because of the parameters income, education level, profession of household head is related with the age, an increase in these parameters lead to an increase in WFS usage frequency.

In conclusion of the survey, even though people were aware of the replacement of filter cartridges, one of the most important aspects of the water filter devices, and get warned about this replacement by the vendors; the importance of the replacement is not fully understood by the public.

Keywords— Clean water, public health, residential water filtration systems, public awareness.

Elliptic Filter Based Noninvasive Blood Pressure Analyze with LabVIEW

Abstract— The blood in the vein is called blood pressure or tension. It depends on the amount of blood pumped by the heart and the resistance of the vessels to this flow and the flexibility of the arterial walls. Very low values than optimum blood pressure and very high values than normal blood pressure are important. With this aim, Noninvasive Blood Pressure Analyze with LabVIEW offers an insight into us. LabVIEW is a graphical programming language that uses a Dataflow model instead of sequential lines of text code. LabVIEW runs principle of Data flow programming that allows multiple operations to work in parallel. So, designers spend less time than a text based programming language. Application areas such as signal processing, image processing and Data analysis are available. In this paper, LabVIEW- based Noninvasive Blood Pressure Analyze (NIBP) using different Data and to obtain systolic/diastolic pressure. As a result of this, the current data are divided into optimum blood pressure, normal blood pressure and prehypertension.

Keywords—LabVIEW; blood pressure; elliptic filter.

I. INTRODUCTION

Blood Pressure (BP) is the pressure that the blood in the vein bed makes to the vein walls during the flow. It depends on the amount of blood pumped by the heart and the resistance of the vessels to this flow and the flexibility of the arterial walls [1]. As the heart contracts, blood is pumped into the arteries. This increases the pressure in the arteries, while the pressure decreases in the heartbeats. As a consequence of this, the BP is indicated by two values, namely systolic pressure and diastolic pressure and the unit is millimeters of mercury (mmHg) [2]. In general, systolic pressure is known as hypertension, while diastolic pressure is known as hypotension. With BP measurement, it is decided which characteristics the person exhibits from optimum, normal, hypertension, hypotension and prehypertension. The optimum BP is below 120/80 mmHg. The normal BP is below 130/85 mmHg. Hypertension is higher than normal accepted values and one of the most important health problems. The BP is above 140/90 mmHg. Hypertension can lead to headache, dizziness, and can lead to heart-kidney disorders, paralysis and visual disturbances if not noticed.

Hypotension is abnormally low BP that is 90/60 mmHg below. It can occur due to many reasons such as sadness, stress, long-term hunger and vitamin deficiency. But every low BP not indicate a health problem. Prehypertension is used to describe patients whose BP is elevated but still within normal limits. The BP is between 120-139 mmHg systolic and 80-89 mmHg diastolic [3]. BP monitors should be considered to prevent serious illnesses and situations that could cause life-threatening injuries. The aim of this paper to investigate LabVIEW- based Noninvasive Blood Pressure Analyze (NIBP) using different Data and to obtain systolic/diastolic pressure. As a result of this, the current Data are divided into optimum pressure, normal pressure and prehypertension.

The structure of this paper is as follows: Second section includes preprocessing of signals, database signals taken from LabVIEW. Third section includes evaluation of results. The last section includes conclusion and future works.

II. MATERIAL AND METHODS

A. Database

Signals required for paper are taken from the LabVIEW own Database. Signals of three Databases that are NIBP_Data_1, NIBP_Data_2, NIBP_Data_3 were used to examine. Each signal is sampled at intervals of 0.002 for 31, 32, 27 seconds, respectively. These signals correspond to prehypertension, normal and optimal respectively.

B. LabVIEW

LabVIEW is a graphical programming language that uses a Dataflow model instead of sequential lines of text code. Comparison of the other language, LabVIEW runs principle of Data flow programming that allows multiple operations to work in parallel [4,5]. It provides that acquires of bioelectrical signal, preprocesses and analyzes them.

LabVIEW is a software based graphical programming language that consists of front panel and block diagram. The sections where the user interface prepares and the code is written correspond to front panel and block diagram, respectively. The

block diagram of designed system is shown in Figure 1. LabVIEW is called a Virtual Instrument (VI) because it resembles the physical instruments used in the laboratory with the way it works [6]. The biomedical workbench toolkit in LabVIEW allows applications such as recording, by sensor with DAQ hardware, and viewing bioelectrical signal, heart rate

variability (HRV) analysis, ECG Feature Extracture and Noninvasive Blood Pressure Analyze By file format converter, the files are converted into different types of file formats for the various applications. For instance, it supports .hea, .tdms, .mat, .rec extensions file [7]. In this paper, .tdms extensions file was used.

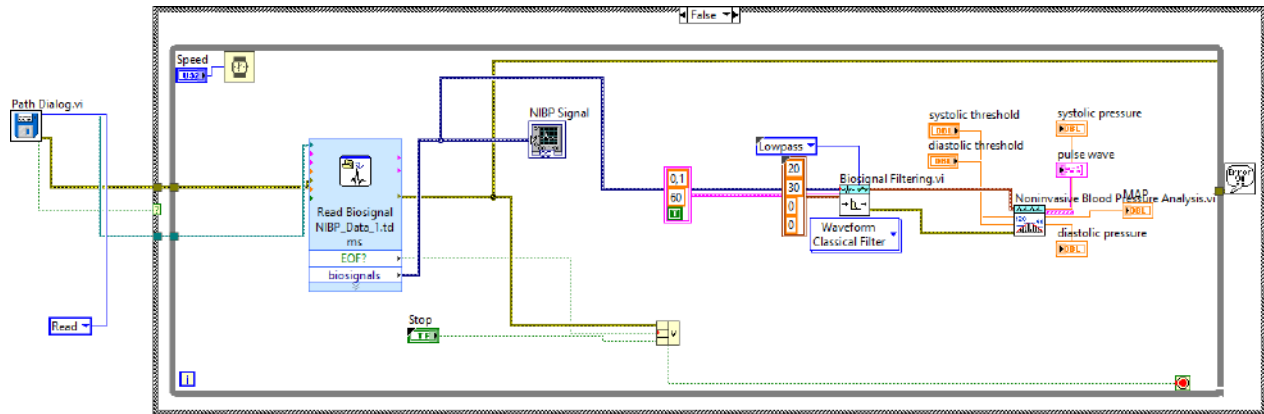

Fig 1. Block diagram of designed system

C. Preprocessing

Used signals are recorded with many low frequency undesired noise caused by the circulatory system. Filtering should be done to suppress them. For this, lowpass elliptic filter was chosen. An elliptic filter is a signal processing filter with equalized ripple behavior in both the passband and the stopband [8]. The level of ripple on each band is a configurable filter. As the ripple in the pass-band approaches zero, the filter becomes a Chebyshev type I filter, as the ripple in the stop-band approaches zero, it becomes a Chebyshev type II filter and both band approaches zero, filter becomes a Butterworth filter. Although this filter has ripple both band, it has a rapid decline from the pass band to the stop band. With this filter, undesired signals removed then with BP analyzer systolic/diastolic and mean arterial pressure (MAP) were obtained.

[9] RESULTS AND DISCUSSION

Mentioned techniques have been applied to BP signals to obtain systolic/diastolic BP and MAP value. In order to interpret the results obtained, the values that the World Health Organization (WHO) prescribes for BP limit values are taken as references. The classification of BP by the World Health Organization International Hypertension Committee is given in Table 1. Obtained BP results are shown in Table 2.

Figure 2 shows NIBP_Data_1, Figure 3 shows the result of the analysis, Figure 4 shows the NIBP_Data_2, Figure 5 shows the analysis result, Figure 6 shows the NIBP_Data_3, and Figure 7 shows the analysis result.

TABLE 1 CLASSIFICATION OF BP

Category	systolic, mmHg	diastolic, mmHg
Hypotension	< 90	< 60
Normal	< 130	< 85
Optimal	< 120	< 80
Prehypertension	130-139	85-89
Stage 1 hypertension	140- 159	90-99
Stage 2 hypertension	160-169	100-109

TABLE 2 OBTAINED BP RESULTS

Category	systolic, mmHg	diastolic, mmHg	MAP mmHg
NIBP_Data_1	131	86	93
NIBP_Data_2	122	72	83
NIBP_Data_3	107	64	72

Fig.2 NIBP_Data_1 Signals

Fig.3 Analyze results of NIBP_Data_1 Signals

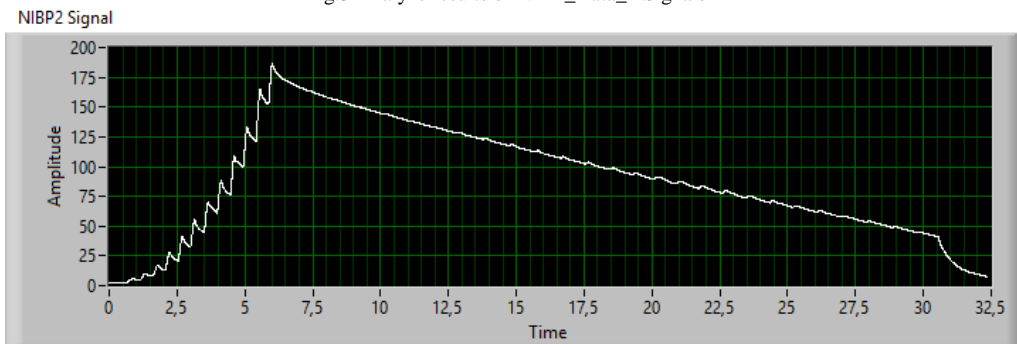

Fig.4 NIBP_Data_2 Signals

Fig.5 Analyze results of NIBP_Data_2 Signals

Fig.6 NIBP_Data_3 Signals

Fig. 7 Analyze results of NIBP_Data_3 Signals

Obtained results show that NIBP_Data_1 corresponds to prehypertension, NIBP_Data_2 corresponds to normal BP and NIBP_Data_3 corresponds to optimal BP.

[10] CONCLUSIONS

Low BP and high BP are important health problems. Especially, hypertension is one of the most important health problems in the world that requires regular checking. Prehypertension is used to describe patients whose BP is elevated but still within normal limits. The optimum BP is below 120/80 mmHg. People with pre-hypertension are more likely to have a risk of myocardial infarction and fallacies than people with normal BP. The normal BP is below 130/85 mmHg. Hypotension is abnormally low BP that is 90/60 mmHg below. It can occur due to many reasons such as sadness, stress, long-term hunger and vitamin deficiency.

So, in this study, it is provided to measure BP level with the developed LabVIEW algorithm. Simple usage of graphical structure allows to observe BP level to the doctor or the patients.

In future studies, classification models will be tried to be improved.

Abstract— *Saffron (*Crocus sativus* L.) is a monocotyledonous plant of the Iridaceae family that produces annual renewal corms which are indispensable for their propagation, since the plant is triploid and sterile (1). Saffron is a cormous plant which is one of the most economic valuable plants as medicinal and aromatic ingredients world wide. Saffron is used mainly dye, food, drug and pharmacology industries. It has analgesic and sedative properties so folk herbal medicines have used for some diseases. Saffron consumption is rising but production is not well-proportional. Plant tissue culture technique like micropropagation has been used for the propagation of saffron. In our study, sprout explants were culture Murashige Skoog media (2) supplemented with various concentration of TDZ (Thidiazuron) or Zeatin. Explants incubated in dark at 25°C. The best corm production was achieved at 4 mg/l TDZ.*

Keywords— *Saffron, TDZ, Zeatin, Corm production.*

Investigation of Infrared Drying of Mixed Algae Culture

Mehmet KALENDER
Bioengineering Department
Faculty of Engineering
Firat University
Elazig, Turkey

Ahmet YAZICIOĞLU
Bioengineering Department
Faculty of Engineering
Firat University
Elazig, Turkey

Abstract—Alga species compose are around approximately 127.000 in the world. Some of these are macro alga which include 9000 species, and others are named as micro alg. *Spirulina*, which is a microalga consists of chemically moisture (76.7 %), protein (17.2 %), carbohydrates (2.4 %), lipids (2 %), and ash (1.7 %) [1]. Alga has a high nutritional value with contents of protein and vitamins (A, B1, B2, B6, B12, E, and K), minerals (Fe, Ca, Zn, K, P, Mn, Cu, and Mg) [2]. Due to anti-oxidant and anti-inflammatory properties, alga is used in cosmetic industry [3]. Also, alga is a good resource in order to produce biofuel [4, 5]. One of the important production stages of algae technology is drying because of high moisture content. Algae drying techniques could affect algal quality and process economics [6]. Thus, drying phenomena of algal biomass should be examined.

In this study, mix algae culture was cultivated in a laboratory scale airlift photobioreactor with volume of 50 L, light intensity of 100 lux during 24 hours, and at room temperature. Zarrouk medium (per L of H₂O: 16.0 g NaHCO₃, 0.5 g K₂HPO₄, 2.5 g NaNO₃, 1.0 g K₂SO₄, 1.0 g NaCl, 0.2 g MgSO₄·7H₂O, 0.04 g CaCl₂, 0.01 g FeSO₄·7H₂O and 0.08 g EDTA.) was used for culture growth [7]. At the end of 10 days, the algal cells that came to the collapsing phase in the photobioreactor were filtered. All wet algae sludges were stored at +4 °C until used in the drying experiments.

Drying experiments were carried out with the infrared dryer (Shimadzu, MOC63u). The drying experiments were performed at the temperature between 50-105 °C. Drying and drying rate curves were obtained from the experimental data. The drying periods of the algae culture for all temperatures studied were generally the falling rate period. Also, effective diffusion coefficients were determined by the experimental data.

Keywords— Drying of algae, Mixed algae, Infrared drying.

Abstract— Activated sludge is a main waste coming from biological water treatment facilities. This waste can be evaluated either for biogas production by an anaerobic fermentation process or as a fertilizer for agricultural areas. On the other hand, in general, it is not preferred as fertilizer due to ethical reasons in Turkey. For that reasons, it is disposed to wide lands and it can cause some environmental problems. Therefore, it is needed to enhance new processes to evaluate this residue. In fact, activated sludge contains significant amount of organic and inorganic matters. Due to high organic matter content, the pyrolysis of the activated sludge is widely investigated to convert some secondary useful products such as some gas and liquid fuels and activated carbon [1]. Also, there are some studies about the using of activated carbon obtained during pyrolysis process in water treatment. Activated carbon obtained from the sewage sludge can be used to remove some pollutants from waters such as heavy metals [2] and dyes [3].

In this study, firstly, it was investigated that the pyrolysis of activated sludge in a fixed bed pyrolysis reactor. Then, dye removal properties of the solid pyrolysis residue obtained at optimum conditions from waste sludge was investigated. The waste sludge was obtained from a municipal waste treatment plant (Elazığ, Turkey). The proximate analysis of the materials showed that it contains 47.1 % of ash, 11.8 % of fixed carbon, 2.9 % of moisture and 38.2 % of volatile matter. Gas, liquid and solid pyrolysis product yields were investigated depending on pyrolysis temperature (200-500°C) and heating time (30-120 min). So, the optimum conditions were determined as to the maximize liquid product yield. Optimum pyrolysis conditions were determined as 400°C of pyrolysis temperature and 90 min of heating time. The liquid, gas and solid product yields were 28.9 %, 12.5 % and 58.6 %, respectively. As seen from the results, it can be said that the solid pyrolysis residue of waste sludge contains significant amount of inorganic constituents. For that reason, it can be said that this residue is not suitable for evaluation as a fuel. Since it contains significant amount of metal oxides and carbon, it can be evaluated for pollutant removal from waters. Therefore, waste sludge pyrolysis residue was used in a dye removing study. The golden yellow was selected as a model dye. In dye removing study, effect of some parameters such as dye concentration, contact time and temperature were investigated. The results obtained were evaluated by using some kinetic and adsorption isotherm models. Also, some thermodynamic evaluations were made. The results of the study showed that the most suitable kinetic models for golden yellow adsorption onto pyrolysis residue is pseudo-second order model and the data best fits to Langmuir adsorption isotherm. Thermodynamic evaluations showed that the sorption process has exothermic and spontaneous nature.

Abstract— Gluconic acid is mainly produced by oxidation of glucose. This oxidation process can be realized by microbial fermentation, chemical catalysis, enzymatic catalysis, electrochemical and bio-electrochemical methods [1]. Microbial fermentation is most widely used method due to its cost efficiency. Some fungus and bacteria are used for microbial fermentation. Most important microorganisms used in gluconic acid production are *Gluconobacter* and *Aspergillus niger* as bacteria and fungus, respectively. In earlier studies, gluconic acid production from glucose by using *A. niger* has been investigated widely [2]. Also, there are some studies about the production from sugar cane molasses. But, there are not sufficient studies about production from sugar beet molasses. Also, *A. niger* is capable to metabolize disaccharides (sucrose) due to it has invertase enzyme [3]. This paper is first part of the study on gluconic acid production by fermentation with *A. niger* from sugar beet molasses and pulp, which are by-products obtained during the sugar production. The results of submerged fermentation study are given in this paper.

In this part of the study, sugar beet molasses obtained from a domestic sugar plant was characterized and then submerged fermentation conditions for gluconic acid production by using *A. niger* were optimized. It was determined that the sugar beet molasses contains about 49.4 % of sucrose and 1.5 % of invert sugars (glucose and fructose). Also, it was determined that it contains about 20 % water and the about 29 % of sugar free dry matter. As well known, sugar beet molasses also contains phosphorus, nitrogen and some metal ions such as calcium and iron. For that reason, it can be said that the sugar beet molasses is a good fermentation media which is not needed addition of any nutrient. The response surface methodology (RSM) was used to the design of experiments. For this purpose, central composite design (CCD) route was selected as design method. The investigated parameters were sugar beet molasses concentration, CaCO_3 amount, temperature and shaking speed. All experiments designed by CCD were conducted depending on the fermentation time. The samples taken on different periods were analyzed by HPLC to determining gluconic acid, oxalic acid, citric acid, sucrose, glucose and fructose concentrations. Optimum conditions for gluconic acid productions from sugar beet molasses by using *A. niger* were determined as 257.8 g/L of molasses concentration, 30.1 g/L of CaCO_3 amount, 31.8 °C of temperature and 135.2 rpm of shaking speed and the maximum gluconic acid concentration was obtained as 57.6 g/L under these conditions for 192 h of fermentation period. Also, a model equation was obtained for the gluconic acid production as below:

$$\text{Gluconic Acid Conc. (g/L)} = -636.865 + 0.823xA + 4.589xB + 20.854xC + 2.776xD + 0.001xAxB + 0.003xAxC - 0.001xAxD - 0.032xCxD - 0.002xA^2 - 0.081xB^2 - 0.272xC^2 - 0.006xD^2$$

Where A is molasses concentration (g/L), B is CaCO_3 amount (g/L), C is temperature (°C) and D is shaking speed (rpm).

It has been determined that citric and oxalic acid productions together with gluconic acid are being occurred in the significant levels. For that reason, it can be said that the *A. niger* can perform citric acid and oxalic acid production by phosphofructokinase and oxaloacetate acetylhydrolase enzymes, respectively [4].

Keywords—Gluconic acid; *Aspergillus niger*; fermentation; sugar beet molasses; response surface methodology

Abstract— Clinically, facial appearance is an important indicator in diagnosing dysmorphic syndromes and it paves the way for computer-aided diagnosis based on facial image analysis. The initial clinical diagnosis of dysmorphic syndromes carried out by clinical geneticists using the comparison method. In this method the specialists compares physical properties of patients with physical properties of who was definite diagnosed patients in the books and databases. This process may take a long time and this method is subjective so the diagnosis success depends on experience of the by clinical geneticists. The early diagnosis of dysmorphic syndromes is crucial for the timely management of patients and disease. To speed up pre-diagnosis and eliminate subjectivity, computer-assisted objective methods are needed. The fast development of image processing and machine learning techniques facilitates the detection of facial dysmorphic features. In this study, we propose a novel method based on machine learning techniques to detect Fragile X, Hurler, Prader Willi, Down, Wolf Hirschhorn syndromes and healthy group automatically. The image database consists of 130 frontal photographs from dysmorphic syndromes and healthy groups. We define the particular facial characteristics of patient affected by each syndrome, after that the reference points are marked on the face images and ratios between the points' distances are taken into consideration as features. Then k-Nearest Neighbor (kNN) and Artificial Neural Network (ANN) classifiers are used to detect syndrome types. k-NN and ANN classifiers are trained by 130 samples and leave-one-out method are used for training and tests. Euclidean distance metric is used for the kNN method. Different k values are implemented and the best results are obtained for k=4. For ANN classifier we used multi layered feed forward ANN. Our method achieved 55% and 75% accuracy with kNN, ANN respectively. The promising results indicate that our method can detect dysmorphic syndromes effectively in a simple, non-invasive imaging data and can be used for pre-diagnosis of the dysmorphic syndromes by clinical experts.

Abstract— Titanium oxide films were produced on commercially pure titanium (Cp-Ti) by thermal oxidation, DC plasma oxidation and by the sol-gel. The structural properties of samples were analyzed by X-ray diffraction, scanning electron microscopy (SEM). Mechanical and tribological properties of untreated and treated samples were observed by microhardness, profilometer and pin-on-disc tribo-tester. Wear tests were performed under both drying and in simulated fluid body (SBF) condition. The results showed that the oxide films produced under three different treatments at 500°C consist of TiO₂ in the anatase structure. Although the XRD pattern obtain from treated samples at 700°C demonstrates the coexistence of anatase and rutile phases. Also, it was seen that the plasma oxidated samples at 700°C have higher intensities of rutile compared to other samples. Test results indicated that the hardness and wear resistance values of treated all samples were higher than the untreated CP-Ti values. Furthermore, the highest hardness and wear resistance values were attained at the plasma oxidated sample at 700°C both in drying and SBF condition. Since, rutile-TiO₂ structure exhibited self-lubrication like behavior.

Abstract: This species was found in Diyarbakır and Elazığ provinces. It has been made to follow the populations in the vineyards of *Z. rhamni*. Each of the vineyard made of population 8.th month between 10. th months. In this study will be contribute vineyard IPM Studies

Keywords—*Zygina rhamni*, Diyarbakır, Elazığ, Mardin, population development, IPM

INTRODUCTION

Zygina rhamni Ferrari (Hemiptera: Cicadellidae: Typhlocybinae) is a mesophyll-feeding leafhopper on *Vitis vinifera* L. This species is facultative heteroecious species of their life cycle. In autumn, it migrates from vineyards to *Rubus* sp and rose, *Rosa* sp (Mazzoni et al., 2008). Females lay eggs at the end of March on these host plants in Italy. Adults that developed on bramble colonize grapevines beginning in May; the leaf fall of rose, which takes place during the first half of April. In Italy; (May–early July) with following, progressive spread through the vineyards, with concentration in areas of high vegetative density (Mazzoni et al., 2008). *Z. rhamni* Ferr. had been listed from Turkey by Metcalf (1968) from Turkey. In additionally; This species was distributed in İzmir, Tekirdağ and Elazığ province of Turkey (Altınçağ, 1987, Karagöz, 1988, Özgen and Karsavuran, 2009). In this study, that have been aimed in *Z. rhamni* population development in Elazığ, Diyarbakır and Mardin provinces.

MATERIAL AND METHODS

In this study, yellow sticky traps work population dynamics of pests methods were applied. Study was carried out a total of twelve vineyard location in Diyarbakır, Elazığ, Mardin cities. maintaining the integrity of the specifications. These locations are Diyarbakır (Ergani, Çermik, Çüngüş 1 and Çüngüş 2), Elazığ (Altınçevre, Akçakiraz Yurtbaşı and Center), Mardin (Mazıdağı, Derik 1, Derik 2 and Ömerli). In each vineyards were collected

specimens on five sticky traps and taken to average to weekly.

RESULTS AND DISCUSSIONS

Population development were summarized in Fig.1, Fig 2, Fig, 3, Fig 4 of *Z rhamni*.

Figure 1. Population Development of *Z. rhamni* in Elazığ city in 2016 years

Figure 2. Population Development of *Z. rhamni* in Elazığ city in 2017 years.

Figure 3. Population Development of *Z. rhamni* in Diyarbakır city in 2016 years.

Figure 4. Population Development of *Z. rhamni* in Diyarbakır city in 2017 years.

Z. rhamni was firstly determined Diyarbakır province. In this location; was distributed commonly white varieties. It was determined that the average population formed with the end of the 8th month and the middle of the 10 th month in each location. It were seen commonly that the Tahannebi, Sireli, Boğazkere grape varieties. This species was found Bois noir infected vineyard in Europe. Bois Noir makes it crucial that phytoplasmic disease be found in vineyards where it is found in vineyards. Since this disease has been detected in the

Aegean, Central Anatolia and Eastern Anatolian vineyards of our country, it is important to prevent the spread of the disease.

Abstract— *Internal diseases are common to adults. Physicians diagnose of internal diseases according to their experimental knowledge and laboratory results. Laboratory tests such as blood analysis, urine analysis are very important for diagnosis of internal diseases. Diagnosis of most internal diseases can be done by evaluating the blood test results. Health care workers and patients have gained great convenience with the implementation of technological developments in the field of medicine. Besides the personal information of the patient, diagnostic information such as laboratory results are started to save electronically in health care units in recent decades. The stored data is analyzed with modern techniques and then served to the doctors and managers. The use of artificial neural network structures for classification systems in medical diagnosis are increasing. In this study, a system based on artificial neural network is developed for diagnosis of anemia, liver disease, kidney failure, B12 vitamin deficiency, diabetes and thyroid disease. The data obtained from blood analysis results of state hospital's database. The blood analysis results are obtained from 62 patients. Multi layered feed forward artificial neural network is used as a classifier to distinguish between internal diseases. Our method achieved 95% accuracy. The promising results indicate that our method can detect internal diseases effectively. Based on this result our method can serve as important and useful method in diagnosis for physicians to avoid unnecessary medical waste and enhance healthcare quality.*

Abstract—Deep marine low density turbidites of Upper Cretaceous Tanjero Formation were studied to present petrographic composition and provenance of the unit in Arbat area. Petrographic works based on modal analysis of the clastic rock fragments and released single minerals in silt, fine to coarse grained sandstone and, in very small quantities pebbly sandstone show that these turbidites are mainly composed of sedimentary rock fragments such as carbonate, microcrystalline and cryptocrystalline quartz bearing siliceous sedimentary cherts, radiolarian bearing cherts, and released radiolarians from the cherts during a short distance transportations. Quartz and feldspar ratios in the whole thin sections are below three percent. The turbidite siltstones and sandstones are litharenite in composition indicating sedimentary source rocks mainly consisting of carbonate rocks and radiolarian and chert rich limestones.

The composition of the clastics suggests a recycled sedimentary sources. Likewise, the QtFL ternary diagram suggests that the sediments are derived lithic recycled provenance which may be the Lower Cretaceous Qulqula Formation.

Keywords— Tanjero Formation, petrography, provenance, Northern Iraq.

Microfacies Analysis of Kocaçay Formation (Middle Eocene) Around Şefaati Township of Yozgat, Central Turkey

Abstract—This study based on biostratigraphic micro facies characteristics of Middle Eocene Kocaçay Formation consisting of layered fossiliferous limestone outcropping at 1,5 km to the east of Deliler Village in Şefaati township, southern Yozgat, central Turkey, show the existence of three main faunal microfaciesses. The measured section of this study was taken on the only clearest outcrop of the unit in a vacated limestone quarry as no any open and suitable section of the limestones exist around the township.

According to the biostratigraphic evidences obtained from thin to medium bedded limestone layers show existence of Miliolidae facies, Alveolina facies and Nummulite facies. These three faunal microfaciesses were interpreted as internal shelfal carbonate and shallow marine for palaeo environment of the formation during Middle Eocene. At the evidences obtained from work place and verifications from works of slim-mid layer limestone with stratigraphic section, three main facies are much in evidence as Miliolide Facies, Alveolina Facies, Nummulite Facies in this forms.

Abstract— *This study outlines a lithofacies analysis of the Upper Cretaceous deep marine turbidites of Tanjero Formation outcropping in the close northwest of Sulaimani area. The outcrops of the unit are seen throughout of the northern Iraq more or less parallel to the Iranian border. This study will trigger further studies on lithofacies analysis of the formation to establish a complete work for depositional model of the unit in the meaning of lobe hierarchy. The turbidites represent a large submarine distal fan depositional system related to the described lithofacies as the lateral continuations of the turbidite beds are visible along tens of kilometers in the area.*

Seven distinctive main lithofacies groups were identified from seven measured sections. Each of them is more than one hundred meters in thickness consisting of fourtyeight subfacies. The groups classified as grain size are coarse grain sandstone beds (CGSB: includes four subfacies), medium grain sandstone beds (MGSB: includes twelve subfacies), fine grain sandstone beds (FGSB: includes eighteen subfacies), very fine grain sandstone beds (VFGSB: includes two subfacies), shale and silt sized thin bedded turbidites (STBT: includes five subfacies), fine sand thin bedded turbidites (FSTBT: includes four subfacies) and medium sand thin bedded turbidites (MSTBT: includes three subfacies). The subdivisions of the groups are seperated according to their internal sedimentary structures. All facies groups represent low density turbidites composed of some divisions of Bouma sequence.

These facies represent about middle part of outer fan and lobe fringe to lobe distal fringe sand rich depositional system for the turbidites outcropping around Sulaimani.

Keywords— *Facies analysis, Upper Cretaceous turbidites, lobe fringe, outer fan, Sulaimani, northern Iraq*

Slip Rates Contradiction Between Geologic And Geodetic Data Along The North Anatolian Fault

Mehmet Köküm

Firat University, Engineering Faculty, Geological
Engineering, 23119, Elazığ, Turkey.
mkokum@firat.edu.tr

Kaj M. Johnson

Geological Science Indiana University Bloomington, USA.
kajjohns@indiana.edu.tr

Abstract— Modeling studies for slip rate along the North Anatolian Fault (NAF) indicate a contradiction between the geologic and geodetic slip rates along the fault segments. Previously published geodetic slip rates are higher than geological long-term slip rates along the NAF. An apparent contradiction between the geologic and geodetic slip rates along the faults is quite common problem for the modeling studies. In this work, we address on this contradiction in order to find out reasons of the different slip rates estimates. There are three potential scenarios to clarify this remarkable difference on slip rate estimates. The first and second scenarios could be that either geodetic slip rates or geologic slip rates are incorrect. There are some limitations to estimate slip rates both on geodetic data and geologic rates. Insufficient geodetic data along the fault zone (e.g., Reilinger et al., 2006) and insufficiency of the model (e.g., sudden change in deformation such as mantle flow, misplaced block boundaries, poor locking depth estimates) or poorly constrained geometry of the submarine faults, which is not defined well (e.g., Ching and Johnson, 2011) could be examples for the limitation of geodetic studies. Large uncertainties on geologic estimates (e.g., Allen et al., 2004) could be examples for the limitations of the geologic slip rate estimates. The third scenario could be that both geodetic slip rates and geologic slip rates are correct. Polonia et al. (2004), hypothesis is that geodetic estimates might represent a recent increase or decrease in slip rate; in this case the geodetic result does not represent the long-term geological motion. Modeling studies reveal the locking depth estimates with slip rates for the major fault system that is very useful information for the earthquake hazard studies. Geodetically determined locking depth estimates are rather deeper than depth of background seismicity along the NAF. We cannot answer of this question ‘which data should be taken into account for slip rate estimates’; however, we may suggest using both geodetic and geologic slip rates as data to have better slip rates estimates. Because slip rates estimates using both data set to build a model are consistent with the depth of background seismicity along the NAF. The question may reach the solution by improving modeling and having more data in the near future.

Keywords— North Anatolian fault; geodetic slip rate, geologic slip rate, contradiction

Lithofacies And Architectural Elements Of The Deep Marine Calciclastic Low Density Turbidites Of Upper Cretaceous Tanjero Formation, Around Arbat, Northern Iraq

Tavan Muhammad Hama Salih

Geological Engineering, 23119, Elazığ, Turkey.
hasancelik@firat.edu.tr

Abstract— *The calciclastic low density turbidites of the Upper Cretaceous Tanjero Formation widely crop out throughout of Northern Iraq. In order to interpret the sedimentary environment of the turbidite cropping out around Arbat six detail measured sections taken from eastern side of a hill oriented about NW-SE direction have been studied. The equated thickness of the measured sections is 45m. The analysis of lithofacies and architectural elements, leads to recognition of three main lithofaciesses and fourtynine total subfaciesses of the turbidites in the location. The main faciesses represent the grain size from fine to coarse grain sandstone. The subfaciesses are consisting of many types of combinations of complete Bouma sequence associated with thin bedded turbidites. These faciesses point out that the environment of the turbidites is inner part of outer fan. In the meaning of lobe hierarchy the turbidite beds in thin and medium thicknesses represent lobe fringe. Only one architectural element recognised in the section is small sandy channel fills in about ten metres lenght and a few metres thick representing beginning of outhter fan or in lobe fringe. The composition of the clastics suggests a recycled sedimentary sources. Likewise, the QtFL ternary diagram suggests that the sediments are derived lithic recycled provenance which may be the Lower Cretaceous Qulqula Formation.*

Geological Engineering, 23119, Elazığ, Turkey.
hasancelik@firat.edu.tr

Abstract—In this study reservoir characterization of the Upper Cretaceous low density calciclastic turbidite sandstones of Tanjero Formation were analysed. The sandstone portion of the unit have been examined through field and laboratory based studies. 7 were measured and described in detail. Average thickness of the measured sections is 158 m. The field logs start from the contact between underlying Shiranish Formation to more than 150 metres in thickness in the turbidite unit. 44 rock samples were taken for petrographic analysis, porosity and permeability tests from the logs for laboratory analyses. The turbidites represent distal fan and low density deep marine depositional sand rich system. The sandstones are litharenite (sedarenite), very fine to coarse and pebbly coarse grained in size consisting of chert, siltstone, mudstone, radiolarian chert and radiolarian mudstone fragments, angular to subangular in shape, and moderately sorted, transported over short distances and submature. Porosity of the studied sandstones range from 5,51 to 11,59 % which is poor to beginning of fair with an average value of 7,11%. The obtained permeability varies between 10,71-2315,65 md and their mean value is 866,35 md representing high permeability. As the modal components of the sandstones are made up of 97 % sedimentary rock fragments (average and mainly reworked carbonate fragments) and calcite minerals, the reservoir quality of the turbidite sandstones was strongly negatively influenced by the alteration of these elements creating mainly calcite and some clay cementations. The combined effect of calcite and clay occurrences and the plugging of pores by these cements causes a final reduced porosity. As a result the turbidite sandstones of the Tanjero Formation cropping out to the northwest of Sulaimani have general poor porosity and a very good permeability.

Abstract—Drilling fluids are used in drilling operation for many reasons such as lubricating and cooling the drill bits, elimination of cuttings from wellbore, ensuring the stability of the hole and preventing crossflow of fluids between borehole and formation. Therefore selection of a convenient drilling fluid makes drilling operations easier and economical. For this purpose, researches have been concentrated on improving the related properties of drilling fluids by adding additives different in composition and size. In this study ultra fine micro-sized fly ash, which is the combustion product of coal fired power plants, is combined with drilling fluids in order to investigate the changes on rheologic and filtration properties of drilling fluids. Fly ash is mostly consists oxides of Silica (SiO_2), Alumina (Al_2O_3), Iron (Fe_2O_3), Calcium (CaO), Magnesium (MgO) and Sodium (Na_2O) respectively. Chemical composition of fly ash is determined by X-Ray Fluorescence (XRF) and X-Ray Diffraction (XRD). Fly ash is added to water based bentonite clay drilling mud in different concentrations (% 0.05, % 0.1, % 0.5, % 1, % 2, % 3, % 4, % 5 and % 10) (%w/v). Plastic viscosity (PV), yield point (YP), visible viscosity (AV) and gel strength are examined with Fann Viscometer as rheological properties, filtrate loss and filter cake thickness are examined with API fluid loss testing equipment as filtration properties.

Result of this study show that addition of fly ash into water based drilling fluids improve filtration and rheological properties of drilling fluids. Use of fly ash provides benefits both in environmentally and economically since a waste combustion by product is utilized and circulating fluid amount is saved by decreasing fluid loss to formations.

Keywords—Fly Ash, Drilling Muds, Rheological Properties, Filtration Properties.

The Evaluation Of Hydrochemical, Geothermal Energy Potential And Balneotherapy Of The Some Important Geothermal Waters, Central Anatolia, Turkey

Abstract— *There are many geothermal waters with low-middle enthalpy in central Anatolia. In this study, some important geothermal waters in Nevşehir, Kırşehir, Aksaray, Nigde, Kayseri geothermal fields were evaluated for origin, geothermal energy potential and balneotherapy point of view.*

The basement of the fields forms metamorphics which comprise marble, gneiss and quartzites in ages Paleozoic. These units are overlaid by different units from Cenozoic to Quaternary age. Occurrence of the waters is mainly related to tectonism and volcanism. The primary and secondary aquifers of the geothermal waters are of marbles (Paleozoic in age) and limestones (Tertiary in age), respectively.

Types of waters are Na-Cl-HCO₃ for the long circulating groundwaters (Kemerhisar, Incesu, Kozakli, Ziga) and Ca-Na-HCO₃-Cl for relatively shorter circulating groundwaters (Bayramhaci, Terme, Narligöl). The sources of dominant ions of Ca²⁺ and HCO₃⁻ in the waters are mainly related to the high CO₂ contents resulting from interactions with the carbonate rocks; whereas, the high Na⁺ concentration is derived from the increasing of albites in volcanic rocks, by ion exchange occurred between the tuff, clay, sandstone and granites/syenites. Na⁺ and Cl⁻ in some geothermal waters are increased as a result of short contact time with evaporitic sequences (halite etc.) and also paleowaters in the old basins.

All the waters are of meteoric origin according to isotope analyses (18O, 2H, 3H), and cold waters have shallow and fast circulation, and geothermal waters have relatively deep and low circulation. The deviation of some waters from global meteoric water line is mainly due to the high CO₂ contents and increase the δ18O values as a result of water-rock interaction. 14C ages of the waters are not real ages of the waters, but they are the measures of contribution of modern biogenic carbon in total dissolved carbonate or bicarbonate. 14C apparent values of the waters are increasing from young waters to old waters, whereas per cent modern (pmc) carbon and 3H values are decreased in the same order. The sources of CO₂ in the waters may suggest freshwater carbonate, marine carbonate and metamorphic according to the results of δ13C. The origins of δ34S in the waters may atmospheric, evaporitic, volcanic and/or carbonate rocks.

The estimated reservoir temperatures (50-123°C) of the rock of the geothermal waters by silica geothermometers denote the higher geothermal energy potential of these waters. Heat sources of these geothermal systems are geothermal gradient, volcanism and granite/syenite intrusions in the areas.

This region has the natural possibilities for the human health protection and treatment of diseases. These geothermal waters have capacity for specific applications in balneoclimatherapy; Aksaray city having the highest open air curative summer day with 175.5 days over 20°C. Kayseri city is favorable for healthy persons and sportsmans due to the high actinic stimulant. In this connection, all the geothermal waters comprising dominant ions such as Na, Cl, HCO₃ and CO₂ are also useful for the treatment of psoriasis, some gastrointestinal, metabolic, urinary trac, some rheumatological and dermatological disorders in balneotherapy-climatherapy. Controlled clinical studies are required especially for long-lasting benefits.

Abstract—Wellbore instability is the most important problem in drilling operation, especially in high temperature and pressured shale formations. This problem can be accomplished in drilling industry with the help of nano particules like that nano zeolites. Nano zeolites can bring benefit to the industry in various manners such as improving the quality of mud cake, decreasing the frictional resistance in the well, minimizing the risk of pipe sticking, improving rheological properties, preventing reservoir from formation damage. For this purpose, in this study, effect of nano zeolite addition to drilling fluid is investigated in terms of rheological and filtration properties. Nano zeolites that planned to be added to drilling fluids, are the alumino silicate members of the family of microporous solids known as "molecular sieves" mainly consisting of Si, Al, O, and metals including Ti, Sn, Zn, and so on. Additionally, nano zeolites at different concentrations (% w/v) to improve the drilling fluid of water based bentonite added. The rheological behavior, the filtration loss property, pH and density test of each drilling fluid developed is measured using API recommended standard procedures. The rheological properties like that visible viscosities (AV), plastic viscosity (PV), flow-point (YP), gel strength, of the nano-zeolite-added mud were measured using with fann viscometer. Also, the filtration, pH and density test were also carried out using an API Filter Press, pH meter and mud balancer respectively.

As a result of this study; it was found that the nano-drilling fluid has better rheological properties when compared to the results of the water-based bentonite drilling fluid and the nano-zeolite-added drilling fluids. It was also observed that the loss of filtrate was reduced and the filtrate cake thickness decreased.

Abstract—Genetic Algorithm (GA) is an effective nonlinear inversion method. In this paper, we combine the micro-seismic and GA to inverse the acoustic emission locations. A 3D synthetic model is set and solutions are achieved through the establishment of two objective functions. Contrast their accuracy and convergence speed, we find that their differences of error ratio can be about 2.7 times and the one of time costing can be triple times. Basing on the result, we chose objective function II for field data. From the application of a certain curve well, we clearly know about the crack growth direction. The spatial distributions of three fracturing sections are demonstrated in different views. The fractures are all concentrated at corresponding perforations, but form to different directions. We believe it can provide the basis for evaluation and adjustment of fracturing schemes.

Keywords—GA; hydraulic frecturing; inversion; micro-seismic

I. INTRODUCTION

Genetic algorithm (GA) is an adaptive technology, of which probabilistic search approach increases the flexibility of computing process, and also a progressive global search method. From 1960s, Professor J. Holland and his students from the University of Michigan began a series of studies [1]. Then into the 1990s, GA ushered in a prosperous period of development. Since it does not need to calculate the derivative of objective functions in the optimization search process with GA, especially for the discrete problem, nonlinear problem and optimization of complex issues which cannot be explicitly represented by functions, so in various fields GA has been widely used [2]. Since 1995, researchers began to use GA for solving the problems of Geophysics as follows [3]: residual statics in the seismic survey [4-5], parameters inversion in the multi-layer density interface [6], anisotropic elastic parameters calculation [7], speed parameters inversion [8-9], wave impedances inversion [10], Amplitude Versus Offset (AVO) [11], bending ray imaging [12], multi-electrode resistivity logging and 2D magneto-telluric [13], estimation of logging interpretation parameters [14-17] and so on. Wang discussed the effect of GA used in micro-seismic [18].

On the other hand, the micro-seismic monitoring began from the mining industry in the 1940s and in the 1990s, the data processing has made great progress. Theoretically, with the observation and analysis of small seismic events, the source location of micro-seismic and causative events can be determined, thus the spatial distribution and geometry of

fracture in the fracturing process can be described. In the process of exploration and development of oil and gas reservoirs, using micro-seismic monitoring technology can optimize the low permeability injection and production programs, reduce the development costs and increase the oil and gas production. It has become an effective way to solve the short supply problem of oil and gas production at present.

Based on the above, this paper combines the GA and micro-seismic to portray the hydraulic fracture

II. SYNTHETIC DATA INVERSION

The ultimate goal of hydraulic fracturing micro-seismic is to determine the spatial distribution and development of fractures, which is a nonlinear inversion problem. GA is used to calculate the source distribution of a three-dimensional layered medium model as follows.

A 3D layered micro-seismic model is shown in Figure 1. Where, the (x_s, y_s, z_s) is the micro-seismic source location; t_s is the event's break time; (x_i, y_i, z_i) , $i=1, \dots, n$ is the coordinate of the i th detector respectively; t_i indicates the time when the event is monitored at all levels of detectors; t_{si} is the theoretical value, which represents the travel time between the layers from the micro-seismic source to the i th detector computed with the piecewise Ray Tracing method.

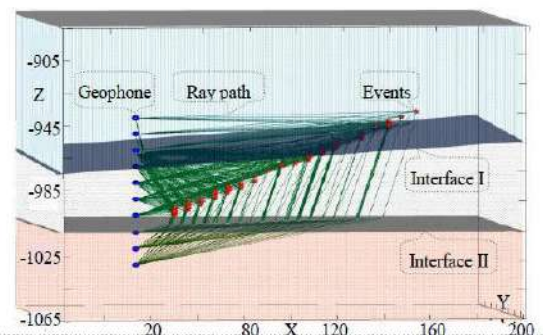

Fig. 1. 3D layered micro-seismic model

The fracture parameters are: the fracture development azimuth angle is 30 degrees and the dip angle is 5 degrees; the speed of the fracture developing in the reservoir is 1m/s. The fracture center is (100, 200, -1,000); the focal complex distribution is the range of 5m at the fracture surface. The

detector parameters are: the plane coordinates are all (20, 219); the Z-axis of the first detector is -940 and that of the tenth one is -1,030, as the interval is 10m. There are 5,000 sampling points in the forward micro-seismic record and the sampling rate is 500ms; the location and origin time of each event generate randomly. In order to be more realistic, the random noise is added to the forward modeling process. One event is shown in Fig. 2. X, Y, Z component are shown on the left, center and right side, respectively.

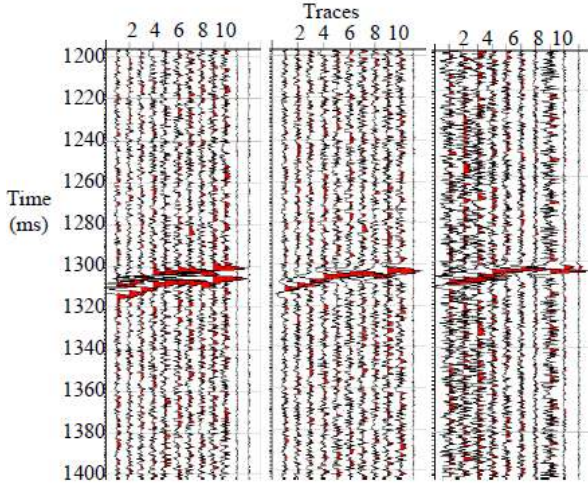

Fig.2. One event of hydraulic fracturing (Left: X component; Center: Y component; Right: Z component)

To one micro-seismic event, there is the following relationship between time parameters:

$$\Delta t_i = t_i - t_{si} - t_s \quad (1)$$

And the theoretical traveling time can be written as:

$$t_{si} = \sum_{j=1}^{m-1} \frac{\sqrt{(x_i - x_{ij})^2 + (y_i - y_{ij})^2 + (z_i - z_{ij})^2}}{v_j} + \frac{\sqrt{(x_m - x_s)^2 + (y_m - y_s)^2 + (z_m - z_s)^2}}{v_m} \quad (2)$$

Where x_{ij} , y_{ij} , z_{ij} are the coordinates of the j th ray path between the i th detector and source, v_j is the formation velocity where j th ray is traveling in; and m is the number of layers where the rays pass through

The nonlinear equation (objective function I) of the seismic source and the origin time can be presented as follows:

$$\max : F(x_s, y_s, z_s, t_s) = \sum_{i=1}^{10} |\Delta t_i| = \sum_{i=1}^{10} |t_i - t_{si} - t_s| \quad (3)$$

The amounts to be solved in (3) are the coordinates of micro-seismic source and the origin time. They can be gotten when the known parameters are brought into this Formula.

On the other hand, taking into account the negative impact of the origin time on the results, by minimizing the time between the adjacent detectors, we establish the objective function II:

$$\begin{aligned} tt_i &= \Delta t_{2i} - \Delta t_{2i-1} \\ &= (t_{2i} - t_{s2i} - t_s) - (t_{2i-1} - t_{s2i-1} - t_s) \\ &= (t_{2i} - t_{2i-1}) - (t_{s2i} - t_{s2i-1}) \end{aligned} \quad (4)$$

GA is used to make optimization. The calculation process and parameter settings are shown as below, respectively:

Population: 5

Crossover way: Single-point;

Crossover probability: 0.8;

Mutation probability: 0.05;

Range of X offset (m): $0 \leq x \leq 200$;

Range of Y offset (m): $0 \leq y \leq 300$

Range of Z offset (m): $-800 \leq z \leq -1200$;

Range of $t_s \in$ (Automatic picking time ± 20)

Remarks: Phase Only Corresponding method is applied for Automatic time picking.

For the established objective function I, the optimal fitness function change curve can be gotten after 600 iterations with GA, as shown in Fig. 3. While, for objective function II, the optimal fitness curve can be gotten with 200 iterations (Fig. 4). It can be seen that, the objective function II is convergent only after 50 iterations, so the convergence rate is 3 times faster than that of the objective function I.

Fig. 3. Fitness curve of objective function I

What is worth mentioning is that, due to the model using a single vertical monitoring well, it is unable to determine the real plane coordinates (x, y) of seismic sources. Therefore, in the inversion, X and Y components are directed by the Covariance Matrix method. Therefore, the optimal solution can be obtained finally. Take the fracturing center (100, 200, -1,003) as an example, the output results of objective function I and II are (98.8623, 201.8541, -1,003.2147) and (100.1324, 200.7530, -1,003.2639), respectively, both with less calculation errors. However, the objective function I has a 3D spatial error of 2.1858m, and the latter one is 0.8088m. The error ratio is 2.7025.

Fig. 4. Fitness curve of objective function II

Comparing the inversion values between the above two objective functions, we can see that the positioning results of the objective function II is closer to the theoretical value with a higher accuracy and a faster convergence rate. And the origin time of the seismic can be solved with known data and calculated source value. Therefore, the establishment and selection of the objective function should be considered, and this paper will choose the objective function II to do the inversion of source location for the real micro-seismic.

III. APPLICATION IN FIELD DATA

In order to check the effectiveness of GA to field micro-seismic data, we chose a certain area. There are two wells, one is for fracturing and the other one is for monitoring. Both of their depths are more than 2,200m. And the wellhead distance between fracturing well and monitor well is 713m, while, the target distance is 219m, because the wells are not vertical. In the fracturing well, three fracturing sections are designed as 2,187-2,191m, 2,176-2,179m, and 2,159-2,163m, respectively. Ten geophones are set in the monitoring well from 2,173 to 2,083m, with the interval of 10m.

The initial layered medium model is built based on logging data and the times of events are automatically gained based on Phase Only Correlation method. Then, according to the objective function II (seen in (4)), the fracture spatial distribution of fracturing section I is inverted. We demonstrate different plane pictures: the top view (X-Y direction) is in Fig. 5, the lateral view of (X-Z direction) can be seen in Fig. 6, and the lateral view of (Y-Z direction) is shown in Fig. 7. Meanwhile, the total events are calibrated in the 3D graph of Fig. 8. With respect to the results, we can see that, the fracture has a specific direction, with the azimuth of 32 degrees north by west. Most of the events are concentrated nearby the corresponding fracturing section.

Then, the positions of the other two fracturing sections are solved as the same as the section I. The total fracture positions are gained. Fig. 9 represents the plane view of fracture spatial distribution of three fracturing sections, which is along the direction of the two wells connection. This is a good evidence to evaluate the effect of hydraulic fracturing. According as the distribution, we could say that the construction meets the original expectations. Otherwise, the total positions of fracturing events can be seen from Fig.10. It's a comprehensive top view. Through observation we know that all the three fracture are happened around perforated intervals. Each fracture development has specific direction.

Fig. 5. Top view of inversion for fracturing section I (X-Y direction: X axis points to the east direction of the geography, and Y axis represents the north direction of the geography)

Fig. 6. Lateral view of inversion for fracturing section I (X-Z direction: Z axis is the depth)

Fig. 7. Lateral view of inversion for fracturing section I (Y-Z direction: Y-north direction; Z-depth)

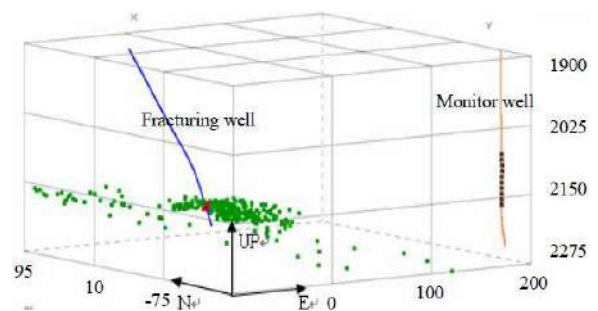

Fig. 8. 3D graph of fracture spatial distribution of fracturing section I

According to the positions of all acoustic events, we can get the fracturing parameters. And the total solutions are summarized and shown in Tab. 1. The accuracy of the fracturing parameters is proved by the subsequent mining process.

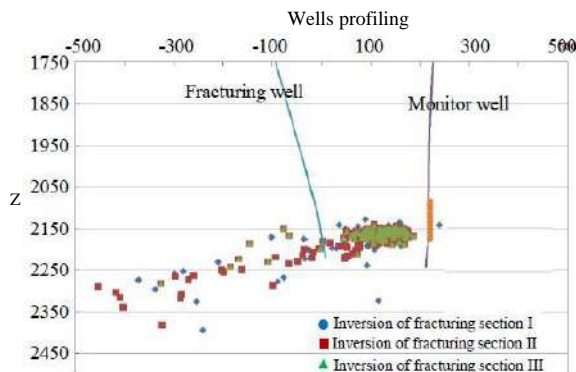

Fig. 9. Plane view of fracture spatial distribution of three fracturing sections (Along the direction of the two wells connection)

Fig. 10. Comprehensive top view of fracture spatial distribution of three fracturing sections

Tab. 1. Summarized fracturing parameters of three sections

Fracturing Section			I	II	III
Fracture azimuth			32° N by W	8° N by E	72° N by W
Depth domain	Thickness (m)	maximum	250	260	160
		average	175	100	85
Plane domain	Length (m)	maximum	250	125	250
		average	150	75	100
	Width (m)	maximum	40	20	35
		average	20	15	25

IV. CONCLUSIONS

This paper is focused on fixing positions of micro-seismic events during hydraulic fracturing based on GA.

We establish two different objective functions and inverse sources for a 3D layered synthetic data. Comparison results show that differences are produced not only in the accuracy but also the convolution speed. In this example, the error ratio could run up to 2.7025, and time-costing reaches a difference of 3 times. So, we should consider and choose the reasonable one even for the same question. After that, a field micro-

seismic data is also processed. From a series of different views and the total solutions, we could evaluate the fracturing effect. While, it should be pointed out that, the inversion progress is somewhat too simple. As the properties of hydraulic fracturing mediums are often unknown and not elastic, but exist attenuation or porous, the corresponding wave-fields are complex. Therefore, more parameters should be introduced to describe reservoirs more accurately. And wave equation should be combined. Taking these as the basis and establishing suitable objective function is the future subject.

Abstract—The study area is located in the Derindere drill hole, around Bismil, Diyarbakır, southeast of Turkey. Investigated Early Silurian-Early Devonian organic rich Dadas Formation is one of the main source rocks for oil. Formation consists of grayish-green, organic-matter rich dark colored shales, limestones, mudstones and sandstones. Samples were collected from the Derindere drill hole. Element analysis of 20 representative samples were carried out, using ICP-AES for the determination of major and trace elements. 20 total organic carbon (TOC) analysis was performed by the pyrolysis method using the Rock-Eval 6 analyzer. Al_2O_3 , Fe_2O_3 , Na_2O , TiO_2 and Cr_2O_3 , Sc, Ba, Co, Cs, Ga, Hf, Rb, Nb, Ta, Th decrease at the between 3000-3020 m. showing lower detritic contribution at these levels. On the other hand CaO is higher at these levels show carbonate occurrences. Cu, Pb, Zn, As sulphophile elements are lower at the 3060. meter showing lower sulphide minerals at these level. TOC values increase between 2890–3070 meters. These variations in elements and TOC concentrations reflect changes in paleoclimate, paleoredox and paleoproductivity in Paleozoic sedimentation. The positive correlations between SiO_2 , Al_2O_3 , Cs, Ga, Nb, Rb, Ta, Th, Sc reflect silicates and, positive correlations between Cu, Pb, Zn, Ni show sulphide occurrences. Negative correlations of TOC and SiO_2 , Al_2O_3 , Fe_2O_3 reflect that these elements depend on silicates than organic materials. The correlations between Ga, Rb, Ta, Th and TOC show detritic silicate- organic material discriminations.

Abstract— Red-bed type Cu deposit between Delice and Terzili villagers is associated with stratiform sedimentary basin (Oligo-Miocene) and co-existing with evaporites. The red-bed type Cu deposits are in the form of layers and lenses and formed in red, brown, purple sandstones, mudstones, conglomerates and shale layers. The color of the ore zones is green, gray and greenish grid.

For the biogeochemical studies around the Delice and Terzili Cu mineralizations, collected samples of *Euphorbia cyparissias* (sparrow) which grows naturally in the region and analyzed by ICP-MS. The obtained results were evaluated statistically. The mean Cu value of this plant in the stems, leaves and associated soil are 413.6 mg/kg, 123.3 mg/kg and 70.4 mg/kg.

In this study, it was determined that there is a positive correlation between Cu concentrations in the leaves of *Euphorbia cyparissias* (*E. cyparissias*) plant and Cu concentrations in the soils ($n = 10$, $r = 0.42$) for Cu concentrations. Accordingly, it can be said that the leaves of *E. Cyparissias* plant may be the indicator plant for Cu. The mean enrichment coefficient of this plant stems and leaves is 0.48 and 0.27 and is less than 1. This coefficient indicates that the plant may be a medium-bioaccumulator plant for Cu. It can be said that *E. cyparissias* plant can be used for ore exploration by biogeochemical method, for improving contaminated areas by Cu (phytoremediation) and environmental pollution.

Keywords— biogeochemistry; bioaccumulator; indicator; Red-bed; soil

I. INTRODUCTION

Oligo-Miocene aged Red-Bed copper (Cu) deposits are a type of stratiform sedimentary beds [1], [2], which are associated with evaporites. In Turkey, red-bed type Cu deposits are located around and in the Yozgat, Çorum, Çankırı, Sivas [2]. In these beds, the ore is in the form of lenses and thin plates in red-colored levels [3].

Red-bed type Cu deposits are formed in red, brown, and gray sandstones, mudstones and shale layers. The red color of the side rocks of these deposits is due to the deposition of hematite and limonite around the grains as a result of the oxidation of $Fe + 2$ to $Fe + 3$. The color of the lens and layer of the ore in the reductive environment is green and greenish grid. The thickness of these ore deposits varies from mm to meters and the width is extended for kilometers [4].

There are three different views on the formation of red-bed type copper deposits: syngenetic, diagenetic and epigenetic. According to the synergetic view, mineralization has taken the form of stratiform [5], [6], [7], [2]. According to the epigenetic view, the mineralization has taken place after precipitation due to diagenesis [4], [8], [9], [3]. Some researchers [10] suggest that this mineralization is similar to the formation of "roll-type" uranium deposits. According to the diagenetic view, the ore melts are found in the sedimentary environment. Because, as a result of the melt and gases filling the space between pre-deposited materials, ore minerals have formed.

In this study, elemental analysis of collected *E. cyparissias* plant (stem and leaf) and soil samples related to this plant were done. By statistically evaluating the analysis results the correlation coefficient between the elements, plant organs with high accumulation of metal in the structure, indicator plants and biogeochemical relationships between plant and mineralization were determined.

II. GEOLOGY

The age of the Red-bed type Cu deposits ranges from Precambrian to Pliocene (probably Quaternary). Especially Precambrian aged have metamorphism in these deposit. However, the deposits in Turkey were not affected by metamorphism since the original sedimentary features and structures were not damaged. Delice – Yerköy Cu deposit (Fig. 1) is located in Bayat Formation in Çankırı Basin. In Fig. 2, Bayat Formation (Middle-Upper Eocene), Kocaçay Formation

(Upper Eocene), İncik Formation (Upper Eocene-Middle Miocene), Kızılırmak Formation (Upper Miocene), Bozkır Formation (Middle Miocene), Yoncalı Formation (Late Paleocene - Middle Eocene) and Yozgat magmatics (Late Cretaceous) [12]. [13] named Bayat Volcanics as Yozgat Volcanics. These researchers have suggested that andesites, basalts, basaltic andesites and dacites are volcanic.

Fig. 1. Location map of the study area and its surroundings.

Fig. 2. The geological map of the study area ([11])

III. MINERALIZATION

The mineralizations in the study area are in the form of thin beddings and a wide field survey, indicating that these deposits are semi-economic deposits [3]. The samples taken from ore zones between Delice and Terzili indicate that these deposits originate from Lutetian volcanic rocks. The high concentration of Ag and Cu in these rocks, such as andesite and basalt, and the high U in rocks such as rhyolite, support this view [3]. It is known that such deposits are closely related to the evaporites. For this reason, evaporites occur along with mineralization and around the mineralization [14]. The main minerals in these beds are; Pyrite, chalcopryrite, chalcocite, bornite, native copper, native silver and uraninite. In addition, the secondary minerals are azurite, malachite, covellite and cuprite. Gangue

minerals are iron oxide minerals, gypsum, anhydrite, dolomite, quartz, feldspar, chlorite, illite and barite [3].

IV. SAMPLING AND ANALYSIS METHODS

Samples of *E. cyparissias* plants were collected from the study area (Fig. 3) and brought to the laboratory. The collected samples were separated into their branches and leaves and washed first with tap water and then with distilled water. The plant samples dried at room temperature are then completely dried by recovering from moisture the sample at 95 °C for 24 hours. From these dried samples, ash was obtained by burning flamelessly up to 550 °C, starting at a temperature of 50 °C and increasing a temperature of 50 °C per hour.

Fig. 3. A view from the plant cyperissias (a) Example no: 1 and (b) Example no: 3

Samples from the soil associated with the plant of *E. cyparissias* were taken from the study area and bagged. The samples brought to the laboratory were dried at room temperature by passing through a 2 mm sieve. 0.10 g of ash and 2 ml of concentrated HNO₃ were added to the soil samples and dried by heating at 95 °C in microwave for 1 hour. The dried samples were added after cooling to a mixture of 2 ml of HNO₃ and the prepared HCl-HNO₃-H₂O (6 ml of each 1: 1: 1 mixture and 0.10 gr of ash and soil sample). The resulting mixture was diluted with pure water to 50 ml and the calculations were made according to the final volume.

BILTEM (Bozok University, Science and Technology Application and Research Center) with elemental analysis of Cu, Ag, Co, Mo, Ni, Se, Pb, U, V and Zn of soil and plant samples, Inductively Coupled Plasma Mass Spectrophotometer (ICP- MS), Yozgat, Turkey.

V. CONCLUSIONS AND DISCUSSION

The results of the analysis obtained from samples of *E. cyparissias* planted and its surroundings and in the Delice-Terzili related soil samples were evaluated statistically and the results are given in Table 1.

The elemental concentrations of soil samples were Sb: 941.08 mg/kg (mean), As: 37.43 mg/kg (mean), Cu: 403.25 mg/kg (mean), Pb: 21.09 mg/kg (mean), Mn: 922.6 mg/kg (mean), Ni: 101.34 mg/kg (mean), Se: 133.96 mg/kg (mean), Ag: 2.51 mg/kg (mean), Th: 7.51 mg/kg (mean), U: 1.88 mg/kg (mean), V: 90.8 mg/kg (mean) ve Zn: 170.99 mg/kg (mean) (Table 1)

In soil samples indicated by [9] Sb: 2 mg / kg, As: 7.5 mg / kg, Cu: 15 mg/kg (mean), Pb: 17 mg / kg (mean), Mn: 320 mg/kg, Ni: 17 mg/kg (mean), Se: 0.31 mg/kg (mean), Ag: 0.1 mg/kg (carbonated rock), 0.25 mg/kg (sandstone), 0.19 mg/kg (shale) (mean), Th: 13 mg/kg (mean), U: 1 mg/kg (mean), V: 57 mg/kg (mean) ve Zn: 36 mg/kg (mean). In the case of soil samples specified by WHO (World Health Organization) Ni: 0.15-1.03 mg / kg, Cr: 4.12-6.74 mg / kg, Cu: 0.54-1.50 mg / kg, Pb: 0.06-0.46 mg / kg, Fe: 0.0143-0.0313 mg / kg, Zn: 0.03-0.35 Mg / kg [15].

Element values of soil samples in the surrounding and Delice-Terzili according to the specified element values can be considered as anomalous values (except for Th; according to [9]).

In plant ash samples specified by [9] Sb: 1 mg / kg, As: 0.25 mg / kg, Cr: 6.3 mg / kg, Co: 5 mg / kg, Cu: 130 mg / (mean), Fe: 0.16% (mean), Pb: 30 mg / kg, Mn: 6700 mg / kg, Ni: 18 mg / (mean), V: 5 mg / kg (mean) and Zn: 570 mg / kg (mean): 0.1-1 mg / kg, Th: 20 µg /kg. The maximum amount of Ni: 10 mg / kg [16], Cr: 1.30 mg / kg, Cu: 10 mg / kg [16], Pb: 2 mg / kg, Fe: 0.0020% [17], Zn: 50 mg / kg [17] [15].

While it is found in the stem of *E. Cyparissias* plant (mean) Sb: 645.12 mg / kg, As: 28.16 mg / kg, Cr: 6.22 mg / kg, Co: 6.56 mg / kg, Cu: 125.1 mg /kg, Fe: 0.57%, Pb: 6.61 mg / kg, Mn: 258.97 mg / kg, Ni: 52.12 mg / kg, Se: 68.64 mg /kg, V: 15.54 mg / kg and Zn: 111.87 mg / kg in the range of Ag: 0.98-4.25 mg / kg, Th: 1.04 mg /kg, in the leaf of this plant (mean) Sb: 726.22 mg / kg, As: 16.56 mg / kg, Cr: 68.26 mg / kg, Co: 5.39 mg / kg, Cu: 69.95 mg /kg, Fe: 0.66% (mean), Pb: 4.49 mg / kg, Mn: 483.61 mg / kg, Ni: 408.36 mg / kg, Se: 75.48 mg/kg, Ag:8.89-32.65 mg/kg (range), Th: 1.22 mg/kg, U: 0.50 mg/kg, V: 25.69 mg/kg ve Zn: 13.75 mg/kg (Table 1).

In the stem of the plant samples taken in the study area (maximum) Ni: 97.65 mg/kg, Cr: 8.86 mg/kg, Cu: 150.8

mg/kg, Pb: 8.35 mg/kg, Fe: 0.68 %, Zn: 210.14 mg/kg and in the leaf Ni: 546.66 mg/kg, Cr: 181.6 mg/kg, Cu: 89.6 mg/kg, Pb: 5.78 mg/kg, Fe: 0.78 %, Zn: 138.84 mg/kg (Table 1).

In the stem of the plant taken from the study area Sb, As, Co, Fe, Ni, Se, Ag and V (according to [9]), elemental values in the leaf Sb, As, Cr, Co, Fe, Ni, Se, Ag, Th and V (according to [9]) and the values of Ni, Cr, Cu, Pb, Fe and Zn in both the stem and the leaf (according to [15]) show anomaly values according to the above values. It is thought that these elements, which show anomalies in the soil, stem and leaf, have similar dissolution, migration and sedimentation.

Sperman Correlation Coefficients (rs) show similar behavior of element pairs in ore deposits. Correlation coefficient values are negative in some element pairs in some element pairs. These movements can also have meaning as origin. Positive correlation values indicate that element pairs increase or decrease together, that is, they move together, while negative correlation values indicate that an element increases while the other decreases, that is, they move in opposite directions [17].

When we look at Sperman correlation relations among the elements in the soil samples collected in Terzili and its surroundings; a high positive correlation was observed between the two groups, Al-Cr (rs:0.77, p<0.01, % 99 confidence), Co-Ni: (rs:0.89, p<0.01, % 99 confidence), Cu-Fe (rs:0.89, p<0.01, % 99 confidence), Mn-Sb (rs:0.87, p<0.01, % 99 confidence); Al-Mn (rs:0.66, p<0.05, % 95 confidence), Al-Sb (rs:0.75, p<0.05, % 95 confidence), Co-Se (rs:0.71, p<0.05, % 95 confidence). There was a high negative correlation between Ag-Th (rs:-0.82, p<0.01, % 99 confidence), Fe-Pb (rs:-0.92, p<0.01, % 99 confidence); Cu-Pb (rs:-0.76, p<0.05, % 95 confidence), Th-U (rs:-0.71, p<0.05, % 95 confidence).

Correlation coefficients between the soil-stem and the soil-leaf of the *E. cyparissias* plant growing in the surrounding and Terzili are shown in Fig. 4. In this study, positive correlation was found between values in the stem of *E. Cyparissias* plant

and values of soil for As, (n = 10, r = 0.92, P <0.01, 99% confidence), Sb (n = 10, r = 0.76, P < 0.01, % 99 confidence) and Pb (n = 10, r = 0.53, P < 0.05, % 95 confidence). Accordingly, it can be said that the stem of *E. cyparissias* plant may be the indicator plant for As, Sb and Pb.

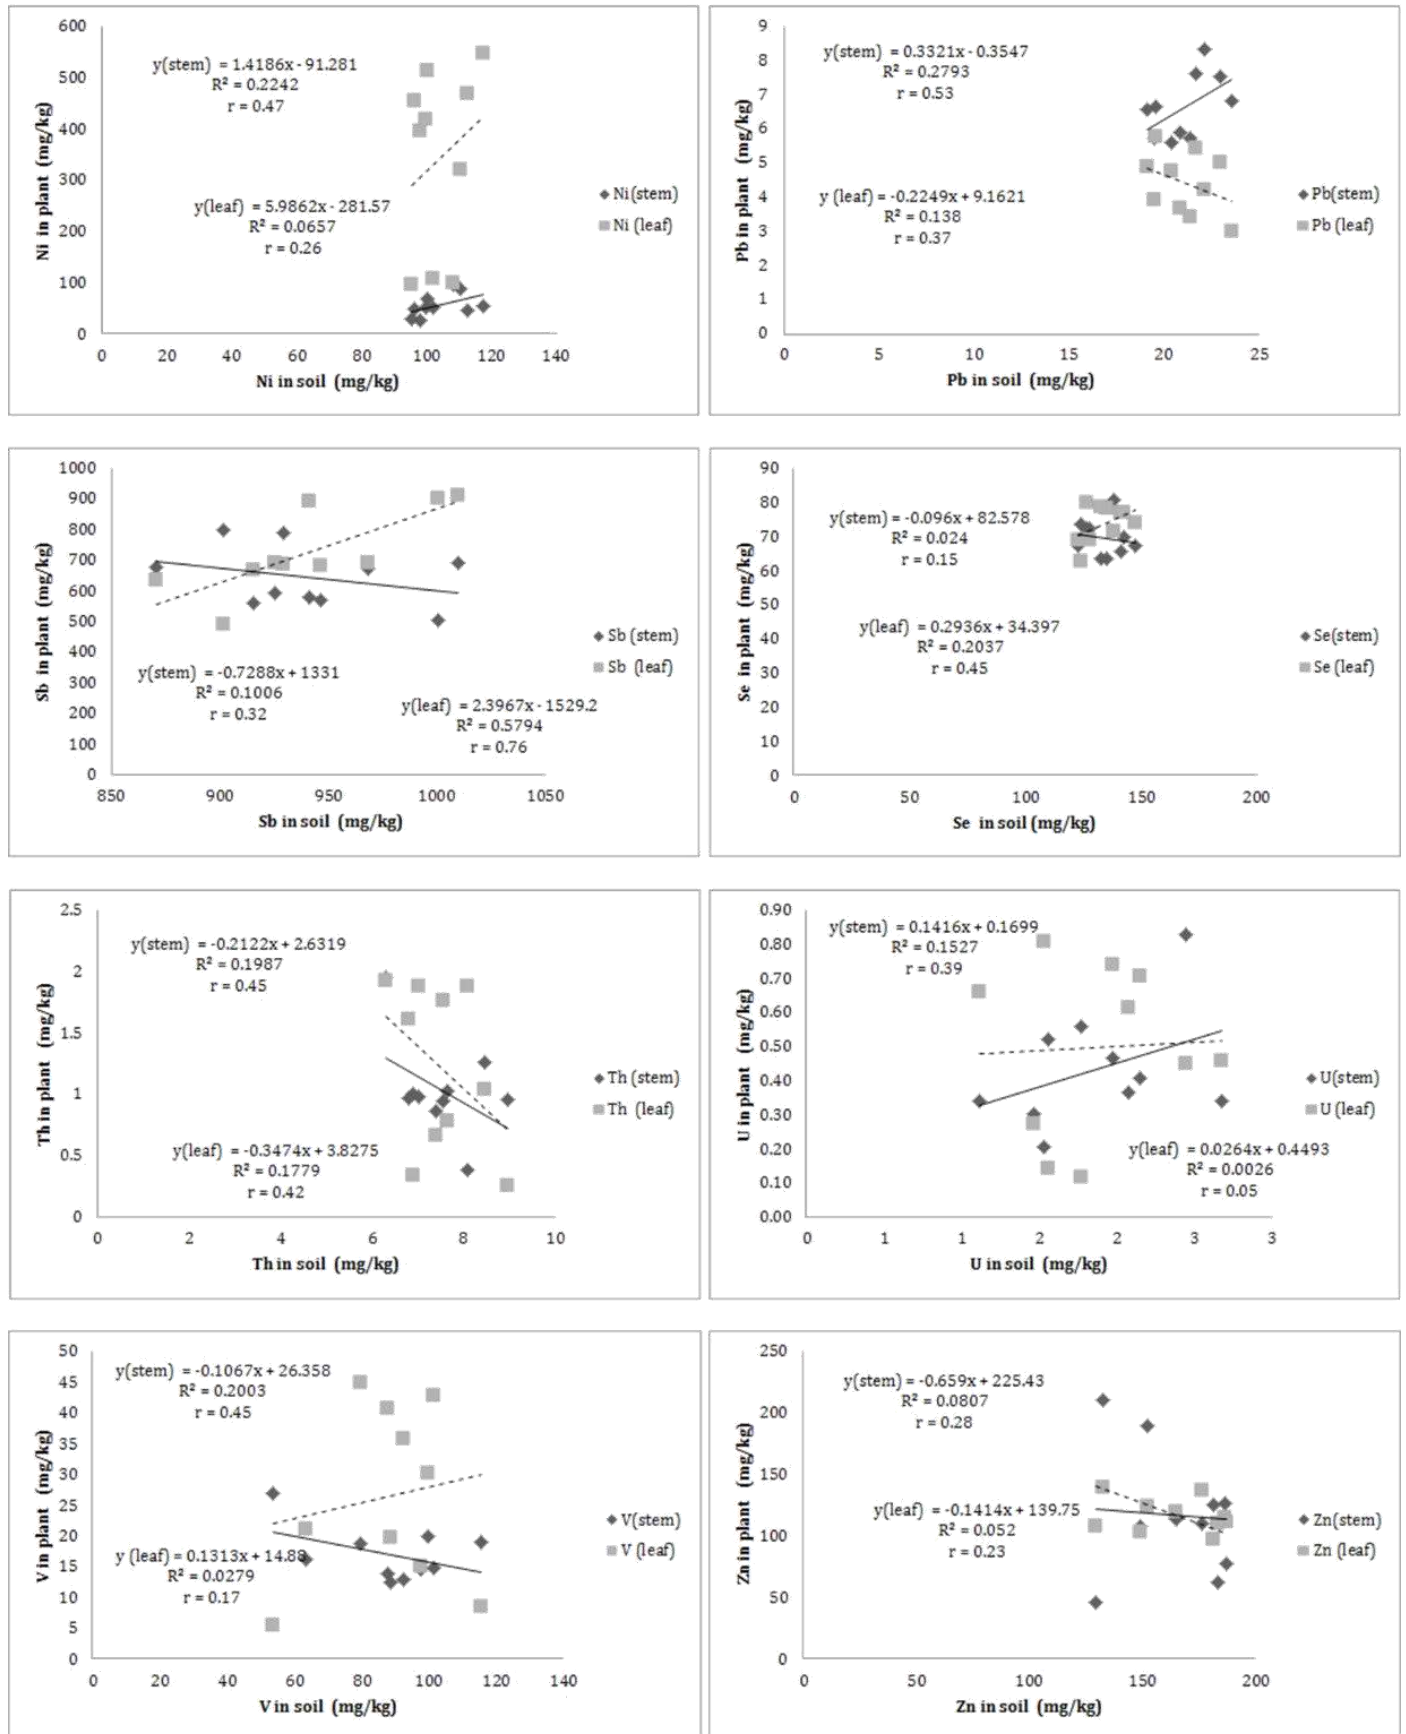

Fig. 4. Correlation between soil-stem and soil-leaf of elements of *E.Ciparissias* plant

ACKNOWLEDGMENT

This work was supported by the project BAP Unit 2015 MMF / A181. Analyses of plant and soil samples were carried out at BILTEM (Bozok University, Science and Technology Application and Research Center) (Yozgat, Turkey).

Abstract –Designing the occupational health and safety management system for the small-scale industries is more challenging due to their limited plant space and other constraints. The essential for the proper implementation of occupational health and safety management system in any of the industry is based on risk identification process in relation to the overall system. Therefore, occupational health and safety management process depends upon the scope of the industry as it varies according to the functions and scale. In this study, the application field has been chosen small-scale marble factory which state in Turkey that have been exposed to different types of occupational hazards in the workplace. The risks in considering marble plant can be determined by failure mode and effects analysis (FMEA) method, since FMEA is a widely used engineering technique for designing, identifying and eliminating known and/or potential failures. For this purpose, firstly, the general information and methodology are given, then the risk priority indicator has been calculated and all failure types have been ranked according to the risk priority. The purpose of this study is to propose an alternative layout by considering the determined risks and their priority. Finally, current layout and proposed layout are compared in terms of the requirements of worker health and safety regulation. As a result, it is found that “current layout” is more risky than “proposed layout” for the marble factory. In this way, the hazards and risks in terms of layout occupational health and safety management can reduce at acceptable levels by applying the proposed layout.

Abstract — The different chaotic methodologies are applied to identify possible chaotic behaviors of soil radon gas and related earthquake magnitudes. Relations between magnitudes of earthquakes and the radon concentrations are non-linear, and therefore, the radon emissions exhibit chaotic behaviors. In order to depict the nonlinear relationship between the radon concentrations and earthquake qualitative and quantitative chaotic time series analysis methodologies are employed including Lyapunov exponent and power spectrum analyses by using FIR (Finite Impulse Response). This study used that signal process techniques and showed nonlinear behavior of ^{222}Rn gas.

Keywords—Chaos Analyses, Radon, Earthquake, Radon time series, Lyapunov exponent, FIR (Finite Impulse Response).

I. INTRODUCTION

Earthquakes are complex natural events and their generation mechanism's explanation is one of the most difficult problems in geophysical sciences. In order to understand dynamical, mechanical, chemical and other aspects of earthquakes is important on the one hand for scientific developments and on the other hand for the society alert Earthquake behaviors are, in general, among the non-linear topics of physics. Unfortunately, researches could not yet propose a complete mathematical model for earthquake behavior prediction, due to the non-linear behavior of earthquakes under a set of dependent factors [1]. Among such factors are strain, fault creep, tilt, foreshocks sequences, underground water, seismic wave velocity changes and oil flow, earth currents, radon variations, and geomagnetic effects [2,3].

Soil gas radon concentration measurement are the most commonly used indicator in earthquake prediction studies. The most significant isotope of radon gas is ^{222}Rn , which has half-life 3.82 days. It is produced in the radioactive decay series of ^{238}U and tends to migrate from its source mainly upwards in the earth crust [4].

Chaotic systems cannot be estimated by random variability, because they are the deterministic factors. The reason why the chaotic systems are unique is due to their sensitive dependence on the initial conditions. Even a slight change in the initial

parameters of the system may cause entirely different trajectories [5]. There are various methodologies for detecting the chaotic behavior of any system.

II. MATERIAL AND METHODS

A- FINITE IMPULSE RESPONSE (FIR)

The time series obtained from a nonlinear dynamic system can be used to reconstruct the phase space of the system, but if the time series obtained from the nonlinear dynamic system is passed through a linear filter, the phase space of the system can be reconstructed [6]. Noise is the dispersion of the signal to be transmitted by the obstacles or other effects that is encountered in the transmission channel, and getting the signal weaker in the other side in out of the desired range. It is obvious that it is produced by a kind of physical system showing noisy chaotic behavior. In order to eliminate the effect of these unwanted components on the mark, the so-called filters are used. Filtering is the process of intensifying the desired frequency values of the sign, undermining the unwanted frequency values. Finite impulse response (FIR) filters; It is a simple and effective structure in digital filter design, it gives fix results constantly in non-repetitive applications, it is easy to get results in linear phase.

They are often preferred due to their efficient use for multiple / fast and adaptive filter designs, the ability to specifically match amplitude responses to obtain easy-to-understand designs, the availability of some software and hardware specifically with FIR filters, and the low sensitivity of the quantization effect [7].

FIR, the sign in the filter bank applied to the input is divided into lower bands at different speeds. These markings are obtained after the signal processing techniques have been applied at different frequencies (at speeds). The use of window functions for FIR digital filter design is also well known, quite efficient and very convenient for processing digital signs. FIR filters with "Kaiser Windows" are user-friendly because of their adjustable parameters [7].

FIR filters have been shown in studies that do not alter the size and chaotic properties of the time-series signals. In support of this study, the ^{222}Rn signals were filtered using a FIR filter that passes the signals at a 10-degree-high frequency with a sharp cut-off frequency of 100 Hz to remove the noises.

B- TIME SERIES ANALYSIS AND CHAOTIC APPLICATION METHODS

Time series analysis is the most useful method of providing information about data. This method is used for visible of data. In this study were used Lyapunov exponent method and power spectrum method. Further, time series graphics are allowing us to see the trend of data [8].

While performing chaotic application the most frequently used qualitative methods power spectrum analysis and Maximum Lyapunov exponents. Power spectrum is used that a statistical based approach among quantitative methods. Also, Maximum Lyapunov exponent calculating is that determining the non-linearity.

Lyapunov exponents are defined as the exponential increase or decrease of minor perturbations on an attractor. Maximum Lyapunov exponent is one of the most descriptive methods. To define is used chaotic behavior in a system. Lyapunov exponent is very close to each other to monitor both the starting point that is based in different trajectories [9, 10]. Its sign gives information about the system dynamics. If exponential value is positive then system indicates chaotic behaviors [11]. Maximum Lyapunov exponent is calculated according to the following expression Equation (1).

$$L_{\max} = \lim \left[\ln \left[\frac{d(t)}{d(0)} \right] \right], \quad (1)$$

The Fourier power spectrum analysis is used for decomposition of a given time series into a set of regular orthogonal sine and cosine signal combinations at different frequencies. Fourier power spectrum is obtained by making use of the fast Fourier transform procedure [12]. If the system is chaotic then there is continuity in the power spectrum. Otherwise, there are jumps at a set of definite frequencies. In any time series existence of a wide band power spectrum indicates a definite peak implying chaotic behavior. Entirely random signals have random fluctuations around a constant level in the power spectrum. In Equation 2, for a given time series, the power spectrum is defined as,

$$\tilde{s}(f) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} s(t) e^{2\pi i f t} dt \quad (2)$$

where $s(t)$ is a function, Equation 3 is defined squared modules.

$$\tilde{s}_k = \frac{1}{\sqrt{N}} \sum_{j=1}^N s_j e^{2\pi i k n / N} \quad (3)$$

The power spectrum of a process is defined as the squared

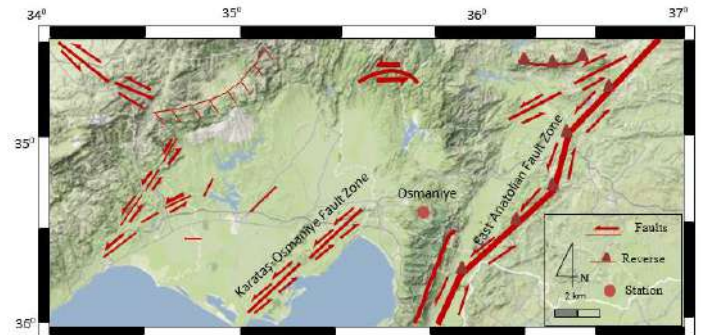

modulus of the continuous Fourier transform $S(f) = |\tilde{s}(f)|^2$. It is helpful for understanding the basic frequencies in the dynamical system, because it will yield broader peaks at dominant frequencies and frequency of signal is described in Equation (4).

$$S(f) = (1/f^\alpha) \quad (4)$$

where $S(f)$ is the system's power spectral density f is the frequency and α is a positive real number. Commonly, the dynamics systems that are under dynamic equilibrium having noise capture the signature of uncorrelated or white noise [13].

III.RESULT AND DISCUSSION

This section presents analysis of the ^{222}Rn gas in Osmaniye region for 2009 year (Figure 1). Time series for ^{222}Rn values given in counts per 15 min recording interval (Figure 2).

Location map of radon monitoring sites and EAFZ

Time series for ^{222}Rn in Osmaniye region (2009 year)

Matlab filter design for ^{222}Rn in Osmaniye region (2009 year) 10. degrees filter

10. degrees FIR Kaiser window for ^{222}Rn concentration in Osmaniye region (2009 year)

Figure 5 present the time series generated from one-year maximum Lyapunov exponent for ^{222}Rn in Osmaniye region (2009).

The maximum Lyapuniv exponent for ^{222}Rn (m :embedding dimension, τ : delay time)

Power spectrum is used for chosen random peak into broad band. Figure 6 indicates the power spectrum of chaotic behavior Osmaniye region.

Power spectrum for ^{222}Rn data Osmaniye region

IV.CONCLUSION

Geophysical observations and indicators showed nonlinear periodic behavior. Chaotic measurements are offers an opportunity to detect irregularities behaviors. For measurements data filter was applied to prepare for signal processing methods and smoothing of measurements taken from the soil. Chaotic applications have been used to implement ^{222}Rn data taken from the Osmaniye Region on the East Anatolian Fault Line. In this study, has been proved that show non-linear behavior of ^{222}Rn gas.

Abstract— Kesikköprü iron skarn deposit, located in the northwestern part of Central Anatolian Crystalline Complex (CACC), occurred at the contact between marble, and mafic-ultramafic rocks composed of gabbro and pyroxenite, and granitoids defined as granite, granodiorite and monzonite. The skarns are characterized by local endoskarn and widespread exoskarn zones in granitoid and marble/mafic-ultramafic rocks, respectively. Alteration in Kesikköprü iron deposit is defined as dominantly calcic, rich in garnet, pyroxene, epidote in marble, and partially magnesian described with formation of phlogopite at the contacts with mafic-ultramafic rocks. Iron comes from exoskarn zones as massive, bands and lenses, and total reserve of which is 12,7 Mt with grades of average 39-61 % Fe. The aim of this study is to compare with the geochemistry of Kesikköprü granitoid, and the geochemistry of granitoids associated with skarns worldwide, and in order to reveal the potential for different types of mineralization associated with the Kesikköprü granitoid.

The Kesikköprü granitoid are geochemically calc-alkaline, and shoshonitic in character, and has metaluminous-partly peraluminous features. The granitoid is especially characterized by enrichment in Large Ion Lithophile Elements (LILE) relative to High Field Strength Elements (HFSE) with significant depletion in Ta, Nb, P, Ti and Y. In the tectonic classification diagrams, granitoids plot in volcanic arc field, and close to the boundary between syncollisional, within plate granite and volcanic arc granite. The major element composition of the Kesikköprü granitoid is compared with both the worldwide average compositions of granitoids associated with Fe, Au, Cu, Zn, W, Mo and Sn skarns, and some of skarn related granitoids such as Ertsberg (Irian Jaya) Cu-Au, and Edong (China) Cu-Fe, and Çelebi (Turkey) Fe-W. As a result, geochemical characteristics of Kesikköprü granitoid resemble the geochemistry of plutons associated with Cu, and Cu-Fe skarn, suggesting new exploration possibilities for copper in the region.

Petrographic And Geochemical Properties Of Sarıcakaya (Eskişehir) Magmatic Mass

Hacer Bilgilioğlu

Aksaray University Geological Engineering, Turkey
bilgiliogluhacer@gmail.com

Bahattin Güllü

Aksaray University Geological Engineering, Turkey
bahattinogullu@gmail.com

Abstract—The study field is approximately an area of 150 km² which includes the settlement of Sarıcakaya in the north of Eskişehir province. The Paleozoic rocks composed of blueschist, gneiss and amphibolites in the region are cut by Carboniferous age Sarıcakaya Magmatic Mass. The basement units are covered by lithostratigraphic units in range of ages from Jurassic to Quaternary.

According to modal mineralogical datas, the magmatic mass have different compositions such as gabbro, diorite, granodiorite and granite. They are cutted by felsic and mafic units with several directions varying from K20D to K40B (longitude?).

Hypidiomorphic granular textured Sarıcakaya magmatic mass has contains oval-rounded shaped and holocrystalline textured mafic microgranular enclaves which diorite and quartz diorite in composition and range from 1 cm to 50 cm in sizes.

The geochemical analysis datas indicate that, Sarıcakaya Magmatic Mass have sub-alkaline, ranging from tholeiitic to calc-alkaline and metaluminous character

The primitive mantle normalized to trace element distributions of the mass show generally enrichment in terms of, large ion lithophile elements (LILE) and high field strength elements (HFSE) Similarly, The chondrite normalized rare earth element diagrams of the rocks show enrichent of light rare earth elements (LREE) showing depletion of heavy rare earth elements (HREE).

All petrographic and petrological datas of the Magmatic Mass of Sarıcakaya are interpreted as reflecting the enrichment of the subduction derived magma and the crustal contamination is effective during the rise of the mantle.

Contribution Specification This work was supported by Aksaray University Scientific Research Coordination Unit with BAP project no 2015-77. The authors would like to thank Aksaray University for their contributions.

Geological Engineering, İstanbul, Turkey.

Abstract— Continental volcanism accompanies lacustrine sedimentary units (Soma and Deniz Formation) in the large basins at Miocene Periods divided into two subgroups in Kınık district of NE Aegean. Adilköy Volcanites settled by magmatic intrusion in Soma Formation units and Kalemköy Volcanites interfinger and/or overlapping with Deniz Formation units. In this study, geochemical and petrographic features of Kalemköy and Adilköy Volcanites have been examined and their stratigraphic relationship investigated together with other sedimentary units. Adilköy Volcanites are defined by calc-alkaline basaltic andesite rocks whereas according to K_2O and SiO_2 compounds, Kalemköy volcanites are generally defined by dacite, rhyolite, rhyodacite, trachydacite, andesite type rocks which formed by high potassium and shoshonitic series in base. According to petrographic data on polarizing microscope, Adilköy Volcanites defined to Andesite, basalt, basaltic andesite whereas Kalemköy Volcanites have different composition which dacite, rhyolite, rhyodacite, trachyandesite and andesite.

According to $^{40}K/^{40}Ar$ age analysis in Neogene aged volcanites, First volcanism at Upper Oligocene time started 25.5 my ago (Chattian) in area. On the other hand, Adilköy Volcanites show 22.2 my age (Aquitian), whereas Kalemköy Volcanites are 17 my age (Burdigalian).

Geochemical studies refer to decreasing Ta, Nb, P, Ti elements in trace element diagrams of both magmatic phase and presence of the loser component in magmatic reservoir area or contamination of continental crust in Adilköy and Kalemköy Volcanites. High content of Fe, Mg, Cr, Ni and Co elements in Adilköy Volcanites showed aged mantle materials are located by intrusion on the surface. Adilköy Volcanites located in mantle fractional part on tectonic discrimination diagrams and contains mantle derived materials. Kalemköy Volcanites refer to develop from a subduction-influenced source and derived from a magma by continental crust assimilation at syn- collisional and post-collisional setting.

Abstract—Sarıcakaya granitoid is located to the north of the Sakarya River and approximately 50 km north of Eskişehir province, consists of gabbro, diorite, granodiorite and granite types of rocks. The general mineralogical composition of the granitoid is composed of quartz, plagioclase, orthoclase, hornblende, biotite, \pm microcline \pm zircon, \pm apatite minerals. The geochemistry shows changes according to the defined rock type. In this context, geochemical data that taken from geochemical analysis of geochemistry data should transform into surfaces covering the entire study area. Spatial interpolation methods have been developed for the purpose of expressing the point data on the spatial basis. These methods calculate the values of the areas between these points based on the reference data of the referenced point geometry, and express the results as raster surfaces.

In this study spatial interpolation methods used for the evaluation and presentation of the geochemical data of the Sarıcakaya granitoid. The method with optimal performance for mapping geochemical data were determined based on spatial distribution of data sources within the study area and characteristics of the data. The accuracy of distributions produced by different interpolation methods (IDW, Kriging, Natural Neighbor) had been calculated. It turns out that the Kriging method is more useful when it comes to generate geochemical distribution maps. Considering the petrographic properties and generated geochemical distribution maps of the Sarıcakaya granitoid, it is revealed that SiO_2 distributions controlled by quartz mineral. MgO distributions controlled by amphibole and pyroxenes. $\text{CaO-Na}_2\text{O}$ distributions controlled by plagioclase and K_2O distributions controlled by presence of orthoclase minerals.

Abstract— Gaziantep University has over than 40 thousands of students, 1500 academic and 1200 administrative staff who spend most of their time in 30 different facilities. To prevent traffic congestion and decrease the amount of personnel vehicles, an efficient ring planning is essential inside the campus. To do so, a study to design the ring services in Gaziantep University campus is considered. First of all, 15 bus-stop and 30 demand points are determined. Then, a set covering problem is applied to assign the bus-stop points to each demand point under different accessible distances. Finally, different ring plans which minimize the number of bus-stops and maximize the coverage are generated. Results show that all the demand points can be reached within 12 minutes. Since the existing route cannot cover all demand points, proposed four different routes are better than the existing route.

Keywords—ring planning; set covering problem; campus; case study

Internal and External Factors Affecting Open Innovation

Abstract— Open innovation refers to an innovation approach where there are no boundaries for the knowledge inflow and outflow and additionally, risk and reward are shared by two or more sides. Open innovation is becoming a widely used approach since it provides agility, flexibility, concentration on core competencies, identifying and diversifying risk and sharing uncertainty. Identifying factors which affect open innovation performance is important to be better manage this approach. In literature there are limited number of studies investigating facilitators of open innovation for only SMEs (small medium sized enterprises) (Brunswick & Vanhaverbeke, 2015), (Güzel, Sağ & Sezen, 2016) and science park companies (Şimşek, 2015). Yet, there has not been any comprehensive and elaborate study identifying both external and internal facilitators and impediments of open innovation for various sectors and company sizes (small, medium or large sized).

The aim of this study is to identify the internal and external facilitator factors of open innovation from a comprehensive review of the literature. Considering the meaning of facilitator, it encompasses the acceleration, benefit, usefulness and systematic operations for open innovation activities. Moreover, this study also indicates and focuses out the impediment factors that obstruct the operation of OI activities.

A structured methodology is followed in this study. First of all, literature is reviewed and analyzed rigorously. In reviewing the literature, the studies are investigated according to the relationship between various factors and open innovation. Studies are identified and analyzed according to the factor name in publication, construct measures, effect on open innovation performance, data collection method, conceptual framework and data analysis method. Then the factors are separated, if they facilitate or prevent OI. Facilitating factors of OI are divided into two groups: external facilitator factors of OI and internal facilitator factors of OI. For all of these two groups main heading, subheading factors and other lower level heading factors are determined.

Findings indicate that there are various factors which have positive or negative effect on open innovation. Four external main factors are identified that have positive effect on open innovation. These are environment outside the company, OI funding, OI technological resources and OI network connections. Three internal main factors are identified that have positive effect on open innovation. These are integrative organizational practices, time management and company's culture. For each main factor, sub-factors are also identified. Some of the identified factors have both positive and negative effects on OI mechanisms. The main headings of the impeding factors are: OI technological resources, OI network connections, environment outside the company, some subheadings of integrative organizational practices and company's culture.

This study contributes to the literature by determining facilitating and impeding factors for open innovation. There are several implications for the practitioners. For instance, existing business owners or new entrepreneurs can easily analyze market conditions, accomplish main goals and destinations of their companies, decrease risk and decrease uncertainty while implementing and managing open innovation approaches and activities by considering the findings of this study.

Keywords—open innovation; facilitators; impeditors

skulluk@erciyes.edu.tr

Abstract—Data mining is the process of extracting useful information from large databases. Today, data mining is used in many areas such as marketing, banking and finance, health, telecommunications, tourism, education and transportation successfully. In this study, a data mining application is done in order to estimate the sales values of the future years by using the sales data of a company operating in Kayseri. For obtaining future forecasts, firstly the factors affecting the sales values are determined and then function estimation function of data mining is performed with the help of five different models appropriate for the structure of the problem. The study is aimed to reach the critical information and significant points related with the company's sales.

Keywords—data mining; sales data; sales forecasting

I. INTRODUCTION

Today, there are quite a lot of raw data in the databases of big companies. The amounts of raw data are increasing day by day, but using these data is not very convenient. Raw data plays an important role in moving companies forward, especially in marketing, manufacturing, management and investment. Therefore, processing these data and extracting useful information from them is very important. Data Mining (DM) methods are very helpful in processing huge amounts of data.

Data mining has been defined as the nontrivial extraction of implicit, previously unknown and potentially useful information from data [1]. The general goal of DM is to discover knowledge that is not only correct, but also comprehensible and interesting for the user. DM encompasses a number of different technical approaches such as clustering, data summarization, learning classification rules, finding dependency networks and detecting anomalies [2]. Among the various data mining tasks function estimation is popularly used to estimate the target variable in many areas. In function estimation the target variable is continuous in contrast to the classification which has discrete outputs.

Function estimation function of data mining to sales forecasting has been widely studied in the literature. Among these studies Krause-Traudes et al. [3] presented a use case of spatial data mining for aggregate sales forecasting in retail

location planning. Özsağlam [4] forecasted the sales of a Turkish consumer electronics store company by using regression and naïve bayes classifier methods. Huang et al. [5] proposed a novel trigger model for sales prediction with data mining techniques. Beheshti-Kashi et al. [6] presented state-of-the-art methods in the sales forecasting research with a focus on fashion and new product forecasting. İşlek and Ögüdücü [7] addressed the problem of forecasting various product demands of main distribution warehouses and provided an appropriate methodology for demand forecasting. Wu et al. [8] developed and compared different models to forecast new product sales data with increasing sales trend and multiple predictor inputs. Zhang and Li [9] presented the retail commodity sale forecast model based on data mining. They firstly selected the profit ratio which was on behalf of commodity profit element and several other key sale attributes including the season ratio and the sale volume to establish the SPV Model, secondly done commodity sale state segmentation based on the SPV Model with ID3 decision tree algorithm, and on this basis they predicted the sale state of the commodity at some future time. Gahirwal and Vijayalakshmi [10] focused on how the best models of one series can be applied to similar frequency pattern series for forecasting using association mining.

Sales forecasting can have a crucial impact on the success and performance of companies. Motivated by this situation, future sales of a cable factory is estimated by using data mining algorithms in this study. Simple linear regression, Multi-Layer Perceptron (MLP), Sequential Minimal Optimization for regression (SMOreg), Gaussian functions and REPTree, M5P, RandomTree, RandomForest algorithms are used to estimate the future sales of the factory. SMOreg function outperforms the other algorithms in terms of error rates.

II. DATA MINING

A. What is Data?

Data is a set of values of qualitative or quantitative variables. Pieces of data are individual pieces of information. While the

concept of data is commonly associated with scientific research, data is collected by a huge range of organizations and institutions, including businesses (e.g., sales data, revenue, profits, stock price), governments (e.g., crime rates, unemployment rates, literacy rates) and non-governmental organizations (e.g., censuses of the number of homeless people by non-profit organizations) [11].

B. What is Data Mining?

Data mining, the science of extracting useful knowledge from such huge data repositories, has emerged as a young and interdisciplinary field in computer science. Data mining techniques have been widely applied to problems in industry, science, engineering and government, and it is widely believed that data mining will have profound impact on the society [12].

The actual data mining task is the automatic or semi-automatic analysis of large quantities of data to extract previously unknown, interesting patterns such as groups of data records (cluster analysis), unusual records (anomaly detection), and dependencies (association rule mining, sequential pattern mining). This usually involves using database techniques such as spatial indices. These patterns can then be seen as a kind of summary of the input data, and may be used in further analysis or, for example, in machine learning and predictive analytics. For example, the data mining step might identify multiple groups in the data, which can then be used to obtain more accurate prediction results by a decision support system. Neither the data collection and data preparation, nor result interpretation and reporting is part of the data mining step, but do belong to the overall knowledge discovery in databases process as additional steps as shown in Fig. 1.[13].

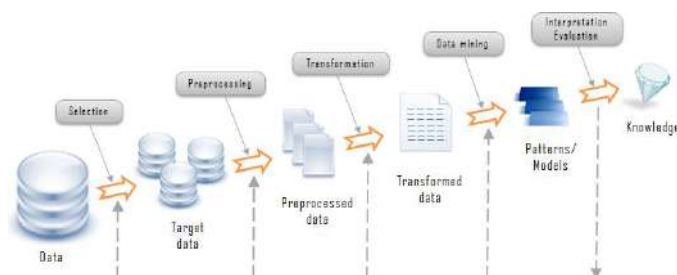

Fig. 1. Knowledge discovery process

III. DATA MINING ON SALES DATA

A cable manufacturer operating in Kayseri wants to know the monthly sales for 2017 according to the past 9 year sales data of the firm. Company executives determined the variables that will affect the sales quantity as follows:

- Months: 12 months of the year is taken as first input variable.
- Types of Cables: Five different types of cables as A, B, C, D and E are manufactured in the factory and taken as input to the problem.

- Constantly changing USD / TL exchange rate which is effective in raw material purchasing is another input variable that affects the sale quantities.
- The price of copper on LME (London Metal Exchange), which is also effective in purchasing raw material, is the last variable affecting the sales.

So there are totally four input variables for the sale forecasting problem. The first two variables are nominal and the remaining variables are continuous attributes. The output variable, sales quantity is also a continuous attributes leading us to the regression model. Looking at the structure of the problem, it is obvious that it will be solved by the regression method. In this context, function estimation is performed by using 8 different models/algorithms using Weka 3.9.1 data mining software. According to the results, the probabilistic suitability of the models/algorithms is examined.

A. Methods

Four function-based methods and four tree-based algorithms that use regression logic from Weka data mining software are used for the sales forecasting problem. Brief description of the methods and algorithms used in this study are as follows:

Simple Linear Regression; is a technique that aims to identify the relationship between two continuous variables (the dependent variable and the independent variable being estimated). It aims to form a state equation using technical data. When this state equation is established, it is ensured that the rectification is optimized by minimizing the squares of the distance, which is estimated from all the data points [14].

A multilayer perceptron is a feed forward artificial neural network model that maps sets of input data onto a set of appropriate outputs. An MLP consists of multiple layers of nodes in a directed graph, with each layer fully connected to the next one. Except for the input nodes, each node is a neuron (or processing element) with a nonlinear activation function. MLP utilizes a supervised learning technique called back-propagation for training the network [15, 16].

Sequential Minimization Optimization for regression - SMOreg is a new algorithm for training Support Vector Machines (SVM). This implementation globally replaced all missing values, transformed nominal attributes into binary ones and also normalized all attributes by default. SMOreg is a support vector machine for regression problems linear regression. It's beyond the scope of these forums to discuss the theory behind kernel methods like SVMs [17].

In probability theory and statistics, a Gaussian process is a statistical model where observations occur in a continuous domain, e.g. time or space. In a Gaussian process, every point in some continuous input space is associated with a normally distributed random variable. Moreover, every finite collection of those random variables has a multivariate normal distribution. The distribution of a Gaussian process is the joint distribution of all those (infinitely many) random variables, and as such, it is a distribution over functions with a

continuous domain, e.g. time or space [18]. Viewed as a machine-learning algorithm, a Gaussian process uses lazy learning and a measure of the similarity between points (this is the kernel function) to predict the value for an unseen point from training data. The prediction is not just an estimate for that point, but also has uncertainty information -- it is a one-dimensional Gaussian distribution (which is the marginal distribution at that point) [19]. Gaussian method in Weka implements Gaussian processes for regression without hyper parameter-tuning.

REPTree uses the regression tree logic and creates multiple trees in different iterations. After that it selects best one from all generated trees. That will be considered as the representative. In pruning the tree the measure used is the mean square error on the predictions made by the tree [20].

M5P model tree is used for numeric prediction and at each leaf it stores a linear regression model that predicts the class value of instances that reach the leaf [21].

Random trees have been introduced by Leo Breiman and Adele Cutler. The algorithm can deal with both classification and regression problems. Random tree is a collection (ensemble) of tree predictors that is called *forest* (the term has been also introduced by L. Breiman). The classification works as follows: the random trees classifier takes the input feature vector, classifies it with every tree in the forest, and outputs the class label that received the majority of "votes". In case of a regression, the classifier response is the average of the responses over all the trees in the forest [22].

Random forest is an ensemble learning method for classification, regression and other tasks, that operate by constructing a multitude of decision trees at training time and outputting the class that is the mode of the classes (classification) or mean prediction (regression) of the individual trees [23].

B. Data set and Partitioning

As mentioned before the sales data has two nominal, two continuous inputs and a continuous outputs. The dataset totally has 540 instances.

For partitioning the dataset into training and testing sets a well-known ten-fold cross-validation procedure is applied to the dataset. Dataset is partitioned into ten data subsets and algorithms/methods are executed once for each partition. Each time a different partition is used as testing set and the remaining 9 are grouped together to build training set. The training set is used to train the algorithm for good learning capability, while the testing set is applied to evaluate the generalization capability of the algorithm/method.

C. Performance metrics

Correlation Coefficient: A correlation coefficient (*corr*) is a number that quantifies a type of correlation and dependence, meaning statistical relationships between two or more values in fundamental statistics.

$$corr(x, y) = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{(\sum_{i=1}^n (x_i - \bar{x})^2 \sum_{i=1}^n (y_i - \bar{y})^2)^{1/2}} \quad (1)$$

Mean absolute error: In statistics, the mean absolute error (MAE) is a quantity used to measure how close forecasts or predictions are to the eventual outcomes. The mean absolute error is an average of the absolute errors.

$$MAE = \frac{1}{n} \sum_{i=1}^n |forecast_i - sales_i| = \frac{1}{n} \sum_{i=1}^n |e_i| \quad (2)$$

Root Mean Squared Error: The root-mean-square deviation (RMSD) or root-mean-square error (RMSE) is a frequently used measure of the differences between values (sample and population values) predicted by a model or an estimator and the values actually observed. The RMSD represents the sample standard deviation of the differences between predicted values and observed values. The RMSD serves to aggregate the magnitudes of the errors in predictions for various times into a single measure of predictive power.

$$RMSE = \sqrt{\frac{\sum_{t=1}^n (\hat{y}_t - y_t)^2}{n}} \quad (3)$$

Relative Absolute Error: The relative absolute error (RAE) is very similar to the relative squared error in the sense that it is also relative to a simple predictor, which is just the average of the actual values. In this case, though, the error is just the total absolute error instead of the total squared error. Thus, the relative absolute error takes the total absolute error and normalizes it by dividing by the total absolute error of the simple predictor.

$$RAE = \frac{\sum_{t=1}^n |\hat{y}_t - y_t|}{\sum_{t=1}^n |\bar{y} - y_t|} \quad (4)$$

Root Relative Squared Error: The root relative squared error (RRSE) is relative to what it would have been if a simple predictor had been used. More specifically, this simple predictor is just the average of the actual values. Thus, the relative squared error takes the total squared error and normalizes it by dividing by the total squared error of the simple predictor. By taking the square root of the relative squared error one reduces the error to the same dimensions as the quantity being predicted.

$$RRSE = \sqrt{\frac{\sum_{t=1}^n (\hat{y}_t - y_t)^2}{\sum_{t=1}^n (\bar{y} - y_t)^2}} \quad (5)$$

IV. PERFORMANCE ANALYSIS

Before applying function-based methods and tree-based algorithms the sales dataset is randomized in order to balance the learning. Tables 1 and 2 show the error rates of the ten-fold-cross-validation results of function-based methods and tree-based algorithms respectively.

TABLE I. ERROR RATES OF FUNCTION-BASED METHODS

	Linear Regression	MLP	SMOreg	Gaussian
Correlation Coefficient (R)	0,9349	0,8559	0,9355	0,9348
R ²	0,8740	0,7326	0,8752	0,8739
Mean Absolute Error	363141,47	569479,66	323192,41	367062,94
Root Mean Squared Error	665264,45	1000190,2	663310,73	665626,69
Relative Absolute Error	25,4526 %	39,9148%	22,6525%	25,7274%
Root Relative Squared Error	35,4004 %	53,2226%	35,2964%	35,4197%

According to Table 1, it is clear that the MLP method has the smallest correlation coefficient, mean absolute error and largest relative absolute error even though all of the models have very close error values. MLP is the model that gives the worst result to this problem.

R², the square of the correlation coefficient indicates the degree of linear relationship between the variables. Therefore, reliability of the model increases by the increase of the R² value. It is easy to see that the values of R² in the table are very close to each other. As seen in the table, the highest value of R² is the SMOreg method. Also, if we look at the values obtained by the SMOreg method, we can see that it has the lowest rate of both error rates. As a result, we can clearly say that the SMOreg method gives the best result for this problem.

TABLE II. ERROR RATES OF TREE-BASED MODELS

	REPTree	M5P	Random Tree	Random Forest
Correlation Coefficient (R)	0,9342	0,9323	0,8782	0,9287
R ²	0,8727	0,8692	0,7712	0,8625
Mean Absolute Error	287747,25	326924,33	405270,24	311759,83
Root Mean Squared Error	668977,27	678182,78	937621,41	699480,31
Relative Absolute Error	20,1682 %	22,9141 %	28,4054 %	21,8512 %
Root Relative Squared Error	35,5980 %	36,0878 %	49,8932 %	37,2211 %

When the tree-based algorithms given in Table 2 analyzed and compared with each other, RandomTree is the function that gives the worst result to this problem. REPTree algorithm gives the highest R² value and smallest error rates.

If both function-based methods and tree-based algorithms compared altogether, SMOreg algorithm outperforms the other algorithms in terms of error rates and R² values. The firm can use the SMOreg algorithm to estimate their future sales.

Multi-layer perceptron method gives the worst rates among the eight algorithms. Remaining algorithms give near values to each other.

V. CONCLUSION

In this study, a cable manufacturer sales potential is estimated by using eight function-based methods and tree-based regression focused algorithms. The dataset consists of four inputs and a continuous output for the last nine years. Ten-fold-cross-validation procedure is used to partition the datasets into training and testing sets. Correlation coefficient, R² and some error rates are used as performance metrics for analyzing the performance of the algorithms. SMOreg algorithm outperforms the compared algorithms and can be used to predict the sales of the cable manufacturer.

E-mail: ahmety@khas.edu.tr

Abstract— Power companies require sophisticated tools to manage fuel-coal supply chains which include multiple suppliers, coal contracts, and multimode transportation routes. In this research, an integrated multi-objective model for supplier, transportation, and coal order is developed for the coal supply network in which multiple suppliers, coal contracts, and multimode transportation routes exist. The model simultaneously optimizes multiple objectives such as minimizing purchase costs and transportation costs and it also presents a decision framework on the selection of suppliers, transportation routes, and coal products that will achieve these objectives. The network and capacity constraints of suppliers and transportation routes are included in the model. The methodology for the solution is illustrated via a case study and an alternative evaluation process is presented. The study demonstrates that the model can be used by power companies to find desired solutions and has the potential to apply to other industries.

Keywords— fuel coal supply; supply chain; supplier mix; transportation optimization

I. INTRODUCTION

Coal is the most abundant and commonly used energy resource in the generation of electricity. Since it is readily available, flexible to use, and accessible all around the world, it is one of the most reliable resources. However, coal as a product has different characteristics and each coal type differs. The heat content ranges from low to high, which affects the amount of energy gained when it is burned. Power producers tend to purchase coal with high heat content as it generates more electric power in comparison with the same amount of coal with lower heat content. Also, not all coal products can be burned in a power plant, and it is necessary to purchase the right coal product to most efficiently use plant resources and minimize costs.

Although coal is crucial for the industrialized world, the environmental impacts should be carefully handled. The land where coal is mined becomes temporarily unavailable for other uses such as agriculture, and it makes the land susceptible

to soil erosion in addition to creating noise, water pollution, and dust. Moreover, coal mines are a source of methane gas which is harmful to the environment, and the gas is released during mining. Also, coal has environmental impacts when it is burned, which is its major challenge. The oxides of sulphur (SO_2) and nitrogen (NO_x), CO_2 , particulate, and trace elements such as mercury can have serious impacts on nature. It has been found that the release of greenhouse gas emissions derived from human activities is related to global warming, and increasing amounts of sulphur and nitrogen oxides lead to acid rain. For these reasons, coal-fired power plants are known to be a major source of air pollution [1]. If a coal resource is not carefully chosen, the cost of power generation and the environmental hazards can be higher for power producers.

Suppliers provide coal contracts for each coal type which are sold via a merchandise exchange to power companies. A coal contract includes the amount, type, price, heat content, ash content, sulfur content, and chemical structure of the coal that will be delivered to the power company. The price for each contract is different and often times the mine mouth-price does not include transportation costs. Suppliers issue different coal contracts each of which has its own price and related product descriptions. Power companies must contend with the problem of choosing the best coal contracts that will meet the demand in a cost-effective way given that there may be multiple power plants at different locations.

It is best to locate a coal-fired power plant near to a coal mine, but this is not usually the case as a generation point should also be in close proximity to where power is consumed. Coal then must be transported from where it is blended or mined to its final destination plant, and it is usually shipped by professional transportation companies; it is also common, however, for power companies to have their own fleet for coal transportation. In the US, railway companies have the largest share of coal transportation as they have their own railroads and specialized transport cars. Other methods of transportation include coal barges on waterways and trucks on highways, and with these, coal can be transported directly to the power plants. Coal can also be transported to a trans-load location where it is loaded to another vehicle at a hub point for further shipment to

power plants or to another trans-load location. While the final destination is the power plant, transportation costs differ based on the method, the distance, and selected route mix. Also, the transportation capacity of each route is limited and the tariff to ship coal can differ. For these reasons, power companies must ensure that effective transportation methodologies are chosen at a minimum cost.

Power companies are required to make decisions about suppliers, transportation, and order mix selection in a supply chain where suppliers, products, and a diversity of transportation possibilities exist. The overall objective can be classified in two different ways. The first is related with suppliers and coal selection, and the aim is to minimize the purchase cost of orders. The second is related with transportation, and the aim is minimal costs and the reliable transportation of coal resources.

A limited amount of research exists in the literature that integrates suppliers, transportation, and order diversity for the power industry. Author presents a fuzzy multiple-objective linear programming model for production-transportation planning problems in a supply chain in [2]. The proposed model attempts to simultaneously minimize many objectives like total production and transportation costs along with the number of rejected items, total delivery time, and labor level. The fuzzy data is in a modifiable format so that a decision-maker can develop a satisfactory solution that will improve the supplier-distributor relationship. Authors develop a model for a manufacturer's supply network in which there are numerous suppliers with capacity limitations, numerous products, and uncertain demand in [3]. The model considers market demand uncertainty, costs, and product characteristics, and the main objective is to find how much of each material to order from each supplier given that supplier and manufacturing companies have a limited capacity. Author develops a model to select the best routes in international intermodal networks where multiple commodities and multimode transportation opportunities exist [4]. The objectives are to minimize the total flow cost and the total travel time where a time window constraint is imposed. The problem is NP-hard and hence Lagrangian relaxation and a decomposition method with a heuristics method is used to solve the problem. The existing research considers supplier-transportation, supplier capacity-product and multiple products-transportation, and it develops methods to solve problems for a supply chain. However, these studies do not respond to problems when they involve multiple products, multimode transportation, order diversity, and supplier diversity with capacity constraints. Furthermore, the operational constraints in coal-fired plants impose new limitations on coal, such as energy content and non-homogeneity. This body of knowledge assumes that products are identical and do not have operational constraints.

Authors develop a method to optimize a regional railroad network in [5]. The main objective is the minimization of total costs in transportation when there is increased coal shipment traffic and resources are allocated among demand

points. In [6], Shih (1997) proposes a mixed integer programming method for the planning of fuel-coal imports for power plants. A diversity of supply sources for power companies that have more than one plant complicates coal logistics. The main objective is the minimization of total inventory costs and holding costs, and the constraints are harbor unloading capacity, demand balance, and inventory balance. The model is developed for the central coal logistics system of a Taiwanese power company to demonstrate its validity. In [7] authors present a model for coal blending and cleaning silos for supplies of coal from different resources and delivery to customer locations to meet demand. In [8], a model is developed for a coal loading port in China. The coal is first transported to the port via trains and then barges are used to deliver the coal to the final destinations. They develop a Markov decision model that minimizes holding costs, shortages, and transportation costs by integrating ordering and delivery decisions. The study briefly considers product and route diversities which are usually the decision variables that make the problem challenging.

Authors provide a simulation methodology for coal shipment from mines in western Canada to power stations in the east [9]. The transportation cost for such distances becomes increasingly important as it is a major component of final coal prices. They simulate alternative routes across Canada and present the possible outcomes of each scenario for strategic route planning. A research is presented on the existing coal distribution infrastructure and four scenarios are developed lasting until 2050 to analyze coal consumption and possible problems for meeting coal demand [10]. Tu and Guldman (2001) develop a model and a tool called the Geographic Information System to identify coal transportation routes considering coal production sites, power plants, and costs of transportation [11]. They visualize the transportation process and validate the model in a case study developed for Ohio. The author in [12] presents a comprehensive study on coal transportation to power plants and its reliability in the US. He explores major coal resources and discusses transportation reliability issues while noting the importance of coal for energy supplies. In [13] a model is proposed for coal blending and transportation in which an inter-model transportation network for coal import exists. The coal supply, quality, price, and demand at the power plant are included in the model, and it is a mix-integer zero-one programming problem in which the main objective is overall cost minimization.

In this research, a linear model that considers multimode transportation alternatives, multiple products, and multiple suppliers is developed for the efficient management of the coal supply of an electric power company with more than one plant at different locations. The methodology is able to optimize the supply of fuel-coal over the network and also able to help configure the supply chain. Capacity limitations on transportation routes, supplier capacity for a particular product, and plant burn capability constraints are also considered in the model. The remainder of the paper is organized as follows:

Section 2 formulates the problem Section 3 provides a case study developed for a power company in the Midwestern USA. Conclusions are given in section 4.

II. FUEL-COAL SELECTION PROBLEM

The coal is first mined and transported to a silo where the stones and refuse are removed at the supplier's site. The next step is to crush the coal and sort it before the washing process. Then it is ready to be blended to get the desired level of physical specifications. The last step is to load the coal onto trains, barges or trucks to ship it to its next destination. The coal transportation network is heavily dominated by private railroad companies as they have their own fleet with specialized coal transportation cars and railroads for transportation. Barges on waterways are also used, especially for large power companies that have their own coal transportation fleet. The coal is transported directly to the power plant or often times it is transported to a trans-load location where it is loaded to another vehicle of a supplier or another company. The trans-load location is a hub point that is used to efficiently manage the transportation network.

The coal supply chain can be represented as a network in which suppliers, transportation routes, trans-load locations and power plants are natural entities. Fig. 1 gives a description of a coal supply network. The coal $q \in Q$ is supplied at supplier $i \in I$, and it is transported to power plant $j \in J$ directly or via trans-loading at trans-load location $t \in T$. The coal can also be shipped from a trans-load location t to another trans-load location $t' \in T$ where $t' \neq t$. The decision variable that should be found for each power plant is $X_{i,j,q}$, the total amount of coal q transported from supplier i to power plant j , where

$$X_{i,j,q} = X_{i,j,q} + X_{i,t,q} + X_{t,j,q} + X_{t,t',q} + X_{t',j,q}.$$

The decision variable includes the total coal q transported directly to plant j , the coal transported to a trans-load location t then transported to plant j , and the coal further transported to other trans-load locations t' then transported to plant j .

Fig. 1. Coal transportation network

The main components of the objective are the cost of purchase and the cost of transportation to the destination power

plant which are related with supplier selection, the transportation route, and coal type. Accordingly, the main objective of the problem is the minimization of purchase and transportation cost. Selection of coal suppliers depends on their location and the specifications of their product, and whether they offer different price ranges for coal contracts. However, the availability of alternative transportation routes, trans-loading locations, and associated costs also force power companies to optimize the coal delivery process. The detailed formulations are as follow:

- Purchase cost: This objective function finds purchase cost by multiplying the price of coal q with the total amount of coal q transported from supplier i whether directly to plant j or trans-load location t .

$$f_1 = \sum_{i \in I} \left(\sum_{j \in J} \sum_{q \in Q} X_{i,j,q} P_{i,q} + \sum_{t \in T} \sum_{q \in Q} X_{i,t,q} P_{i,q} \right) \quad (1)$$

$P_{i,q}$ is the given price of coal q at supplier i . The first part of the objective function is the cost of purchased coal that is transported directly to the plant without trans-loading. The second part calculates the purchase cost of coal q that it is transported to a trans-load location t .

- Transportation cost: The cost of transportation over the transportation network is minimized in this objective.

$$f_2 = \sum_{q \in Q} \left(\sum_{i \in I} \sum_{j \in J} X_{i,j,q} TC_{i,j} + \sum_{i \in I} \sum_{t \in T} X_{i,t,q} TC_{i,t} + \sum_{t \in T} \sum_{t' \in T, t' \neq t} X_{t,t',q} TC_{t,t'} + \sum_{t \in T} \sum_{j \in J} X_{t,j,q} TC_{t,j} \right) \quad (2)$$

$TC_{i,j}$, $TC_{i,t}$, $TC_{t,j}$, and $TC_{t,t'}$ represents the transportation cost of coal from supplier i to plant j , from supplier i to trans-load location t , from trans-load location t to plant j and from trans-load location t to trans-load location t' ($t' \neq t$), respectively.

Electricity is a non-storable commodity that must be produced and consumed in real-time. The power plant j keeps a coal inventory that is sufficient to meet F_j (days) of power demand and orders coal that is sufficient to meet D_j (days) of power demand assuming that the plant would work at its maximum capacity. The heat content of coal q , H_q (BTU/lb) is released during the burning process and is converted into electric power. The total power amount that can be gained from coal q is H_q multiplied with the reserve of coal q at plant j (ton), which is the accumulation of the current inventory of coal q , $I_{j,q}$ (tons), and the coal inflow of coal q from suppliers and trans-load locations. As a result of the energy release process, the total BTU units of energy can be derived from coal q at power plant j to meet demand. However, the efficiency of a power plant in converting the potential energy output into electricity should be considered. The power generated from a coal-fired power plant is approximated with its heat rate R_j (mmBTU/MWh). Note that in order to generate M_j (MWh) of power for each hour, $R_j \times M_j$ (mmBTU) units of energy is needed. Hence, the necessary

condition is that the potential power output in terms of BTUs should be higher than the required BTUs to generate M_j amount of power for $D_j + F_j$ days. After necessary unit conversions, the equation can be represented as:

$$\sum_{q \in Q} \left(I_{j,q} + \sum_{i \in I} X_{i,j,q} + \sum_{t \in T} X_{t,j,q} \right) H_q \geq (D_j + F_j) (24 M_j) (R_j / 500) \quad \text{for all } j \in J \quad (3)$$

The amount of coal that is processed and blended at each supplier i is limited and usually determined by market conditions. The total amount of coal q transported to trans-load locations and power plants from supplier i is limited to its capacity. Note that $X_{i,t,q}$ is the amount of coal q that is transported to a trans-load location from supplier i , and it can be further transported to another trans-load location or to a power plant. On the other hand, $X_{i,j,q}$ is the amount of coal q that is directly transported to power plant j . Since both of them were sent from supplier i , the total should sum up the amount of coal q that is provided by supplier i which has a limited capacity.

$$\sum_{t \in T} X_{i,t,q} + \sum_{j \in J} X_{i,j,q} \leq O_{i,q} \quad \text{for all } i \in I, q \in Q \quad (4)$$

Not all coal types can be burned in a coal fired power plant. Technological infrastructure, environmental constraints, and regulations require plants to burn pre-defined coal types. Additionally, the grindability index (size) of coal q , gi_q , should be in an interval of minimum grindability permitted in plant j , $gi_{j,min}$, and maximum grindability permitted in plant j , $gi_{j,max}$. Similarly the percentage of moisture content in coal q , mc_q , should be in an interval of $mc_{j,min}$ and $mc_{j,max}$ which are the minimum and maximum percentage of moisture allowed at plant j . To lower the SO_2 outputs from coal it is desirable to keep the sulfur content in coal q , S_q , within the limit of maximum and minimum sulfur percentage permitted at plant j , which are $S_{j,min}$ and $S_{j,max}$ respectively. The equations can be gathered in a single representing formula as given below:

$$X_{i,j,q} = \begin{cases} 0 & \text{if coal } q \text{ cannot be burned at plant } j \\ & \text{and/or if } gi_q \notin [gi_{j,min}, gi_{j,max}] \\ & \text{and/or if } mc_q \notin [mc_{j,min}, mc_{j,max}] \\ & \text{and/or if } S_q \notin [S_{j,min}, S_{j,max}] \\ X_{i,j,q} & \text{Otherwise} \end{cases} \quad \text{for all } q \in Q, i \in I \quad (5)$$

$$X_{t,j,q} = \begin{cases} 0 & \text{if coal } q \text{ cannot be burned at plant } j \\ & \text{and/or if } gi_q \notin [gi_{j,min}, gi_{j,max}] \\ & \text{and/or if } mc_q \notin [mc_{j,min}, mc_{j,max}] \\ & \text{and/or if } S_q \notin [S_{j,min}, S_{j,max}] \\ X_{t,j,q} & \text{Otherwise} \end{cases} \quad \text{for all } q \in Q, t \in T \quad (6)$$

The coal transportation network has multiple transportation routes that are used if they are more economical. The total coal amount that can be transported on a route is limited to the transportation capacity of the arc in the network.

$$\sum_{q \in Q} X_{i,t,q} \leq U_{i,t} \quad \text{for all } i \in I, t \in T$$

$$\sum_{q \in Q} X_{t,j,q} \leq U_{t,j} \quad \text{for all } j \in J, t \in T \quad (7)$$

$$\sum_{q \in Q} X_{t,t',q} \leq U_{t,t'} \quad \text{for all } t, t' \in T, t \neq t' \quad (8)$$

$$\sum_{q \in Q} X_{i,j,q} \leq U_{i,j} \quad \text{for all } i \in I, j \in J \quad (9)$$

Total coal transportation between supplier i to trans-load location t is limited with that of arc capacity in eq. 7. Eq. 8 gives the capacity constraint of transportation between trans-load location t and plant j , eq. 9 gives the transportation limit between trans-load location t to another trans-load location t' , and eq. 10 gives the direct transportation capacity from supplier i to plant j .

Total coal transported to a trans-load location t is transported either to another trans-load location t' or power plant j .

$$\sum_{t \in T} X_{i,t,q} - \sum_{t \in T, t \neq t'} X_{t,t',q} - \sum_{j \in J} X_{t,j,q} = 0 \quad \text{for all } i \in I, q \in Q, j \in J \quad (10)$$

The non-negativity constraints are also included to ensure non-feasible solutions.

$$X_{i,j,q}, X_{i,t,q}, X_{t,t',q}, X_{t,j,q} \geq 0 \quad \text{for all } i \in I, q \in Q, j \in J, t, t' \in T, t \neq t' \quad (11)$$

Let

$$X = \{X_{i,j,q}, X_{i,t,q}, X_{t,t',q}, X_{t,j,q}\} \quad \text{for all } i \in I, q \in Q, j \in J, t, t' \in T, t \neq t'$$

be a feasible solution set for the linear fuel coal supply problem, and the objective of the problem is to determine the optimum

suppliers, coal products, and transportation routes that will minimize total purchase and transportation cost.

It is important for power companies to report operational expenses in their financial reports. Each cost item has to be explained in the report and they affect the financial performance of the company, which is released to shareholders. As a result, they need to be careful to separate the cost of coal and the cost of transportation. The price of coal is determined by market conditions and it can thus be explained. However, a high cost of transportation decreases the performance of the company. For this reason, these costs have to be treated with different weights and have to be separated.

III. CASE STUDY

The proposed methodology is illustrated for a case study for the Midwestern USA. The electric power supply in the region is dominated by coal-fired generation. 4 suppliers (S_1, S_2, S_3, S_4), 9 alternative contracts (q_1, q_2, \dots, q_9), 4 trans-load locations (T_1, T_2, T_3, T_4) and 3 power plants (Plant 1, 2 and 3) are taken into consideration. The power company has 3 coal-fired power plants located in Indiana, Ohio, and Kentucky. Table I provides the coal contract specifications.

Table 1 Coal contracts and specifications

Product	Contract	Heat Content (BTU)	S (%)	GI	MC(%)	Ash (%)
q_1	CAPP	12500	0.90	41	10	13.50
q_2	CSX Compliance	12500	0.80	43	7	12.00
q_3	CSX	12500	1.00	43	7	12.00
q_4	NS Compliance	12500	0.75	44	7	12.50
q_5	NS Rail	12500	1.00	44	7	12.90
q_6	NYMEX Big Sandy	12000	1.00	41	10	13.00
q_7	PRB 8800	8800	0.80	51	27	5.50
q_8	PRB 8400	8400	0.80	51	30	5.50
q_9	Pittsburgh Seam	13000	3.00	55	8	8.00

The fuel supply department contacted suppliers and was offered the following coal contracts. The supplier price and daily capacity for each product are provided in Table II.

Table 2 Supplier prices and capacities

Supplier	Price & Capacity	Coal Products								
		q_1	q_2	q_3	q_4	q_5	q_6	q_7	q_8	q_9
S_1	Price (\$/ton)	63.5	57.1	67.5	65.5	64.8	28.1	15.0	14.9	41.0
	Capacity (ton)	8640	13440	25920	0	0	0	0	0	11520
S_2	Price (\$/ton)	62.4	56.2	66.4	63.2	63.1	26.8	15.2	15.1	42.1
	Capacity (ton)	13440	11520	0	17280	0	0	0	0	13440
S_3	Price (\$/ton)	63.8	56.8	68.0	64.6	64.2	25.5	14.5	14.0	40.8
	Capacity (ton)	0	0	19200	10560	13440	18240	11520	17280	0
S_4	Price (\$/ton)	64.1	54.8	65.2	66.7	66.3	27.1	15.8	15.8	42.9
	Capacity (ton)	0	0	10560	11520	9600	12480	13440	11520	0

The power company also has the data given in Table III for its coal fired power plants. Note that not all plants are able to burn the available coal products provided from suppliers, and those are represented with a 0.

Table 3 Plant specifications

Plant	Demand (MWh)	Heat Rate (mmBTU/MWh)	q_1	q_2	q_3	q_4	q_5	q_6	q_7	q_8	q_9
Plant 1	2862	9.2	1	0	1	0	1	0	1	1	0
Plant 2	1185	9.8	0	1	0	1	0	1	0	0	1
Plant 3	820	10.2	1	0	0	1	0	0	1	1	0

Table IV gives the coal specific plant constraints which include grindability index, moisture content, and permitted maximum and minimum sulfur rate at the plants.

Table 4 Plant constraints

Plant	GI	MC (%)	S_{min} (%)	S_{max} (%)
Plant 1	[40-60]	[5-35]	0	1.2
Plant 2	[39-58]	[6-33]	0	1.9
Plant 3	[39-57]	[5.5-32]	0	3.8

Each power plant has a current inventory that is a mix of available products. Table V shows the current inventory level at each power plant. As a policy, power companies would like to keep a safety stock that is sufficient to provide three days of energy. On the other hand, in addition to current inventory and safety stock levels, companies seek to maintain fuel that is sufficient to meet two days of power demand.

Table 5 Plant coal inventories

Plant	q_1	q_2	q_3	q_4	q_5	q_6	q_7	q_8	q_9
Plant 1	29432	0	2000	0	0	0	37440	29823	0
Plant 2	0	4000	0	2450	0	34839	0	0	450
Plant 3	8000	0	0	15100	0	0	0	13376	0

In addition to coal offers, the company has to decide about transportation routes. It is possible to deliver the coal directly from the supplier to the power plant; however, the transportation cost is usually higher. Coal is shipped via train-cars on railways, barges on waterways, trucks, or by using a multimode that utilizes a trans-load location. For the multimode alternative, there are 4 trans-load locations where the coal can be transferred to another form of transportation for further shipment. The transportation costs and capacities between each point are given in Table VI and Table VII, respectively. Note that the trans-loading cost is included in transportation costs.

Table 6 Transportation costs (\$/Ton)

Location	Destination						
	T_1	T_2	T_3	T_4	Plant 1	Plant 2	Plant 3
S_1	6.95	9.65	15.68	13.47	21.75	23.52	24.60
S_2	8.25	4.50	9.20	12.35	24.48	20.45	19.40
S_3	7.32	8.85	11.45	12.25	23.43	18.26	23.16
S_4	4.60	4.20	10.25	10.10	19.45	17.26	18.06
T_1	0.00	8.46	7.99	6.11	13.72	12.21	14.49
T_2	10.92	0.00	4.53	10.17	15.06	12.47	13.58

T_4	7.79	9.66	2.86	0.00	5.40	5.87	6.74

Table 7 Transportation capacities (Ton)

Location	Destination						
	T ₁	T ₂	T ₃	T ₄	Plant 1	Plant 2	Plant 3
S ₁	7392	17040	19344	24576	19440	24720	17856
S ₂	11616	25680	18720	22128	27696	23280	16560
S ₃	10512	11232	13008	11424	26736	18240	11424
S ₄	9744	9696	9168	12096	26736	18768	9840
T ₁	0	30000	25392	33216	21984	25056	26016
T ₂	20784	0	20832	23712	29040	28608	30048
T ₃	21936	21264	0	20640	17040	25776	26688
T ₄	29424	34704	35856	0	29424	34704	35856

The transportation and coal specification data has been gathered from EIA [1] and verified in [14]. The data for the coal fired power plants has also been gathered from the same sources; however, they have been slightly modified for confidentiality reasons in the market. The illustrated case is coded in GAMS (General Algebraic Modeling System), a high level modeling and optimization tool. The solutions were obtained using a CPLEX 12.1. The computations were performed on a computer with an Intel Core 2 duo 2 Ghz CPU with 4 GB RAM. Table VIII provides the a solution to presented case study.

Table 8 Solutions for suppliers and transportation

supplier	First Trans-load Location	Second Trans-load Location	Plant	Coal Type	Amount (ton)	Transportation Cost (\$/ton)	Transportation Cost /Final Price
S ₁	-	-	1	q ₁	3472	21.75	58%
S ₂	-	-	1	q ₈	11520	19.45	55%
S ₃	T ₁	-	1	q ₇	7056	18.58	56%
S ₃	T ₁	T ₁	1	q ₁	5616	22.07	26%
S ₃	T ₂	T ₂	1	q ₇	4368	20.51	58%
S ₃	T ₂	T ₁	1	q ₁	13440	20.07	24%
S ₃	T ₁	T ₄	1	q ₁	632	18.46	22%
S ₄	T ₁	T ₁	1	q ₇	9372	16.11	50%
S ₄	T ₁	-	1	q ₇	595	15.50	49%
S ₄	T ₂	T ₄	1	q ₇	96	24.42	63%
S ₄	T ₁	T ₄	1	q ₈	5288	18.83	57%
S ₄	T ₁	T ₃	2	q ₈	372	17.24	39%
S ₄	T ₂	T ₁	2	q ₈	9696	13.38	33%
S ₄	T ₂	-	2	q ₈	5952	16.10	39%
S ₄	T ₁	T ₃	3	q ₈	5224	21.08	60%
S ₄	T ₂	T ₁	3	q ₈	6768	19.15	52%

The transportation route is represented in such a way that the first column is the beginning point (supplier), the second column is the first trans-load location, the third column is the second trans-load location, and the fourth column is the destination power plant. Notice that usage of more than two trans-load locations is also possible but no solution was found for such a case.

Based on the results shown, the demand of plant 1 is supplied from 4 suppliers in different amounts. S₁ and S₂ supply q₁, S₃ supplies q₇ and S₄ supplies q₇ and q₈. A mixed strategy for transportation seems optimum for plant 1 as all the transportation is made via different routes.

The coal demand of plant 2 is provided by S₃ and S₄ with coal type q₆. Trans-load locations T₁, T₂ and T₃ are used for transportation of coal. All of the coal demand for plant 3 is provided from S₃ with coal type q₈. Two different transportation routes using T₁, T₂ and T₃ are preferred. The total transportation cost and its ratio on final cost are also provided. Notice that when the purchase price is low, the ratio of transportation on total cost becomes higher.

The amount of coal supplied from each supplier is different. Fig.2. shows the percentage of total coal supplied by each supplier. Ignoring the coal types, a large amount of coal is supplied by S₃ and S₄, whereas a small amount of coal is supplied by S₁. Also, the decision-maker can apply a coal-type analysis for each supplier to make further comparisons.

Fig. 2. Comparisons of Supplier by Total Coal Supplied

It is also useful to do a comparison for the procured coal types. Fig.3. shows the percentages of each coal type transported to the plants. It is shown that q₂, q₃, q₄, and q₅ are not preferred coal types at this time. On the other hand, the range of preferences for four coal types is relatively close, with q₈ being the most preferred and q₁ being a lesser preferred coal.

Fig. 3. Supplied Coal Types by Percentage

The results show that the coal price is more important as regards product selection than its heat content, as q₈ and q₇ have lower prices and lower heat and ash contents whereas q₆ has a moderate price and a higher heat and ash content. q₁ on the other hand has a higher price, heat and ash content, and it is less preferred while the other coal products are not preferred. The amount of coal transported via each trans-load location should also be evaluated. Fig.4. shows the usage of trans-load locations, indicating that most of the coal is trans-loaded at T₃, followed by T₂, T₃, and T₁.

Fig. 4. Usage of Trans-Load Locations

IV. CONCLUSION

In this paper, a method is developed for the selection of the best supplier, transportation alternative, and coal orders given multiple suppliers, contracts, and multimode transportation routes in a fuel-coal supply chain. The solution method is applied to a case study for a power company located in the Midwestern USA. The results provide a mix of suppliers, transportation routes, and coal products for the power company to meet its needs. For the presented case, it is possible to do a benefit/cost analysis based on the results and this is considered for future extensions of the research. The ratio of the transportation cost in terms of the final price is presented for comparison purposes. The output analyses of the presented results are required to help the fuel supply department with future decisions. The methodology can be implemented as an integrated software using a graphical user interface (GUI) and it has the potential to be used by managers. Although the model is validated for a particular case study, the proposed methodology is applicable to manage any supply chain as it includes network constraints, demand constraints, and product characteristics. The model is especially suitable for commodities such as oil, liquefied natural gas, wheat, corn, wood, and metallic materials, with some required modifications due to the nature of the material.

Abstract—Today, we are faced with a growing need for recycling strategies in many industries as a result of limited capacity of reserves of natural sources and rising population which leads to increasing amount of consumption and waste. Marble is one of these industries. Since considerable amount of waste materials are produced in the mining, processing and polishing stages which also have a serious impact on the environment. Therefore, companies have a social responsibility to protect the environment and ensure the sustainable use of the natural resources. Marble wastes from the processing plant can be divided into two main product groups. The first product group is large-sized pieces of marble waste and the second product group is dust waste. Large-sized piece of marble wastes are stored in marble waste storage area for reusing in plants or selling to other small firms. On the other hand, marble dust wastes are sent to recycling centers for using in different industries such as cement production, glass production etc. In this paper, a linear programming (LP) model is proposed for a remanufacturing system of marble industry, which includes both forward and reverse flows. The objective of the model is to minimize the transportation, recycling, cutting operation, holding and fixed opening costs in a reverse logistics network. Revenues obtained from selling the reused parts and solid dust wastes are also considered in the proposed model. Application of the proposed model is illustrated by a numerical example. Several closed-loop supply chain scenarios are discussed on this example in order to show the performance and applicability of the proposed model in the marble industry.

Abstract—This work studies a problem of integrated three-dimensional loading and vehicle routing problem which consists of some practical thoughts related to vehicle capacity such as physical feasibility of arrangements. Despite their practical importance in transportation operations, these cases usually do not considered in a realistic way in the previous studies. This is mainly due to the fact that adding these constraints increase combinatorial complexity of problem considerably. This work aims to present a mathematical model that strengthen the formulation of these two combinatorial optimization problems (“Vehicle Routing Problem with Time Windows” and “Container Loading Problem”) in an integrated way. In order to test the quality and efficiency of the proposed mathematical model a sample problem is solved. The result of the integrated approach is also compared with the separate solution of these two problems. The test results demonstrate that the proposed approach has a potential to solve this complex problem.

Keywords—vehicle routing problem with time windows, container loading problem, mathematical modeling

Investigation of the companies' perspective on occupational health and safety culture in scope of joint health and safety agencies

Abstract— In the globalizing world; technological, scientific, artistic, and cultural developments, regardless of industry, nowadays require the need for businesses to become structured with innovative ideas, sustainability conscious developments while attending the workers' health and safety. Businesses are now obliged to ensure that employees are in a healthy and safe working environment before, during and after work within the scope of occupational health and safety (OHS) regulations. The provision of this environment is possible through the establishment and dissemination of OHS culture. With the employment law no. 6331 enacted on 2012 and the further legislations enacted due to the EU harmonization, Turkish companies are obliged to attend these issues on their own or with the help of a joint health and safety agency (JHSA). As stated by legislation No: 28512, JHSA acts as a private establishments comprised of work health and safety professionals who are authorized by the Ministry of Employment and Social Security, established to provide businesses with work health and safety services and possess the physical and medical capability required by the regulation. In this study, perspectives of companies on OHS culture were investigated.

In the scope of this study, a survey is conducted to businesses operating in Western Marmara Region that work with JHSAs to receive services for the obligations required to be fulfilled in terms of OHS. The purpose of the survey is to determine whether or not the OHS culture varies according to the demographic features of employees and reveal whether or not there is a connection between the OHS applications of the JHSAs in workplaces and the safety communication perception. The survey results are analyzed with the SPSS 21.0 program. This analysis provides a an insight of OHS culture from eight different views; i.e. procedures/policies, accidents, ergonomics, personal protective equipment, physico-social factors, awareness, training/attitude, the usage of control list that were developed by the Ministry of Labor and Social Security, especially to be used in these kinds of businesses. In this context, the results clearly show that businesses that fulfill their OHS obligations with the help of JHSAs do not fully comprehend the importance of the OHS culture and as a result they cannot internalize the concept of OHS. Inevitably, the businesses do not consider this culture as a part of their management system. Using the detailed analysis of the results, it can be clearly stated that while providing all the work health and safety services, JHSAs should also carry out awareness activities to increase businesses' understanding of the OHS concepts and implement sector specific training programs. Additionally, business should not let the agencies to provide the services but also they have to take active part in OHS management during agencies' services to form an interactive relationship and communication structure. Specifically, to overcome these types of problems, there is a greater need for conjoint attempts including both sides of the relationship.

Abstract— Social innovation is finding and implementing new solutions, strategies to social problems in order to create social value and provide a sustainable life for people, society and the planet. Social entrepreneurs can either be an individual, a group/team or a firm/company who are willing to contribute to the solution of the problems we face today with social innovation projects. Every project realized by social entrepreneurs does not only contribute to the solution of the problem discussed but at the same time changes the attitudes, perceptions, behaviors and methods that cause the problem to arise. Institutions engaged in social innovation do not consist only of public institutions, foundations, associations and non-profit-making companies. Profit-oriented companies may also conduct projects for social innovation, and their gathering can make a significant contribution to a sustainable life. Since innovative social projects require multilateral work, a variety of projects have recently been produced by public, private and non-governmental organizations. In actualizing these projects usually organizational, sectoral or disciplinary boundaries need to be spanned.

The main difference that distinguishes social innovation from other innovations is that the main purpose of the innovation process is not to achieve financial gain but to aim for generating social value. The purpose of a good social innovation project depends on for whom it is done. For this reason, social innovation has been explored as the main method in solving problems such as the lack of communication emerging in the society and the coming generations and conflicts between communities, with the rapid technological development, rapid city experience and the social media entering more to our lives.

This paper focuses on successful examples of social innovation development and implementation to identify the main success factors. First, the definition of social innovation is given. Then the scope and characteristics of social innovation are discussed. Following this, main actors involved in solving social issues and their roles are mentioned. Additionally, main success factors are derived based on successful examples of social innovation development and implementation.

The case study research method, which is an empirical inquiry that investigates a contemporary phenomenon using multiple sources of evidence within its real-life context when the boundaries between phenomenon and context are not clearly evident, is used in this study. First of all, a literature review about related topics are made. Then, the appropriate cases are selected. The secondary data are gathered for each case. Then the data is evaluated and interpreted in order to find linkages between the research object and the outcomes with reference to the research questions. When examining case studies on social innovation, the reasons for the emergence of the problem in the society, the actors involved in the solution of the problem, the aim and way of their involvement, factors that affect the success are examined.

Findings demonstrate that various actors can be involved in social innovations such as government, international organizations, civil society organizations, private companies, social enterprises, social entrepreneurs, social movements, social media, universities and there is a mission and method diversity on social innovation actors. Based on the major contributions of different actors, social innovation can be considered to have two main phases, development and implementation. Main factors for successfully implementing social innovation include awareness about social issues, good problem definition, availability of resources, use of technology, having different viewpoints, collaboration with inquisitive and creative organizations for effective presentation, number of voluntaries involved, developing a strategic policy for social innovation.

Abstract – Creating sustainable business success cannot be achieved only through maximizing short-term profits. Beside the economic missions, there are also social missions of businesses. Customers expect social benefits from the firms that also provides sustainability. One of the most important tools to create a positive image is social innovation activity. Consequently, social innovation is becoming important for corporations. Today's companies focus on the social and environmental problems to obtain business success to be competitive. Resource allocation in the social fields such as arts, culture, education, environmental protection, health care etc., to create a social investment strategy for it, set up partnerships with non-governmental organizations, to launch innovative initiatives to solve social problems/needs, allocating employees to the social projects are increasingly adopted strategies for social innovations by companies.

The aim of this study is to evaluate the customer perception of social innovations on brand image, firm performance and customer loyalty. A web-based survey is developed and conducted. Survey was applied to 129 people. 109 surveys were valid. In the first part of the survey, information about social innovation is provided and a sample project is mentioned. The second part contains demographic information. The third part consists of the social innovation perception questions. The data obtained from the survey have been tested using SPSS 22. Explanatory factor analysis was used in this study to identify the main factors related to customer perception of social innovation effects. Responses are also analyzed to understand whether perceived social innovation effects differ according to a number of demographic variables. T-test was used for bivariate variable (gender) and ANOVA test was performed for multivariate groups such as (income, age) and results were evaluated.

Findings demonstrate that social innovations positively impact customer beliefs and attitudes. Demographic factors make a significant difference on customer perception. Two factors explain the %55.975 of the total variance which are named as firm performance and customer loyalty. Beside the social innovation activities, customers consider other factors (such as price, quality, past experience) for buying product or service. Research indicate that the main objectives of social innovation activities in firms are creating an image that is sensitive to social issues, working for social issues and making advertisement.

Abstract—A metaheuristic approach is proposed to solve joint dynamic flexible job shop scheduling (DFJSS) and maintenance scheduling problem in this study. An event-driven DFJSS with dynamic events is studied under sequence-dependent setup times. Moreover, order acceptance/rejection decision and Order Review Release (ORR) mechanism are adapted to the proposed approach in order to execute capacity adjustments regarding to customer due date requirements. A greedy randomized adaptive search procedure (GRASP) is proposed to deal with DFJSS with preventive maintenance. A preemptive goal programming based logic is considered with four objectives: mean tardiness, schedule instability, makespan and mean flow time. Benchmark problems are composed for different problem scales under dynamic events with preventive maintenance to emphasize real scheduling environment better. Fixed completion time of the preventive maintenance and non-fixed completion time of the preventive maintenance cases are considered. The results of the two preventive maintenance approaches are analyzed. Extensive computational tests are presented that the proposed GRASP algorithm can improve the job shop performance in comparison to employing basic dispatching rule based approaches for scheduling/rescheduling problems with maintenance activities.

Abstract—The effect of machine flexibility on the scheduling performance of dynamic job shops with different flexibility levels are analyzed in this study. Four different flexibility levels are defined for operations. A greedy randomized adaptive search procedure is proposed for event-driven dynamic flexible job shop scheduling problem under sequence-dependent setup times with order acceptance/rejection decision and order review release mechanism. In order to depict the performance of the proposed algorithm, six dispatching rules are evaluated according to mean tardiness as the performance criteria for the scheduling system. Benchmark problems are presented for different problem scales under dynamic events. Performance variations of the proposed algorithm and dispatching rules among different flexibility levels are determined and analyzed statistically. It is found out after the analysis that the effect of machine flexibility on dynamic job shop performance increases as the machine flexibility increases. The results are showed that the proposed algorithm is very effective and able to provide good schedules under event-driven scheduling scenarios.

Abstract— Nurse scheduling is a crucial part of hospital personnel scheduling. For effective nurse scheduling, fair workload and job satisfaction should be taken into account, because these factors directly affect the quality of service in healthcare systems. In this study, nurse scheduling constraints for a surgical suite are determined according to government regulations, hospital management requirements, and nurse preferences. First, the nurses can determine their preference for off days based on the priority of importance; for example, for their own planned surgeries, wedding day, or birthday. Then, shifts are assigned subject to the constraints that ensure fair workload in addition to the regulatory constraints. To generate an optimal nurse schedule which provides fair workload and satisfies nurse preferences for off days, a multi-objective integer program with hard and soft constraints is formulated in GAMS and solved using CPLEX as a goal programming model. Our main goal is increasing nurse motivation in order to help reduce the mistakes caused by fatigue as a result of working too many shifts. Therefore, service quality can improve in terms of patient care while optimizing the work schedule of nurses. The optimal schedules under various scenarios are compared to show the improvement in the schedule quality in terms of performance measures such as the proportion of nurse preferences met and distribution of unmet preferences.

Keywords—nurse scheduling; multi-objective optimization; integer program; goal programming; nurse preferences; fair workload distribution

I. INTRODUCTION

Healthcare systems have experienced drastic changes in the last few decades as a result of increasing population and technological developments that both increased life expectancy and incurred additional costs. There have also been budget cuts that force hospitals to use their resources more efficiently. Healthcare organizations have to work twenty-four hours a day for every day of the year and shift work is used in healthcare organizations in order to provide continuous service for patients. An important resource of a hospital is its surgical suite of operating rooms where nurse scheduling is one of the most challenging workforce planning problems since the quality of care provided by nurses depends greatly on their shift assignments and, thus, job satisfaction. Compared to the globally increasing demand for healthcare, the supply and retention of

qualified nursing staff has been insufficient [1]. This makes nurse scheduling one of the most significant issues in terms of hospital managements' expectations to use their budget wisely, patient expectations of continuous high quality care, and nurses' expectations of fair workload distribution.

Nurse scheduling is the task of specifying the work pattern for individual nurses and it can be generated manually by a head nurse or using software systems for scheduling. In most hospital units, nurse schedules are still manually developed by experienced head nurses who have to gather information from nurses about their time conflicts and have to adjust schedules as needed. However, developing a fair schedule manually is time consuming and difficult because of the vast number of possible schedules and all the constraints to consider. In practice, nurse schedules are typically developed for a period of four weeks. These schedules can be flexible, changing every period, or fixed. Fixed (or cyclical) schedules generally provide good solutions, but they cannot easily address staff preferences or fluctuating demand [2]. While generating nurse schedules, significant constraints should be considered such as observing work regulations, distinguishing between permanent and temporary staff, ensuring that night and weekend shifts are distributed fairly, allowing for leave and days off, and accommodating a range of employee preferences [3]. In this study, we address the flexible scheduling of nurses in a surgical suite where the nurse preferences for shifts are used as input to generate fair shift assignments.

The remainder of this paper is organized as follows. In section II, we review relevant work from the nurse scheduling literature. In section III, we present our integer programming model for nurse scheduling. We describe the solution methodology by formulating the goal programming model in section IV and demonstrate the use of this model with a case study in section V. We conclude the paper with our discussion of the study results and possible extensions of this work in section VI.

II. LITERATURE REVIEW

In this section, we provide an overview of existing literature on nurse scheduling, which is a special case of personnel scheduling. Personnel scheduling can be defined as generating

and arranging duty timetables for employees while considering certain work regulations, coverage constraints, or personnel preferences in order to satisfy the demand for the goods and services of organizations. Personnel scheduling has been studied widely for several decades in various application areas such as transportation systems, healthcare systems, call centers, emergency services, restaurants, hotels, and retail stores [3-8].

Our paper focuses on the nurse scheduling problem in a surgical suite (or operating theatre) that consists of operating rooms (ORs) and recovery rooms. This is especially a significant issue since the surgical suite has high operating costs and workforce planning directly impacts the efficiency of not only this unit, but also other units of the hospital that are related to the surgical suite [9]. According to Health Care Financial Management Association Report, ORs have been estimated to account for more than 40% of a hospital's total revenues, and it is both the greatest source of revenues and the largest cost center for hospitals [10]. Therefore, management of the workforce of a surgical suit is a crucial and complex issue for hospital administration. Nurse scheduling plays an important role in the efficiency of surgical suites.

In order to develop a nurse schedule, first of all, the required number of qualified nurses from various skill sets should be determined for each shift to meet the demand based on the number of patients in the wards or a predetermined patient-to-nurse ratio. Then, adequate nurses should be assigned to shifts in order to meet the service needs. The quality of nurse scheduling directly affects the quality of healthcare and job satisfaction of nurses [11]. Therefore, the schedule must strive to satisfy nurse preferences, distribute shifts fairly among nurses, and distinguish between full-time and part-time staff, in addition to abiding by work regulations determined by governments or other authorities and other hospital-specific constraints. These constraints can be classified as hard constraints, that cannot be violated, and soft constraints, that can be violated at a cost. Finding an optimal solution that minimizes the costs can be complicated regarding all these constraints at the same time. A wide range of solution methods are used to solve these complex problems, such as mathematical programming, simulation, queueing, constraint programming, and metaheuristics [3, 8].

Several studies have been published since the 1960s on various aspects of computerized healthcare personnel scheduling. Mathematical programming methods such as linear and integer programming are widely used for solving nurse scheduling problems [11]. While most of the mathematical programs have a single objective function subject to a restricted set of constraints as a result of oversimplifying assumptions, there are also several studies that use goal programming or multi-objective decision making. The most commonly used objectives of nurse scheduling problems are versions of cost minimization, that may either directly consider recruitment costs, nurse wages, and overtime costs or consider penalty costs for violating a set of soft constraints. Ozkarahan and Bailey [12] defined three goals to avoid understaffing while maximizing coverage and the utilization of nurses, then solved the problem

using a two-phase approach that first determines the day-of-week schedules and then the time-of-day schedules. Arthur and Ravindran [13] proposed a goal programming model solved similarly in two phases, first by assigning day-on/day-off patterns using goal programming and then by assigning shifts using a heuristic. Berrada et al. [14] treated the problem as a multi-objective model with hard and soft constraints, where soft constraints are used to define goals, and they solved the problem by goal programming and tabu search. Azaiez and Al Sharif [15] developed a 0-1 goal program with five goals and solved the monthly scheduling problem by subgrouping the nurses and workloads into manageable sizes. Wright and Mahar [16] compare centralized and decentralized nurse scheduling across two multi-unit hospitals and show that the centralized model performs better in terms of scheduling cost and schedule desirability.

The literature on nurse scheduling in surgical suites can be considered scarce compared to nurse scheduling in other hospital units. Belien and Demeulemeester [17] solve an integrated nurse and surgery scheduling problem using column generation. The daily surgery assignment of nurses is modeled as a multi-objective integer programming model and solved using a solution pool method and a variant of goal programming in [18]. Similarly, a nurse scheduling model with the objectives of minimizing labor costs, patient dissatisfaction, nurse idle time, and maximizing job satisfaction is presented in [19].

Although there is a considerable amount of literature on nurse scheduling, there are only a few studies that are based on nurse preferences to improve job satisfaction and that have multiple goals for equitable shift assignment among nurses. In this study, we give nurse preferences the highest priority after the demand-related hard constraints and consider multiple goals to ensure fair workload distribution. Next, we introduce our multi-objective integer programming model.

III. MODEL DEVELOPMENT

The nurse scheduling model proposed in this study is an integer programming model with the objectives of minimizing schedule cost and maximizing job satisfaction for nurses. The assumptions of our mathematical model for our multi-objective nurse scheduling problem are as follows:

1. Minimum number of required nurses in each shift is deterministic and known based on experience of demand since mostly elective surgeries are performed in the surgical suite.
2. There are two 12-hour shifts in a day: (1) from 7:00-19:00 and (2) from 19:00-7:00 (day and night shifts for 7 days a week, and 24 hours a day).
3. There are two skill classes of nurses: regular nurses and intern nurses.
4. Minimum staff level requirements must be satisfied.
5. Each nurse has to work at least 24 hours and at most 72 hours per week.

6. Nurses cannot work for more than 6 consecutive working days.
7. A nurse should not work more than 3 consecutive night shifts.
8. Each nurse works at most one shift a day. This is especially a necessary constraint for a surgical suite because of the high service level expectations and more arduous workload than other hospital units.

The notation used in the model formulation are explained below.

Sets

I	the set of nurses
J	the set of shifts in a day, where $j = 1$ for day shift and $j = 2$ for night shift
T	the set of days in the scheduling period
W	the set of weeks in the scheduling period

Parameters

p_{it}	$\begin{cases} 1, & \text{if nurse } i \in I \text{ prefers to work on day } t \in T \\ 0, & \text{otherwise} \end{cases}$
R	the number of regular nurses
NR_{jt}	the number of regular nurses required for shift $j \in J$ on day $t \in T$
NI_{jt}	the number of intern nurses required for shift $j \in J$ on day $t \in T$
h_L	lower limit on the number of hours that a nurse can work per week
h_U	upper limit on the number of hours that a nurse can work per week
cr_i	cost of regular nurse $i \in \{1, 2, \dots, R\}$ per shift
c_i	cost of intern nurse $i \in \{R + 1, \dots, I \}$ per shift

Decision Variables

$$x_{ijt} = \begin{cases} 1, & \text{if nurse } i \in I \text{ is assigned to shift } j \in J \\ & \text{of day } t \in T \\ 0, & \text{otherwise} \end{cases}$$

The mathematical model for the nurse scheduling problem is presented as follows.

Model Formulation

$$\text{Min } cr_i \left(\sum_{i=1}^R \sum_{j \in J} \sum_{t \in T} x_{ijt} \right) + c_i \left(\sum_{i=R+1}^{|I|} \sum_{j \in J} \sum_{t \in T} x_{ijt} \right) \quad (1)$$

Subject to

$$\sum_{i \in I} x_{ijt} \geq NR_{jt}, \quad \forall j \in J, t \in T \quad (2)$$

$$\sum_{i \in I} x_{ijt} \geq NI_{jt}, \quad \forall j \in J, t \in T \quad (3)$$

$$\sum_{t=7(w-1)+1}^{7w} \sum_{j \in J} x_{ijt} \geq h_L/12 \quad \forall i \in I, w \in W \quad (4)$$

$$\sum_{t=7(w-1)+1}^{7w} \sum_{j \in J} x_{ijt} \leq h_U/12 \quad \forall i \in I, w \in W \quad (5)$$

$$\sum_{j \in J} x_{ijt} \leq 1 \quad \forall i \in I, t \in T \quad (6)$$

$$x_{i2t} + x_{i1(t+1)} \leq 1 \quad \forall i \in I, t \in T \quad (7)$$

$$\sum_{j \in J} \sum_{t=k}^{k+6} x_{ijt} \leq 6 \quad \forall i \in I, k = 1, 2, \dots, |T| - 6 \quad (8)$$

$$\sum_{t=k}^{k+3} x_{i2t} \leq 3 \quad \forall i \in I, k = 1, 2, \dots, |T| - 3 \quad (9)$$

$$\sum_{t \in T} x_{i2t} \geq 3 \quad \forall i \in I \quad (10)$$

$$\sum_{j \in J} x_{ijt} - p_{it} \leq 0, \quad \forall i \in I, t \in T \quad (11)$$

$$\sum_{t \in T} x_{i2t} - \sum_{t \in T} x_{i1t} \leq 0 \quad \forall i \in I \quad (12)$$

$$\left(1 - \sum_{j \in J} x_{ijt} \right) + \sum_{j \in J} x_{ij(t+1)} + \left(1 - \sum_{j \in J} x_{ij(t+2)} \right) \leq 2 \quad \forall i \in I, t = 1, 2, \dots, |T| - 2 \quad (13)$$

$$\sum_{j \in J} x_{ijt} + \left(1 - \sum_{j \in J} x_{ij(t+1)} \right) + \sum_{j \in J} x_{ij(t+2)} \leq 2 \quad \forall i \in I, t = 1, 2, \dots, |T| - 2 \quad (14)$$

$$x_{ijt} \in \{0, 1\}, \forall i \in I, j \in J, t \in T \quad (15)$$

The initial objective function (1) minimizes the total cost of nurses assigned to shifts. Constraints (2) and (3) ensure that the required numbers of regular nurses and intern nurses are met, respectively, for each shift on each day. Constraints (4) and (5) bound the total weekly hours assigned to a nurse using the minimum and maximum allowed working hours, respectively. Constraint (6) avoids the assignment of more than one shift per day to a nurse. Assigning a day shift followed by a night shift or a night shift right before a day shift is prevented by constraint (7). According to constraints (8) and (9), a nurse can work for at most 6 consecutive days and can be assigned at most 3 consecutive night shifts, respectively. Constraint (10) ensures that each nurse is assigned at least 3 night shifts over the scheduling period. Constraint (11) avoids shift assignments on days that are not preferred by a nurse, in other words, over-assignment. Constraint (12) requires the total night shifts assigned to be at most as many as the total day shifts assigned to a nurse. Constraints (13) and (14) avoid the “0-1-0” or “1-0-1” types of assignments where a day on would be between two days off or a day off would be between two days on, which are both undesired cases from the nurse’s perspective. Constraint (15) defines the binary decision variables.

In this model, hard constraints that cannot be violated are (2)-(10) and soft constraints are (11)-(14). In the following section, the goal programming model is formulated by incorporating the penalty of violating these soft constraints in the objective function.

IV. SOLUTION METHODOLOGY

In the proposed model, soft constraints are (11)-(14). Therefore, in order to penalize the violation of these soft constraints, appropriate decision variables should be added to the model as explained below.

Goal 1: We modify the soft constraint (11) as follows:

$$\sum_{j \in J} x_{ijt} - p_{ijt} - o_{it} + u_{it} = 0, \quad \forall i \in I, t \in T \quad (16)$$

where the binary decision variables $o_{it} \in \{0, 1\}, \forall i \in I, t \in T$, and $u_{it} \in \{0, 1\}, \forall i \in I, t \in T$, represent the over- and under-assignment of shifts based on nurse preferences, respectively. It would be undesirable if a nurse is assigned to a shift on a day the nurse does not prefer as well as if a nurse is not assigned a shift

on a day the nurse prefers to work. Therefore, both of these variables are penalized using the following objective function:

$$\text{Minimize} \quad \sum_{i \in I} \sum_{t \in T} (\alpha o_{it} + \beta u_{it}) \quad (17)$$

where α is the penalty cost for assignment of a shift that a nurse does not prefer and β is the penalty cost for not assigning a shift that a nurse prefers, such that $\alpha > \beta$ because over-assignment is even more undesirable than under-assignment.

Goal 2: Soft constraint (12) is modified as follows to allow for deviations:

$$\sum_{t \in T} x_{i2t} - \sum_{t \in T} x_{i1t} - d_i^+ + d_i^- = 0 \quad \forall i \in I \quad (18)$$

where $d_i^+ \in \{0,1\}, \forall i \in I$, and $d_i^- \in \{0,1\}, \forall i \in I$, are the positive and negative deviations from the goal of assigning more day shifts than night shifts in total. The positive deviations from this goal is penalized by adding the following objective function:

$$\text{Minimize} \quad \sum_{i \in I} d_i^+ \quad (19)$$

Goal 3: Soft constraint (13) is modified as follows to allow for deviations:

$$\left(1 - \sum_{j \in J} x_{ijt}\right) + \sum_{j \in J} x_{ij(t+1)} + \left(1 - \sum_{j \in J} x_{ij(t+2)}\right) - da_{it}^+ + da_{it}^- = 2 \quad \forall i \in I, t = 1, 2, \dots, |T| - 2 \quad (20)$$

where $da_{it}^+ \in \{0,1\}, \forall i \in I, t \in T$, and $da_{it}^- \in \{0,1\}, \forall i \in I, t \in T$, are the positive and negative deviations from the goal of avoiding isolated days on. Only the positive deviations from this goal is penalized by adding the following objective function:

$$\text{Minimize} \quad \sum_{i \in I} \sum_{t \in T} da_{it}^+ \quad (21)$$

Goal 4: Soft constraint (14) is modified as follows to allow for deviations:

$$\sum_{j \in J} x_{ijt} + \left(1 - \sum_{j \in J} x_{ij(t+1)}\right) + \sum_{j \in J} x_{ij(t+2)} - db_{it}^+ + db_{it}^- = 2 \quad \forall i \in I, t = 1, 2, \dots, |T| - 2 \quad (22)$$

where $db_{it}^+ \in \{0,1\}, \forall i \in I, t \in T$ and $db_{it}^- \in \{0,1\}, \forall i \in I, t \in T$ are the positive and negative deviations from the goal of avoiding isolated days off. Only the positive deviations from this goal is penalized by adding the following objective function:

$$\text{Minimize} \quad \sum_{i \in I} \sum_{t \in T} db_{it}^+ \quad (23)$$

As a result of these goal formulations, the initial objective function is modified as follows.

$$\begin{aligned} \text{Min } z = & cr_i \left(\sum_{i=1}^R \sum_{j \in J} \sum_{t \in T} x_{ijt} \right) + c_i \left(\sum_{i=R+1}^{|I|} \sum_{j \in J} \sum_{t \in T} x_{ijt} \right) \\ & + \sum_{i \in I} \sum_{t \in T} (\alpha o_{it} + \beta u_{it}) + \sum_{i \in I} d_i^+ \\ & + \sum_{i \in I} \sum_{t \in T} da_{it}^+ + \sum_{i \in I} \sum_{t \in T} db_{it}^+ \end{aligned} \quad (24)$$

The objective function (24) is weighted sum of five different objectives: (i) minimizing the total cost of nurses assigned to shifts as in (1), (ii) minimizing the total penalty cost for the

undesired shift assignments according to nurse preferences as shown in (17), (iii-v) minimizing the total violation of soft constraints as shown in (19), (21), and (23), respectively.

Next, we describe our case study and present the computational results of our proposed model in terms of various performance measures.

V. COMPUTATIONAL RESULTS

In this section, we provide a numeric example for illustrating the nurse scheduling model presented above. Consider a surgical suite in which 30 nurses are employed in total. 8 of these nurses are intern nurses who are still in training. The other 22 regular nurses are more experienced and they have higher priority in terms of shift preferences and taking time off work. The planning horizon is four weeks (28 days, including the weekends). The minimum required number of nurses in each shift are generated based on the work regulations and are provided in Table I. The cost of a regular nurse per shift $cr_i = 3, i = 1, 2, \dots, 22$ and the cost of an intern per shift $c_i = 2, i = 23, 24, \dots, 30$.

TABLE I. MINIMUM NURSE REQUIREMENTS

	$j = 1$	$j = 2$
NR_{jt}	10	3
NI_{jt}	4	1

In order to measure the performance of the model solutions, we define the following terms (25) and (26).

Let ω be the number of nurses who are over-assigned, i.e., that are assigned a shift on a day they did not prefer to work, as shown below.

$$\omega = \sum_{i \in I: o_{it}=1} 1 \quad (25)$$

Let ρ be the ratio of the total number of over-assigned shifts to the maximum possible number of over-assigned shifts, i.e., the total number of days that nurses do not prefer to work on, as shown below.

$$\rho = \frac{\sum_{i,t} o_{it}}{|I|*|T| - \sum_{i,t} p_{it}} \quad (26)$$

The optimization model is formulated using GAMS 24.6 and solved using CPLEX 12.6 software on a 2.20GHz Windows laptop computer with 6GB RAM.

Base Case Scenario 1:

In our Base Case Scenario 1 all nurses are available on all days over the planning horizon, i.e., $p_{it} = 1, \forall i \in I, t \in T$. Assuming that $\alpha = \beta = 1$, the optimal value for the objective function (24) is $z^* = 1708$, $\sum_{i,j,t} x_{ijt} = 504$, which is exactly the total minimum required number of nurses (18 nurses/day*28 days=504 nurses), and $\sum_{i,t} u_{it} = 336$. In this case, since there cannot be any over-assignment, $\rho = 0\%$.

Base Case Scenario 2:

The other extreme is having all preferences set to zero, i.e., $p_{it} = 0, \forall i \in I, t \in T$. Assuming that $\alpha = \beta = 1$, the optimal value for the objective function (24) in this scenario is $z^* = 1895$, $\sum_{i,j,t} x_{ijt} = \sum_{i,t} o_{it} = 505$. In this case, $\rho = 60.11\%$.

These base case scenarios show us the limits on the objective function value and the limits on the quantity $\sum_{i,t} o_{it}$, as well as ρ , when $\alpha = \beta = 1$ at the two extreme nurse preference values.

Two different Preference Scenarios (PS) are developed to test the performance of the scheduling model. The first scenario, PS1, is designed such that 4 regular nurses each take a week off consecutively and all the other nurses have a preference of taking one weekday and one weekend day off. The preference matrix in this scenario results in the total number of undesired days by nurses to be $|I| * |T| - \sum_{i,t} p_{it} = 260$. In the second scenario, PS2, 4 more regular nurses each take a week off in addition to the PS1 preferences. Therefore, PS2 is a more restrictive scenario in terms of nurse availability. The total number of undesired days by nurses are $|I| * |T| - \sum_{i,t} p_{it} = 280$ in PS2. The problem is solved for these scenarios with different penalty cost α values for not meeting nurse preferences and all the problem instances are solved to optimality within at most 2 seconds. We present the optimal solutions of the proposed model for the two scenarios for various α values in Table II and Table III below.

When PS1 is used, the best possible schedule in terms of the total number of over-assignments is achieved for $\alpha \geq 5$ and at least 28 over-assignments can be made for at least 14 nurses as can be seen from Table II. There is a cost of 112 units for reducing the number of nurses over-assigned, ω , from 17 to 14.

According to the results shown in Table III, when the more restrictive PS2 is used, the best possible schedule in terms of the total number of over-assignments is achieved for $\alpha \geq 8$ and at least 32 over-assignments can be made for at least 17 nurses. PS2 is resulting in less under-assignment as expected, because the maximum possible under-assignments is less than that in PS1

TABLE II. RESULTS FOR PS1

α	z^*	$\sum_{i,t} o_{it}$	$\sum_{i,t} u_{it}$	da_{it}^+	db_{it}^+	ω	ρ

10	1835	32	88	11	44	17	0.1143

due to regular nurses having more days off preferred.

The positive slack variable for constraint (18), d_i^+ , is almost always zero, which means that the total day shift assignments almost never exceed the total night shift assignments.

In Fig. 1, the effect of increasing the penalty cost for over-assignment (α) on the proportion of over-assignments (ρ) is shown. Increasing α not only reduces ρ and the total over-assignments, but also the number of over-assigned nurses. This results in higher nurse satisfaction in terms of their shift preferences.

Fig. 1. The proportion of over-assigned shifts, ρ , for various α levels for the two preference scenarios, PS1 and PS2.

VI. CONCLUSIONS

In this study, we focus on the nurse scheduling problem where nurse preferences are given the highest priority after meeting the demand-related constraints that cannot be violated. We develop a multi-objective integer programming model with

hard and soft constraints and solve the model using goal programming. The model is designed to produce the best possible schedule in terms of meeting the shift preferences of nurses and fair distribution of workload. We illustrate the performance of the proposed model with an example under two different nurse preference scenarios. Computational results show that the multi-objective nature of the model leads to higher job satisfaction for nurses by avoiding the assignment of shifts that are not preferred, by avoiding isolated days on or off, and by avoiding unbalanced night shift assignments.

This model can be extended to allow more shifts per day, express the workforce requirements by surgery types, and to consider multiple skill sets for nurses based on these surgery types. Another extension could be using stochastic demand as input rather than deterministic demand so as to include emergency surgeries. Our model considers a wide set of constraints already, however, there are other scheduling constraints in the literature that can easily be added to this model such as constraints dealing with annual vacations or minimum number of weekend days off.

Abstract— This study focuses on building a layout plan by allocating storage space to products in a warehouse of a homeware retailer which allows for the minimum total travel distance of operators for order picking or placing. The study is carried out by (1) performing regression analysis for sales forecasting for each product class, (2) applying Analytical Hierarchy Process (AHP) for determining product class weights, and (3) formulating and solving an integer programming model to minimize the weighted total distance between storage locations, collecting area, and loading dock using GAMS. Optimal solution results in 26.8% less distance required for order picking than the previous layout.

Keywords—warehouse planning; storage location allocation; integer programming; AHP

I. INTRODUCTION

Storage of goods in warehouses has emerged with the purpose of protection of basic necessities from environment and climate conditions. Warehouse systems have changed and improved in terms of scope, purpose, and implementation with the improvement of industrial systems. Warehouses have become essential components of the supply chain of companies in the increasingly globalized and competitive world market. Nowadays, warehousing is commonly utilized in an attempt to not only store and protect goods but also to provide continuous raw material or product flow, to fulfill customer orders, and to carry out other relevant tasks such as packaging or inspection [1]. Producers purchase vast amounts of raw materials to be used in production to minimize the cost and time spent for raw material supply and they store them in their warehouses for later use at the expense of inventory holding cost. In order to reduce inventory holding costs, warehouse operations should be controlled such that deliveries are timely and storage space is available when needed. Well-designed storage systems, selection of appropriate storage policy and methods, and determination of the order in which the goods are stored increase the efficiency of warehouses and the whole supply chain [2].

The main areas in a warehouse are loading and unloading docks and storage area. Warehouses can be designed to use different levels of automation for storing and picking items. Operations can be manual (picker-to-product), automated

(product-to-picker), or completely automatic [3]. In a manual warehouse system, products need to be stored or distributed by operators and the location allocation of products affects the time and effort spent for order picking, thus, the performance of warehouse operations significantly. There are several storage location allocation policies such as randomized, dedicated, or class-based storage and the optimal policy can be different for each warehouse depending on the products and operations involved. This work focuses on building a layout plan by allocating storage space to classes of products in a distribution warehouse of a homeware company where manual order picking policy is practiced. The main issue that the company faces is late deliveries of items due to the time picking randomly stored products requires after an order is received. The goals of this study are (1) to determine the best location of different classes of products in a warehouse, (2) to minimize total weighted travel distance and order picking time, and (3) to maximize warehouse utilization.

The remainder of this paper is organized as follows. In section II, we provide a review of the relevant warehouse management literature. In section III, we present our integer programming model for storage location allocation. We describe our solution methodology in section IV and demonstrate the use of this model for a textile products warehouse in section V. We conclude the paper with our discussion of the study results and possible extensions of this work in section VI.

II. LITERATURE REVIEW

Order picking is the task of collecting items requested by customers from their storage locations and it is the most expensive operation in a warehouse, especially when the system is manual, in terms of the time and labor it requires. The cost of order picking is estimated to be almost 55% of the total warehouse expenses [4]. In our study we consider a distribution warehouse that operates with manual order picking policy. The time and labor spent for order picking depends on the layout, location of the goods, classification of the goods, and picking method. Considering the vast number of times that warehouse employees need to pick orders, even a small improvement of these factors would have a remarkable effect on the performance of warehouse operations.

Storage location assignment can be made by forward-reserve allocation, separating the bulk stock in a reserve area and the pick stock in a forward area [4]. Most frequently used storage policies are random storage, closest open storage, dedicated storage, full-turnover storage, and class-based storage. Random storage may increase space utilization, but causes long travel distance. At the other extreme, dedicated storage can result in low space utilization, but order picking is easier. In full-turnover storage, products with highest turnover rates are located in easier to reach areas. Class-based storage combines mainly dedicated storage and full-turnover storage. Products can be classified using ABC analysis where the fastest moving products are in class A.

Retail stores also require efficient location allocation of products to improve product visibility and accessibility. Hwang, Choi, and Lee develop a model for shelf space allocation and inventory control with an objective to maximize the retailer's profit [5]. Chen and Lin apply the multi-level association rule mining to the problem of product assortment and shelf space allocation for a retailer [6].

Making decisions based on the distances in the warehouse and product classifications are common features of warehouse storage allocation studies. Roodbergen and Vis study travel length expressions for two different route heuristics and they use these expressions for optimization of the warehouse layout [7]. Ng developed a weighted linear optimization model for solution of ABC stock classification model. All criteria are converted to a single scalar score and stock classification is performed with the ABC method with the evaluated score [8]. Bragg emphasized the ABC classification to be an effective method in the majority of research done in this area [9]. He recommended the assignment of location codes to all inventory locations. Öñüt et al. planned a particle swarm optimization algorithm to design a multi-level unit load warehouse employing class-based storage where classification is made in terms of effectiveness [10]. Heragu et al. develop a mathematical model for product allocation and determining the functional area size simultaneously with a heuristic algorithm that minimizes handling and storage costs [1].

The relevant research on order picking and storage allocation suggests that class-based storage results in a better warehouse performance. We present our mathematical model in the next section.

III. MODEL DEVELOPMENT

We develop an integer linear programming model that will find the storage location allocation that has the minimum weighted distance from loading dock and collecting area for all products. Assumptions of the model are as follows:

- Storage locations are represented on a two dimensional space such that the vertical racks are merged into one storage location.
- Storage locations have equal space and are identical, i.e., any product class can be stored in any storage location.

- The minimum unit of products is called a *pallet* which is equivalent to the capacity of a single storage location.
- Distances are measured from the center of each storage location to the center of the collecting area or the loading dock.
- Euclidean-distances are used considering the shortest (straight) path from the storage location to the end of an aisle and the shortest path from the end of an aisle to the destination (collecting area or loading dock).
- Even though demand is stochastic, the maximum number of pallets of products of each class that needs to be stored in the warehouse can be determined based on historical sales data.

The notation used in model formulation is defined below.

Sets

- I the set of product types stored in the warehouse
 J the set of storage locations in the warehouse

Parameters

- d_j distance between storage location $j \in J$ and loading dock of the warehouse
 k_j distance between storage location $j \in J$ and the collecting area
 W_i AHP-based weight of product type $i \in I$
 P_i total number of pallets of product type $i \in I$ to be stored in the warehouse

Decision Variables

- x_{ij} binary variable that is equal to 1 if product type $i \in I$ is stored in storage location $j \in J$

The model formulation is shown below.

$$\text{Min } z = \sum_{i \in I} \sum_{j \in J} W_i (d_j + k_j) x_{ij} \quad (1)$$

Subject to

$$\sum_{i \in I} x_{ij} \leq 1 \quad \forall j \in J \quad (2)$$

$$\sum_{j \in J} x_{ij} \geq P_i \quad \forall i \in I \quad (3)$$

$$x_{ij} \in \{0,1\} \quad \forall i \in I, j \in J \quad (4)$$

The objective function (1) is to minimize the total weighted distance to loading dock and collecting area for each product with the product weights. Constraint (2) ensures that there has to be one pallet in one cell. Constraint (3), uses the total amount of each product type as the lower bound on the number of pallets placed. Constraint (4) is for the binary decision variables.

Next, we discuss the methods used for obtaining the required input parameters and the solution of the optimization model.

IV. SOLUTION METHODOLOGY

In order to find the optimal storage location allocation of product classes, first we need to determine (1) the sales forecast for each product class, and (2) weights for each product class based on the share of a product class in total sales. Below we explain the procedure used to obtain the aforementioned values.

A. Regression Analysis

Regression analysis is used for estimating relationships between two or more variables. The knowledge of the existence of relationship between variables, and if exists its strength can be acquired with regression analysis. Linear regression demonstrates the relationship between variables as dependent and independent variables with a linear equation. In the general multiple linear regression model, there are p independent variables and the regression model is $Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_p x_{ip} + \varepsilon_i$, where x_{ij} is the i^{th} observation on the j^{th} independent variable, and where the first independent variable takes the value 1 for all i (so β_1 is the regression intercept). The least squares parameter estimates are obtained by solving the system of p linear equations. We use linear regression to forecast sales of product classes so that the maximum number of pallets to be stored in the warehouse can be determined. We demonstrate sales forecasting for our case study in section V.

B. Analytic Hierarchy Process

Analytical Hierarchy Process (AHP) is a decision making method that involves pairwise comparisons of criteria and relies on expert judgement to prioritize these criteria [11]. At the top of the hierarchy, there is the goal of the decision. At the lower levels of hierarchy the elements that contribute to the goal exist. Details of these elements can be increased at the lower levels. At the lowest level of the hierarchy, decision alternatives or options exist. Based on the decision hierarchy, pairwise comparison matrices are constructed. Upper level elements are used to compare the elements in the level below. Priorities for each element are found and finally the overall priority of each element is obtained. AHP is used for finding the weights of homeware product types based on the quantity, income, and volumetric weight criteria in section V.

V. CASE STUDY AND COMPUTATIONAL RESULTS

Our case study is based on one of the most popular textile companies in Turkey that entered the Turkish market in 2008. As of the end of 2016, the company has more than 280 stores in Turkey and more than 70 stores in other countries such as Bulgaria and Ukraine. The company has two warehouses. One of them is located in Gebze, Kocaeli. It is used for products which are shipped to stores. This warehouse has 11,300 m² and up to 130,000 products can be stored here. There are 110 employees that can collect or load approximately 18,000 pallets within their daily operations. The second warehouse is located in Akyazı, Sakarya. It is used for products of the online store and returned products. This warehouse has 5,000 m² and up to 60,000 products can be stored here. There are 55 employees that can process approximately 9,000 pallets per day. Both of these

warehouses operate with a randomized storage method and manual order picking. In our case study, we focus on the Akyazı warehouse since online shopping has recently increased and timely delivery of products purchased online is deemed more important at this point in terms of customer satisfaction.

Necessary inputs are the physical distance between each storage location and the order collecting area, k_j , the distance between each storage location and the loading dock, d_j , and the AHP-based weight of each product class, W_i . These input data are determined and the integer programming model is solved as explained in the following subsections.

A. Distances

The physical layout of the warehouse consists of 46 rows of storage space with five racks vertically. In order to work on a two-dimensional layout, five racks in one column are considered as a single storage location that can contain one pallet of products. In each row there are 68 columns, therefore, our storage area can be represented as a 46-by-68 matrix with 3128 cells where each cell represents a storage area, i.e., $J = \{1, 2, \dots, 3128\}$.

We calculate the distance for each cell to the loading dock and to the collecting area in the warehouse, therefore we created two matrices for distance. For example, we calculate the distance between cells and the collecting area using Euclidean distances as shown in Fig. 1. A storage location $j \in J$ can have a distance of $k_j = a$ or $k_j = x + y$ depending on its location in the aisle.

B. Sales Forecast

The products are grouped in 17 classes, i.e., $I = \{1, 2, \dots, 17\}$, such as “Accessories”, “Blankets”, or “Carpet & Rugs”. The number of products in each class sold in each month between 2010 and 2015 are obtained and converted to the number of pallets by dividing the number of products by the pallet capacity for each product class. By using linear regression, we performed the sales forecast for each month in 2016 based on the same month's sales in the past six years such that the seasonal changes in sales are accounted for. The results of the linear regression are adjusted according to expert opinion about the sales of each product class and the warehouse capacity that can be used for these products. The sales forecast in terms of pallets is used for choosing the maximum number of pallets for each product class as parameter P_i , $i \in I$, as shown in Fig. 2.

C. Product Class Weights

The weight for each product class is determined through AHP using Super Decision software. First, a goal node is created in the program and three criteria are added: (1) quantity expected to be stored, (2) income obtained from sales, and (3) volumetric weight. The alternatives are defined as the product classes. The goal node is connected to criteria and criteria is connected to alternatives as can be seen in Fig. 3.

Fig. 6. Optimal randomized location allocation in the warehouse.

When the proposed class-based storage policy is used, the optimal objective function value for the proposed model with the class-based storage policy is 177,121 m. This is the sum of distances of each product from the dock and collecting area multiplied by the product class weights. The optimal solution leads to a location allocation for the 17 product classes as shown in Fig. 7, placing more demanded product classes in closer locations to the collecting area and the loading dock.

Comparison of the two policies shows that the proposed class-based storage decreases the total weighted distance by 26.8%. By using this model, warehouse employees will take fewer steps and they will collect products and prepare the orders faster than in the randomized model. In the long run, if the company uses this model they may not need as many as 55 employees in a single warehouse to maintain the same level of service. As this warehouse is mostly for online store products, the company can improve customers' online shopping experiences by implementing a product class-based storage.

VI. CONCLUSIONS

The main objective of our project was to construct a model to allocate storage locations for products to improve the order picking performance. An integer programming model is used to minimize a distance measure weighted by product class priorities. Linear regression is used to forecast sales and AHP is used to determine product class priorities or weights. The results show that the class-based product locations result in shorter travel distances and, thus, time. As stated in the comparison section, results are 26.8% more effective than the randomized product storage. Model results are satisfying and this work is suggested to be applied at the company warehouse.

Fig. 7. Optimal class-based location allocation in the warehouse.

However the model has some limitations. The model can be improved by considering the specific order picking algorithm to evaluate distance travelled more accurately. Besides, five racks of items are assumed as one pallet to achieve a reasonable problem size in a two dimensional system, so, the model can be expanded to a three dimensional model. Additionally, more store constraints can be added on volume and weight of products, for example, heavy products are better stored in lower racks than higher racks.

Warehouses are vital elements of a supply chain and any improvement of the warehouse affects the supply chain performance. The proposed product storage location allocation model in this study is shown to have a strong potential to improve the order picking process and lead to more timely deliveries.

Abstract— Diffusion of innovations is a theory developed by Rogers that examines to explain how, why, and at what rate new ideas and technology disperse. Rogers suggests that the innovation itself, communication channels, time, and a social system are the main elements of generating new idea, and humans are the key for spreading the innovation.

Any idea, practice, process or technology that is perceived as new by people or organization can be considered as innovation. Adopters are individuals, but can also be organizations such as firms, hospitals or schools. Rogers offers five categories of adopters in order to systematize the usage of adopter classes in diffusion research. Adopter categories are defined as pioneers, early adopters, early majority, late majority, and laggards according to the degree of accepting a new idea.

The purpose of this study is to classify healthcare personnel in hospitals in Turkey according to their acceptability of new technology (information systems) based on Roger's Diffusion of innovation theory. With this framework, hospital management can have the opportunity to predict the risks of innovation by evaluating their own personnel in an implementation of new technology or idea. Thus the management can manage the change easily.

The survey has been applied on a total of 149 health personnel from the hospitals called "Adana Numune" in Adana and the results are compared with Roger's innovation categories. The individual innovation measurement model of Hurt et al. (2013) was used to evaluate the degree of innovativeness of health staff. First, the data were compiled and formulated for each category based on the categories of Rogers with the help of MS Excel (2007). Then the data were analyzed with SPSS 21 software program and descriptive statistics were generated.

As a result, while Roger's innovation categories were constructed from five classes, four classes emerged in this study. There were no pioneers among the adopters of health personnel in the hospital. The class of traditionalists known as "Laggards" was only 7% in this study. According to Roger, this value is 16%. Late Majority (34%) category defined by Roger is greater than the results of this study (21.5%). The percentage of the personnel in the Early Majority group is more than half (61.1%) of the respondents while it was mentioned as 34% according to Rogers. Only 16.8% respondents belong to the Early Adopters category.

In conclusion, the hospital has the most personnel from the category of Early Majority. This means that these employees adopt the innovation longer time later than pioneers and early adopters. Their social statuses are above the average, they are both cost sensitive and also risk averse. The management of the hospital has to support them by convincing the benefits of innovation since seldom they behave as opinion leaders in the system and they prefer to interact frequently with peers.

A Decision Support System for the Optimum Log Transportation

Ahmet Yücekaya

Department of Industrial Engineering, Faculty of Engineering,

Kadir Has University

İstanbul, TURKEY

E-mail: ahmety@khas.edu.tr

Abstract— Forest product industries deal with loggers, sometimes directly with wood dealers, to cut, shape and transport logs from different locations to different regions. The number of trucks are limited and the drivers have defined work hours and they have to return to hub at the end of their travel. The problem is a variant of truck scheduling problem and it includes time windows, demand constraints and multiple visits. The objective is to determine the most efficient route for given number of trucks, mills, loggers and load demand from the mills. In this paper, the problem is formulated as an integer programming model and a spreadsheet based decision support system is designed to help operation managers to schedule the deliveries. The proposed approach is validated using a real case study and the results are implemented in a Decision Support System for the operation managers

Keywords—log transport; vehicle routing; integer programming; decision support system

I. INTRODUCTION

Especially in the southern US, trees are harvested and processed using what is termed a ‘Tree-length’ approach. The felled trees are first processed (removal of remaining limbs and tops) either manually by capable log makers or by using sophisticated machines. Then the logs are transported to the specific mills such as saw mills and paper mills which are already established in a certain location.

Forest product industries deal with loggers, sometimes directly with wood dealers, to cut, to shape and transport from different locations to different regions. The main problem is that the locations that woods being cut are far away from the actual factories or the regions, so trucks are assigned to make transportations. Most of the time trucks transport the loggers and woods from one location to other and return back as empty; so it causes lots of time consumption and cost increases. In order to make this process efficient and cut the cost and time consumptions, optimal routes and truck transportations method should be found.

Forest industry is forced to be more careful about their costs. The industry in other countries have invested in logging technology and lowered delivered wood costs through

innovation in logistics and the Forest industry need to be decrease their cost in order to compete. Loggers are looking for ways to lower their operating costs.

Currently the scheduling of trucks to loggers and mills is done manually and they do not utilize any solution method to solve the problem efficiently.

The problem is to find optimal route for given number of trucks, mills, loggers and load demand from the mills from loggers. Each truck will be scheduled to some routes and the demand will be met along with the minimized cost.

There are some researches about the log truck scheduling problem that are considered in the literatures of transportation and routing management. Road planning and transportation operations in forestry gets 40% of the costs. Any improvement can help save money in current logistics system.

As the log-truck scheduling problem is a subset of vehicle-routing problem, the researches are classified in vehicle routing studies. Relevant literatures are being reviewed in this chapter.

Gerdesson [1] has made an attempt to solve the vehicle-routing problem with trailers. The problem is solved in two phases. Construction heuristics are first used to obtain a feasible solution and then improvement heuristics are used to obtain an improved solution from the initial solution.

Chao [2] models a truck and trailer routing problem and uses the tabu search heuristic to solve the problem. The customers are assigned to the trucks by relaxing the integrality constraint and obtaining a linear initial solution. Sumichrast et al. [3] have compared the solutions obtained by a heuristic algorithm with that of a lower bound integer programming solution from a commercial solver. The problem size used in the paper was small in terms of demand met for the day and in the number of trucks used to meet the demand.

Thangiah et al. [4] have developed a heuristic algorithm for the vehicle routing problem with backhauls and time windows. The loading time, unloading time and waiting time were exclusively accounted for when calculating the total route time of the trucks. Czech et al. [5] have used parallel simulated annealing algorithm to solve a vehicle routing problem with time window without any backhauling. The objective function minimized the number of vehicles used as

well as the total distance traveled. The truck could only serve customers whose total demand is less than the total capacity of the truck in one trip.

Ronnquist [6] describes the scope for optimization in various stages of forestry beginning with harvesting, bulking, crew scheduling, road building, fleet management, truck scheduling and ending with production planning. Solution methods such as dynamic programming, linear programming methods, branch and bound methods, heuristics and column generation were used for the optimization. Bent et al. [7] have modeled the dynamic vehicle routing with stochastic service times and customer locations using the Multiple Plan Approach and Multiple Scenario Approach. The Multiple Plan approach's main idea is to generate and maintain all possible sets of routing plans along with the main routing plan. Weintraub et al. [8] discusses the need to centralize ownership of the trucks in order to schedule the trips efficiently. The paper explains that the trucks should start and end the day from a place which is very near to the driver's home. The paper mainly aims at meeting the demand and did not take into consideration any optimization or heuristic approach to reduce the unloaded miles traveled. Palmgren et al. [9] proposed a solution approach based on column generation and pseudo branch and price for the log-truck scheduling problem. The solution approach starts with generating an initial set of feasible routes followed by pricing using dual variables in order to reduce the cost of the routes. Hirsch et al. [10] have used four different tabu search approaches and a few post optimization heuristics to solve the timber transport vehicle routing problem. One standard tabu search approach searches a large neighborhood whereas the tabu search with limited neighborhood approach searches a very limited neighborhood, and the third approach is a combination of the above two approaches. Valenzuela et al. [11] have designed a transportation scheduling system for silvicultural projects considering project due dates, precedence relationship and transportation costs. They considered five different classes of resources. The solution approach consists of two stages starting with simulating the network and then improving the solution using a search heuristic. Haridass et al. [12] use simulated annealing for scheduling a log transport system. They have modified operators and they return better results comparing the the existing system.

In this research, an integer model that considers time windows, speed limit, trip constraints and demand requirements developed for the efficient management of a log transport system. Then the model is integrated with a Decision Support System to help operations management decisions. The remainder of the paper is organized as follows: Section 2 formulates the problem, Section 3 provides a case study developed for a company in Luisiana, USA. Conclusions are given in section 4.

II. LOG TRANSPORTATION PROBLEM

In the pooled transport management system, trucking resources are distributed among a group of loggers. The trucking resources are dispatched by a centralized operator.

In order to find the solution to the problem, a 0-1 Linear / Integer Programming has been developed to find the set of routes that minimizes total traveled unloaded distance.

The objective is to minimize the total unloaded miles traveled. In other words, we will minimize the cost by minimizing total unloaded miles traveled. The notation for the model is given in Appendix A.

$$\text{Min } F = \sum_{i=1}^T \sum_{l=1}^L \sum_{m=1}^M \sum_{j=1}^N Y_{ilmj} D_{lm}$$

Decision Variable (0, 1)

Distance (Miles)

The model has some constraints related with trucks and related with loading. A truck can make at the most one trip at a time to a mill which can be represented as below:

$$\sum_{l=1}^L \sum_{m=1}^M X_{ilmj} \leq 1 \quad i = 1 \dots T, j = 1 \dots N$$

A truck also can make at the most one trip at a time to a logger.

$$\sum_{l=1}^L \sum_{m=1}^M Y_{ilmj} \leq 1 \quad i = 1 \dots T, j = 1 \dots N$$

If a truck travels from any logger to mill m , then it must travel from mill m to any logger in the next trip. This is because the unloaded truck in the mill should go to a logger to get loaded.

$$\sum_{k=1}^L Y_{imkj} \leq \sum_{k=1}^L X_{ikmj} \quad i = 1 \dots T, m = 1 \dots M, j = 1 \dots N$$

If a truck travels from any mill to logger l , then it must go to any mill in the next trip. This is because the loaded truck in the logger should go to a mill to get unloaded.

$$\sum_{k=1}^M X_{ilkj+1} \leq \sum_{k=1}^M Y_{iklj} \quad i = 1 \dots T, l = 1 \dots L, j = 1 \dots N-1$$

Total number of loads transported from logger l to mill m by all trucks must be equal to the number of loads at logger l with destination m . This is the demand constraint.

$$\sum_{i=1}^T \sum_{j=1}^N X_{ilmj} = S_{lm} \quad l = 1 \dots L, m = 1 \dots M$$

A driver drives no more than 8 hours at an average speed of 45 Mph and 360 miles totally. This is the driver's constraints.

$$\sum_{l=1}^L \sum_{m=1}^M \sum_{j=1}^N (X_{ilmj} + Y_{imlj}) d_{lm} \leq 360 \quad i = 1 \dots T$$

X and Y are binary variables since we do use integer programming.

$$X_{ilmj}, Y_{imlj} \in (0,1)$$

The Problem is a variant of classic truck routing problem which is The truck routing problem is a complex combinatorial problem and few approaches to solve the problem have been proposed in literature. There are many heuristic approaches like tabu search, column generation, branch and bound heuristics to solve the general vehicle routing problem where the destinations are visited only once. But in case of the log truck scheduling problem multiple visits to a single mill or logger are required to meet the demand. Since this involves repeated visits to the customer sites, it can't be easily solved using the existing heuristic approaches. A schematic view of the system is given Fig. 1.

Fig. 1. A Log transport system

III. CASE STUDY

The proposed methodology is illustrated for a case study for a company in Luisiana, USA. For the illustration of the solution approach, a real data-set from the company is provided and checked with the classical method. In a typical day the company has T=4 trucks, M=2 mills, L=3 loggers and N=4 trips. In this case of the log truck scheduling problem with multiple visits to a single mill or logger, there are 192 variables and 146 constraints. The distances between loggers and mills are provided in Table 1 whereas daily demand from mills are provided in Table 2.

Table 1. Distances Between Mills and Logs (Miles)

Logging sites	Mills
---------------	-------

	M1	M2
L1	70	67
L2	65	76
L3	45	51

Table 2. Daily demands from mills

Logging sites	Mills	
	M1	M2
L1	1	2
L2	2	3
L3	2	1

The problem is a complex combinatorial problem and the number of iterations increases as the number of trucks, mills, loggers and trips increase. A problem with a data-set given above can still be solved in a spreadsheet. The problem is modeled in a spreadsheet and it is designed as a decision support system. Basically, the decision support system converts the solution to a more acceptable information. A solution for the Truck 1 is given in Fig.2. the information from the provides the information

Fig. 2. A Solution for Truck1

The decision support system solves the problem for 4 trucks and determine a daily schedule for the trucks. The solution to log truck scheduling problem with 4 trucks, 2 mill, 3 loggers and 4 trips is given in Table 3.

Table 3 Daily Trip demands from mills

Truck #	Logger	Mill	Logger	Mill	Logger	Mill	Travel (Mil)
T1	L2	M2	L1	M2			207
T2	L2	M1	L3	M1	L3	M2	287
T3	L2	M1	L2	M2	L1	M2	332
T4	L1	M1	L3	M1	L2	M2	336

Note that the schedule also includes the travel distance. The objective of the model is to minimize the total unloaded mileage traveled from mills to logger. The total unloaded travel to this solution is 399 miles. The DSS is in modifiable format and can be used to solve the problems with different data-sets. The detailed screens for the DSS is provided in Appendix B.

IV. CONCLUSION

In this paper, a method is developed for the log transport optimization of a logger company. The problem is a variant of truck scheduling problem and it includes time windows, demand constraints, multiple visits and limited rest times. The problem is formulated as an integer programming model and a DSS is developed for the logger transport company.

The model successfully reaches to an optimal solution in an acceptable time for the given problem. All of the constraints are met and decision variables deliver the routes which then are converted as schedules by DSS. A spreadsheet, however, is limited with certain number of constraints and variables so a larger problem needs more sophisticated computation and solution methods.

APPENDIX A: NOTATION

T : Number of Trucks
M : Number of Mills
L : Number of Logger
N : Number of Trips
i : Denotes truck i ($i=1, \dots, T$)
m : Denotes Mill m ($m=1, \dots, M$)
l : Denotes Logger l ($l=1, \dots, L$)
j : Denotes trip j ($j=1, \dots, N$)
 D_{lm} : Distance from logger l to mill m
 S_{lm} : Number of loads going from logger l to mill m (Demand)
 X_{ilmj} : Equal to 1 when truck "i" goes from logger "l" to mill "m" during trip "j"
 Y_{imlj} : Equal to 1 when truck "i" goes back from mill "m" to logger "l" during trip "j"

APPENDIX B : DECISION SUPPORT SYSTEM

Welcome Workbook

There is an explanation about the problem and company history. Then it will continue to the main menu.

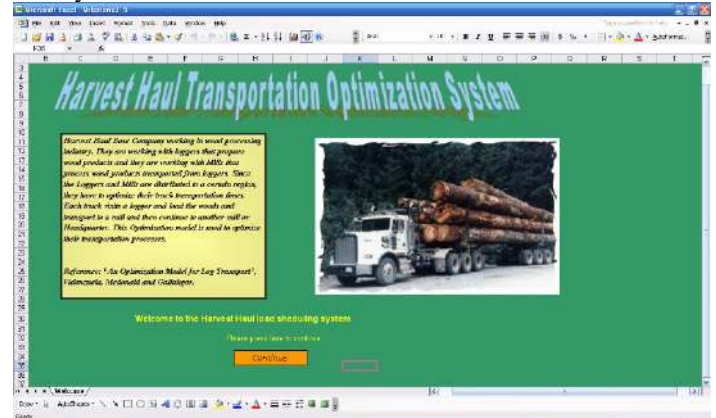

Fig. 3. Welcome workbook

Main Menu

There will be links to other workbooks and solution to the problem.

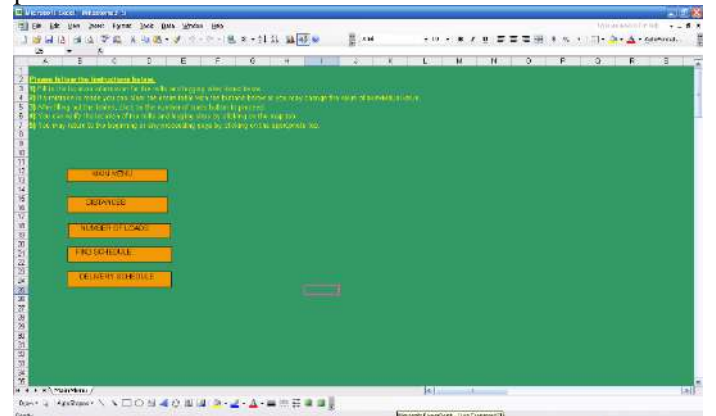

Fig. 4. Main menu workbook

Distances

In this workbook, the matrix shows the distances between mills and loggers. A user will be able to input and change the distances.

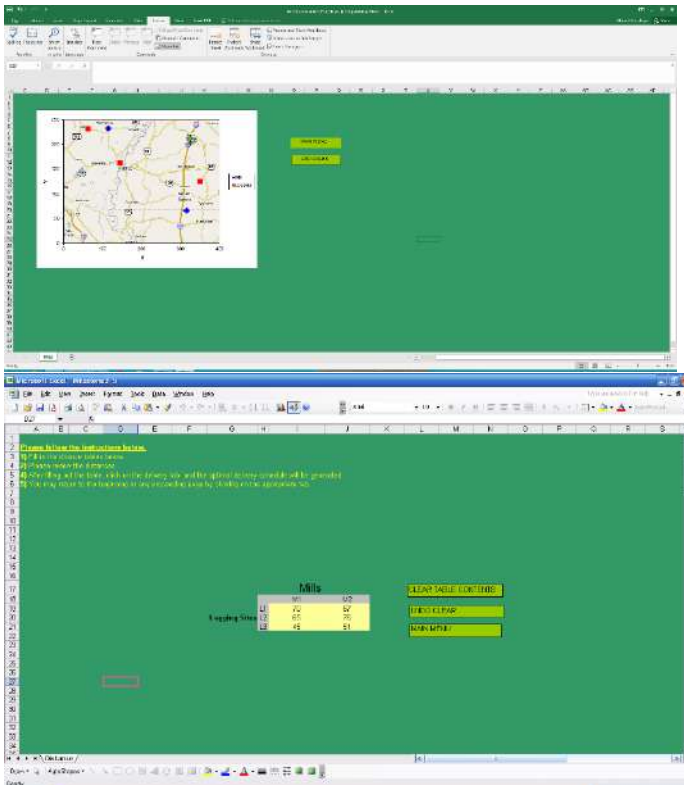

Fig. 5. Distance workbook and distance matrix

Load Information

In this workbook, the matrix shows the loads to mills from each logger. A user will be able to input and change the loads.

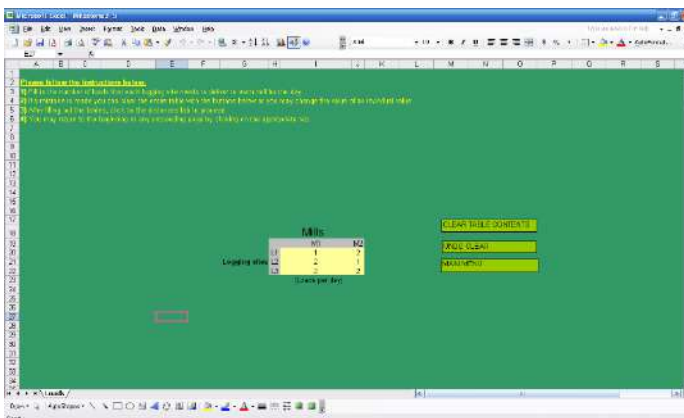

Fig. 6. Loads workbook and load matrix

Find schedule and model

This button will run the excel solver in the model section. This is a macro that is run in background.

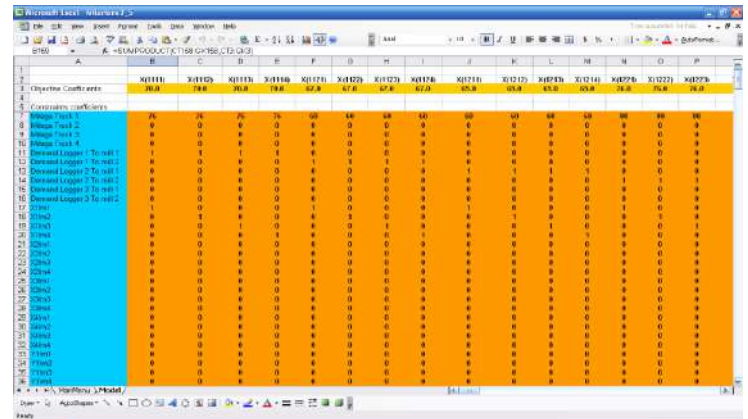

Fig. 7. Model workbook that include constraints and variables

Delivery schedule

The workbook shows the routes of the trucks that will optimize the transportation and meet all of the demand. The workbook also shows the total mileage of each truck.

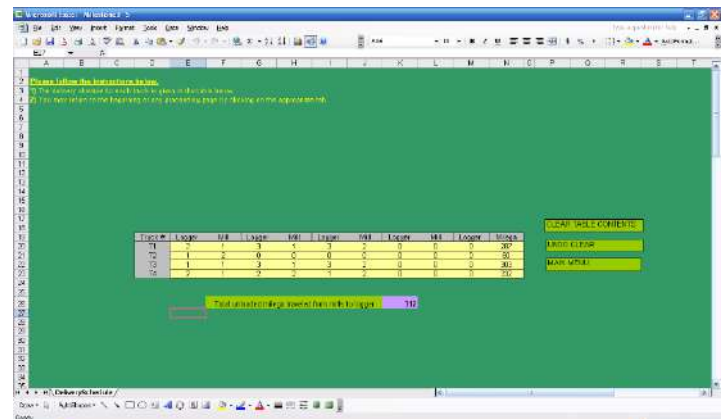

Fig. 8. Delivery schedule workbook that shows the route of the each truck

Abstract—In this article, it is aimed to reveal the profile of the students of Kocaeli University Engineering Faculty by means of data mining method for making future deductions in the light of this information by extracting valuable information from large amount of data. In this study, the relationship between the variables such as gender, birth place, registered province, high school graduation type, high school grade-point average, university entrance scores and university grade-point average of students which have registered in Kocaeli University Faculty of Engineering in 2017 were examined by data mining techniques. In the study, a decision tree was created with the help of entropy-based algorithms, a concept that measures the uncertainty in the dataset using related variables. In addition, the number of branches is determined for the problem when decision trees are constructed so that the decision tree can be easily interpreted and easily integrated with the database systems. The results of the study decision tree will shed light on not only determining the current profiles of the students, but also determining the academic achievement status of the students who will be newly enrolled at the university. For this reason, the decision tree that will be created in the study will be used to facilitate decision-making at the election stage for students who will be selected as future scholarships or part-time employees.

Introduction to Grey Systems

Erkan KÖSE

Nuh Naci Yazgan University

Industrial Engineering Department, Kayseri, Turkey,
erkankose93@gmail.com

Abstract-In the natural world, uncertain systems with small samples and poor information exist commonly. The grey systems theory, established by Julong Deng in 1982, is a methodology that focuses on the study of problems involving small samples and poor information. It deals with uncertain systems with partially known information through generating, excavating, and extracting useful information from what is available. Research and its application covered by grey theory include systems analysis, data processing, prediction, decision-making and control. In this study we intend to introduce main concepts of grey system theory and emphasize its differences between other nondeterministic methodologies.

Keywords-grey system; black system; white system; uncertainty

I. INTRODUCTION

Many systems, such as those that are social, economic, agricultural, industrial, ecological, or biological in nature, are named based on the fields and ranges to which the research subjects belong. In contrast, the name grey systems was chosen based on the colors of the subjects under investigation. For example, in control theory, the darkness of colors has been commonly used to indicate the degree of clarity of information. One of the most well accepted representations is the so-called “black box.” It stands for an object with its internal relations or structure totally unknown to the investigator. Here, we use the word “black” to represent unknown information, “white” for completely known information, and “grey” for that information which is partially known and partially unknown. Accordingly, we name systems with completely known information as white systems, systems with completely unknown information as black systems, and systems with partially known and partially unknown information as grey systems, respectively. Having “incomplete information” is the fundamental meaning of being “grey”. In different circumstances and from different angles comparison between black, grey and white systems can be summarized as in Table 1 [1].

TABLE I. Comparison between black, grey and white systems [1]

	Black	Grey	White
Information	Unknown	Incomplete	Known
Appearance	Dark	Grey	Bright
Process	New	Replace old with new	Old
Property	Chaos	Complexity	Order
Methodology	Negative	Transition	Positive
Attitude	Indulgence	Tolerance	Serity
Conclusion	No result	Multiple solution	Unique solution

Grey system theory is an interdisciplinary scientific area that was first introduced in early 1980s by Deng [2]. Since then, the theory has become quite popular with its ability to deal with the systems that have partially unknown parameters. As superiority to conventional statistical models, grey models require only a limited amount of data to estimate the behavior of unknown systems [3].

One characteristic of grey systems theory is that it makes the most and best use of the available “minimal amount of information.” The “principle of minimal information” can be seen as a dialectic unification of “a little” and “a lot.” One advantage of grey systems theory is its ability to handle such uncertain problems with “small samples” and/or “poor information.” Its foundation of study is the concept of “spaces of limited information.” “Minimal amount of information” is the basic territory for grey systems theory to show its power. The amount of information acquirable is the dividing line between “grey” and “not grey”. Making sufficient discovery and application of any available “minimal amount of information” is the basic thinking logic of problem-solving used in grey systems theory [4].

II. COMPARISON BETWEEN NONDETERMINISTIC METHODS

Probability and statistics, fuzzy mathematics, and grey systems theory have been the three most- often applied theories and methods employed in studies of non-deterministic systems. Even though they study objects with different uncertainties, the commonality of these theories is their ability to make meaningful sense out of incompleteness and uncertainties. It is the differences among the uncertainties studied in these theories that three areas of scientific study, each of which has its

own characteristics, on uncertainties have been established.

The power of fuzzy mathematics lies in its capability to find solutions for the problems with cognitive uncertainties. All objects studied by fuzzy mathematics, has the clear interiority and recessive extension characteristics. For example, “young man” is a fuzzy concept. When a young man is considered everybody know what is being implied, however it is quite difficult to say which age groups are addressed to. Different from the fuzzy mathematics, objects studied through grey system theory, has got clear extension and recessive interiority characteristics. For example in the statement of “T.C Republic is planning to maintain its population till 2050 at the numbers of 90 to 100 million” the 90 to 100 million interval is a grey concept which we do not know the exact number but we know the borders clearly [5].

Probability and statistics are used in the solutions of stochastically uncertain problems. In the solution quest, most of its ambitions are used to make out statistic course existent in the past data. This theory, in order to produce reliable solutions needs a great sampling which is considered to be coming from the same distribution.

The characteristics of grey systems can hardly be described by fuzzy mathematics or probability and statistics. Technically, fuzzy mathematics mainly deals with problems of the phenomenon with cognitive uncertainty by experience with the help of affiliation functions. Probability and statistics need special distributions and samples of reasonable size to draw valid inferences. Different from the two theories, grey system theory has been developed to find solutions for the problems where there is small sampling and lack of data. At the following table, the differences between three theories have been summarized [6].

TABLE II. Comparison between nondeterministic methods [6]

	Grey System Theory	Probability & Statistics	Fuzzy Mathematics
Objects of study	Poor information uncertainty	Stochastic uncertainty	Cognitive uncertainty
Basic sets	Grey hazy sets	Cantor sets	Fuzzy sets
Methods	Information coverage	Probability distribution	Function of affiliation
Procedure	Grey series generation	Frequency distribution	Marginal sampling
Requirement	Any distribution	Typical distribution	Experience
Emphasis	Intention	Intention	Extension
Objective	Laws of reality	Laws of statistics	Cognitive expression
Characteristics	Small samples	Large samples	Experience

III. MAIN CONTENTS IN GREY SYSTEMS THEORY

The grey theory is a feasible mathematical means to deal with systems analysis characterized by poor information. Grey system theory is applied to an uncertain system, for which information is insufficient to build a relational analysis or to construct a model to characterize the system. Grey theory considers each stochastic variable as a grey quantity that change within a given range. The theory does not rely on a statistical method to handle grey quantities. Rather, it deals directly with original data, and searches for the intrinsic regularity therein.

Through nearly thirty years of development, grey systems theory has been built up as a newly emerging scientific discipline with its very own theoretical structure consisting of systems analysis, evaluation, modeling, prediction, decision-making, control, and techniques of optimization. Its main contents contain [7]:

- Grey numbers and algebraic system, grey matrices, grey equations, etc., constitute the foundation of grey systems theory. In terms of the theoretical beauty and completeness of the theory, there are still a lot of problems left open in this area.
- The sequence operators mainly include buffer operators (weakening buffer operators, strengthening operators), mean generation operators, stepwise ratio generators, accumulating generators, inverse accumulating generators, etc.
- Grey incidence analysis refers such materials as grey incidence axioms, degree of grey incidence, generalized degree of grey incidence (absolute degree, relative degree, synthetic degree), the degrees of grey incidence based on either similar visual angles or nearness visual angles, grey incidence order, superiority analysis, and others.
- Grey cluster evaluation focuses on such contents as grey variable weight clustering, grey fixed weight clustering, cluster evaluations based on (center-point or end-point) triangular whitenization weight functions, and other related materials.
- Through grey generations or the effect of sequence operators to weaken the randomness, grey prediction models are designed to excavate the hidden laws; and through the interchange between difference equations and differential equations, a practical jump of using discrete data sequences to establish continuous dynamic differential equations is

materialized. Here, GM(1, 1) is the central model that has been most widely employed.

- In terms of grey predictions, they produce quantitative forecasts on the basis of the GM model. Based on their functions and characteristics, grey predictions can be grouped into sequence predictions, interval predictions, disaster predictions, seasonal disaster predictions, stock-market-like predictions, and system predictions, etc.
- The grey combined models include grey econometric models (G-E), grey Cobb-Douglass models (G-C-D), grey Markov models (G-M), grey-rough mixed models, etc.
- Grey decision-making involves multi-attribute weighted grey target models, grey incidence decision-making, grey cluster decision-making, grey situation decisions, grey stratified decisions, etc.
- The main contents of grey control cover the control problems of essential grey systems, the controls composed of grey systems methods, such as grey incidence control, GM(1, 1) prediction control, etc.

Grey numbers, grey elements, and grey relations are the main subjects of research in grey systems theory. So, the entire theory of grey systems lies on the foundation of grey numbers and their operations, grey matrices, and grey equations. In this part, we briefly review some relevant definitions and the calculation process in grey theory [4].

Definition 1. A grey number is a number whose exact value is unknown, but a range which comprises its value is known. Following are the several classes of grey numbers.

(1) Grey numbers with only lower limits are denoted as $\otimes \in [\underline{a}, \infty)$ or $\otimes(\underline{a})$ where \underline{a} , a fixed real value, represents the lower limit of the grey number \otimes .

(2) Grey numbers with only the upper limits are denoted as $\otimes \in (-\infty, \bar{a}]$ or $\otimes(\bar{a})$ where \bar{a} , a fixed real number, stands for the upper limit of the grey number \otimes .

(3) Interval grey numbers are the numbers with both lower limit \underline{a} and upper limit \bar{a} , denoted as $\otimes \in [\underline{a}, \bar{a}]$.

(4) Black and white numbers. When $\otimes \in (-\infty, +\infty)$ or $\otimes \in (\otimes_1, \otimes_2)$, i.e. when \otimes has neither upper nor

lower limits, or the upper and the lower limits are all grey numbers, \otimes is called a black number. When

$\otimes \in [\underline{a}, \bar{a}]$ and $\underline{a} = \bar{a}$, \otimes is called a white number.

Definition 2. Grey number operation is an operation defined on sets of intervals, rather than real numbers. Assume that we have grey numbers $\otimes_1 \in [a, b]$, $a < b$, and $\otimes_2 \in [c, d]$, $c < d$. The operations between grey numbers are as below:

(1) The sum of \otimes_1 and \otimes_2 : $\otimes_1 + \otimes_2 = [a+c, b+d]$

(2) The difference between \otimes_1 and \otimes_2 : $\otimes_1 - \otimes_2 = [a-c, b-d]$

(3) The product of \otimes_1 and \otimes_2 : $\otimes_1 \times \otimes_2 = [\min(ac, ad, bc, bd), \max(ac, ad, bc, bd)]$

(4) The division of \otimes_1 and \otimes_2 : $\otimes_1 \div \otimes_2 = [\min(\frac{a}{c}, \frac{a}{d}, \frac{b}{c}, \frac{b}{d}), \max(\frac{a}{c}, \frac{a}{d}, \frac{b}{c}, \frac{b}{d})]$

(5) The scalar multiplication of k and \otimes_1 : $k \times \otimes_1 = [ka, kb]$

(6) The reciprocal of \otimes_1 : $\otimes_1^{-1} = [\frac{1}{\bar{a}}, \frac{1}{\underline{a}}]$

Definition 3. The length of grey number $\otimes \in [\underline{a}, \bar{a}]$ is defined as $L(\otimes) = [\bar{a} - \underline{a}]$.

Definition 4. For two grey numbers $\otimes_1 \in [a, b]$, $a < b$, and $\otimes_2 \in [c, d]$, $c < d$ the possibility degree of $\otimes_1 \leq \otimes_2$ can be expressed as follows:

$$P\{\otimes_1 \leq \otimes_2\} = \frac{\max(0, L^* - \max(0, b - c))}{L^*}$$

where $L^* = L(\otimes_1) + L(\otimes_2)$.

For the position relationship between \otimes_1 and \otimes_2 , there exist four possible cases on the real number axis. The relationship between \otimes_1 and \otimes_2 is determined as follows:

(1) If $a=c$ and $b=d$, we say that \otimes_1 is equal to \otimes_2 , denoted as $\otimes_1 = \otimes_2$. Then $P\{\otimes_1 \leq \otimes_2\} = 0.5$.

(2) If $c > b$, we say that \otimes_2 is larger than \otimes_1 , denoted as $\otimes_1 > \otimes_2$. Then $P\{\otimes_1 \leq \otimes_2\} = 1$.

(3) If $d < a$, we say that \otimes_2 is smaller than \otimes_1 , denoted as $\otimes_2 < \otimes_1$. Then $P\{\otimes_1 \leq \otimes_2\} = 0$.

(4) If there is an intercrossing part in them, when $P\{\otimes_1 \leq \otimes_2\} > 0.5$, we say that \otimes_2 is larger than \otimes_1 , denoted as $\otimes_2 > \otimes_1$. When $P\{\otimes_1 \leq \otimes_2\} < 0.5$, we say that \otimes_2 is smaller than \otimes_1 , denoted as $\otimes_2 < \otimes_1$.

IV. CONCLUSIONS

Grey theory is one of the methods used to study uncertainty, being superior in the mathematical analysis of systems with uncertain information. In grey theory, according to the degree of information, if the system information is fully known, the system is called a white system; if the information is unknown, it is called a black system. A system with information known partially is called a grey system. In reality, many processes of interest in environmental management are in the grey stage due to inadequate and fuzzy information.

Grey system theory is relatively a new theory in the solution of uncertain systems. In this study we try to introduce main concept of grey systems. We mentioned comparison between grey system theory, probability, statistics and fuzzy mathematics. It is our hope that a reader who does not know anything about this branch of scientific exploration will gain an understanding of the basics of the grey system theory.

Abstract— Emergency rooms (ERs) are the sole subsystems of a hospital system that provide patients nonstop emergency care at any time of the day. Owing to the changing demand in the number of arrivals at these units, accurate forecasting gains vital importance in order to arrange staffing and scheduling policies. Therefore, we deal with forecasting modelling of patient arrivals from three different hospital ERs located in Istanbul using autoregressive integrated moving average (ARIMA) and exponential smoothing (ES) methods. The daily patient arrivals from each hospital ER were gathered by the hospital information management system. Results of the study show that ARIMA models developed for each ER give better accuracy values than ES models in terms of mean absolute percentage of error (MAPE). ARIMA model of ER-2 is found to be the best model for the data under study (MAPE is 6.51%, 5.42%, 8.27% for each ER, respectively). This study contributes to the knowledge from two aspects: (1) Usage of statistical forecasting tools in planning of hospital environments against the increased city population has become compulsory by decision makers. (2) This study includes forecasting results of multi ER daily patient demand in terms of two methods that is, enables decision makers making comparison between these tools.

Keywords—emergency room; patient arrival; exponential smoothing

I. INTRODUCTION

Emergency room (ER) is one of the most important units of a hospital system and is considered as the most crowding department [1]. These units provide non-stop emergency care for patients at any time of the day. In times of a patient surge, ED medical staff and treatment areas may become insufficient and this situation may cause overcrowding [2-5]. Therefore, accurate forecasting of patient demand, in other words patient arrivals, has vital importance in order to set ER resource planning. Key performance indicators for service quality through ERs are relating with length of stay (LOS) and waiting times, which are affected by high levels of ED arrivals [6-8]. According to the numbers of Turkish Ministry of Health, ER arrivals are increasing rapidly which reflects a

worse condition compared to the countries such as USA and UK [9].

Increased patient arrivals may lead to prolonged waits and overcrowding. In order to enhance ER processes, a better balance between ER resources (doctors, nurses, beds, medical equipment and etc.) and demand (patient arrivals) is required. Accurate forecasting of ER patient demand can provide managerial implications on long and short term staffing policies so that the ERs can be better prepared for the coming demand variations [8]. Regarding the theme of ER patient arrival forecasting, several investigations were carried out.

However, the knowledge is satisfied enough with the work done up to now, the current works on ER patient arrival forecasting cover mostly single site and single method based models. But in our study, ER patient arrivals have been forecasted based on a collection of related data obtained from three different public hospital ERs. We used two separate methods namely, ARIMA and ES to make a daily analysis of the data. By comparing these two methods in terms of forecasting patient demand using MAPE, we aim to determine the optimum method in order to plan hospital ERs.

In the lights of above mentioned points, this study aims to present multi-site and multi-method forecasting modelling of patient arrivals providing case studies performed in three public hospital ERs in Istanbul. It contributes to the literature providing usage of statistical forecasting tools in planning of hospital environments against the increased city population especially for metropolitans such as Istanbul.

The remaining of the study are organized as follows: In section II, a short literature review is given within the concept of ER patient demand forecasting. The data and forecasting methods used in the study are introduced in Section III. In section IV, application of the methods using the related data is provided. In the final section, the conclusion and discussion about the models are presented.

II. LITERATURE REVIEW

Although studies on developing patient demand forecasting were many, we do not have enough space here to discuss all of them in details. Wargon et al. [10] presented a systematic review study that covers nine ER and walk-in clinic visit forecasting models. Researchers applied various methods to forecast ER patient demand such as regression, time series and data mining. The first method is regression, which may be investigated under linear, logistics and Poisson and consisted of looking for correlations between patient demand and a series of independent variables, such as calendar or meteorological variables. The second method is time series based forecasting models that view patient demand as a time series and predict future values from past values [10]. The last method is concerned data mining based forecasting models. Within the context of this class, artificial neural networks (ANNs), support vector machine (SVM), decision trees and Bayesian networks can be mentioned.

Among the studies, many variants of regression models exist as linear [5,8,12-14], logistic [15-16] and Poisson [17]. LR models are used in ER patient demand forecasting as in Eq. (1):

$$y_i = \alpha_i + \beta_1 x_{i1} + \dots + \beta_p x_{ip} + \varepsilon_i \quad (i = 1, \dots, n) \quad (1)$$

where y_i is the number of patients per time period estimated by the model, α_i is a constant, $x_{i1} + \dots + x_{ip}$ are independent variables or input variables (e.g., day of the week, month of the year, temperature), β is a p-dimensional parameter vector and it is also called weighting coefficient of each of these variables and ε_i is called the error term.

In a logistic regression model, the dependent variable is categorical. Logistic regression is divided into the classes as binomial, ordinal or multinomial. Poisson regression models are based upon the assumption that the events in one time period are independent of the events in another time period [17].

Except from regression based models, several authors or investigators proposed time series methods to forecast ER patient demand. In the literature of ER patient arrival forecasting, different time series models were applied. ARIMA model is the most widely used time series method proposed by [13,18-21].

ES is also one of the most important time series method applied mostly by researchers in the field of ER patient demand forecasting. Calegari et al. [22], Aboagye-Sarfo et al. [23], Bergs et al. [24], Jones et al. [20] and Champion et al. [25] used and successfully applied ES method to their data regarding ER patient arrivals.

The data mining based models used to forecast ER patient demand include ANNs, SVM and decision trees. ANNs are applied to several practices such as forecasting. For ER operations, ANNs are frequently applied to forecasting ER patient arrivals [5,8,13,26].

III. MATERIAL AND METHODS

A. Data

The daily data for each ER used in this study consist of 275, 642 and 707 patient records in the calendar years of 2011-2013. The data are obtained from each hospital information management system database. We study on appropriate time units to create time series, make daily forecasts. The data used in the analyses are collected in the related ER, in which arrivals are time-stamped and electronically recorded. Much of the effort to generate the ER arrival forecasts includes organizing the raw data in a way that it can be used to forecast the suitable ARIMA and ES models. The time series used for the models are shown in Fig. 1.

Fig. 1. ER arrivals used for each ARIMA and ES models

B. Forecasting methods

In this section, the explanation of the ARIMA and ES are given in details. autoregressive model is considered one of the simplest time series [11]. In this process model, understandings are assumed to result from a linear combination of past understandings.

A first order AR model, symbolized as AR (1), can be presented as

$$y_t = \hat{\phi} + \phi_1 y_{t-1} + \varepsilon_t \quad (2)$$

where ϕ_1 and $\hat{\phi}$ present unknown, “to-be-forecasted” parameters and ε_t presents error component.

The moving average (MA) model, in which actualizations are stated as linear combinations of shocks. MA (1) presented of a first order moving average model as follows [11]:

$$y_t = \mu + \varepsilon_t - \theta \varepsilon_{t-1} \quad (3)$$

The autoregressive moving average model (ARMA) contains merging the AR() and MA() model into combined method. ARMA (1,1) presented model of first order in both components model as follows:

$$y_t = \hat{\phi} + \phi_1 y_{t-1} - \theta \varepsilon_{t-1} + \varepsilon_t \quad (4)$$

ARIMA models stated notation as p, d, q; for example, the notation ARIMA (4,3,2) assign to a fourth order autoregressive component, third order differencing, and a second order moving average component.

Exponential smoothing is developed by Robert G. Brown's work as an operation research analyst for the US Navy during World War II [27]. It can be very useful for forecasting [28] if the weights decline exponentially when the observations get elder.

Considering that f_t is the forecasted data at some point of the time series and y_t is the actual data, hence the errors is obtained as follows:

$$e_t = y_t - f_t \quad (5)$$

The single exponential smoothing method (SES) takes the forecasted for the previous period and regulates it using the forecasted error. Thus, the forecasted for the next period is:

$$f_{t+1} = f_t + \alpha(y_t - f_t) \quad (6)$$

where α is a constant between 0 and 1.

When α close to 1 means that the new forecast will contain a considerable modification for the error in the previous forecast. On the contrary, if α is close to 0 means that the new forecast will contain very slight modification.

IV. APPLICATION

This study was conducted in three public hospital ERs in Istanbul which is Turkey's largest and most advanced city and used a dataset extracted from *HBYS* databases. The ER-1 data utilized for analysis includes 275 days' data of patients who visited the ER from January, 1 2013 to October, 10 2013. The ER-2 data similarly provides 642 days' data of patients who arrived at the ER from April, 1 2011 to December, 31 2012. The data of ER-3 presents 707 days' data from January, 1 2012 to December, 12 2013. The daily number of patients arrived at the ERs was considered as a dependent variable for each of the models. The daily number of patients arriving at the ERs was calculated by counting the number of visiting patients from 12 a.m. to the following 12 a.m. For this study, ARIMA and SES models were applied, from other models relating to the time series analysis methodology. Firstly, in order to examine the stationary of the data used, Augmented Dickey-Fuller Test was carried out as shown in TABLE I. It is observed that each ER data used through the study is stationary in its level (see the last column of TABLE I).

TABLE I. ARIMA DIFFERENCE TESTS

Augmented Dickey-Fuller Test (Exogenous: Constant, Linear Trend) Null Hypothesis: Number of Patience has a unit root			
Hospital ER	Lag Length Automatic-based on SIC	t-Statistic	Prob
LNB (ER-1)	1	-6.563808	0.0000
BAY (ER-2)	7	-4.125858	0.0060
ARN (ER-3)	13	-4.763412	0.0006

To make a comparison between built ER models in terms of accuracy and performance, R^2 and MAPE values are calculated. MAPE values show the relative measure of the forecasting error between the forecasted value, which is a series variable, and the observed actual value. The smaller the error, the more accurate the forecasting model is. In TABLE II, it is seen that among ARIMA models developed for each ER, ER-2 results in better accuracy values than other models in terms of MAPE. According to the R^2 values, ER-3 has a higher value than the others (65%).

The figures that include comparison between the forecasted and actual values in the three ER sites represents that the ER-3's forecast visually demonstrates the mean of the observed value, hence reflecting its insufficiency as a prediction model (Fig. 2). In contrast, the ER-2 ARIMA model displays a pattern of change similar to the observed values.

TABLE II. STATISTICAL VALIDATION MEASURES APPLIED TO DATA

ER	LNB (ER-1)	BAY (ER-2)	ARN (ER-3)
ARIMA	(8,0,2)	(4,0,3)	(14,0,8)
R^2	0.3272	0.5968	0.6549
MAPE	6.513	5.417	8.273

Fig. 2. Actual vs. forecasted ER arrivals

A MAPE comparison of the accuracy of each SES model's forecasting ability shows that ER-2 model scored a 5.81%, the ER-1 model scored 6.89%, and the ER-3 model scored 13.3%, thus identifying the ER-2 SES model as the most accurate forecasting model among others (Table III). Also, a comparison of the actual and forecasted values for the best SES model in terms of MAPE (ER-2 model) were given in Fig. 3.

TABLE III. COMPARISON MEASURES IN TERMS OF TWO METHODS

MAPE (%)	ARIMA	SES
ER-1 (LNB)	6.51	6.89
ER-2 (BAY)	5.42	5.81
ER-3(ARN)	8.27	13.13

Fig. 3. Actual vs. forecasted ER-2 arrivals according to SES modeling

V. CONCLUSION

In this study, a multi-site and multi-method forecasting modelling of hospital emergency room patient arrivals was taken into consider in order to show applicability of these methods and contribute to the observed ERs. Two methods were assessed to forecast ER arrivals of three public hospitals in Istanbul, Turkey: autoregressive integrated moving average and single exponential smoothing. The historical data of ER arrivals were collected from the information management system of the hospitals. ARIMA(4,0,3) was found to be the best model for the ER data used for the study. The results of this study show that among ERs, ER-2 had the best model performance (MAPE is 6.51%, 5.42%, 8.27% for each ER, respectively). As a creative contribution to the knowledge, accurate forecasting modeling of ER arrivals enable stakeholders arranging appropriate staff levels at the ER and other inpatient units and reducing boarding times.

ACKNOWLEDGMENT

We thank the General Secretary of Istanbul Fatih Association of Public Hospitals and the emergency departments' staff for their guidance and help in gathering daily patient demand data.

Abstract—An assembly line is a manufacturing process which consist of a set of workstations connected together by transfer mechanisms such as conveyor systems. The problem of assigning tasks to workstations so that the total time required at each station is nearly the same by considering some constraints about cycle time or precedence relationships is known as the assembly line balancing problem. In this study, single model assembly line balancing problem with task parallelizing is considered. Firstly, a new mathematical model is presented to solve the problem. Then, the proposed model is tested with a case study. Finally, some computational analysis are conducted to assess the performance of the proposed mathematical model.

Abstract— The ground state nuclear properties of the heavy nuclei between $Z=80-100$ region have been determined by using Hartree Fock Bogolibov (HFB) and Relativistic Mean Field (RMF) models. The results were compared with each other and experimental values in the literature. The ground state binding energies, two-neutron and two-proton separation energies, neutron, proton and charge radii, electric quadrupole moments and deformation parameters of these nuclei were calculated. In HFB method, Sly5 Skyrme forces and in RMF model, DEFNE interaction parameter sets were used for determination of the nuclear properties.

***Abstract—** The activated sludge process has found wide application as one of effective methods in wastewater treatment. The performance of the activated sludge process depends largely on the balance between filamentous and flocking bacteria. Excessive growth of filamentous bacteria causes various problems. Bulking and foaming phenomena are the major problems referred usually resulting in poor sedimentation of sludge and low-quality final effluents. The application of biological selector reactor technology has become one of the promoted methods for the control of filament proliferation, enhancing sludge settleability in activated sludge systems. In this study, the biological selector reactor technology used to control the sludge bulking was examined.*

Abstract— *This present study aims at evaluating the efficiency of *P. chrysosporium* to degrade the different concentration of malathion (50, 100 and 150 mgL⁻¹) under agitated (130 rpm) submerged culture conditions with reduction of chemical oxygen demand (COD). We have previously screening the growth of fungus in Saboroud Dextrose Agar medium for 10 days. We have also determined the laccase activity during degradation process for 15 days. According to our results the fungus have achieved 99.6, 98.8 and 98.7 % COD reduction at concentration of 50, 100 and 150 mgL⁻¹ respectively the end of the 15 days. The highest laccase activity (180±5,69 U/L) was measured at concentration of 50 mgL⁻¹ the end of the 15 days and the lowest activity (36±3,26) was determined at concentration of 150 mgL⁻¹ the end of the 15 days. The dried biomass of fungus was weighted at end of the 15 days and we have determined that malathion in culture medium reduced the biomass production compared the control group (SDB + P.c). Our results showed that, *P. chrysosporium* could be an effective bioremediation tool for treatment of malathion containing wastewater*

Abstract— With the development of society and scientific technology, more attentions have been paid to environmental issues which were caused by the discharge of wastewater. Metal nanoparticles (NPs) with controlled size and shape are of great interest because of their morphology dependent properties and potential applications in a lot of fields. Metal NPs have attracted considerable interest because of their novel properties and their potential application. Binding capacity of noble metal NPs with dyes are more when compared with other NPs. Novel metal crystallites provide a more interesting research field due to their close lying conduction and valence bands in which electrons move freely. The free electrons give rise to a surface plasmon absorption band, which depends on both the particle size and chemical surrounding. Right now, shape-controlled synthesis of NPs has been achieved either by using geometric templates, or by using some additive, such as polymers, or inorganic anions, to regulate the particle growth. Accurate controls of size, composition, morphology and stability, and the use of environment-friendly procedures are highly desirable for the synthesis of NPs. Biosorption is rather difficult to define because many mechanisms may contribute to the overall process depending on the substance to be sorbed, the biosorbent used, environmental factors and the presence or absence of metabolic processes in the case of living organisms. Biosorption may be simply defined as the removal of substances from solution by biological material. Such substances can be organic and inorganic, and in soluble or insoluble forms. Biosorption is a physico-chemical process and includes such mechanisms as absorption, adsorption, ion exchange, surface complexation and precipitation. It is a property of living and dead biomass (as well as excreted and derived products): metabolic processes in living organisms may affect physico-chemical biosorption mechanisms, as well as pollutant bioavailability, chemical speciation and accumulation or transformation by metabolism-dependent properties. This work we use *Bacillus subtilis* ATCC 6051 (BS) and MgO (n-MgO) nanoparticles. This work deals with the preparation, characterization and dye adsorption properties of novel biocomposite composite (*Bacillus subtilis* ATCC 6051–magnesium oxide nanoparticle) (BS/n-MgO). Physical characteristics of BS/n-MgO were investigated. The textile dye reactive orange was used as model compound. The isotherm and kinetics of dye adsorption were studied.

Abstract— *In this study, effect of oxytetracycline (OTC), which is widely used in the treatment of fish diseases, on serum response was investigated. We conducted two experiments, the first with intraperitoneal (IP) injection and the second with immersion (IM) bath administration of OTC. For this purpose, fish was injected IP 20 mg/kg fish weight dose of OTC every day for 4 days. After 24 hours the last treatment serum were collected. In trial second, fish were exposed to 50 mg/L concentration of OTC for 48 hours. The several immune parameters (lysozyme, myeloperoxidase and total protein activities) and bactericidal activity against *Yersinia ruckeri* were studied. The present results demonstrate that immune parameters (lysozyme and myeloperoxidase activities) slightly decreased after the injection administration of OTC. But, The immersion administration of OTC in fish had no effect on this parameters. The serum bactericidal activity of all groups showed a increase in comparison with control untreated group.*

Abstract— Carbamazepine (CBZ) is widely used to help people with epilepsy control seizures. CBZ have been detected in many environmental samples. The present study was conducted to investigate the biochemical effects of CBZ on whole body of carp fry (*Cyprinus carpio*). The fish used in this study were an average weight of 0.65 g. Fishes were treated with 0, 1, 10 and 100 µg/L of CBZ during 96 hours and 14 days. Total protein, fat and glycogen levels were measured after of CBZ treatment. The immersion administration of CBZ in fish had no effect on all the parameters in 96 h. But, the showed that in fish significantly decreased total protein, fat and glycogen levels in 14d of CBZ administration ($P<0.05$). In conclusion, administration of CBZ up to 1 and 10 µg/L has no toxic effect on whole body biochemical parameters of fishes. However, dose of 100 µg/L of CBZ caused toxicity biochemical parameters of fish.

Abstract— *Microbial fuel cells (MFCs) are bioreactors that convert organic matter into the electricity by using microorganisms. In MFC reactor, microorganisms on the surface of anode electrode generate electrons and transfer them to the anode electrode. However, the electricity generated from MFC is relatively low for practical applications. The performance of MFCs is directly related to efficiency of anode compartment. In a MFC reactor, the most important part of the anode compartment is the anode electrode. Studies so far have widely used carbon materials as anode and cathode electrodes in MFCs. In the past ten years, there has been significant new developments in electrode materials which has resulted in several-fold increase in achievable electricity. This paper reviews, recent advances in the construction of novel electrode materials for MFCs*

Abstract— The peanut hull was used to prepare carbon in this study. It was produced by carbonization in carbon dioxide atmosphere at 500 °C for 1.0 h. The adsorption of phenol onto peanut hull carbon (PHC) was studied as a function of initial pH, temperature, initial phenol concentration and adsorbent dosage. The maximum phenol adsorption capacity was obtained as 23.10 mg g⁻¹ for 300 mg dm⁻³ initial phenol concentration at the temperature of 35 °C at pH = 8.0. The Freundlich and Langmuir adsorption models were used for the mathematical description of the adsorption equilibrium and isotherm constants were evaluated at different temperatures. The adsorption equilibrium was well described by the Langmuir model, although they could be modeled by the Freundlich equation. Batch adsorption models, based on the assumption of the pseudo-first order and pseudo-second order mechanism, were applied to examine the kinetics of the adsorption. The results showed that kinetic data were followed more closely the pseudo-second order model than the pseudo-first order. The thermodynamics constants of the adsorption process: ΔH^0 , ΔS^0 and ΔG^0 were evaluated. The results show that adsorption of phenol on PHC is an endothermic and spontaneous in nature

Abstract— Biochar derived from weeds modified with nitric acid (HNO_3) at optimum condition was utilized as adsorbent to remove methylene blue (MB) from aqueous solutions. The effects of solution pH, initial dye concentration, agitation time and solution temperature on MB adsorption were investigated by the optimal oxidized weeds char (OWC). The kinetic data followed the pseudo-second order kinetic model. The equilibrium data were best represented by the Langmuir isotherm model. The maximum MB sorption capacities of WC and optimal OWC were determined as 39.68 and 161.29 mg/g, respectively, under detected optimum conditions (pH 7.4, OWC dosage 0.1 g/50 mL, agitation time 480 min and temperature 50 °C).

Keywords—biochar; modification; methylene blue; adsorption

I. INTRODUCTION

Biochar is a stabilized, recalcitrant organic carbon compound obtained when biomass is heated to temperatures between 300 °C and 1000 °C under low (preferably zero) oxygen concentrations [1]. Biochar is an effective adsorbent derived from agricultural and industrial solid wastes [2] and is frequently applied to remove various pollutants, including dyes, pesticides, and heavy metals, from aqueous solutions [3].

The presence of dyes in wastewater has become a significant source of water pollution, due to textile, paper and printing industries. Methylene blue (MB) is one of the most commonly used azo dyes in industry [4], having various detrimental effects on human and aquatic

life when released into the environment [5].

Until now, the study on methylene blue (MB) desorption using biochar and its oxidized form produced from weeds has not been reported in literature. The weeds hinder the efficient agricultural production. Therefore, these bio-wastes are removed from their millions of tons of fertile soil, and discarded into the environment.

This work aims to (i) prepare OWC from weeds (W), (ii) to optimize the MB sorption onto the OWC according to the process parameter such as solution pH, sorbent dosage, initial concentration, agitation time and solution temperature, (iii) to evaluate in terms of kinetic and

equilibrium isotherm parameters to explain the MB sorption mechanisms of the OWC.

II. MATERIALS AND METHODS

Synthesis of modified (WC-HNO₃) adsorbent

The biochar was prepared by pyrolyzing the weeds were supplied. The herbal-based biochar named WC was obtained by slow-pyrolyzing from weeds at 500 °C for 1 h under oxygen-limited conditions. HNO₃ modified biochar was made by the following steps: 1.0 g of dried WC powder was treated

with 25 mL of 20, 40, and 65% of HNO₃ solution for 1 h in the 80 °C (reflux under continuous stirring).

From surface chemical analysis results, the WC65 was selected as optimal OWC sample. It was used in the sorption experiment of MB dye from the aqueous phase in this study.

Batch aqueous MB adsorption

To optimize the sorption conditions, the effects of various operating parameters such as initial solution pH (2-10), sorbent dosage (0.1-0.5

g), initial MB concentration (50-400 mg/L), agitation time (5-480 min) and solution temperature (20-50 °C) were studied. After each process, the samples were centrifuged (5000 rpm, 10 min) for solid-liquid separation and the residual MB concentration in solution was analyzed by a UV-vis spectrophotometer (Perkin Elmer-Lambda 25) at its λ_{max} (665 nm).

III. RESULTS AND DISCUSSION

Effect of various operating parameters on the Methylene blue dye adsorption

The optimum pH for MB adsorption onto WC65 was found to be 7.4. Optimum dosage of WC65 was found to be 0.1 g/50 mL. The amount of MB adsorbed onto WC65 increased from 27.21 to 77.77 mg/g with increase in initial MB concentration from 50 to 400 mg/L. This may be caused to an increase in the driving force between the aqueous and solid phases and increase the number of collisions between MB dye ions and WC65. The sorbed amount of MB with increase from 20 to 50 °C of temperature was found to increase from 67.57 to 161.29 mg/g. The increase in the adsorption capacity might be due to the possibility of increase

in the number of active sites for the adsorption with the increase of temperature.

Removal of Lambda Cyhalothrin by Ralstonia eutropha in a Batch System: Effect of Carbon Starvation and Some Growth Conditions

Abstract— In this study, biodegradation of Lambda C by free *Ralstonia eutropha* was performed in batch system. Glucose was used as carbon source in addition to pesticides. The effects of initial pH, temperature and initial pesticides concentrations on the substrate removal and specific growth rates and yields were investigated. Optimum initial lambda c concentrations, initial pH and temperature were determined as 2 mg-1, 6 and 20 °C, respectively for free cells. In these optimum conditions, the maximum microorganism's specific growth and pesticide removal rates were determined as 0,0878 h-1 and 0,0408 mg/g dry cell/h for lambda c., respectively.

Lambda C had a strong inhibitory effect on the microbial growth. substrate inhibition was observed at concentrations higher pesticide concentrations than 2 mg/L. At experiments, where substrate inhibition was not observed, microorganism's specific growth was implied with Monod Equality depending on substrate concentration. In these conditions, microorganisma inhibition constant values was determined as $K_s = 0,8540$ for lambda c. The results show that the growth of *R. eutropha* was not effective for biodegradation of Lambda C.

Abstract— Lots of the heavy metals and their salts are widely used in the industrial applications. As a result of their widespread use, heavy metal pollution in waters is an important environmental problem encountered at industrial areas. Heavy metals are extremely toxic and their adverse effects can last for a long time in nature. Therefore, the wastewater containing heavy metals must be treated with an effective treatment method such as chemical precipitation, ion exchange, membrane processes and adsorption before the discharging [1]. Among these methods, adsorption is recognized as a promising method owing to the properties of high adsorption capacity, easy operation, low-cost and eco-friendly nature.

Usages of the low-cost adsorbents such as agricultural wastes and residuals, metallurgical slags, fly ashes and different minerals have been used or tested for heavy metal removal from the wastewaters recently [2-6]. Agricultural wastes or residues have become the subject of considerable interest due to their low cost, abundant and readily available. Starting from this information, in this study; effects of the some parameters such as pH, adsorbent dosage, contact time, particle size, initial Pb(II) concentration and temperature on Pb(II) removal from aqueous solutions by agro-based adsorbent prepared from grape stalk were investigated. The data was analyzed with first and second-order kinetics models and Langmuir and Freundlich adsorption isotherms. It was found that the adsorption kinetics followed the second-order rate law and adsorption fitted to the Langmuir isotherm. The Pb(II) maximum adsorption capacity of the grape stalk was calculated to be 32.8947 mg/g at 25°C.

Compacted Geolayer Design from Coal Boiler Bottom Ash, Fly Ash and Geosynthethics- Bottom Seal Layer for Municipal Waste Landfill

Yıldırım Tosun

Şırnak University, Engineering Faculty

Şırnak, Turkey

yildirimismailtosun@gmail.com

Abstract— The stability analysis has been made in terms of geotechnical points at the potential and active landslide areas at Şırnak Province. By making engineering geology map in 1/10.000 scale of an area of 2 km² at the research area of Waste Fill Dumping and surrounding it, the mechanical characteristics of the outcropped soil and sub soil units have been defined. By the topographical maps of 1/5000 scale of the dumping slopes, the landfill areas of S2, S3 and S4 were investigated. Bottom layer units on the local small scale sections have been made. By laboratory tests the physical and mechanical characteristics of the slope have been made on the samples taken from the land.

Keywords—landfill; municipal slurry; bottom layer; geolayer; permeability

I. INTRODUCTION

The main factors affecting the gravitational mass movements as well as the geology of the rock material, precipitation, erosion, earthquakes and the vegetation can be classified as withdrawal. In determining the risk of slipping and possible future limits its ability to estimate the dynamic tension and equilibrium analysis gives accurate results (Hoek and Bray, 1977; Lamb and Whitman, 1969).

Heavy rainfall, seismic, and changes in the level of groundwater, erosion, climate processes such as decomposition, topography creates a natural slope parameters for triggering the shift in critical areas. These effects increase the shear stress or reduce the shear strength of the slope material (Bishop, 1955; Hoek, 1970). The growing urbanization brought on the landfills, housing, trade, the creation of social and infrastructure activities can disrupt stability, such as the realization of the implementation of urban land use.

According to appropriately measured and weighted factors of each GEO5 hazardous cross-sections, A landfill susceptibility map for each data layer is developed using an algorithm that combines factors in weighted linear combinations. To verify the practicality of the susceptibility map was compared with a landfill map containing few active landslide zones. The outcome was that the active critical zones do not completely fit into the high and very high susceptibility class. But 33% of these zones fall into the high and very high susceptibility zones.

The area shown in Figure 1 was chosen as municipal landfill area and concluded that 54 and 63.1% areas of the province are close to ground water sources with regard to landfills hazard, respectively. In conclusion, we can say that this basin suffers from a relatively high

potential of instability to make us largely hesitate to develop the basin for urban use.

The city province may develop in future so that we have to know the mechanism and the properties of the landfill in the future, is important basic information to assess landfills may develop in similar or adjacent areas, geotechnical. Especially in developing countries, land is used according to the topology and improper land use in mountainous areas increases the likelihood of water drainage development. Therefore, the physical environment of the relevant fields, exchange and sustainability cannot be achieved in terms of efficiency (Bishop, 1955; Hoek, 1970).

A geological map of the provinces of Şırnak and the surrounding area has been identified geotechnical engineering unit of surface features (Anonymous, 2012). The slope, was one of the first large-scale topographic maps of the bottom preparation work in the region on the geological map processing. The determination of the engineering properties of slope, is intended to draw attention to the critical importance of geotechnical and municipal development plans in the future in the construction field.

It was examined as potential criteria for waste storage piles stability of slopes in static challenges. Mass of the examined parameters affecting slope stability is indicated on the map possible anomalous situations and risk analysis. Something that will not threaten the environment of coal waste piles and construction will be put into operation shortage in size is recommended. Seismic design of the static properties of materials characterization and solid waste storage is a difficult task. Due to the heterogeneity of the batch material must be made large static and dynamic analysis. In this direction, in the province of Şırnak area, waste heaps of the coal mines in the south and 7 km from the city center (Figure 1) is evaluated within the city. The study area and an area of around 3 km² 1 / 1,000 scale topographic map made of engineering, also performed drilling and laboratory engineering properties of materials are determined by geotechnical tests (c Anonymous 2011). Close accordance with the settlement, the bottom of the stream and pond design will save the nature and condition of the masses slope stability analysis was performed by examining the geotechnical characteristics of the program GEO5 programs in different ways. This project covers whole part of urbanization area, a 7 km² area covering the work area and the environment, which will be open to urban use. The general scale engineering map of 1/15,000 of the field and laboratory studies has been prepared as a result has also generated topographic map of every four slopes with field studies using the polar coordinate system.

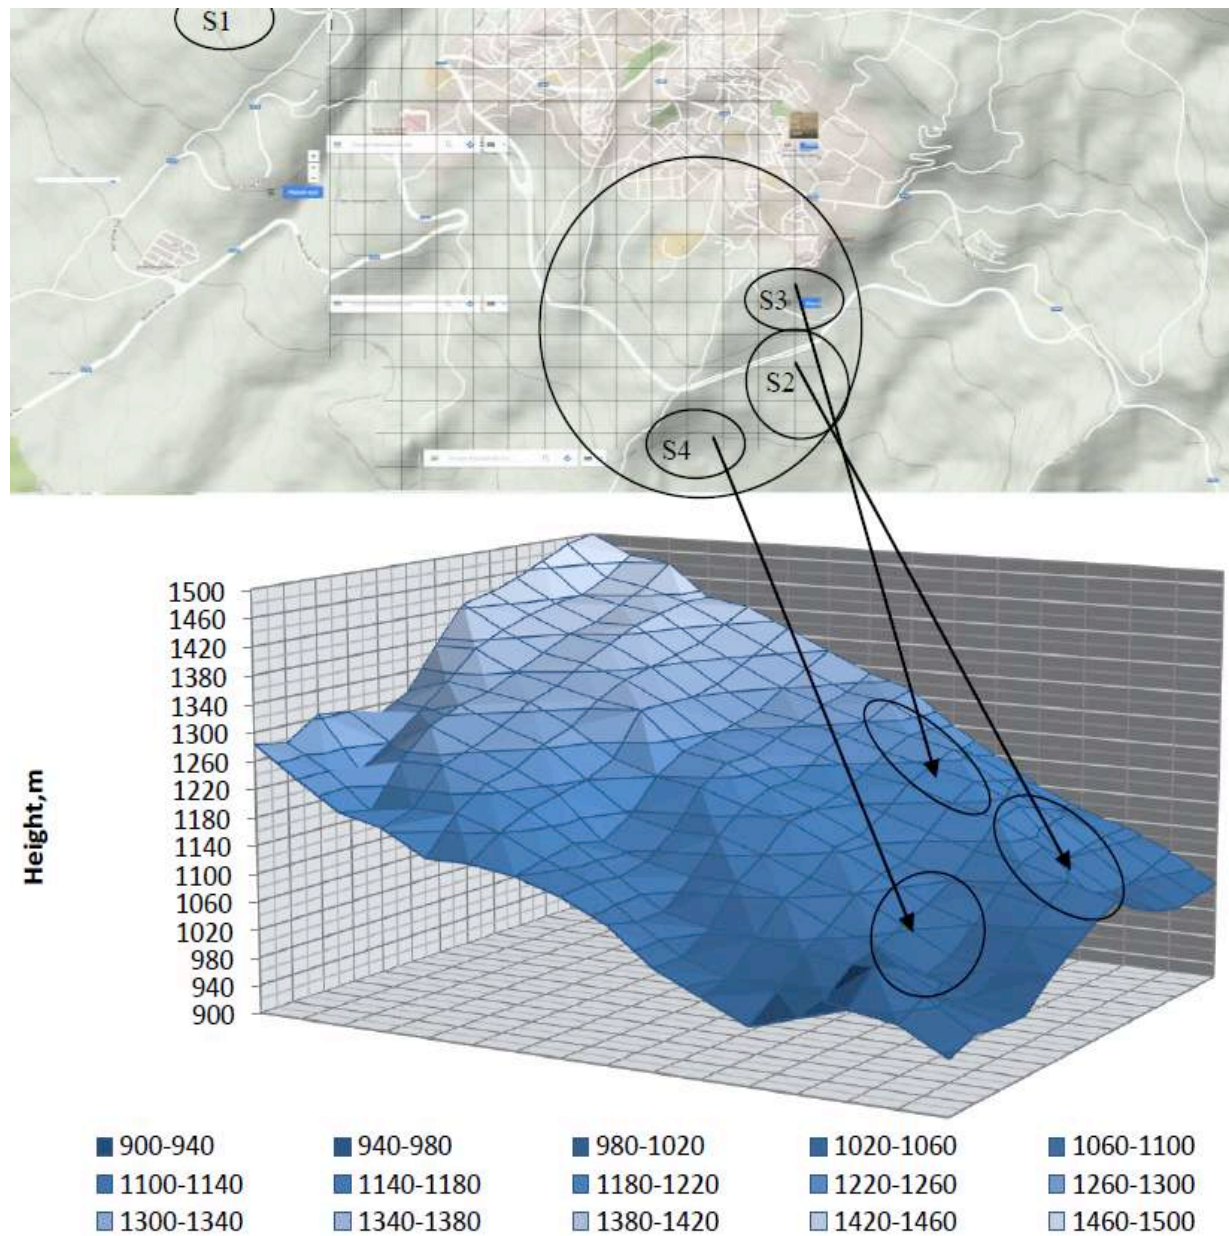

Fig 1. A scale of 1/15,000 engineering map of the field and topographic image

Table 1. chemical composition values of Sirnak province boiler bottom slag, volcanic slag and Tatvan pumice

Component%	Sirnak boiler bottom ash-slag	Volcanic slag	Tatvan pumice	Şırnak Fly Ash

Ign.Loss.	10,9	0,21	4,12	1,9	
SO ₃	0,32	0,12	0,52	0,22	

II. METHOD

A. Physical Quality of Geomaterials

American Standard (ASTM 3080) experiments were carried out in the fill area. The specimens were tested to determine the geotechnical properties based on the representative masses in the study area, where the soundings of content are given in Table 1. S2, S3 and S4 fields of investigation were made in 2013. The micro pictures of used bottom ash-slag and volcanic cinder and pumice are seen from Figure 2 and grain size distributions of the material used as bottom layer in the landfill are shown in Figure 3.

Figure 2. The macro and micro images of Boiler slag, volcanic slag, Tatvan Pumice.

B. Quality the Geobottom Layer

Municipal waste heaps in the study area (Figure 1) showed gray marl, shale outcrops of new alluvial deposits observed to the south. Some parts of this section are generally covered by silty soil consists of sandy and clayey zones. The investigations in the area of the landfill to the south located the grain size of coarse sand and fine clay was observed as soil. By sorting and grading, the thickness of the soil ranged from 10-35 cm.

Figure 3. Particle Size Distribution of Bottom Layer Clay and Slag

III. RESULTS AND DISCUSSIONS

The free dumping of municipal waste were carried on the slopes of landfill bottom layer of slag-fly ash, such as compacted fine-grained parts-upper geotextile and disturbed samples of bottom layer were taken. The experiments were conducted on compacted layer. The grain size distribution curves of the samples showed fine grains unit weight over 80% which limited consistency of coarse was less.

By the cutting box test effective cohesion (c) the effective shear strength and friction angle (ϕ°) of bottom layer and soils were determined.

Water content in the ground, the ratio of clay and fly ash affected significantly. As the evaluated according to the percentage of clay and fly ash in the samples showed cohesive or low cohesive property. The saturated unit weight is given in Table 2. Fixed level permeability test instrument is used to determine the permeability of the ground. Degree of permeability of the soil was determined by evaluating the test results (Table 3). As examined in Table 3, S2, S3 and S4 floors were permeable ground. Proctor tests showed the slag-fly ash effect on compaction,

IV. CONCLUSION

The bond between the grains at geolayer and the compaction was critical in strength. The weathering of rocks in the study area is weakening quickly change the height and tilt angle of the slopes to erosion and slope. Dissociation seen in geolayer materials in the study area also offers a negative contribution to permeability problems. The compression strength could be easily tested by indentation on the landfill as shown in Figure 2. The durability of the landfill bottom layer was tested easily on the chart of fly ash and slag mixture content as given in the Table 2.

As a result of the geotechnical analysis performed in the study area should be considered in the future danger of very large stacks and site reclamation methods are suitable to be determined. In addition, the working area of the project due to be opened to urban use contraceptive methods studied and developed instability poses a special importance.

Hatay, Turkey

Abstract—elenium is both essential and toxic for biological and environment system. There is a very sensitive balance between the toxic and beneficial state of selenium species that depending on the element concentration. So it is very important to determine of amount of selenium speciation in soil.

This study aimed to determine relations to between selenium species that different geochemical fractions (soluble, exchangeable and carbonate-bound, iron / manganese oxide bound, organic matter bound and residual) with physico-chemical properties in soil series Amik Plain.

Selenium analyzes were performed according to the method that described by Wang and Liang, (2012) using the high resolution continuous atomic absorption spectrophotometer (HR-CS AAS) hydride system. Routine soil parameters which the exchangeable cations by the ammonium acetate method, organic matter by the Walkley Black method, available phosphorus by sodium bicarbonate method, pH and EC in soil-water suspensions, lime equivalent by Scheibler calsimeter and texture analyzes by hydrometer were determined to soil samples. The data were subjected to correlation and regression analysis with SPSS programme. The statistical analyzes show that no significant relations between selenium species with soil physico-chemical properties. But there is a significant relationship between total selenium with total of exchangeable cations and organic matters.

***Abstract—** The present study were aimed to determine some productivity parameters of soil belong to Amik plain, which is located in Hatay province, Turkey. For this purpose, 179 soil samples were collected at 2 km intervals in 0 – 30 cm depth of the agricultural lands. pH, EC, lime, organic matter, useful phosphorus, total exchangeable cations and structure (Sand, Silt and Clay) of the soil samples were analysed.*

The study results were determined as pH: 7.00-8.90, EC: 78-1188 (μ S), lime:0-43.9 (%), organic matter: 0.095-4.0 (%), useful phosphorus: 0.010-71.4 (mg.kg-1), total variable cations: 53-140.9 (mmol), clay: 0.010-58.8 (%), sand: 4.60-70.9 (%), silt: 15.6-88.8 (%).

In conclusion, the current data suggested that the use of unnecessary fertilization could be decrease with agricultural activities more consciously of the local people. The results will provide an important contribution to our national economy in future.

Abstract— Arsenic is creating potentially serious environmental problems for humans and other living organisms. Arsenic contamination is caused by natural processes such as mineral weathering and dissolution resulting from a change in the geo-chemical environment to a reductive condition and by human activities such as mining wastes, petroleum refining, sewage sludge, agricultural chemicals, ceramic manufacturing industries and coal fly ash. Arsenic occurs in the forms of organic and inorganic in waters. The organic arsenic usually occurs less than 1 µg/L in natural conditions. Arsenate (as $H_2AsO_4^-$ and $HAsO_4^{2-}$) is the predominant and stable inorganic arsenic form in the oxygen-rich aerobic environments, while arsenite occurs primarily as H_3AsO_3 and $H_2AsO_3^-$ (above pH 9.3) in reducing anaerobic environments. Owing to epidemiological evidence linking arsenic and cancer, maximum concentration level in drinking water has been limited to 10 µg/L by WHO.

Many treatment technologies have been developed such as lime precipitation, oxidation, coagulation/filtration, adsorption, ion exchange and membrane processes to remove arsenic from water. Among these methods, adsorption method seems to be promising. Activated carbon is the most widely used adsorbent. Particularly, it can be obtained the most suitable adsorbents for different pollutants by modifying its surface properties. In this study; a magnetic activated carbon prepared from almond shell, apricot and peach stones mixture with $FeSO_4$ chemical activation was used as an adsorbent to remove the arsenic and effects of the some parameters such as adsorbent dosage, contact time and initial arsenic concentration on the arsenic adsorption were examined. It was found that whole arsenic in the solution (10 mg/l) was removed by using 2 g/l of magnetic activated carbon at the pH range of 2-9 at 25°C for 60 min.

Keywords— Magnetic activated carbon; Arsenic; Adsorption; Almond shell; Apricot stone; Peach Stone.

Abstract— *The parameters and data controlling hydrologic processes by Geographic Information Systems (GIS) have become an integral part of hydrologic studies. The main management is to bring together the use GIS to model s and hydrologic data. The general distribution of the inputs and parameters can control the surface sources or underground loss. GIS maps commonly describe topography, land use and cover, soils, rainfall, and meteorological variables may become model parameters or inputs in the simulation of hydrologic processes.*

This investigation of water logging can be extremely useful in suitable water management strategies by reclaiming existing water logged areas. The problems of water logging and quality mostly exist in the irrigated areas like in South Eastern rocky plains of Batman, Turkey. The climate change and ground water changes generally results in over irrigation, seepage losses through channel and distributions, poor water management practices and inadequate control of drainage system. Analysis of high water table in water logged areas and drainage of irrigated areas have not been paid adequate attention in the planning and management of water resources, partly due to lack of requisite data and partly due to flood and rainfall in the country. In order to develop suitable water management strategies and controlling the extent of water logging in the area. GIS may facilitate the reconstruction of the ecological environment but also to accommodate the sustainable development of the water resources and waste water.

In this study, the hydrological characteristics of the Batman city were explained and the effect of these characteristics on the the city was examined. In the investigation, hydrological features and the urbanization with new settlements needs modeling regarding available water source. The hydrological property of settlement areas with dense populated areas in the model was determined by Geographic Information Systems (GIS) techniques. The main purpose of this study is to investigate the effect of settlement on the basic hydrological structure by studying the characteristics of the ground topography, ground water elevation, slope and viewing. GIS techniques were used in the creation of the thematic maps and in the analysis of the parameters. Finally, the GIS study models created , the available water source change and a stream network model was provided sufficient source control at the Batman province. The presence of this stream network structure in the Batman province reveals the potential flood scale and flood risk. This study produced more systematic data with hydrological studies carried out with GIS support. GIS has made it possible to obtain more qualified data by enabling the use of multi-criteria decision making method in this research.

IV. CONCLUSIONS

Based on the obtained results, the following conclusions can be drawn: The kinetic and equilibrium data were well represented by the pseudo-second order kinetic and Langmuir isotherm models, respectively. The maximum sorption capacities for MB onto WC and WC65 were found to be 39.68 and 161.29 mg/g at 50 °C, respectively.

Consequently, this study shows that WC65 acts as a potential and low-cost sorbent for the removal of hazardous dye MB from aqueous medium.

Abstract— *The microbial fuel cell (MFC) production from biodegradable organic wastes is considered as a new concept based on the recent molecular discovery of specific microbes capable of catalyzing efficient half reactions at electrode surfaces. Typical double chamber MFCs consist of two separate chambers which can be inoculated with any type of liquid. These two chamber reactors have an anaerobic anode chamber and an aerobic cathode chamber, generally separated by a PEM such as Nafion (Oh and Logan, 2004). MFC is the possibility of combining waste degradation with energy generation. This technology uses microorganisms to catalyze the direct production of electricity from organic materials (Rezaei et al., 2007, Logan and Regan, 2006). This study has investigated the electricity production from waste activated sludge taken from meat processing industry wastewater treatment plant. The double chamber MFC reactors were designed at laboratory scale and different electrodes as Pt/C carbon paper and carbon cloth were used during experiments. Sludge characterization studies were first done before feeding the reactors. Maximum power, maximum current, power and current densities were calculated for all experimental series. Double chamber MFC- Pt/C carbon paper reactor has 33.80 mW/m² and 12.99 μ A/cm² maximum power and current densities while double chamber MFC-carbon reactor has 60.30 mW/m² and 17.36 μ A/cm² maximum power and current densities. Double chamber MFC Pt/C gave a positive reaction to NaCl additions. This paper debugs the experimental results in details.*

Abstract—The objective of this study was to investigate the effect of polyvinylpyrrolidone (PVP) and propionic acid (PA) on the structure and gas transfer performance of polyvinylidene (PVDF) hollow fiber membranes by wet spinning. PVDF hollow fiber membranes were fabricated using wet spinning process.

Keywords—Hollow fiber membrane, wet spinning, polymer additives, gas transfer.

I. INTRODUCTION

By changing the regulations on drinking water quality and wastewater discharge standards and decrease in available fresh water supplies in all over the world, this situation has prompted researchers to find and develop new technologies in water and wastewater treatment. Due to membrane technologies can produce high quality reusable water from wastewater for irrigation, reuse and agricultural purpose water, researchers have

focused on the development of this technology. The membrane biofilm reactor (MBfR) is developing technology for water and wastewater treatment. It is composed of hydrophobic membranes that provide gas transfer [1]. Certain gaseous diffuse from the inside of membrane fibers to the biofilm located on the outer surface of each fiber [2]. This system appears to be more advantageous than conventional biofilm systems. One of the most important advantages of MBfRs is that the gas, which may vary according to contaminant species desired to be removed from wastewater, delivered to each membrane fiber is diffused from the inside to the outside without bubble formation. The manufacturing of gas transfer membrane has crucial potential in the development of this technology. In this study, we tried to produce gas transfer hollow fiber membranes by wet spinning process.

II. MATERIALS and METHODS

Polyvinylidene fluoride (Solef 6010 homopolymer) was purchased from Solvay was used as the polymer in the dope solutions. N-Methylpyrrolidone (NMP) was used as solvent and bore liquid component supplied from Asland. Polyvinylpyrrolidone (PVP K10) and propionic acid (PA) were used as a polymer additive supplied from ISP and Merck respectively. Chemicals used other than PVDF have not undergone any pretreatment. Hollow fiber membranes were fabricated by wet spinning. Based on study, polymer material wt. %20 of PVDF was used in dope solutions. N-Methylpyrrolidone (NMP) with

wt. %77,5 and %80 was used as a solvent. PVP K10 and PA were used with wt. %2,5 as a polymer additives. Mixture of water and NMP (10 wt. % water and 90 wt. % NMP) was used as a bore liquid. Tap water was used in the coagulation bath and the air gap distance was zero. Spinning parameters (dope and bore flow rate, take-up speed etc.) were kept constant. PVDF was dried for 1 day at 60°C, NMP was added to the dope solution after being sure that PVDF dissolved in NMP, polymer additive (PVP K10 or PA) was slowly added into the dope solution and dope solution mixed for 2 days at 70°C. To remove air bubbles from the dope solution before spinning, the solution was sealed under vacuum. Pressurized nitrogen gas (2 atm) pumped the dope and bore solutions to the spinneret where all solutions were combined. From the

spinneret, the solution immediately immersed into the first coagulation bath and formed fibers moved from the first coagulation bath to the second coagulation bath. Ultimately fibers were collected on the take up roll. The produced membranes were room temperature. Morphology of hollow fibers membranes was characterized by using scanning electron microscope (SEM). Surface functionalization of hollow fiber membranes was characterized using FTIR Spectrophotometer. Hydrophilicity of hollow fiber membranes was found by conducting contact angle measurements. For mechanical testing of hollow fiber membranes

stored in distilled water in a container for minimum 3 days to remove solvent and additives. After this process, the membranes were dried to determine the characterization and gas transfer performance at

DMS instrument was used. The produced membranes were made into modules to determine gas transfer performance. Oxygen concentrations values were recorded versus time at constant 2 psi. Spinning parameters and the contents of dope and bore liquid solutions are given in Tables I and II, respectively.

Table I. Contents of solutions

Membranes	Dope solutions			Bore solutions	
	<i>PVDF</i> (wt. %)	<i>Solvent</i> <i>NMP</i> (wt. %)	Additive (wt. %)	Solvent (wt. %)	Water (wt. %)
HF1	20	80	-	90	10
HF2	20	77,5	2,5 (PVP K10)	90	10
HF3	20	77,5	2,5 (PA)	90	10

Spinning parameters	M1	M2	M3
Dope solution velocity (mL/min)	6	6	6
Bore liquid velocity (mL/min)	3	3	3
Take-up speed (m/s)	0,1	0,1	0,1
Air gap (cm)	-	-	-
Coagulation baths temperature (°C)	25	25	25

Table II. Spinning parameters

III. RESULTS and CONCLUSIONS

SEM images of the produced hollow fiber membranes are shown in Figure I. It can be observed by scanning electron microscope (SEM)

that pristine (HF1) and containing PVP K10 (HF2) hollow fiber membranes have thin and long finger-like cavities, containing PA (HF3) hollow fiber membrane has macrovoid defects.

Figure I. SEM images of hollow fiber membranes from left to right HF1, HF2, and HF3 respectively.

The graphs of contact angle, mechanical strength and diffusion coefficient values of the produced hollow fibers are given in Fig. II, Fig. III and Fig. IV, respectively. As can be seen that with the addition of PVP K10 and PA in the dope solution, contact angles of the hollow fibers decreased. According to the results, the highest Young's Modulus of hollow fiber was dope solution contained wt. %2,5 of PVP K10. Diffusion coefficients of hollow fiber membranes were

decreased with the addition of PVP K10 and PA in the dope solution. Pristine hollow fiber membrane was the highest. Due to same peaks were observed between three hollow fiber type only pristine hollow fiber membrane FTIR-ATR measurement is given in Fig V. 762, 796, 858, 975, 1070, 1178 cm^{-1} peaks (α -phase) and 839, 1275 and 1401 cm^{-1} peaks (β -phase) were observed from FTIR-ATR measurements.

Figure II. Contact angles of the produced hollow fibers.

Figure II. Young's Modulus of the produced hollow fibers.

Figure IV. Diffusion coefficients of the produced hollow fibers.

Figure V. FTIR-ATR of the pristine hollow fiber.

Abstract— Sludges produced at different treatment stages in biological wastewater treatment plants have rich organic materials in their characteristics. Recent research studies dealing with the sludge related problems have focused on the energy recovery from sludge due to its high organic content. Gasification process is a thermal conversion technology transforming the chemical energy contained in a solid fuel into thermal energy and electricity (Bruno, 2006, Arena and Mastellone, 2005). The inspiration point of the study is based on the successful gasification applications by using different organic materials like coal, walnut, wood chips, etc. The sludge produced from the wastewater treatment plants has a fuel merit with its high calorific value for usage of supplementary fuel as in the cement factories or recovery of energy from sludge while it is processing with the different valorization processes like gasification. Using the insight that sludge gasification may also be admitted as an energy resource, new and fundamental research approaches can be presented that are likely to produce syngas or combined heat and power production in a cost effective way and to minimize the ultimate waste amount to be landfilled.

The most important by-product of the gasification process is syngas including a mixture of CO, CH₄, H₂ and other gases to be used as fuel. In this study, the energy recovery from leather industry sludge taken from a leather industry wastewater treatment plant located in İzmir, Turkey by means of gasification process was investigated. A pilot scale downdraft type gasifier was used during the experimental studies. The produced syngas was converted to electrical power by using a gas engine. According to the experimental results, leather industry sludge was found as an appropriate material for gasification studies and remarkable energy recovery was obtained interims of power production by using syngas in an engine. This paper presents on the research results in detail.

Abstract— Various kinds of synthetic dyes appear in the effluent of industries such as textiles, leather, paper, plastics, etc. The textile dyeing industry consumes large quantities of water at its different steps of dyeing and finishing, among other processes. Since a very small amount of dye in water is highly visible and can be toxic to creatures in water, the removal of dye from wastewater becomes environmentally important. Among several chemical and physical methods, the adsorption process is one of the effective techniques that have been successfully employed for dye removal from wastewater. The use of microorganism for biosorption of arsenic ions from water is an enormously effective process, due to which it is becoming widespread day by day. Biosorption plays an important role in the removal of dyes from aqueous solutions to control water pollution. Low operating cost, reusability of biomaterial and improved selectivity for specific metals of interest, removal of heavy metals from wastewater irrespective of toxicity, short operation time and minimal sludge generation convinced many environmental managers in the mining and dyes smelting industry to attempt biological systems. Biosorption is a passive process which uses the cell wall of biomass for sequestering the metal ions from wastewater. It is a metabolism independent process and so can be done by both living and dead cells. The mechanisms of biosorption may be categorized into three types: (1) cell surface sorption/precipitation (2) extracellular accumulation/precipitation and (3) intracellular accumulation. This can take place by adsorption, coordination, complexation, ionexchange, chelation and microprecipitation. The cell wall of a microorganism mostly contains proteins, polysaccharides and lipids that deliver predominantly profuse dye binding functional groups for example hydroxyl, phosphate, carboxylate, sulphate, sulfhydryl, amino, amido and imidazole groups. This work we use *Paenobacillus barcionensis* (PB) and MgO (n-MgO) nanoparticles. This work deals with the preparation, characterization and dye adsorption properties of novel biocomposite composite (*Paenobacillus barcionensis*–magnesium oxide nanoparticle) (PB/n-MgO). Physical characteristics of PB/n-MgO were investigated. The textile dye reactive black 5 was used as model compound. The isotherm and kinetics of dye adsorption were studied.

Abstract— Membrane distillation (MD) is a well-known process for its application with high performance in desalination. However, the quality of the treated solution, as well as high transmembrane flux (TMF) and low membrane fouling, depend on many parameters including the feed solution salt content. In the present study, the salt content of the permeate solution and the TMF flux of a direct contact membrane distillation (DCMD) were evaluated during the desalination of various saline solution with different salt concentration. The treatment was performed using two hydrophobic membranes made of polytetrafluoroethylene (PTFE) and Polyvinylidene Fluoride (PVDF) 0.45 μm pore sizes, at 60 $^{\circ}\text{C}$ feed temperature. The results showed that at moderate salinity, the salt participated to increasing the TMF, and very high salt rejection took place as well. But at very high salt concentration, the flux dropped, and the effluent quality was reduced. The highest flux (around 12.89 $\text{L}/\text{m}^2\cdot\text{h}$) was obtained with 40 mS/cm conductivity of the feed solution when using PTFE membrane and the salt rejection reached 99.84% in the same condition. Similarly, with a higher salt content of the feed solution (60 mS/cm conductivity), the TMF reduced to 9.8 $\text{L}/\text{m}^2\cdot\text{h}$, however, the salt rejection was still high. It is obvious that an efficient control of salt concentration in real scale desalination can lead to a cost-effective MD for clean water supply from sea water.

Abstract— *Organized Industrial Districts (OID), are models that purpose to minimize and/or to remove environmental problems originating from industries. The Elazığ OID is located on an area of 322 hectares, 11 km east of the Elazığ province center. Industrial and domestic wastewaters of the OID are discharged to Elazığ Wastewater Treatment Plant via common channel. In this study, a trial work was carried out to determine the properties of wastewater taken from the OID common channel and its physico-chemical treatability. In the study, the pollution parameters expressed as chemical oxygen demand (COD), biological oxygen demand (BOD5) and suspended solids (SS) were determined as average 720 mg/L, 290 mg/L and 270 mg/L, respectively. In physico-chemical treatability studies; COD, SS and Total Nitrogen (TN) removal yield was around 50-70 %, 90- 95 % and 30-60 %, respectively. It was suggested to use $Al_2(SO_4)_3 \cdot 18H_2O$ for chemical treatment as a result of physico- chemical preliminary treatability tests using $Al_2(SO_4)_3 \cdot 18H_2O$ and $FeCl_3 \cdot 6H_2O$ with wastewater from OID common channel.*

Abstract— Gyroscopes are devices that use rotational motion and balance for finding direction and measuring velocity. Gyroscopes, which were initially in normal size, have been transformed into gyroscopes created by Micro Electro-Mechanical Systems (MEMS), which have been progressively smaller in size with advances in technology over the years. The gyroscope consists of two axes perpendicular to each other and to the axis of rotation around an axis. It is made in such a way that it can freely turn around one or both of its axes and its mass center is fixed. Unlike other rotary sensors, gyroscopes have the ability to measure the motion of an object without an external signal. In this study, two control methods for tracking sinusoidal trajectories of triaxial MEMS gyroscopes have been investigated. Mathematical model of a triaxial MEMS gyroscope has been presented and modeled in MATLAB / Simulink environment. The proportional-integral-derivative controller and the Sliding Mode Control based approach have been implemented to control the system with the generated block diagrams. Both control methods have enabled triaxial MEMS gyroscopes to follow the desired sinusoidal references. The results obtained by both control methods have been examined.

Keywords—Triaxial Gyroscope; Micro Electro-Mechanical Systems; Robust Control; Sliding Mode Control.

I. INTRODUCTION

The gyroscope consists of two axes perpendicular to each other and to the axis of rotation around an axis. Gyroscopes can rotate freely around one or both axes. They have the ability to measure the motion of an object without an external signal [1]. Gyroscope examples can be found in a variety of forms, and although it has been around for a long time, little is known about this device until the 19th century. Jean Bernard Leon Foucault in 1852 gave the name of the gyroscope that he made to show the world's return. However, the gyroscope has remained the game of scientists for about 60 years since the rotational motion cannot be sustained continuously. As steel is used in ships, the confidence in the magnetic compass is reduced and the gyroscopic compass becomes more important. Gyroscopic instruments have been developed to control the movement of ships and aircraft. Gyroscopes that inhibit roll motion in ships are also used to give direction to the torpedo. In 1943, a gyroscope was used to direct sea vessels and with the emergence

of the Second World War, the gyroscope began to develop rapidly [2].

Fei et al. have developed an adaptive drive mode control strategy that combines the benefits of drive mode control and indirect adaptive fuzzy control to regulate the triaxial MEMS gyroscope against outer disturbances, uncertainties and nonlinearities. This control strategy has helped the model in the presence of external disturbances and uncertainties and in controlling position of MEMS gyroscope. Adaptive fuzzy systems in both the equivalent control circuit and the switching control circuit are used approximately in the control of drive mode. Then the switching control has become continuous and the noise disturbances are weakened. Numerical simulations have been investigated to verify the effectiveness of the proposed adaptive fuzzy control schemes [3].

Fang et al. constructed a MIMO Takagi-Sugeno (T-S) fuzzy model based on the nonlinear model of MEMS gyroscope [4]. A robust adaptive drive mode control is proposed for the estimation of the uncertainty parameters of the model and for the upper limits of the external distributions. Based on the Lyapunov methods, these adaptive laws can guarantee asymptotic stability and robust mass force in x and y directions for oscillation in the given amplitude and frequency. The controller was also implemented on the MEMS gyroscope nonlinear model. Numerical simulations have been investigated to verify the effectiveness of the proposed control scheme on T-S and nonlinear models [4].

Park et al. has provided an adaptive control method for a MEMS gyroscope that can carry out both vibration axes and controls in all applications of the gyroscopes [5]. Leland has proposed an adaptive control method for a MEMS gyroscope using rebalancing force [6]. John et al. has proposed a new concept for adaptive control of a triaxial angular velocity sensor device [7]. Fazlyab et al. have designed an intelligent controller for applications in mono-axial vibrating MEMS gyroscopes [8]. First, a micro-gyroscope unknown parameters with unknown time constants of angular velocity are estimated continuously through the least quadruple algorithm. Then, the two fuzzy sliding-mode control ranges are added to match the resonance frequency and compensate for unwanted mechanical

connections. The main purpose of this control strategy is to increase the robustness against gyroscope parameter changes, external disturbances and noise measurements. Consistent estimates of the parameters can be guaranteed and the stability of the closed-loop system is ensured through Lyapunov stability theory. In order to validate the effectiveness of this proposed method, a number of simulations, both fixed and time-varying, have been performed [5].

The performance of MEMS gyroscopes is determined by time-varying parameters, external disturbances caused by quadrature errors and oscillation incompatibility between two oscillating axes. In recent years, the application area of triaxial angular velocity sensors has increased considerably with the rapid development of MEMS production technology. Control methods such as intelligent control or adaptive control are adaptable control methods for MEMS gyroscope control. Various control approaches have been proposed to control the triaxial MEMS gyroscope [9].

Leland, produced two adaptive controllers in a vibrating gyroscope to adjust the frequency of the drive axis to a specified frequency and to reduce the vibration of the detection axis to zero to rebalance the force [6]. Batur et al. have developed a Sliding Mode Controller for a MEMS gyroscope [10]. Sung et al. have developed a phase-space design to work on mode adaptive control of the gyroscope [11]. Antonello et al. have studied extreme values search control to automatically match the vibration mode on vibrating MEMS gyroscopes [12]. Park et al. proposed an adaptive controller that controls both the vibration axis and entire performance of the gyroscope [5]. John et al. developed a new control concept to adaptively control the triaxial angular velocity sensor device [7]. In other studies, Sliding Mode Control approach has been used in adaptive control scheme to control MEMS gyroscopes, [13-14].

This study includes the mathematical model of a triaxial MEMS gyroscope in order to provide sinusoidal trajectory tracking. In order to improve tracking performance two methods: tuned PID and SMC-based control approaches are implemented in the MATLAB/Simulink environment. The effectiveness of the controllers to track sinusoidal trajectory is demonstrated with the simulation results in x , y and z axes.

The paper is organized in six sections. In the Section I, literature review about basic gyroscopes is included. Studies related with triaxial MEMS gyroscopes and their controls are given in Section II. Dynamic model of the triaxial MEMS gyroscope is also obtained in Section III. PID and SMC based control of the system are presented in the Section IV and V, respectively. Finally, simulation results are given in Section VI.

II. DYNAMIC MODEL OF THE TRIAXIAL MEMS GYROSCOPE

Let assume that the gyroscope moves at a constant linear velocity, then it rotates at a constant angular velocity. If the centrifugal forces are neglected and the gyroscope is thought to move along the x , y , z axes, then the triaxial MEMS gyroscope dynamic equations can be given with (1-3) as [9]:

$$\begin{aligned} m\ddot{x} + d_{xx}\dot{x} + d_{xy}\dot{y} + d_{xz}\dot{z} + k_{xx}x + k_{xy}y + k_{xz}z \\ = u_x + 2m\Omega_z\dot{y} - 2m\Omega_y\dot{z} \end{aligned} \quad (1)$$

$$\begin{aligned} m\ddot{y} + d_{xy}\dot{x} + d_{yy}\dot{y} + d_{yz}\dot{z} + k_{xy}x + k_{yy}y + k_{yz}z \\ = u_y + 2m\Omega_z\dot{x} - 2m\Omega_x\dot{z} \end{aligned} \quad (2)$$

$$\begin{aligned} m\ddot{z} + d_{xz}\dot{x} + d_{yz}\dot{y} + d_{zz}\dot{z} + k_{xz}x + k_{zy}y + k_{zz}z \\ = u_z + 2m\Omega_y\dot{x} - 2m\Omega_x\dot{y} \end{aligned} \quad (3)$$

In these equations, m represents the mass. The production errors mainly affect the asymmetric spring coefficients ω_{xy} , ω_{xz} , ω_{yz} .

d_{xy} , d_{yz} , d_{xz} are asymmetric damping coefficients. ω_x , ω_y , ω_z are the spring coefficients and d_{xx} , d_{yy} , d_{zz} are the damping terms in the x , y , z axes. Ω_x , Ω_y , Ω_z are the angular velocities and u_x , u_y , u_z are the control forces in the x , y , z axes.

Our control objective on the triaxial MEMS gyroscope is to force the system outputs in the x , y , and z axes sinusoidally to track the desired trajectories. Table I [9] presents desired parameters. In the table, (x_m, y_m, z_m) indicate desired sinusoidal trajectories and $(\omega_1, \omega_2, \omega_3)$ also indicates frequency of trajectories.

TABLE I. DESIRED PARAMETERS

x_m	$\sin(\omega_1 t)$
y_m	$1.2 \sin(\omega_2 t)$
z_m	$1.5 \sin(\omega_3 t)$
ω_1	6.71 kHz
ω_2	5.11 kHz
ω_3	4.17 kHz

System parameters of the MEMS gyroscope is given in Table II [9]. Since the settlement range is at micrometer levels, the reference length q_0 is selected as 1 μm and the expressions we use in kHz are assumed to be Hz in this study, so ω_0 is taken as 1000 Hz.

TABLE II. SYSTEM PARAMETERS OF THE TRIAXIAL MEMS GYROSCOPE

Parameters	Values
m	0.57e-8 kg
ω_0	1000 Hz
d_{xx}	0.429e-6 Ns/m
d_{yy}	0.0429e-6 Ns/m
d_{zz}	0.895e-6 Ns/m
d_{xy}	0.0429e-6 Ns/m
d_{xz}	0.0687e-6 Ns/m
d_{yz}	0.0895e-6 Ns/m
Ω_z	5 rad/sn
Ω_x	3 rad/sn
Ω_y	2 rad/sn
λ	1000
K	20
τ_i	0.001

III. PID CONTROL OF THE TRIAXIAL MEMS GYROSCOPE

The system is controlled with the help of the PID controller in continuous time. The MATLAB / SIMULINK block diagram of the entire system is illustrated in Fig.1. Table III shows the PID controller parameters applied to the system. These parameters are obtained from the "auto tuning option" of the PID block.

Fig. 1. Block diagram created with MATLAB / Simulink of PID control of the triaxial MEMS gyroscope

TABLE III. PID CONTROL PARAMETERS

Axes	Coefficients		
	K_p	K_i	K_d
x axis	962	15898055	8.2×10^{-4}
y axis	836	8333102	7.6×10^{-4}
z axis	731	6810265	7.103×10^{-6}

IV. SMC-BASED CONTROL OF THE TRIAXIAL MEMS GYROSCOPE

SMC is a robust control technique with many attractive features such as sensitivity to external disturbances and robustness to parameter changes [15, 16]. In SMC, the phase trajectories formed by the system curves are provided with the help of the switching function on the tangent line passing through the equilibrium point, and the variables are kept on this line. Therefore, the switching function has a great importance. Switching function directly affects performance and robustness of the control [16].

In this study, a control structure based on the SMC as well as the PID controller is used for the same system dynamics and reference inputs for a triaxial MEMS gyroscope. In this control structure, the control signal can be described as [17]:

$$u = KS \quad (4)$$

here K is the constant gain value and switching function S can be given with;

$$S = \lambda e + \dot{e} \quad (5)$$

Slope of the sliding surface is represented by λ . In Fig. 2, a MATLAB / Simulink block diagram is shown in which a control structure based on a SMC is implemented to triaxial MEMS gyroscope.

Fig. 2. MATLAB / Simulink block diagram of the system using SMC

The coefficients for the x, y and z axes are chosen as 1000, 20 for λ and K, respectively. The saturation value is also preferred as [100 -100]. Fig. 3a shows the SMC-based control structure, Fig. 3b shows the internal structure of the controller.

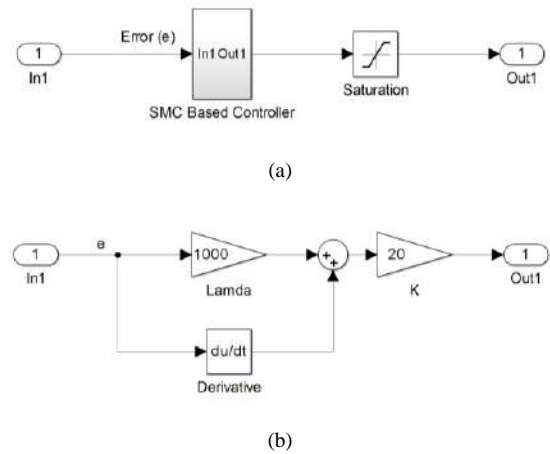

Fig. 3. a) SMC-based control structure b) internal structure of the controller.

V. RESULTS

A triaxial MEMS gyroscope is constructed by using dynamic equations and the system is controlled by PID and SMC-based control method. The triaxial MEMS gyroscope system has sinusoidal reference inputs with amplitude 1 at x axis and frequency 6710 Hz, amplitude 1.2 at y axis, frequency 5110 Hz, amplitude 1.5 at z axis and frequency 4170 Hz.

The simulation results obtained in the x, y and z axes with PID are shown in Fig. 4. The SMC-based controller is also implemented to obtain more robust control output on the x, y and z axes for the triaxial MEMs gyroscope as illustrated in Fig. 5. The error signals in the x, y, and z axes are also illustrated in Fig.6 in order to compare the results obtained with the PID controller and SMC-based controller.

VI. CONCLUSION

In this study, dynamic model of a triaxial MEMS gyroscope is investigated to perform sinusoidal trajectory tracking. System is modeled in MATLAB/Simulink environment to illustrate trajectory performance by using two methods: PID tuned with auto tuning option of the PID block and SMC-based control approach which uses switching function to reach the minimum error faster with a very simple control structure.

The error signals in the x , y and z axes, obtained from the SMC-based controller have a smaller value than the tuned PID controller for the same conditions as can be seen from the figures.

Abstract— Today, driving simulators are used in many fields. However, vehicle driving simulators are expensive to use driving evaluation or education. The aim of this study is that to design and control 2-DOF low cost vehicle simulator. This system is designed using SOLIDWORKS program. Finite element and structural analysis of the system is analyzed using ANSYS program. Also, kinematics equations are delivered of the system and PID control is applied to this kinematic model in MATLAB environment. SOLIDWORKS model of the system is imported to SimMechanics. Therefore, Mass, inertia, and center of gravity coordinate system of each part is automatically transferred to body blocks in SimMechanics. PID control parameters is applied to SimMechanics model of the system. Physical system is mechanically robust and controlled successfully due to the SimMechanics simulation results. This approach can be applied to design low cost vehicle driving simulator systems.

Keywords—ANSYS, driving simulator, SimMechanics and Solidworks

I. INTRODUCTION

Vehicle simulators are the mechanisms which provide to feel like moving a real vehicle platform. Nowadays, vehicle simulator systems are used in many fields such as educational, driving evaluation and aerospace industry. Traffic accidents is dramatically increased in Turkey over the past ten years. A major current focus on vehicle simulators are how to decrease traffic accidents in Turkey. In the literature, Vehicle simulators are designed to use commercial or educational. The first studies on this study begin with ‘Stewart Platform’ in 1965 for flight simulator [1]. Stewart Platform consisted of 6 DOF parallel mechanisms and has been named from D. Stewart. This platform used many researches such as robotic and industrial areas. The first model of the Stewart platform is shown in Fig. 1.

Parallel robots and mechanisms have been used for various applications. These systems have high carrying capacity, suitable dynamic, kinematic performance and precision. If degree of the freedom increases, then the precision of the system will increase [2]. Thus, 6 DOF system is the best solution for simulation but controlling the platform will be more complicated. On the other hand, 2 DOF systems has not better precision when they compared 6 DOF systems.

Driving simulators are used effectively for vehicle system development and other purposes by enabling to reproduce actual driving conditions in a safe and tightly controlled.

Fig 1. Stewart Platform

A low-cost motion platform has two degree of freedom (2 DOF) that is designed and built. The main aim of this project is that to design low-cost fully functional driving simulator for education and driving evaluation. This system is useful for the driver's behavior study in related driving exams as shown in Fig. 2 [7-9].

Like other related studies this project consist of steering wheel, gear shift and pedal, driving seat, components of a computer system of a motion platform.

Fig 2. Driving simulator in use

According to chronological order Volkswagen, IFAS, VTI, Daimler-Benz, Mazda, Ford, BMW, JARI, Nissan and WIVW, NADS-1, SimuSYS, Renault, Katech, SimCar, UoLDS, Toyota such as many companies have managed to become a global giant technology with produced motion simulators [3-6]. These are more expensive and complicated systems then our project. This

system as mentioned above has low cost, good calibration and dynamics and optimal solution for simulation [10].

The remainder of this paper organizes Section 2 discusses how to design mechanically to the system Section 3 examines SimMechanics model of the system and in Section 4 consists of the conclusion and discussion part of the system.

II. MECHANICAL DESIGN

The current design involved mechanical analysis part and SimMechanics part to control low-cost 2-DOF vehicle simulator. In mechanical analysis part, Solidworks model of the system was designed. Motion analysis was carried out using Solidworks Motion Analyze. Statics and rigid analyze is done using ANSYS program. Mechanical design of the system is shown in Fig. 3 and Fig. 4.

Fig 3. Mechanic Design of the System

The simulator will consist of two main parts: mechanical and electronic modules.

Mechanical parts will be part of the general movement of the user's location that will be transferred to the mechanical system.

Electronic system is the control and processing part of the project. This part is processed using a computer program, the data will be transferred to the motors to move the system. Thus, when the steering control program set by the computer in the control synchronously. Computer, Microprocessors, Motor Driver, Motors motion simulation environment will be designed providing the platform.

Fig 4. Mechanic Design of the System

Static, transient and rigid analyzes are examined using ANSYS environment. Revolute joint is used all revolute links. In static analyze 1000 N force is given to the system. Stress of the system maximum reaches 23.9 MPa value shown as in Fig. 6.

When using the transient analyze, giving 15-degree rotation to the system transient analyze is obtained. Maximum total deflection of the system is 0.28m as shown in Fig.7.

Using rigid method results is compared to nonlinear finite elements solution methods as shown in Figure 8. Also Maximum velocity prob. is tested 0,044 m/s.

Fig 5. Stress analyze of the system

Fig 6. Total Deformation Results

Fig 7. Rigid Dynamics Results

Motion analyze is applied to our Low-cost 2 DOF vehicle simulator using SolidWorks. Three different motion analyze is examined to the system. They are angular displacement, angular velocity and angular acceleration. 90 degrees with 1Hz oscillation frequency is carried out to system. Motor power is 2A at rated current and 10 A at under load. Due to the test results, Motor works with 12V DC supply and 240W power that carry 100kg load. The results shown in Fig. 8.

Fig 8. Angular Displacement of the System

The motors scan an angle of 40 degrees in both axes for 16 seconds. This gives us the angular positions required for the planned simulator. An angular displacement relationship between the motor shaft and the platform was monitored. It is

observed that the output is sinusoidal because the applied motor speed is oscillatory.

Fig 9. Angular Velocity of the System

When the motors were rotated and oscillated at a 90-degree angle for 16 seconds, a 90-degree sinusoidal motion was seen between the motor shaft and the platform. The results of this graph and the angular displacement graph are similar.

Fig 10. Angular acceleration Results of the System

We have also obtained a synchronous motion graph similar to the angular velocity and displacement graphs in the direction of motion when we apply the angular acceleration-time graph to the motor mills.

III. CONTROLLING OF THE SYSTEM

Solidworks Assembly design is imported to MATLAB SimMechanics environment. The main advantage of the SimMechanics is that automatically generate MATLAB model using SolidWorks files. The SimMechanics model consists of the joints, actuators, sensors and links of the system. PID control parameters is determined MATLAB control toolbox using SimMechanics model. In Fig. 12 SimMechanics model is shown.

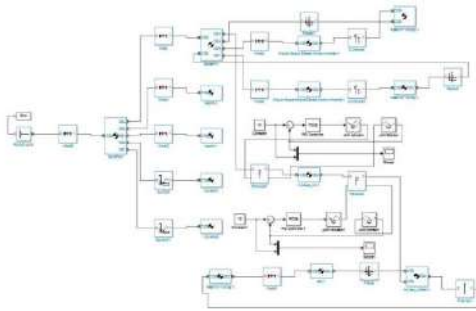

Fig 11. SimMechanics Model of the System

PID control response graphics are shown in Fig. 13 and Fig. 14. System is two degree of freedom therefore two angle called as theta and Fi that is controlled using SimMechanics PID. Desired position of the system is set to reference position of the system effectively. SimMechanics 3-D model is shown in Fig 15.

Fig 12. theta angle of the system

Fig 13. Fi angle of the system

Fig 14. 3-D SimMechanics Model

IV. CONCLLUCION

In this study, low cost 2 DOF vehicle simulator is designed and controlled. Solidworks and ANSYS programs are used for mechanical design of the system. SimMechanics model is used for controlling the vehicle simulator. Due to the test results, the simulator controlled effectively. It is observed that Low cost vehicle simulator model is very useful for education and driving evaluation. In the future work, fuzzy logic control algorithm will be applied to the system.

ACKNOWLEDGMENT

The work presented in this paper has been done at Sensor Laboratory of Mechatronics Engineering Department.

Abstract— Researchers have placed great emphasis on controlling and modeling of landing gear systems since these systems are very essential tools for aircraft. In this paper, a landing gear system is modeled to analyze and control by using general modeling method. The closed loop control performance is provided by adding zeros to cancel the poles affecting stability and a simple proportional control is implemented to obtain reduction on vibration of the gear system. The root locus curve is presented to observe stability of the system. Zeros are assigned very close to the poles to prevent the branches of the root locus curve passing through the right half s plane and a very simple proportional controller ensures the distinctive reduction on vibration of the gear system.

Keywords—Landing Gear System, Root Locus Design, Close Loop Control.

I. INTRODUCTION

An aircraft consists of many different parts such as fuselage, wing, winglet, and landing gear. These parts have been subject to a lot of work from maintenance to control [1]–[5]. For example, Fard and Melachrinoudis have examined maintenance span of airplane parts for reducing repairing cost and early detection of error in their own study [2]. In the other work, Currey has talked about what the landing gear is and how to designing [1]. Landing gear is one of the most important aircraft pieces due to landing, taxiing, and taking off aircraft. There are many different landing gear systems such as helicopter landing gear system or plane landing gear system [3], [4], but they have been usually consisted of three parts as mechanics, electronic and hydraulic [5]. Therefore, the systems are very complex and nonlinear.

This complex and nonlinear issue has attracted the attention of many scientists and engineers. While Yin and his team have investigated crosswind velocity, oil leak, liquid capacity, etc. effect on a landing gear system, Sivakumar and Haran have generated dynamic model of the system and then controlled via proportional integral derivative (PID) controller, which is one of traditional control methods [5], [6]. In another study, Li et.al has modeled the system using state space model and controlled by using Fuzzy PID controller, one of the adaptive control methods [7]. Zhu et.al have followed up same trace in 2012 [8]. The system model has been generated and controlled by

using the same controller in this study. Li et.al has controlled different from to other work by using Model Opredictive Control (MPC) [9].

It is very important to obtain the dynamic model of the system in order to predict the behavior of the system. There are many different methods to obtain system dynamic model. These methods are separated two main parts as simulation and analytic methods. First method is the way to obtain a dynamic model using simulation programs such as MATLAB/SimMechanics. Akpolat et.al have obtain dynamic model of robotic fish by using SimMechanics environment [10]. Second method depends on mathematical identification of physical facts. The analytic methods are divided into many ways like Hamiltonian, Lagrange, and Newton Mechanics. Newton Mechanics uses forces while the other mechanics methods use energies to obtain the mathematical model of the system. Applied forces are certain at the landing gear system. Hence, Newton Mechanics is preferred when the landing gear system is modeled.

The system is also controlled to track desired behavior. For this purpose, there are many algorithms such as PID, MPC, and Fuzzy Logic. If a system is wanted to be controlled by using traditional control methods, root locus curves may be benefited to set parameters of the controller. Root locus curves give a lot of information, such as stability, transient, and steady state of a system, so root locus curves are very necessary tools to analyze and control a system. The curves generally are obtained for single input single output (SISO) linear time invariant (LTI) systems [11]. The SISO LTI system block is given Fig 1.

Figure 1. Single Input Single Output (SISO) System Block

Many researchers have studied root locus curves in order to control various systems. In 2016, Kwon and Chang examined root locus curves so as to design PI controller [12]. At another study, buck and boost converters have been designed by using root locus method [13]. In this study, two models of converters have been transformed discrete time model and controllers have been designed. Then, experimental results have been compared to each other. Iranian scientists have developed root locus curves of the fractional order systems [14]. Wellman and Hoagg generated quadratic root locus curves as different perspective [15]. At this approach, unlike the general root locus curves, there are gain and gain square.

In this study, Newton Mechanics is preferred to create the mathematical model of the landing gear system since applied forces are certain at the system. The mathematical model of the system is examined by using root locus curve and the closed loop roots of the system are provided at the left half s plane to ensure stability of the system by adding two zeros very close to poles. Thus, the system can be controlled by using very simple proportional controller.

The paper is organized as follows. Section II presents problem description. Then, the controller design is given in Section III. Section IV illustrates simulation results of the system. Finally, conclusion is presented in Section V.

II. PROBLEM DESCRIPTION

As soon as a plane lands on airport, vibrations are formed, due to sudden shock effect. The vibrations distribute to the plane passenger and crew. In order to understand this discomfort state, dynamic model of the landing gear system ought to be generated. For this aim, the structure of the system illustrated in Fig. 2 is used in order to obtain mathematical model of the system. At the figure, m_p and m_s indicate plane and wheel structure mass, respectively.

Figure 2. Landing gear system

Where, x_p , x_s and x_R are plane, wheel structure and way position with order. k_1 and k_2 are spring coefficient system.

C is passive damping coefficient and F_a is active adjustable damping force. To easier analyses, the system is converted free body diagram as Fig 3.

Figure 3. Free body diagram of landing gear system

In this figure, F_{k_1} , F_{k_2} and F_C are force of k_1 , k_2 spring and C damping elements, respectively. The sums of net forces of m_s and m_p are shown with Eq. (1), (2).

$$\sum F_{m_s} = F_{k_1} + F_C + F_a - F_{k_2} \quad (1)$$

$$\sum F_{m_p} = -(F_{k_1} + F_C + F_a) \quad (2)$$

If these equations are extended, dynamic equations are obtained as below.

$$\ddot{x}_s = (k_1(x_p - x_s) + C(\dot{x}_p - \dot{x}_s) + F_a - k_2(x_s - x_R)) / m_s \quad (3)$$

$$\ddot{x}_p = -(k_1(x_p - x_s) + C(\dot{x}_p - \dot{x}_s) + F_a) / m_p \quad (4)$$

Newton's second law is proved that the sum of forces equals to multiply of the mass and acceleration and it is known that the acceleration is second order derivative of the position. Parameters in Eq. (3) and Eq. (4) are given in Table I [7].

TABLE I. SYSTEM PARAMETERS

Symbol	Value	Unit
m_p	250000	kg

m_s	800	kg
k_1	600000	N/m
k_2	3200000	N/m
C	50000	Ns/m

III. CONTROLLER DESIGN

Usually, root locus curves are drawn so as to analyze steady state and transient performance of a system. Hence, root locus curves inform about stability state such as stable or unstable. This method also gives information about the performance specifications.

In order to draw root locus curve of the landing gear system, the system transfer function is obtained from Eq. (3) and (4) as:

$$G_p(s) = \frac{X_p(s)}{X_R(s)} = \frac{800(s+12)}{(s-0.07 \pm 1.42i)(s-31.28 \pm 61.34i)} \quad (5)$$

for active adjustable damping force (output of the controller) $F_a = 0$. Root locus of Eq. (5) is illustrated in Fig.4.

Figure 4. Root locus curve of landing gear system

It can be seen from the figure that the system can be controlled by a proportional controller. A tuned gain value of the proportional controller is found approximately as $K_p = 100$. The step response of the closed loop landing gear system given in Fig. 5 is presented in Fig.6.

Figure 5. The block diagram of the closed loop landing gear system with proportional controller

Figure 6. The step response of the closed loop system

In order to improve the control performance of the system, a controller is proposed as:

$$G_c(s) = K \frac{(s+30 \pm 60i)}{(s+300 \pm 400i)} \quad (6)$$

Zeros and poles of the controller are chosen such that the root locus moves to the left half s plane and the system response becomes faster owing to the new dominant roots of the characteristic equation. The root locus of the system with proposed controller is shown in Fig.7.

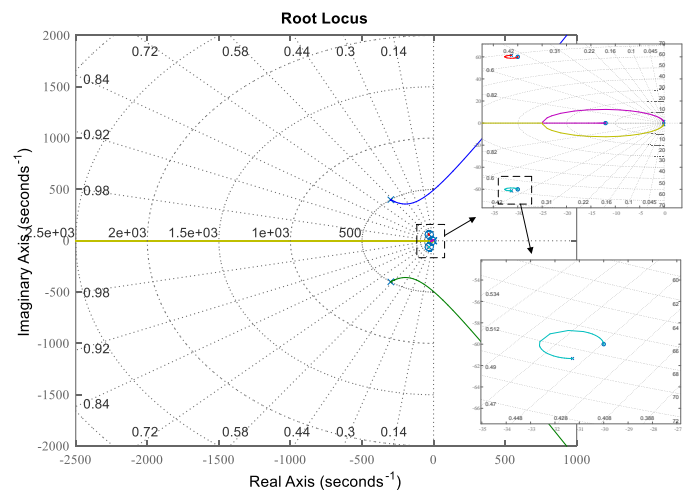

Figure 7. The root locus of the system with proposed controller

The gain value K of the controller given in Eq. (6) is determined as 40177 from the root locus shown in Fig.7 to obtain faster and more robust control performance.

IV. SIMULATION RESULTS

The system is simulated by using *MATLAB/Simulink* toolbox. So as to simulate the system, parameters given in Table 1 are used. These parameters are provided from the study of Hua-Lin et.al [7].

The step response of the open loop system shown in Fig. 8 is presented in Fig.9.

Figure 8. The block diagram of the open loop system

Figure 9. The step response of the open loop system

In order to show the performance of the proposed controller the Simulink block diagram, involving proportional controlled system and the system with proposed controller, is constructed for comparison as shown in Fig.10.

Figure 10. The simulink block diagram for comparison

Step responses of the closed loop systems are illustrated in Fig.11.

Figure 11. Step responses of the closed loop systems

In order to show the performance of the controllers against external disturbance and practical road condition, external inputs are included in the block diagram as shown in Fig.12.

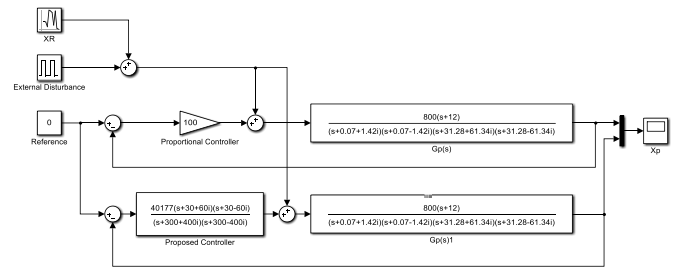

Figure 12. The simulink block diagram for comparison

Note that x_R represents the practical road condition and external disturbance corresponds to an obstacle on the road such as a small stone. Amplitudes of the external inputs are exaggerated to show the difference between control performances of the controllers. Fig.13 shows the responses to external inputs for zero reference.

Figure 13. Responses to external inputs for zero reference

Fig. 11 and 13 show the superior performance of the purposed controller. This is achieved by adding zeros at $-30 \pm 60i$ very close to the poles of the open loop transfer function at $-31.28 \pm 61.34i$ and adding poles far away from the origin at $-300 \pm 400i$ resulting a faster and better control performance.

V. CONCLUSION

In this study, landing gear system is studied in order to reduce vibration during the landing span. A landing gear system is modeled by using Newton method. The control system analysis and design are realized using root locus of the system. When the root locus of the open loop system is examined, it can be easily seen that a proportional controller is suitable for this system. However, control performance of the proportionally controlled system does not seem to be satisfactory. Therefore, a new controller is introduced in order to achieve better control performance. The proposed controller includes pairs of complex zeros and complex poles. In addition, the proposed controller performance against external disturbance and practical road condition is also investigated and simulation results showing the effectiveness of the controller are presented.

In the future work, the system may be modeled for more degree of freedom with nonlinear dynamics and the nonlinear

model can be controlled by using intelligent and robust control methods.

Performance analysis of 20 Gb/s QPSK modulated dual polarization coherent optical OFDM systems

Ahmet Güner

Bingöl University, Faculty of Engineering and Architecture

Bingöl, Turkey

aguner@bingol.edu.tr

Abstract— In this study, 20 Gb/s Dual Polarization Coherent Optical Orthogonal Frequency Division Multiplexing (DP-CO-OFDM) system is studied to obtain the relation between the Bit Error Rate (BER) and launch power for different transmission length and polarization mode dispersion (PMD) coefficient. DP-CO-OFDM system is simulated by designing a Monte Carlo simulation. In this simulation, the effects of chromatic dispersion, launch power and PMD coefficient on received signals are demonstrated with constellation diagrams and results are given in form of BER-Launch Power variations.

Keywords— OFDM; optical communication; dual polarization; launch power

I. INTRODUCTION

OFDM is a suitable solution due to its many advantages known in wireless communications. Moreover, it is also used to transmit and receive large data rates in optical communications.

In 2005, the demonstration of the coherent receivers has been caused the increase of interest in coherent optical communications [1]. The main point of coherent communications is to improve sensitivity of the receiver. In addition, it allows the detection of both amplitude and phase increasing the detection capabilities, and combined with advance modulations formats [2].

Recently, the coherent optical communication and OFDM method are combined to obtain both advantages in a communication link. CO-OFDM technique is proposed for long haul transmission to remove inter-symbol interference (ISI) caused by chromatic dispersion in optical communication [3]. CO-OFDM systems allow for equalization of dispersive effects of optical channel.

The first CO-OFDM transmission was reported in 2006 [4, 5]. Dual polarization CO-OFDM has been experimentally demonstrated at 1 Tb/s over 600 km transmission [6]. In conventional coherent optical OFDM systems, training symbols (TSs) are added at the transmitter to facilitate channel estimation, which provides crucial channel information and enables efficient digital compensation of linear fiber impairments such as chromatic dispersion (CD) and polarization mode dispersion (PMD) [7].

In this study, the bit error rate (BER) performance of DP-CO-OFDM system is investigated for different launch powers with the increase in the transmission length under the effect of CD, PMD and the fiber nonlinearity. Also it is shown in constellation diagram the effect of CD, PMD and the higher launch power on optical signals before or after the conventional TS based channel equalization. In section 2, a general dual polarization coherent optical OFDM system is described. In section 3, the TS based channel equalization is described. In section 4, the results of simulated system are reported and finally in section 5, the conclusion is made.

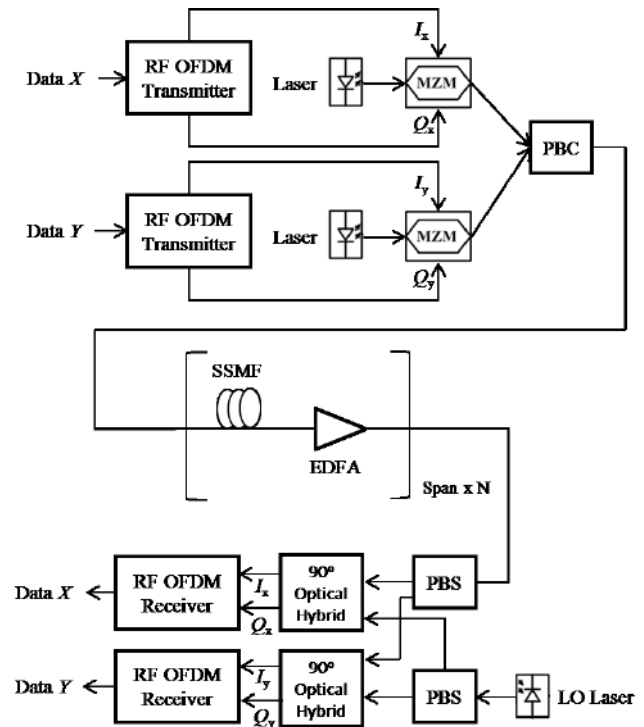

Fig. 1. Block diagram of a DP-CO-OFDM system. PBC : polarization beam combiner, PBS : polarization beam splitter, LO : local oscillator.

II. DUAL POLARIZATION COHERENT OPTICAL OFDM SYSTEM

In Fig. 1, it is shown a general dual polarization coherent optical OFDM system. At the transmitter, the data sets are first mapped to QPSK symbols. Then, training symbols are added into OFDM symbol before IFFT. Two optical IQ modulators are used to convert the electrical signals to the optical signals and a polarization beam combiner combines the two optical signals.

The optical channel consists of many standard single mode fiber (SSMF) spans with CD, PMD, fiber nonlinearity and attenuation. In optical channel, the erbium-doped fiber amplifier (EDFA) for gain is used in line amplification of signal.

In the receiver, two polarization beam splitters are used for mapping X polarization and Y polarization of the optical signal onto optical carrier. The polarized optical signals are passed through 90° optical hybrids that converting the optical signals to an electrical signals along with light of LO laser. Then, the data symbols on each subcarrier are obtained by FFT. The channel estimation is implemented to compensate for the inter-subcarrier interference caused by CD and PMD.

III. CHANNEL ESTIMATION AND EQUALIZATION

The linear fiber impairments in DP-CO-OFDM system can be described by a 2×2 multiple-input multiple-output (MIMO)-OFDM model in frequency domain on subcarrier basis as follows [7]:

$$\begin{bmatrix} R_x^i \\ R_y^i \end{bmatrix} = \begin{bmatrix} H_{xx}^i & H_{xy}^i \\ H_{yx}^i & H_{yy}^i \end{bmatrix} \begin{bmatrix} T_x^i \\ T_y^i \end{bmatrix} \quad (1)$$

Where T and R are the transmitted data and the received data. i is subcarrier index, x and y are polarization indexes. H_{xy}^i is channel frequency response of the i th subcarrier from X polarization to Y polarization. In (1), the noise term is omitted for simplicity.

In CO-OFDM systems, the training symbols (TS) using for estimation of the channel are added at the transmitter. Thanks to the training symbols are orthogonal, all coefficient of H matrix are estimated as follows,

$$H_{xx}^i = \frac{R_x^i}{TS_x^i}, H_{xy}^i = \frac{R_y^i}{TS_x^i}, H_{yx}^i = \frac{R_x^i}{TS_y^i}, H_{yy}^i = \frac{R_y^i}{TS_y^i}, \quad (2)$$

In TS based channel equalizer, the value of \hat{H}_{xy}^i can be obtained by the inverse of H_{xy}^i in (2). Then the signal at the i th subcarrier can be recovered by,

$$\begin{bmatrix} T_x^i \\ T_y^i \end{bmatrix} = \begin{bmatrix} H_{xx}^i & H_{xy}^i \\ H_{yx}^i & H_{yy}^i \end{bmatrix}^{-1} \begin{bmatrix} R_x^i \\ R_y^i \end{bmatrix} = \begin{bmatrix} \hat{H}_{xx}^i & \hat{H}_{xy}^i \\ \hat{H}_{yx}^i & \hat{H}_{yy}^i \end{bmatrix} \begin{bmatrix} R_x^i \\ R_y^i \end{bmatrix} \quad (3)$$

IV. SIMULATIONS RESULTS

In order to get the results of performance analysis, a simulation of DP-CO-OFDM systems was developed by using MATLAB. Optical fiber parameters and basic OFDM parameters are given Table 1 and Table 2 respectively. The data transmission bit rate is 10 Gp/s on each polarization.

TABLE I. FIBER OPTICAL PARAMETERS

Parameter	Value
Wavelength	1550 nm
Velocity of light	200000 km/s
Fiber optical cable length	100 – 1000 km
Chromatic dispersion parameter	16 ps/(nm.km)
PMD coefficient	0.1 – 0.6 ps/km
Nonlinearity coefficient	$1.32 (W.km)^{-1}$
Attenuation	0.2 dB/km
Gain of EDFA	12 dB
Noise figure of EDFA	5 dB
Length of spans	100 km

TABLE II. OFDM PARAMETERS

Parameter	Value
FFT/IFFT length (N_{FFT})	256
Number of subcarriers	128
Cyclic prefix	% 6.25
Modulation	QPSK
OFDM symbol rate	39.06 MHz

In Fig. 2, it is shown output signal constellation diagram before the channel equalization after transmission length 10 km, 50 km, 200 km and 500 km respectively for 0.1 ps/km PMD coefficient. The constellation points increase as the circumference and scatter due to the chromatic dispersion as a function of the transmission length.

Fig. 2. Output signal constellation of X polarization of QPSK OFDM systems with Launch power -2 dBm for different transmission length, (a) $L = 10$ km, (b) $L = 50$ km, (c) $L = 200$ km (d) $L = 500$ km

In Fig. 3, it is shown output signal constellation diagram after the channel equalization by keeping launch power -6 dBm, -2 dBm, 0 dBm and 2 dBm respectively for 0.1 ps/km PMD coefficient after 900 km transmission length. As the launch power increases, the constellation points scatter as a function of the launch power because a higher launch powers lead to a larger nonlinear distortion.

Fig. 3. Output signal constellation of X polarization of QPSK OFDM systems after 900 km transmission for different launch power, (a) -6 dBm (b) -2 dBm (c) 0 dBm (d) 2 dBm

As shown in Fig. 4, the bit error rate (BER) as a function of the launch power decreases initially up to -1 dBm after 800 km

transmission length as the launch power increases. However, at higher launch powers, BER increases due to distortions caused by the fiber nonlinearity.

Fig. 4. BER of DP-CO-OFDM systems versus launch power for different transmission length

As also shown in Fig. 4, as the transmission length increases, value of the launch power at which BER begins to increase varies as a function of the transmission length.

In Fig. 5, it is shown output signal constellation diagram before the channel equalization by keeping PMD coefficient 0.1 ps/km and 0.3 ps/km respectively after 100 km transmission length. The circumference of the constellation points increase due to PMD as shown with red line in Fig. 5

Fig. 5. Output signal constellation of X polarization of QPSK OFDM systems with Launch Power -2 dBm after 100 km transmission for (a) PMD = 0.1 ps/km (b) PMD = 0.3 ps/km

As shown in Fig. 6, the PMD coefficient changes from 0 ps/km to 0.6 ps/km at a step of 0.2 ps/km and BER as a function of the PMD coefficient increases due to the degradation caused by PMD.

Fig. 6. BER of DP-CO-OFDM systems versus launch power after 900 km transmission for different PMD coefficient

V. CONCLUSIONS

We have analyzed performance of DP-CO-OFDM system against transmission impairments such as CD, PMD and fiber nonlinearity through simulations. The simulations are designed by QPSK modulated OFDM signals with dual polarization each with 10 Gb/s. The results of simulation show that at higher launch powers, BER increases due to the fiber nonlinearity and distortions caused by CD and PMD with the

increase of the transmission length. Also the results of simulation are supported by constellation diagrams at fixed launch power and fixed transmission length.

Abstract— Optic interference theory and diaphragm dynamic vibration analysis compose the two principle units of diaphragm based fiber optic interferometric acoustic sensors. The two theories should be analyzed together for a sensor system to operate in linear zone. The sensitivity to acoustic pressure, the linearity and frequency response of the sensor system which combines these two principles can be analyzed quantitatively and these analysis results can be used for choosing the suitable sensor system parameters. With the improved calculation approach, more than one condition is evaluated and most suitable result is calculated easily. Because the software permits multiple calculations the relationship between the parameters can be seen easily in a wide range. In addition, the most suitable dimensions for the measuring conditions can be calculated. In this work, we calculated diaphragm diameter regarding the other mechanical and corresponding optical design parameters of Fabry-Perot interferometric sensor system.

Keywords—*Fabry-Perot interferometer (FPI); optical fiber sensors; acoustic detection*

I. INTRODUCTION

Acoustic detection is now an important area in modern life with its applications ranging from structural health monitoring to medical imaging. The detection and analysis of acoustic waves has become an interesting research area with a wide range of applications over the last few decades. Acoustic methods have proven to be highly informative for understanding of the structures of the materials, their features and different physical processes within them, and consequently the importance of acoustic wave technology has rapidly increased in both modern science and engineering applications [1, 2]. Piezoelectric sensors have been used in many acoustic applications for many years with a reasonable number of success. These sensors are sensitive to small size and different input parameters and also they are cost effective, but despite all these advantages, they have some problems when they are exposed to heavy environments because of their low resistance to chemical factors and high temperatures and they are affected by electromagnetic interference. These systems consist of many electronic components and electrical cabling which can weaken the electronic signals much. This makes them less useful in many conditions where long structures and remote

control are required [2]. Sensors with fiber optics have proven to be much better than conventional sensors based on piezoelectric transducers. Fiber optic sensors have many abilities like multiplexing capacities, direct access to optical transmission lines that classical piezoelectric sensors are unfavorable. These sensors also bring many advantages like having broadband range, no limits on size and shape, and being able to be firmly connected [3-5]. Fiber optic interferometric sensors realize the detection mechanism by means of phase change; that's why these sensors are much more necessary for applications requiring high resolution. Sensitivity and resolution of optical interferometric sensors are better than other sensors based on intensity and polarization [6]. Unlike other interferometers (Mach-Zehnder, Michelson, Sagnac) used in detection, the Fabry-Perot Interferometer (FPI) does not have complex structures. For this reason, FPI is the most preferred method for advanced interferometric sensor applications and a good transducer for many smart sensor applications [7].

In this work, we developed a MATLAB code for calculation of a key design parameter regarding mechanical and corresponding optical design parameters of an FPI sensor system.

II. OPERATING PRINCIPLE OF THE SENSOR SYSTEM

A. Components of the sensor system

Fig. 1 shows the general structure of the FPI optical detection system, which has a single or multimode fiber transmission medium. This system consists of a sensor tip, a semiconductor light emitter capable of operating in different wave lengths, an optical receiver and fibers providing the connection between the components. A 3dB fiber coupler is used to receive the reflected signal and reduce the optical feedback which comes back to the source. The light emitted from the light source is firstly reflected from the end of the fiber. The remaining light passes through the air gap and is partially reflected back by hitting the diaphragm surface. These multiple reflections reach the optical receiver through the same fiber. The general operating principle of the system is that the light from the light source is reflected from two separate layers

and is perceived again, the system is based on measuring the phase difference between the transmitted light and the detected [8].

Optical interference theory and diaphragm dynamic vibration analysis constitute the two basic principles of fiber optic interferometric acoustic sensors with diaphragm base [9]. The acoustic sensor which combines these two principles can quantitatively analyses system's sensitivity to acoustic pressure and system's frequency response. These analysis results are used to determine the sensor system parameters such as geometric dimensions of the diaphragm, the FPI cavity length etc.

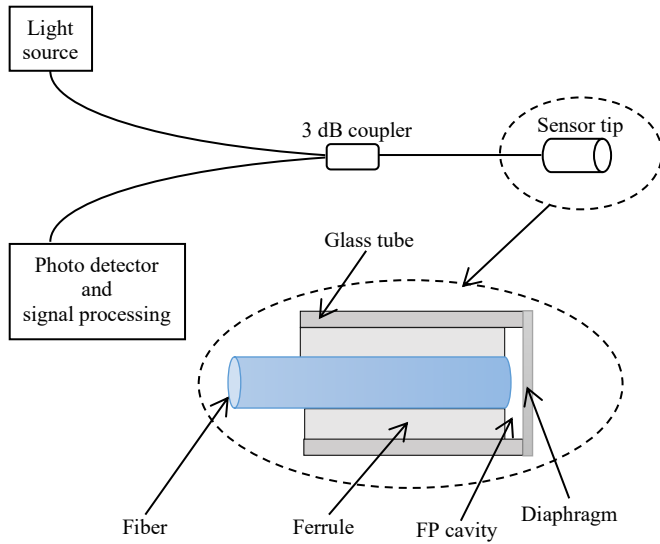

Fig. 7. The structure of diaphragm based fiber optic FPI sensor system.

B. Optic Interference Theory

The schematic representation of the Fabry-Perot (FP) cavity and the typical reflection spectrum are shown in Fig. 2. The incident light leaves the cavity after the reflections and refractions between two parallel reflective surfaces. The reflected light is not taken into consideration. The spectrum of the transmitted light will be symmetrical with respect to the horizontal axis.

Fig. 8. (a) Schematic representation of FP cavity; (b) Typical reflection spectrum of FPI [10].

The intensity of reflected light, I_r in FPI is defined as follows [11].

$$I_r(L, \lambda) = \alpha_0 I_0(\lambda) \frac{R_1 + \eta R_2 - 2\sqrt{\eta R_1 R_2} \cos \phi}{1 + \eta R_1 R_2 - 2\sqrt{\eta R_1 R_2} \cos \phi} \quad (1)$$

Where L is FP cavity length, $I_0(\lambda)$ is the optical density of the incident light which has the λ wavelength, α_0 is a constant that identifies the optical losses in the system. These optical losses consist of couplings in the input / output fibers, optic coupler, connector and so on. R_1 and R_2 are the reflectivity in the fiber-to-space and space-to-diaphragm interface, respectively. ϕ indicates the optical phase and defined as follows,

$$\phi = \frac{4\pi n_m L}{\lambda} \quad (2)$$

where n_m is the refractive index of the medium in the FP cavity η denotes the transmission coefficient of the light coming to and going from in the cavity [12],

$$\eta = \frac{1}{1 + \left(\frac{\lambda L}{\pi n_m w^2}\right)^2} \quad (3)$$

where w is the mode-field radius (spot size) of the fiber used in the system. The analytical definition of a single mode step index fiber with w Gaussian distribution is as follows [10],

$$\frac{w}{a} \approx 0.65 + \frac{1.619}{V^{3/2}} + \frac{2.879}{V^6} \quad (4)$$

V is the normalized frequency of fiber. It is given as follows,

$$V = \frac{2\pi a}{\lambda} \sqrt{n_f^2 - n_c^2} \quad (5)$$

where a is the radius of the fiber core, n_f represents the refractive index of the fiber core, n_c represents the refractive index of the fiber cladding.

The expressions R_1 and R_2 in (1) are given in (6a) and (6b), respectively depending on fiber core refractive index n_f , refraction index of the medium in FP cavity n_m and refraction Index of the diaphragm n_d ,

$$R_1 = \left(\frac{n_f - n_m}{n_f + n_m}\right)^2 \quad (6a)$$

$$R_2 = \left(\frac{n_m - n_d}{n_m + n_d}\right)^2 \quad (6b)$$

When all parameters between (1) and (6) are taken into consideration with regard to their typical values, the spectrum of the reflected light depending on the change of FP cavity length is shown in Fig. 3.

The light intensity measured by the optical detector decreases as the cavity length increase. There must be a linear relationship between the change of cavity length and the optical signal at the output for the operation of the sensor system. Fig. 4. shows the reflection spectrum in three different wavelengths according to FP cavity length. The half of the difference between the cavity lengths corresponding to the successive maximum and minimum values of the reflected signal in a determined narrow region can be evaluated as the maximum amount of the change of FP cavity length. It can be seen in (7). FPI is outside the linear region when values are above this value. This limitation is because of optic interference theory, it is called as optic limitation.

Fig. 9. Calculated reflection spectra of the FPIs. In the calculation, the refractive indices of the fiber core $n_f=1.4492$, $n_c=1.444$, $n_m=1$ (air), and $n_d=1.45$ (silica), fiber radius $a=4.5 \mu\text{m}$, center wavelength of source $\lambda=1310 \text{ nm}$; cavity length is (a) 0-150 μm (b) 0-15 μm .

$$(\Delta L)_{\max} = \frac{L@I_{\max} - L@I_{\min}}{2} \quad (7)$$

Where $L@I_{\max}$ and $L@I_{\min}$ are the FP cavity lengths corresponding to the maximum and minimum points of the output optic power.

The maximum change of FP cavity length can be calculated for different wavelengths from (7) and Fig. 4. These values are given in Table I.

TABLE III. MAXIMUM VARIATION AMOUNT OF FPI CAVITY

Center Wavelength h (nm)	$L@I_{\max}$ (μm)	$L@I_{\min}$ (μm)	$(\Delta L)_{\max}$ (nm)
850	49.9374	49.7250	106.20
1310	50.1073	49.7800	163.65
1550	49.9872	49.6000	193.60

As shown in Table I, as the wavelength of the optic source increases, larger variations are allowed in the FP cavity. The ratio of maximum length variation to wavelength of optical source is determined as a value of 1/8 [13]. In that case, limit value of the maximum amount of diaphragm expansion which will be discussed in the next section is determined here.

Fig. 10. Calculated reflection spectra of the FPIs. In the calculation, the refractive indexes of the fiber core $n_f=1.4492$, $n_c=1.444$, $n_m=1$ (air), and $n_d=1.45$ (silica), fiber radius $a=4.5 \mu\text{m}$, center wavelength of source $\lambda=850, 1310, \text{ and } 1550 \text{ nm}$; cavity length is 49 to 51 μm .

The other sensor-performance parameter which is used for the determination of the FP cavity length is the source coherence length and it stands for L_c . This parameter depends on the central wavelength and the full-width at half maximum (FWHM) of the optic source. L_c is defined as in [10],

$$L_c = \frac{\lambda^2}{\Delta\lambda} \quad (8)$$

where $\Delta\lambda$,

$$\Delta\lambda = \frac{\lambda_{FWHM}}{\sqrt{8 \ln 2}}. \quad (9)$$

$$\xi = 0.6689 \frac{\rho' r}{\rho t} . \quad (12)$$

TABLE IV. THE SELECTION OF FP CAVITY ACCORDING TO OPTIC SOURCE FEATURES

Center Wavelength (nm)	FWHM (nm)	$\Delta\lambda$ (nm)	L_c (μm)
850 (LED)	105	44.590	16.203
1300 (LED)	130	55.206	30.613
1308 (LED)	147	62.425	27.407
1310 (LD)	7.1	3.015	569.187
1550 (LD)	12	5.096	471.448

Providing $L < L_c$ relation between FP cavity length and source coherence length is important for the sensitivity of the sensor system [10]. As shown in Table II, when compared to spectral width values, the laser diodes (LD) exhibit better performances than the LEDs and this enable them to provide larger FP cavity-lengths.

C. The Diaphragm Dynamic Vibration Analysis

The signal that dynamically modulates the cavity length of FPI signal (e.g. acoustic wave) causes a vibration in the diaphragm. The deflection of the diaphragm caused by the acoustic wave can be determined theoretically by the load-deflection method and is given by [14],

$$d = \frac{3(1-\nu^2)Pr^4}{16Et^3}. \quad (10)$$

By using (10), the deflection of a circular diaphragm under a pressure value of P is calculated. Where ν is Poisson's ratio, E is Young's modulus of the diaphragm material, r is the radius of the diaphragm defined by the inner diameter of the cylindrical glass tube, and t is the thickness of the diaphragm. Generally, in order to ensure the linearity of the deflection at the center point, the deflection amount should be less than 30% of the diaphragm thickness [14]. This limitation is similar to the maximum value of the FP cavity length in the optical interference theory. Whichever smaller parameter is taken into account, two conditions will be provided. Therefore, we start our calculation by taking into account this fundamental principle.

The last parameter that must be determined is the frequency band. Depending on the material properties and the geometrical dimensions of the diaphragm (thickness and radius), the resonance frequency is determined from (11) and (12) [14],

$$f = \frac{\varphi_{mn}^2}{2\pi r^2 \sqrt{1+\xi}} \sqrt{\frac{Et^2}{12\rho(1-\nu^2)}} \quad (11)$$

The parameters ρ and ρ' represent the density (kg/m^3) of diaphragm material and the surrounding medium, respectively. φ_{mn} is the roots of the vibration equation for different mode orders ($m = 0, 1, 2, 3, \dots$ and $n = 0, 1, 2, 3, \dots$). The values of φ_{mn} are listed in Table III [14].

TABLE V. VALUES OF φ_{mn} .

$m \backslash n$	0	1	2	3
0	3.196	4.611	5.906	7.143
1	6.306	7.799	9.917	10.537
2	9.44	10.958	12.402	13.795
3	12.577	14.108	15.579	17.005

In Fig. 5, the frequency response of a circular diaphragm that is made of silica is shown for the first 16 resonance frequencies.

Fig. 11. Calculated frequency response of the diaphragm with the radius $r=1500 \mu\text{m}$ and the thickness $t=20 \mu\text{m}$, $E=73\text{GPa}$, $\nu=0.17$, $\rho=2200 \text{ kg}/\text{m}^3$, $\rho'=1.225 \text{ kg}/\text{m}^3$ (air), $f=0-1600\text{kHz}$.

In Fig. 6. the response of the diaphragm around the lowest resonance frequency is shown. The frequency response of the sensor system can be decomposed into two regions which are broad- and narrow-band spectra. The system is defined as a narrow-band sensor in the case of the detection of the signals that are very close to the resonance frequency. On the other hand it is specified as a broad-band sensor in the case of the detection of the signals which have a frequency value lower than the 1/3 of the resonance frequency; additionally a straight response is obtained for a wide frequency range. In this situation, the desired properties for a sensor system can be obtained according to the chosen material and geometric dimensions of diaphragm.

Fig. 12. Calculated frequency response of the diaphragm with the radius $r=1500 \mu\text{m}$ and the thickness $t=20 \mu\text{m}$, $E=73\text{GPa}$, $\nu=0.17$, $\rho=2200 \text{ kg/m}^3$, $\rho'=1.225 \text{ kg/m}^3$ (air), $f=0\text{-}100\text{kHz}$.

III. NUMERIC ANALYSIS RESULTS

A. Optimum Radius Selection

The resonance frequency of the acoustic waveguide and the amount of deflection of the diaphragm depend on the radius of the diaphragm when the other parameters are kept constant (E, ν, ρ, t, ρ'). This relationship was given in (10) and (11). The amount of deflection in this relationship is directly related to the maximum amount of variation in the FP cavity in the optical interference theory. There are two limit values in determining the amount of deflection of the diaphragm. One of them is $\lambda/8$ (optic limit) and the other is $0.3t$ (mechanical limit). The radius value is calculated by considering the smallest of these limits but in this situation the amount of pressure must be taken into consideration. A second radius value is calculated from the frequency value by taking broadband or narrow-band into account. The value which is calculated smaller is considered as a solution because it provides all conditions. The radius value in the calculation result shows the largest value that can be chosen. The diaphragms created under this value will provide the desired conditions. Selection of optimum radius can be explained a flow chart given in Fig. 7.

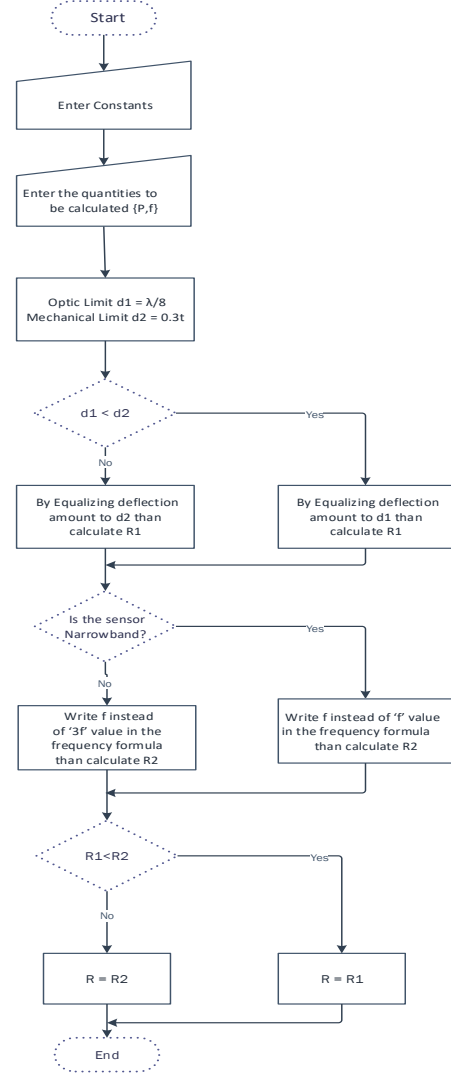

Fig. 13. The flow chart is shown to calculate the most appropriate radius value.

B. Computational Results

In this work, we developed a MATLAB code for calculation of diaphragm diameter. The silica was selected as the diaphragm material. Because it is compatible with the fiber parameters. Properties of Silicon Dioxide (Silica, SiO_2) material, which is used frequently in diaphragm-based FP pressure sensors, are given in Table IV [15]. The center wavelength of the optical source was taken as 1310 nm. Diameter values calculated according to pressure and frequency values to be measured are given in Table V-VIII. By keeping constant the pressure value, the variation of the diaphragm diameter in water is shown in Table V. The same calculations in Table V were applied in the air environment in Table VI. By keeping the frequency value constant, the variation of diaphragm diameter in water is shown in Table VII. The same calculations in Table VII were applied in the air environment in Table VIII.

IV. CONCLUSION

In this work, we calculated an important design parameter for FP interferometer that can be used for acoustic sensing applications. It is concluded in this work that the diaphragm diameters remain constant for some calculation results in the tables than they start to change because of the limitations used in calculations precedes the other. This is actually the aim of the developed software. Evaluating more than one parameter at the same time and studying all of them in the limit values are difficult because they must be calculated separately. More than one condition is evaluated thanks to the software and the most appropriate result is calculated quickly. Since the software allows multiple calculations, the relationship between the parameters in a wide range can be easily seen. Most suitable geometric dimensions for measuring conditions can be calculated. By changing diaphragm materials, detection medium, wavelength which is used as a light source, and thickness of the diaphragm materials, any system designer can see how these parameters affect the frequency and the pressure value to be measured.

Abstract —Orthogonal frequency division multiplex (OFDM) is one of the best approach to overcome frequency selectivity of channels. In multiple-input multiple-output (MIMO) orthogonal frequency division multiplexing (OFDM) systems, we purposed channel estimation with least squares (LS) estimation method in this paper. To improve channel estimation achievement a LS algorithm is developed, so we obtain Bit Error Rate (BER) performance of channel. Mean Square Error (MSE) of LS estimation calculated and depicted in figure. Signal to noise ratio (SNR) indicated notable efficacy in this paper that obtained by using the LS algorithm, in particular channels with variation in time.

Keywords— *Estimation of Channel with LSE, MIMO System, BER, SNR, OFDM.*

I. INTRODUCTION

In recent years in communication systems data rate is getting high and researchers have notable interest on rapid modulation techniques. As a multicarrier modulation technique OFDM is fairly interested by researchers. Because of its basic application and stability, frequency-fading channels are transformed the channel into flat-fading sub channels. OFDM has been performed for a lot of applications, such as high speed telephone line communication, digital audio broadcasting, wireless local area network digital television broadcasting and lines of digital subscriber. In recent communication systems we can realize a remarkable increased capacity OFDM and multiple antennas together and this enhancement obtained due to diversity of transmit and receive sides. [1]. Adding training pilot symbols at the transmitter in practice implementations, CSI is effective estimated at the receiver. Channel estimation with pilot symbol is especially attractive for wireless communication systems in the channel with varying time [2].

Meanwhile a lot channel estimators use for OFDM, error probability examination availability of channel estimation errors has taken notionally less care. In recent days phase shift keying and quadrature amplitude modulation approximations were progressed about BER performance for channel estimation errors of OFDM [3, 4].

OFDM systems consist completely of pilot symbols because of identifying the multiple training channels. This approach for single input and single output (SISO) systems is showed in [5-7], whereas MIMO systems is detailed described in [8]. Like this application firstly any transmission of data we compute estimation of the CSI. When remarkably changes exist for CSI, reobtaining pilot symbols is transmitted. To estimate the CSI in fast time varying surroundings, we must continuously retrain for such systems. About retraining, these systems are experienced an incremented BER because of their antiquated channel estimates. Wiener filter method as based on a known channel correlation function can be used to advance the estimation of channel parameters [9, 10].

MSE of the channel estimation with LS technique is recommended the pilot symbols have an optimum location for SISO OFDM systems. If this channel estimation technique wanted to length to MIMO OFDM systems, seeing that either the location of the pilot symbol or the pilot sequence must be optimized to enhance the MSE value minimum with channel estimation method with LS [11].

In this paper, based on pilot tones MIMO OFDM system is described with a LS channel estimation scheme. MSE of the channel estimation with LS technique is computed, optimum pilot tones of the pilot subcarriers are supplied. LS channel estimation design for multiple OFDM symbols is debated. LS channel estimation algorithm is proposed to advance estimation application.

The organization of this paper is regulated as trace. In chapter II OFDM technique is explained, LSE channel estimation steps are given in chapter III. Analysis of channel estimation is introduced in chapter IV and conclusions are offered in chapter V.

II. OFDM TECHNIQUE

Transmission system of the OFDM about account is depicted in Figure 1. High data rate streams of the random

input signal are transformed into low data rate streams. The low data rate streams are modulated in parallel subcarriers in the OFDM. This parallel stream is dedicated input to the IFFT block structure. The data is transformed from frequency to time before the data accessed the channel by the IFFT block structure. The data is encoded with adding the cyclic prefix as the guard interval and transmission is successful at receiver [12]. Binary source generator produced the digital input data like as BPSK, QPSK and QAM modulation approach are used to modulate the binary data with several different constellations. The data is transformed frequency domain to time domain by the IFFT block in Figure 2. To insert guard interval known as CP succeed the problems like ICI/ISI with acquiring the delay connected problems at the channel. Before the symbols transmitting to the channel, firstly the symbols of OFDM are in the time domain available length. After that all the operations enforced in the inverse direction and obtained OFDM signal as the output of receiver block. CP insertion in the OFDM modulation is the most extensive technique among all the multicarrier modulations because of its facility and its stability across to multipath fading using the cyclic prefix. Even so this technique caused a decrement of spectral efficiency owing to the CP. Also the OFDM spectrum is not dense because of the large side lobe levels resulting from the rectangular pulse [13].

OFDM is a typical multiple channel modulation technique that used to separate to the channel numerous of parallel sub channels and the parallel channels transmit multiple symbols. OFDM has an attractive feature that is considered efficient spectral and also applications of OFDM cope with equalization of dispersive slowly fading channels which is a perfect way. OFDM is used by multiuser systems that exhibited perfect schemes for multiple accesses such as transmission systems with single carrier. When we compared to carrier systems with each other, as a variable modulation technique for multiple access systems OFDM is in that case intrinsically make easy multiple access both time domain and frequency domain.

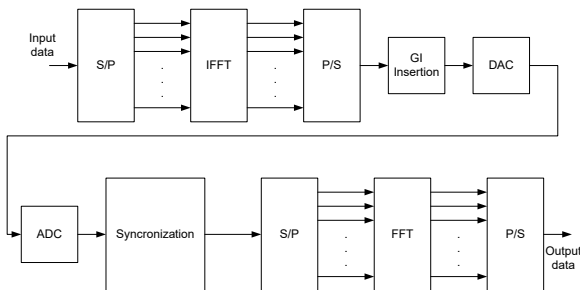

Fig. 14. OFDM transmitter and receiver block diagram.

OFDM also has some imperfections properties. OFDM is sensitive errors of carrier frequency, because a given spectral assignment divides into many narrow subcarriers by OFDM structure with small spacing for

subcarriers inherently. Furthermore, to obtain the orthogonality about subcarriers, it needs linear amplifiers. Because of OFDM systems own a high peak to average power ratio the systems require a large amplifier power back off and a many of bits in the analog to digital (A/D) and digital to analog (D/A) designs. So high requirement is available transmitter and receiver sides in OFDM [14].

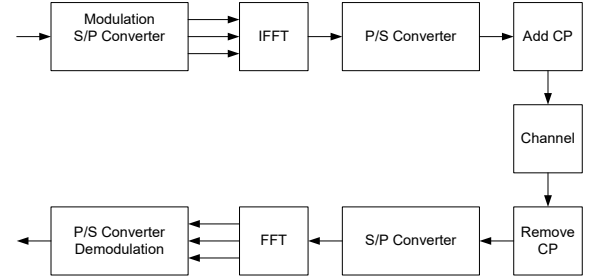

Fig. 15. OFDM block diagram.

OFDM modulation and demodulation block diagram is given in Figure 2. Guard interval is transformed CP in this figure.

III. CHANNEL ESTIMATION WITH LEAST SQUARE METHOD

In this part, channel estimation with LS design is clarified. Data vector is formulated as $X_r(n)$ in Equation 1.

$$X_r(n) = S_r(n) + B_r(n) \quad (1)$$

In Equation 1, $S_r(n)$ is some optional $K \times 1$ data vector, $B_r(n)$ is some optional $K \times 1$ pilot sequence vector and demodulated signal is described in Equation (2).

$$Y_q(n) = \sum_{r=1}^{N_r} \text{diag}\{X_r(n)\} Fh_{q,r} + \Xi_q(n) \quad (2)$$

$$= \sum_{r=1}^{N_r} (\text{diag}\{S_r(n)\} + \text{diag}\{B_r(n)\}) * Fh_{q,r} + \Xi_q(n) \quad (3)$$

Taking to FFT of $Y_q(n)$ in Equation (3) we obtained finally as Equation (4).

$$Y_q(n) = \sum_{r=1}^{N_r} S_{r, \text{diag}}(n) Fh_{q,r} + \sum_{r=1}^{N_r} B_{r, \text{diag}}(n) Fh_{q,r} + \Xi_q(n) \quad (4)$$

We consider the data model as Equation (5).

$$Y_q = Th_q + Ah_q + \Xi_q \quad (5)$$

LS estimate of h_q can obtained as \hat{h}_q and formulated in Equation (6).

$$\hat{h}_q = A^T Y_q \quad (6)$$

Note that equation (6) shows that \hat{h}_q is a composition of the true channel vector h_q and noise vector in the system. We can see whether or not the pilot tones are the same for each ofdm symbol. Namely, same set of pilot tones in ofdm structure is not compulsory.

IV. CHANNEL ESTIMATION PERFORMANCE AND SIMULATIONS

This section presents enhancement of the MSE of the channel estimation with LS. Results of applications are provided to have optimal pilot sequences and optimal placement of the pilot tones in point of the MSE. In Equation 7, L describes the maximum channel length. MSE calculation of the channel estimation with LS is formulated in Equation 7.

$$MSE = \frac{1}{LNt} \mathcal{E} \left\{ \left\| \hat{h}_q - h_q \right\|^2 \right\} \quad (7)$$

Because of obtaining the minimum MSE of the channel estimation with LS linked to a fixed power ρ given for training and zero mean white noise is σ_n^2 in Equation 8.

$$MSE_{\min} = \frac{\sigma_n^2}{\rho} \quad (8)$$

Fig. 16. MIMO-OFDM block diagram.

Figure 3 is depicted block diagram of MIMO-OFDM. In Figure 3 number of transmit antennas is N_t , number of receive antennas is N_r and number of subcarriers is K . Each transmit or receive antenna is utilized in conventional

OFDM modulator or demodulator. Take for the OFDM symbol that is transmitted from the r th antenna at time index n is denoted by $K \times 1$ the vector $X_r(n)$. Before transmission, IFFT is processed to this vector, and v lengthed a cyclic prefix is added. If all channels maximum length is L we obtain that $v \geq L - 1$, which is common practice in wireless communications. Since we extracted the cyclic prefix from the q th receive antenna, $Y_q(n)$ is obtained as $K \times 1$ vector length.

To channel estimation in OFDM is used pilot symbols. OFDM is directly practicable to techniques from single carrier flat fading systems when each subcarrier is flat fading. The sparse insertion of known pilot symbols is found in pilot symbol assisted modulation (PSAM) on channels with flat fading that is in a stream of data symbols in such systems. When the pilot symbols attenuation is calculated the data symbols attenuations among the pilot symbols are characteristically predicted with the fading channel on time correlation features.

Fig. 17. BER versus SNR in LS channel estimation for MIMO OFDM

Fig. 18. MSE of LSE channel estimation for MIMO OFDM

BER versus SNR in LS channel estimation for MIMO OFDM system application is shown in Figure 4. MSE of LS channel estimation in simulation and theory for MIMO OFDM system is depicted in Figure 5. In application we selected that $N_t=2$, $N_r=4$, number of subcarriers is 128 and percentage of guard interval is 0.25. Number of pilot

symbols is 64 plus number of the data symbols is 64 we get all of subcarriers.

In literature most of document explains that channel estimation impressions consist of two steps using the channel correlation property. First, correlation of channel technique is used to measure and smooth the attenuations at the pilot positions. Then complex valued attenuations of the data symbols is estimated by these measurements in the second step. Channel correlation properties are used in this second step by filters interpolation technique or a decision directed technique. [15].

Fig. 19. Power of channel with LSE channel estimation and true channel.

In Figure 6 power of estimated channel and true channel with LSE is depicted. Estimated channel power is fairly close to true channel. So this result shows that LS estimation is appropriate for MIMO OFDM channel estimate.

V.

CONCLUSIONS

This study focused channel estimation with LS method based on pilot tones approach has been evaluated for application of MIMO OFDM systems. The pilot sequences must be equal powered, equal spaced, and obtained orthogonal phase shift to enhance the channel estimation with the minimum MSE. Our results indicates that purposed method about pilot tones the number of transmit antennas are increased so pilot tones for training require more and decreases the efficiency of application. When the channel is slowly time-varying, estimating the channel parameters can reduce this effect over multiple OFDM symbols. Also in next organizations, BER performance will be improve with different from LS estimation method about of MMSE estimation method.

Implementation Of Two Cell Non-Autonomous Cnn Model On FPGA

Bariş Karakaya, Vedat Çelik and Arif Gülten
Department of Electrical – Electronics Engineering
Faculty of Engineering, Firat University
Elazig, Turkey
{bkarakaya, celik, agulten}@firat.edu.tr

Abstract— This paper presents implementation of a chaotic Cellular Neural Network (CNN) on field programmable gate array (FPGA). The network has two non-autonomous cells and exhibits chaotic behaviour. In the implementation stage, Verilog Hardware Description Language (HDL) is used and discrete time model of the network is coded on Xilinx ISE Design Suite 13.2. It seems that the chaotic attractor can be used as entropy source or short key (seed) of chaos based random number generator design.

Keywords— Cellular Neural Network, Chaos, FPGA, Random Number Generator

I. INTRODUCTION

Chaos can be defined as unpredictable behaviors that are sensitive to initial conditions in a nonlinear deterministic system [1]. As chaotic behavior can be undesirable in some applications, there are a lot of application areas which use the chaotic behavior in their structures. In [2], the use of the Field Programmable Gate Array (FPGA) as a controller of a DC-DC boost converter, controlling the output current of a photovoltaic cells and minimizing the effect of the boost converter chaotic behavior on the output voltage are discussed. Micro controllers, Digital Signal Processors (DSP) and FPGAs can be used to design implementations of chaotic systems [3-6]. FPGA realizations of chaotic systems are studied in [7, 8] by using Euler algorithm with both integer arithmetic and floating-point number format. Especially, the Lorenz's chaotic system is implemented onto a FPGA with the help of the fourth order Runge Kutta (RK4) algorithm in [9]. The chaotic behavior can be used in Random Number Generator (RNG) applications in order to generate exactly true random number series which are required for secure communication systems. In literature, the realizations of chaotic systems are proposed by using the Xilinx System Generator technology in order to have the HDL code. In [10], the Lorenz's chaotic system is implemented onto FPGA to obtain chaotic sequence for information security issue and in this design the Xilinx System Generator technology is also used. As Cellular Neural Network (CNN) proposed by Chua [11, 12] has complex dynamics, chaotic behaviour can occur in the CNN structures [13]. In this paper, a chaotic attractor is observed with two non-autonomous cell CNN using opposite-

sign template. This network is reported in [14] and solved with Runge-Kutta iterative solution method.

In recent years, many chaotic CNN applications are implemented on the FPGA. Main advantage of the usage of the FPGA is that it can be programmed with more flexibility during implementation of design. Furthermore, development of any design on FPGA is easier and faster than other microprocessors [15]. Implementation of CNN structure on FPGA platform presents all advantages in the meaning of higher operating frequency, minimum resource utilization, reconfigurable systems and more secure applications.

Herewith this introduction, CNN structure and its mathematical model which exhibits chaotic behavior, are presented in Section 2. In Section 3, the implementation of discrete time chaotic CNN model on FPGA platform is also presented. At the end, final section concludes the paper.

II. THE CHAOTIC CNN STRUCTURE

The two-cell non-autonomous CNN model given in [14] is described by state equations as follow:

$$\dot{x}_1 = -x_1 + pf(x_1) - sf(x_2) + g(t) \quad (1)$$

$$\dot{x}_2 = -x_2 + sf(x_1) + pf(x_2)$$

$$f(x_i(t)) = \frac{1}{2}(|x_i(t) + 1| - |x_i(t) - 1|), \quad i = 1, 2 \quad (2)$$

$$g(t) = A \sin\left(\frac{2\pi t}{T}\right) \quad (3)$$

where $p > 1$, $s > 0$; x_1, x_2 are state variables of each cell and $f(\cdot)$ is an odd piecewise-linear function as defined in Eq. (2). For the CNN parameters $p = 2$, $s = 1.2$, initial condition $x(0) = (0.14, -0.1)$ and a sinusoidal input signal parameters $A = 4.04$ and $T = 4$, the non-autonomous CNN with two-cell given in [14] and chaotic portrait of the system are shown in Fig.1 and Fig.2, respectively.

In Fig 2, the chaotic behavior is observed. It is clearly appeared that the attractor has a roughly point symmetric property. If the Poincaré map of (x_1, x_2) -plane is obtained, it can be seen that the attractor possesses the horseshoe structure [14].

Fig. 1. The non-autonomous CNN with two-cell.

Fig. 2. Phase plane portrait of system with initial condition of $x(0) = (0.14, -0.1)$.

III. IMPLEMENTATION OF DISCRETE TIME CHAOTIC CNN MODEL

In order to implement the model on microprocessor, state equations must be discretized. Discrete time model of the CNN based chaotic system is determined as below.

$$x_1[n+1] = \frac{1}{a} \left[\left(\frac{x_1[n]}{T} \right) + pf(x_1[n]) - sf(x_2[n]) + g[n] \right] \quad (4)$$

$$x_2[n+1] = \frac{1}{a} \left[\left(\frac{x_2[n]}{T} \right) + sf(x_1[n]) + pf(x_2[n]) \right]$$

$$f(x_i[n]) = \frac{1}{2} (|x_i[n] + 1| - |x_i[n] - 1|), \quad i = 1, 2 \quad (5)$$

$$g[n] = 4.04 \sin(\pi n / 2) \quad (6)$$

Discrete time response of the model can be acquired by using CNN parameters as $p = 2$, $s = 1.2$, initial conditions $x(0) = (0.14, -0.1)$, $T = 0.005$, $a = 1 + (1/T) = 201$.

In arithmetic operations, fractional numbers are used as well as integers. There are two types of binary number representation format which are floating-point and fixed-point

format. Any of them can be chosen to represent a fractional number as a fractional binary number. A fractional number representation format should be considered that it represents the fractional number as a decimal and then converts it to a fractional binary number by multiplying the decimal number by 0.5 repeatedly. A binary coded number can be defined by equation,

$$\dots b_2 b_1 b_0 . b_{-1} b_{-2} \dots = \sum_i b_i 2^i \quad (7)$$

where there is a binary radix point in the above equation before b_{-1} [16].

In this study, the fixed-point number format is chosen because of advantages on easy coding. In this format, a signed/unsigned number is stored and this number is scaled by a fixed factor which is determined by user with respect to format parameters. This method implies shifting operation the radix point to the left side [16].

$Qm.n$ is the representation of fixed-point number format that has m bit for integer part and n bit for fractional part as shown in Fig. 3.. As we use signed numbers in discrete time model of our network, $Qm.n$ format has to be arranged as it contains signed two's complement fixed-point fractional binary number [16].

Fig. 3. Structure of the $Qm.n$ fixed-point signed number format.

Since initial values of state variables and parameters are chosen signed numbers as 16-bits in width, the format is arranged to $Q3.12$ and 1 bit is reserved for the sign.

$$x_{[B10]} = \frac{1}{2^n} \left[-2^{N-1} b_{N-1} + \sum_{i=0}^{N-2} 2^i b_i \right] \quad (8)$$

Regarding to equation above (8) where $x_{[B10]}$ represents fractional number in decimal, $N=16$, $x_{min} = -2^m = -8$, $x_{max} = 2^m - 2^{-n} = 7.99975$ and $resolution = 2^{-n} = 2.4414.10^{-3}$ are determined for $Q3.12$ signed two's complement format.

In the implementation stage, three peripheral circuits are used in the CNN core design. These are Clock Generator, CNN Circuit and CNN Cache.

The Clock Generator generates the low frequency clock signal by using the 50 MHz clock signal on FPGA chip. Generated low frequency clock signal is used for iterative solution of model. In FPGA applications, instead of *for loop* operation, a counter module is arranged in order to calculate the next value of state variables repeatedly. Each increment of counter value is admitted as the beginning of the new loop.

The CNN circuit has two state variables, four parameters for state variables, sampling period register and external sinusoidal input register which are all in 16 bit width. The CNN circuit solves the equations (4), (5) and (6) iteratively by using the clock pulse of the Clock Generator circuit. The model requires previous values of the state variables in order to determine the current values. Therefore, the CNN Cache circuit is used.

The CNN Cache needs 20 KB of total memory in order to emulate the discrete time chaotic CNN model. Since FPGA chip has enough memory in BlockRAM, no external memory is needed. 2 BlockRAM modules are defined for this implementation each one of module has 10 KB capacity. Defined BlockRAM modules have a dual-port interface. Therefore, the values at different addresses can be accessible at the same time.

The CNN core is designed, implemented on Spartan 3e XC3S1600e FPGA development board and programmed by Xilinx ISE Design Suite 13.2. When core is programmed, initial values of state variables and parameters are transferred to the core by using built-in communication interfaces and functions in MATLAB. The whole system is illustrated in Fig.4. Table 1 illustrates resource utilization of the CNN core design.

Fig. 4. The scheme of the CNN Core Design.

TABLE XI. RESOURCE UTILIZATIONS OF THE DESIGN

Arithmetic Unit	Number of Used Resource		
	Used Slices	Used FFs	Used LUTs
Clock Generator Circuit	24	33	47
CNN Core Design	4013	5214	6589

After the whole design is implemented, the programming bit stream of the design is generated and FPGA chip is programmed by Xilinx ISE Design Suite. The maximum operating frequency is obtained as 24.67 MHz from Xilinx ISE Design Suite. Fig. 5 shows the discrete time response of

the model, which is very similar to the continuous time response given in Fig. 2. Also, Fig.6 illustrates the discrete time response of each cell. Fig. 5 and Fig. 6 are plotted in MATLAB and the data are obtained from implementation results on Xilinx ISE Design Suite for FPGA of the chaotic discrete time CNN model.

Fig. 5. Discrete time response of the model with given parameters.

Fig. 6. Discrete time response of a) $x_1[n]$, b) $x_2[n]$.

IV. CONCLUSION

In this study, we have presented the implementation of two cell non-autonomous CNN model on FPGA. This study shows that the implemented CNN model have chaotic behaviors and model can be easily adapted to RNG applications using FPGA not only the entropy source of RNG but also the seed of pseudo random number generator application.

Abstract—In recent years, power electronic has become even more popular with the development of semiconductor switching devices. Power electronics applications can be found almost in all systems related to electrical and electronic fields. With the power electronic circuits, ac or dc voltages at various amplitudes can be obtained from constant voltage sources. Ac voltage with constant frequency and variable amplitude with high power factor can be provided by an ac chopper. Purpose of these power electronic circuits is to make the system more efficient, provide output waveforms with higher quality (less harmonics) and prevent power loss in large power systems. In this study, a three-phase PWM controlled ac chopper circuit has been modelled and simulated in MATLAB / Simulink package program. In this simulation, the output statements obtained for the switching devices by a different control method are discussed. Various operating conditions have been examined where a three-phase unbalanced voltage source without and with having the 5th and 7th harmonics was applied to the input side of the chopper. As a result, superiority of the control system used in the PWM controlled ac chopper has been demonstrated by the simulation results.

Keywords—Three-phase PWM ac chopper, Hysteresis band current controller (HBCC), Harmonic analysis, Pulse width modulation (PWM).

I. INTRODUCTION

Along with the developing technology, the amount of energy consumed all over the world has also increased. Due to the amount of energy consumed, new ways have been sought to meet this energy demand. More efficient systems with smaller structures and circuits designed to consume less power loss despite adverse conditions are required. The most popular circuit is the power electronics circuits, which are still being developed. Power electronic circuits reduce energy loss on the earth with renewable energy processing and create efficient systems for it. Power electronic circuits

transform electrical power by using the switching characteristics of semiconductor elements.

Ac chopper circuits of the power electronic family are the basic concept of this study. Ac choppers are, at its most basic definition, a power circuit which can convert a constant frequency ac voltage to another voltage at a desired amplitude [1,2]. Single-phase and three-phase versions of the ac chopper are available. Ac choppers with natural commutation have negative features such as high harmonics on the mains or load sides. Ac choppers are used in many industrial areas. Frequent use of such power electronic circuits has led to poor quality in energy systems [2]. It is possible to further improve ac choppers by eliminating these undesirable features. With the use of power electronic devices which can operate at high switching frequencies, the PWM method has begun to be used in the chopper circuits [3]. PWM ac chopping circuits have reduced side effects of the natural commutated ones as well as have become a special application of these circuits [3,4].

In this study, it is aimed to obtain load current with less harmonics by applying Hysteresis Band Current Controller (HBCC) technique for three-phase PWM ac chopper. The HBCC technique is preferred because of its dynamic response and simplicity [5]. Thanks to this controller, whatever the input voltage of the system is, a load current with very low harmonics at the output is obtained. The results will be quite advantageous for all power electronics-based systems.

II. HYSTERESIS BAND CURRENT CONTROLLER FOR A THREE PHASE AC CHOPPER

Fig.1 shows the circuit schema of the three-phase ac chopper [6]. The simulation model of this circuit using MATLAB / Simulink is shown in Fig. 2 [6]. IGBTs are used as switching semiconductor devices and a three-phase $R-L$ load is used at the output. Depending on the nature of the load used, there will be a load phase angle between the voltage and current space vectors of the source. The reference currents in the ac chopper must have the same frequency as the source voltage and the same phase angle as

that of the load [6]. With the HBCC technique, the reference currents are obtained and the continuity of the load current paths is ensured [6].

Fig. 1. The power scheme of the three-phase PWM ac chopper [6]

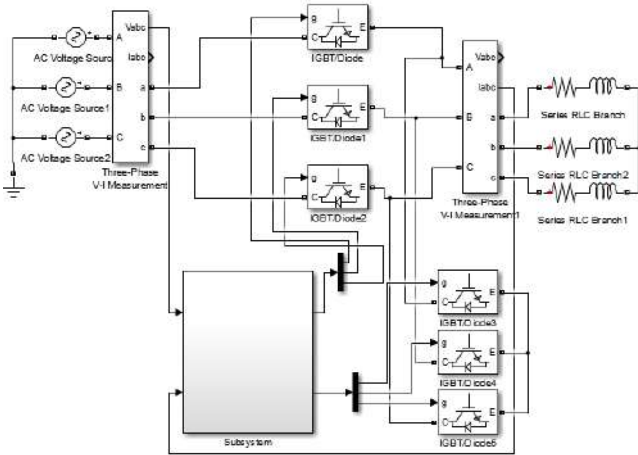

Fig. 2. The Simulink model of the three-phase PWM ac chopper

The reference currents can be obtained using phase locked loop (PLL) or using abc/dq transformations called Park Transform. The continuity of the load current conduction paths is also provided using the technique called the minimum voltage algorithm [3,6]. The minimum voltage algorithm ensures the continuity of the resulting current paths by triggering the correct switch according to the instantaneous values of the source voltage [3,6].

In the proposed model, the on and off states of the switches are provided using specific switching states. The goal is to obtain high quality waveforms at the output whatever the input voltage source is. In order to demonstrate the superiority of the control system, three-phase voltage source having harmonics or unbalanced voltage waveforms are applied to the system input. Undesirable changes in the source voltage (such as noise or harmonic distortion) will directly affect the output voltage and hence the amplitude of the output current. To analyze this situation, the fifth and seventh harmonics of the input voltage source are added to the input with certain amplitude ratios [7].

A. Analysis of HBCC Technique Applied to Ac Chopper

Any kind of load can be controlled with the PWM ac chopper connected to the three-phase source. The PLL block shown in Fig. 3 is used to set the source frequency [6]. The abc/dq transform block is also used to set the load phase. Only the amplitudes of the generated reference currents are input to the control system depending on the demand.

Fig. 3. The application of the HBCC theory [6]

The minimum voltage algorithm can be used in various systems. For instance, in a 3-phase inverter as the 3-phase chopping operation is made independent of each other, the current flow is continuous. In the proposed topology, the chopping procedures depend on each other and the flow paths are separated from each other during the phase chopping operation. The minimum voltage algorithm is used to prevent such undesirable situations. Depending on the instance, the switch with the minimum voltage is kept off while the chopper continues to operate in the other two phases and the sum of these currents returns from the phase with the minimum voltage.

B. Switching States

Besides the values in Table 1, four different switching states have been performed.

TABLE I. SYSTEM PARAMETERS USED IN SIMULATION

Parameters	Values
Source	$V_{SA} = 220$ V (rms)
	$f = 50$ Hz
Load	$L = 20$ mH
	$R = 10$ Ω

By referring to Fig.1, the following switching situations exist:

TABLE II. SWITCHING SITUATIONS

Switching States	ON	OFF
1	S_1, S_1^*, S_2^* and S_3^*	S_2 and S_3
2	S_1, S_3, S_1^* and S_2^*	S_2 and S_3^*
3	S_1, S_2, S_1^* and S_3^*	S_3 and S_2^*
4	S_1, S_2, S_3 and S_1^*	-

III. ANALYZES

In the simulation, two different conditions were performed. The first condition is used to observe the effect of the distorted three-phase input supply on a three-phase $R-L$ load where no power electronic circuit was used and the load is directly connected to the input supply as shown in Fig. 4. The second condition is to observe the effect of the same source voltage on $R-L$ load using HBCC technique applied to PWM ac chopper.

A. Analysis of the Proposed System Fed By 3-Phase Input Supply

In this application, a balanced and undistorted three phase voltage set is applied to the system input. In this case, the wave form of the load current of the system is observed to be smooth. The waveforms obtained are as follows for a complete period:

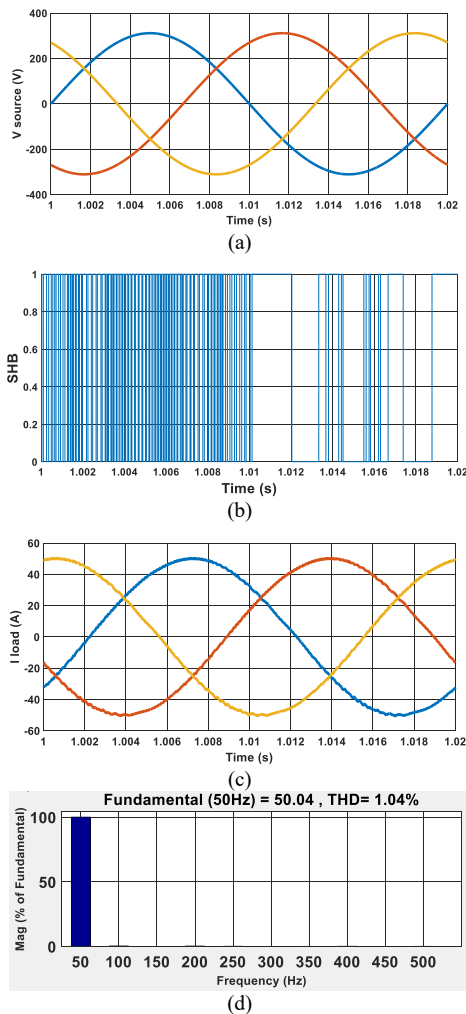

Fig.4. Simulation results of the PWM ac chopper fed by a distorted 3-phase supply and feeding a three-phase star connected $R-L$ load. (a) Voltage

source, (b) Switching signal, (c) Load current, (d) The harmonic spectrum of the load current.

In the Fig.4, 1-1.02 s is selected as a full period interval to see more clearly the waveform and harmonic analysis of the load current. Since the circuit is still in transient state at 0-0.02 s, the waveforms are harmonic. Therefore, the period of 1-1.02 s reached the permanent status has been taken into account. In this range, reference current is $I=50$ A. With the obtained waveforms and FFT analysis, it can be said that the harmonics are at an acceptable level.

In this application, Total Harmonic Distortion (THD) of the load voltage waveform is 1.04%. These results show us how reasonable and feasible the controller proposed for the three-phase PWM chopper.

B. Analysis of 3-Phase Star-Connected $R-L$ Load Fed By A Distorted Three-Phase Input Supply

Undesirable changes in the source voltage such as noise or harmonic distortion will directly affect the output voltage and hence amplitude of the output current. To demonstrate these effects, the fifth and seventh harmonics of the input voltage set are added at certain amplitude ratios in the simulation model.

Fig. 5. A star-connected 3-phase system with harmonic voltage applied to the input

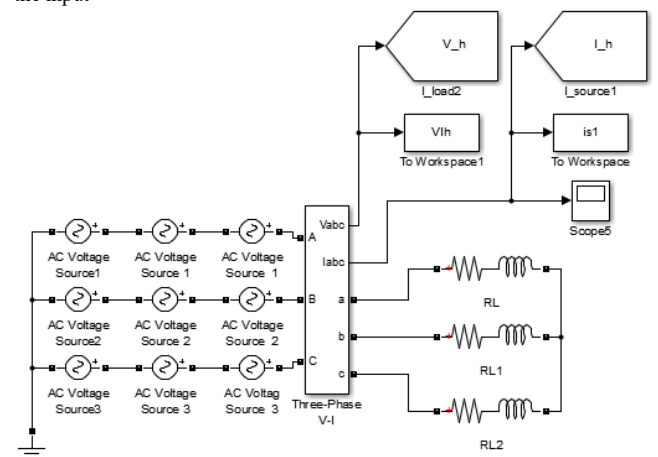

Fig. 6. Simulation Model of the star-connected 3-phase system with harmonic voltage applied to the input

In order to demonstrate the superiority of the ac chopper system used in this work, a distorted supply voltage model is

created in Simulink/Matlab to be used as input to the system. The three-phase sinusoidal voltage source with harmonics is defined as follows:

$$V_{1h} = k_1 \cos(5\omega t) + k_2 \cos(7\omega t) \quad (1)$$

$$V_{2h} = k_1 \cos\left(5\omega t - \frac{2\pi}{3}\right) + k_2 \cos\left(7\omega t + \frac{2\pi}{3}\right) \quad (2)$$

$$V_{3h} = k_1 \cos\left(5\omega t + \frac{2\pi}{3}\right) + k_2 \cos\left(7\omega t - \frac{2\pi}{3}\right) \quad (3)$$

The k_1 and k_2 values in Eq.(1-3) are set to be about 10% of the supply voltages [7]. V_{1h} , V_{2h} and V_{3h} are the harmonic voltages of A, B and C phases, respectively. The resulting simulation waveforms are given in Fig. 6 for a full period.

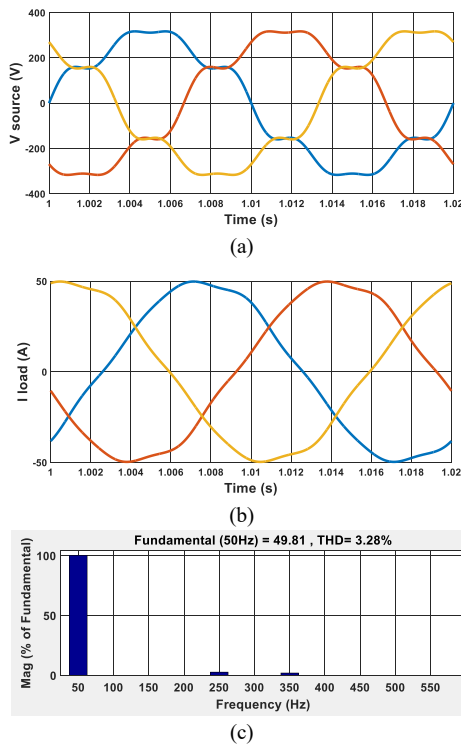

Fig.7. Simulation results of star-connected 3-phase load fed by a distorted 3-phase supply, (a) Distorted source voltages, (b) Load currents, (c) The harmonic spectrum of the load current.

As can be seen in Fig.7, when a voltage source with harmonics is applied directly to the R - L load, all harmonics of the supply are reflected to the output. THD of the load current waveform is 3.28%.

C. Analysis of the Proposed System Fed By A Distorted 3-Phase Input Supply

In this case, three-phase voltage supply with 5th and 7th harmonics used in the previous system was also applied to the input of the PWM ac chopper circuit controlled by the HBCC. The Simulink model of the system including the

distorted voltage supply source is illustrated in Fig.8. Comparing to the previous system, the superiority of the proposed method in [6] is confirmed by the simulation results in Fig.9. It is observed that the system gives successful results, that is, the waveforms of the load currents and voltages have sufficient quality. The simulation results taken for a complete period are shown in Fig. 9.

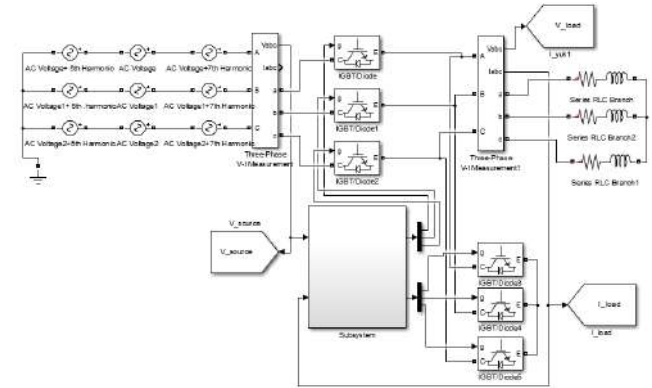

Fig. 8. Simulink model for 3-phase PWM ac chopper fed by a distorted input supply

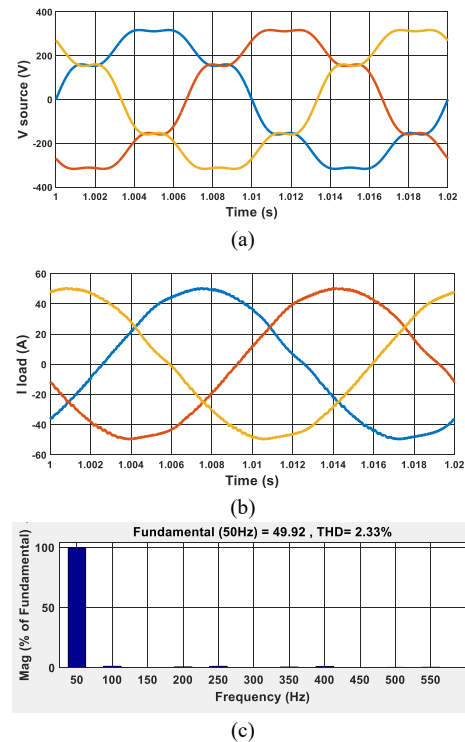

Fig.9. Simulation results of the PWM ac chopper fed by a distorted 3-phase supply and feeding a three-phase star connected R - L load. (a) Voltage source, (b) Load current, (c) The harmonic spectrum of the load current.

As can be seen in the Fig.9 (b), the resulting load current waveforms have less harmonics than expected and their shapes are almost pure sinusoidal waveforms. As seen in

Fig.9 (c), main harmonics are much dominant. This is why the hysteresis band controller is used in the simulation and proposed in [6]. Thanks to this controller the switches used in the chopper are controlled in a manner to have less harmonics at the output. The controller in simulation are designed for analysing the parameter of voltage and current. In general, it has features such as reducing the harmonic components and increasing the power factor of a particular circuit.

In this study, Total Harmonic Distortion (THD) of the load voltage waveform is 2.33%. These results show us how reasonable and feasible the controller proposed for the three-phase PWM chopper.

IV. CONCLUSIONS

In this study, a PWM ac chopper with hysteresis band controller has been modelled and simulated with the Simulink/MATLAB package program. It is aimed to have more efficient chopper comparing to the traditional 3-phase ac chopper. Although, the traditional phase controlled ac chopper has not been simulated in this work, its waveforms are well known. Therefore, it could be easily stated that the performance of the proposed system would be much better than that of the traditional ac chopper. In addition, operating conditions of the PWM ac chopper have been made much worst by adding the 5th and 7th harmonics to the input voltage waveforms. Even so promising simulation results have been obtained. The simulation results show that the proposed control algorithm minimizes the amount of THD at the output currents. Despite of the voltages with harmonics applied to the input, three-phase currents at the output are stable and they consist of very low amount of harmonics because of the HBCC used. As a result, the ratio of harmonics is reduced significantly with the switching control algorithm. These results have been supported by the harmonic analysis.

Abstract

The exploring of new energy resources using renewable energy resources is essential both for environmental impact and for sustainable clean energy. In this study, we present a hydrogen production method using photovoltaic energy as a renewable energy via electrolysis system in Kahramanmaraş city conditions-Turkey. An electrolyser system that we designed for H₂ is introduced, and the efficiency and feasibility are discussed. The efficiency of simple system gives 72%, and it can be used safely in rural areas or the places where city network cannot reach.

Keywords: Hydrogen energy; Photovoltaic; solar energy; photoelectrolysis by electrolysis of water using the electricity produced by the photovoltaic cells

I.

INTRODUCTION

It has been widely recognized that the primary energy sources such as petroleum, coal and natural gas consuming mostly in developed and developing countries have been causing air pollution/green house effect which leads inevitably to the global climate changes and bring about other many problems such as adverse effects on the human's life, rising CO₂, melting of glaciers and floods, etc.. Such reasons challenged the scientists in the field both energy and other disciplines to focus on sustainable and environmentally clean and renewable alternative energy sources and the technologies in the last three decades. In other words, interest in the connection between energy utilization and the environment from the past to the present became more pronounced and so that there has been increasing attention to this connection. However, there is no doubt that the researches on new alternative energy sources are not related only to the environmental effects of the fossil sources, but also the fluctuations of energy market and the truth of limited reserve of conventional energy sources consuming rapidly day by day. Although renewable energy

Kahramanmaraş, Turkey
ayildiz@ksu.edu.tr

Kemal DELİHACIOĞLU

Department of Electricity and Electronics, Kilis, Turkey
kemal@kilis.edu.tr

sources like solar, wind, biomass, etc. have a great potential, their efficient utilization is still difficult task due to their fluctuating and intermittent nature.

Nonetheless, to assure the present and future generations demands, we have to seek and discover environmentally clean/benign and sustainable energy sources combined with the growing concerns of global warming. For example, hydrogen production is, recently, of great significance in seeking a better way to use natural gas resources. Hydrogen is a clean and sustainable alternative to fossil fuels. It has no carbon emissions and offers important improvements in health and quality of life. It is the most economical synthetic fuel to produce environmentally friendly energy source, and can be converted to other forms of energy more efficiently than other fuels. In an overview of Ngoh and Njomo [1] have examined hydrogen production from solar energy and stated that solar energy as a renewable energy is, in particular, seen as a strong driving force capable of maintaining the availability of energy with hydrogen as energy carrier and is an emissions-free way to produce hydrogen, and, conversely, hydrogen offers a way for renewable to generate transportation fuel and reliable power. It is also argued that the future conjunction of hydrogen and renewable energy technology is a promising one if we put together positive and negative aspects of hydrogen energy. These are only a few of the many beneficial possibilities of a hydrogen economy. Clarke *et al.* [2] have discussed a complete stand-alone electrolyser system and indicated that hydrogen as an energy carrier and storage media is expected to play a key role in future power generation and with the development of the fuel cell technology as a transport fuel. There exists various types of hydrogen production methods such as solar thermal (high temperature and low temperature), photovoltaic, photoelectrolysis, biophotolysis, etc. as discussed in detail by Joshi *et al.* [3], but it is still produced

mainly by fossil fuel sources which release green house gases. As it has also been discussed in the recent studies that there are several environmentally benign hydrogen production processes using solar energy such as hybrid-sulphur cycle, metal oxide based cycle and electrolysis of water [3,4,5,6]. Hence, utilizing from solar energy in any processes involving energy is of great importance for protecting environment from green house effects and the other adverse effects.

Turkey is a developing country and dependent considerably on the important energy although it possesses an abundant solar energy potential. In an overview report by IEA [7], the current energy case of Turkey is well analysed and reported that more than 87% of total liquid fuels are important from foreign countries and crude oil imports are expected to double over the next decade. Turkey is also increasingly dependent on natural gas imports, and consumption has increased rapidly over the past decade and reached a new high of 1.7 trillion cubic feet in 2014. Consumption growth is expected to remain strong as industrial sector growth and rising electricity consumption continue to encourage demand day by day. However, it is stated that Turkey's natural gas demand is not flat over the duration of the year, but peaks in the winter months as the detail given in the report. If we superpose all these and the energy crisis experienced in the mid of 1970 plus regional problems going on nowadays, it is apparent how important for any country to develop its sustainable energy resources. Hence, Turkey dependence on foreign oil would be curtailed, and providing establishments with their own power generation capability would reduce the demand on the electric grid.

The goal of this article is to investigate the performance of a photovoltaic –hydrogen production hybrid energy system designed as an example for a stand-alone house system in city of Kahramanmaras, Turkey. The study is also aimed to stimulate in an extent both production of hydrogen energy from renewable energy as a benign alternative energy and encourage using abundant renewable energy potential sources, particularly solar energy for a liveable and clean environment. The study describes the design and feasibility of a 6 kW PV energy system. Hybrid energy system design is site specific, and depends on the resources available and the load demand. Three months recorded solar radiation and estimation of the hydrogen load are used for the design of a hybrid energy system. To pick an optimum hybrid hydrogen energy system, National Renewable Energy Laboratory's HOMER software was used to select an optimum hybrid hydrogen energy system.

II. METHOD

A. Hydrogen production methods

There are several well known hydrogen production methods from non-renewable and renewable energy

resources. Since use of non-renewable energy causes negative impacts on environment and also is not sustainable, the recent studies are focused mostly on renewable energy resources such as solar photovoltaic, geothermal, wind and hydropower. The development of the methods of hydrogen production based on renewable energy sources takes place as much as possible without releasing the greenhouse effect. These methods represent alternative ways for hydrogen production through fossil combustibles [5]. In particular, solar energy are used more extensively in many purposes. For example, hydrogen production from solar energy is outlined under four groups as [5];

- Photovoltaic (PV)
- Photoelectrochemical
- Photobiological
- Solar thermal energy

B. Solar photovoltaic based electrolysis

In this section, we will discuss and illustrate one of hydrogen production methods using PV panels via electrolysis method. In the early of 70s the PV panels were utilized to produce hydrogen by electrolysis of water using the electricity produced by the photovoltaic cells [2,13–15]. The electrolysis of water can be carried out by a current generated by the photovoltaic cells. It needs a higher and extensive research in this area as the hydrogen produced by this technology is not cost effective as the PV technology is costly. The end product of the electrolysis was also oxygen. Fig.1. shows a schematic diagram of hydrogen production system that uses photovoltaic technology [7].

Figure 1. Schematic diagram of photovoltaic hydrogen production system [7].

C. Production of hydrogen via electrolysis method

Electrolysis method, which is the process of separation of H₂O to H₂ and O₂ using DC current, is one of the simplest methods for hydrogen production among the other methods [8]. Basically, the overall reaction of the water is as follows;

Based on the chemical equation (1), a minimum electric voltage (reversible voltage) must be applied to both electrodes for the reaction, and this can be determined from Gibbs equation [8],

$$\Delta G = zFV_{rev} \quad (2)$$

$$V_{rev} = \Delta G / zF \quad (3)$$

$$V_{rev} = \frac{237.2 \text{ kJ/Kmole}}{2 \times 96485 \text{ C/mole}} = 1.229 \text{ V} \quad (4)$$

Where V is the required minimum voltage, ΔG is Gibbs Energy, z is the number of electron, F is Faraday's Constant. On the other hand, the reactions for the alkaline anode and cathode are given, respectively, showing the hydroxyl (OH^-) ion transport [9].

D. Experimental procedure and Results

In the experimental the materials of system are solar cell, battery, charge controller, Pulse Width Modulation (PWM) circuit for adjusting current-voltage, electrolyser which are consisting of 21 plate/cell (15x15 cm size and 1.5cm thickness made from 304L steel), hydrogen flow-meter and KOH compound, which is an alkaline base, to provide conductivity in the electrolyser.

The system works as follows: solar PV panels converts solar energy to DC current that charges battery via the charge controller. The PWM (Pulse Width Modulation) circuit connected to the battery supplied power to the electrolyser at the desired current -voltage level. The amount of hydrogen obtained according to the amount of power supplied to the system has been determined and accordingly the efficiency of system has been carried out. Tommatech trademark solar panels are used for the designed system and the properties of PV panel are given in table 1.

Table 1: PV Power Parameters

Standard Test Conditions Power Parameters	
P(max)	TT250P-60P
Voc	36.3V
ISC	8.71A
Vmp	30.6 V
Imp	8.17A
operating temperature	-40 ⁰ C to +85 ⁰ C

STC: Radiaton 1000W/m² temperature 25⁰C

Moreover, as seen in Fig.2, the electrolyser is consisting of 20 cells and 4 sections connected in parallel and 21 plates of 304L steel as seen in Fig.2 (left hand side). The plates arrangement scheme of electrolyser device are shown in Fig.3

Figure 2. Electrolyzer (left side) and 304L steel plate (right side)

Figure 3. Plates Arrangement Scheme of Electrolysis Device

Theoretically, water separates into ions at 1.229V. Due to the slow response and other reasons, it was given an average of about 2 volts to the cells. It was observed that the measured input voltage at the site during the experiment was around 10.4 Volts and the measured current value was about 18.7 A. The electrolyte used in the system is KOH and the electrolyte solution was prepared at a concentration of 2.13 mol / dm³. The measured voltage values between the cells at 10.4 volts input voltage are shown in Fig.4. As seen in the figure the voltage values are not flat which are expected values.

Figure 4. The voltage values measured between cells

It was obtained that the electrolyser produced 666.66 ml/minutes of H₂ at 18.7 A and 10.4 volts. Hence, the amount of H₂ per minutes is 5.99x10⁻⁵ kg using the density value $\rho = 0.08988 \text{ kg/m}^3$ [10]. If one takes the upper heat value of hydrogen as 140,9 MJ/kg [11], the amount of production energy is then 8442,719 joule. On the other hand, the amount of consumed energy in a minute at 10.4 volt and 18.7 A corresponds to 11668.8 joule. Moreover, the

efficiency of the system, η , has also been carried out from the following equation [10].

$$\eta = \frac{\text{produced energy}}{\text{The energy consumed}} \quad (7)$$

and using the obtained results above, the efficiency is

$$\eta = \frac{8442,643}{11668,8} = 0,722 = \% 72,2 \quad (8)$$

III. RESULTS AND DISCUSSIONS

In this work, a solar energy supported hybrid energy system design was made considering the sunshine amounts of Kahramanmaraş radiation. The designed PEM type electrolyzer produced $0.04 \text{ m}^3 \cdot \text{h}^{-1}$ H_2 at 10.4 volts at 18.7 A current. For production of $1 \text{ m}^3 \text{ H}_2$, 4.86 kWh^{-1} electricity is consumed. The amount of solar radiation in Kahramanmaraş province is seen in figure 5.

Figure 5. Annual amounts of solar radiation of Kahramanmaraş

The amount of photovoltaic energy produced according to these radiation values is also seen in figure 6.

Figure 6. Amount of energy produced per month

The amount of hydrogen produced according to these energy values is shown in Figure 7.

Figure 7. The amounts of hydrogen produced to warm up in the winter months

Energy consumption values are also increased rapidly according to development levels of countries and fossil fuel reserves are also declining day by day. Our country has a very convenient geographical position for insolation. However, since solar energy is not an uninterrupted energy source, solar energy need to be stored in order to be used as a constant energy source. In this case, hydrogen is of great importance for the sun to be stored and used as an uninterrupted energy source. In addition, hydrogen is an environmentally friendly fuel that is stronger than fossil fuels and has no pollutant properties when burned.

The goal of this study was to assess the production and use of H_2 from renewable energy (i.e solar PV systems) in the sectors which are, in particular, depending on imported gasoil/fuel and firewood in rural areas in Turkey since such project will save declining forests in rural areas day by day and reduce important energy dependence and also encourage sustainable clean, diversible, economic and benign energy. In order to achieve this goal, we have evaluated H_2 production by electrolysis method from solar PV energy system. It was achieved the result that the electrolysis system was very simple and cheap although it was argued in literature that H_2 production from solar photovoltaic via electrolysis was one of the most costly methods, which is due to the cost of PV system. However, the cost of production H_2 will go down and the system amortizes its own cost in a couple of years if the low cost equipments are used and a PV system life time is considered as 20-25 years. As a result, it is hoped that photovoltaic supported hydrogen production systems will become even more important in the solar-rich countries in the future.

Abstract—In this paper, texture descriptors of speaker's speech are used for gender recognition. More specifically, Local Binary pattern (LBP) based features are employed for gender classification. LBP is known as a powerful tool for texture image characterization. To directly apply the LBP on speech, a straightforward transformation is needed. Therefore, 1D LBP is considered. After several pre-processing stages, which are considered for normalization and noise removal, LBP coding is applied to all input speech signals. Then, histogram of the LBP descriptors is constructed and is used as features. Support Vector Machines (SVM) and Extreme Learning Machines (ELM) classifiers are used to classify the obtained features as female or male. In experiments, a dataset, which contains 55 female and 41 male speaker's speeches, is considered. With both classifiers an average classification accuracy that are greater than 95% are obtained. Moreover, the obtained sensitivity and specificity values are greater than 95%.

Keywords—gender classification; LBP; speech signals; SVM; ELM.

I. INTRODUCTION

Speech based gender classification has important applications in machine learning and pattern recognition communities. Especially, some of the artificial intelligence based systems may need to detect the gender of interacted persons for various reasons. For instance, a machine learning based advertisement system can be specialized based on the gender of the interacted person or a phone based fortune teller system's persuasiveness can be augmented by the gender recognition. In addition, in a digital forensic view, speech based gender recognition may help to get more clues about the suspicions.

In the reviewed literature, it is seen that so many works have been proposed so far for speech based gender classification [1-8]. In [1], the author firstly extracted the Mel Frequency Cepstral Coefficient (MFCC) and Shifted Delta Cepstral (SDC) features from the speech signals and Support Vector Machine (SVM) classifier was used for detection of the age and gender. Kotti et al. [2] proposed a methodology for gender classification from the emotional speech. Authors firstly extracted a large number of features and a feature selection mechanism was employed to detect the efficient features.

Finally, SVM classifier was adopted to classify the features as man or woman. In [3], a Gaussian mixture model (GMM) was used for speech based gender classification. The authors extracted various features, which were based on the pitch and spectral perceptual linear predictive coefficients. The reported accuracies are in the 95% and 98% interval. In [4], the authors proposed a new method for speech based gender classification. The presented approach was leveraged from pitch feature trajectories. In addition, the authors achieved high classification performance with as little speech as possible. Zourmand et al. [5] explored the fundamental and formant frequencies in speech signal to recognize the gender of Malay children. Distance based classifier and artificial neural nets were used in the classification of the gender of 360 Malay Children. In [6], authors investigated the usage of ensemble based techniques for decision fusion for efficient recognition of gender from speech signals. Each member of ensemble structure was generated via a feature selection mechanism. In [7], authors measured CPP, HNR and $H_2^*-H_4^*$ in conjunction with F0 and formant values for automatic gender recognition. An Acoustic measure based gender classification system was proposed by Shue et al. [8]. The considered acoustic measures were the vocal tract and the voice source. The SVM classifier was adopted for efficient classification.

In this paper, different from the reviewed literature, an image texture based method namely local binary pattern (LBP) is adopted for gender classification from speech signals. LBP, which was original proposed by Ojala et al. [9], is known as a powerful method for texture image characterization. LBP method produces a binary code for a pixel position by comparing its value with its 8 neighbor pixel values. Binary 1 value is assigned a neighbor if its gray scale value is higher than the center pixel gray scale value; otherwise binary 0 value is assigned. Thus, eight bits binary code is produced which is then converted to the decimal value. The adaptation of the 2D LBP to 1D LBP is straightforward [10] and will be described in next section. After obtaining the 1D LBP scheme of the input speech signal, histogram of the coded speech signal is calculated. Different bin numbers for histogram calculation is considered. SVM, Extreme learning machine (ELM) classifiers are used in the classification stage. The experimental works are carried out with a real life dataset containing courtroom

dialogue recordings of 120 people [12]. Almost 70% of the dataset was randomly used in the training, with the remainder used in testing the efficiency of the proposed method. For 100 times run, average 96.46% accuracy is obtained with SVM, and ELM gets 98.91% accuracy.

The paper has been organized as follows: In the next section, a brief review of the theory of LBP is given. In Section 3, the experimental works, related parameter settings and results are given, with the paper concluding in Section 4.

II. LOCAL BINARY PATTERN

As we mentioned earlier, LBP is an important and efficient method for texture characterization. It reveals the local repetitive patterns which are further used for classification purposes. Generally, LBP works on a 3×3 image patches. The center pixel is coded according to its 8 nearest neighbors. An illustrative example is given in Fig. 1. As seen in Fig.1, the center pixel gray scale value is 7. After LBP coding, its new value becomes 103. The first-order neighbor pixels of the center pixel are coded as 0 or 1. This coding is handled by considering the gray scale values of the neighbor pixels. If a neighbor pixel gray scale value is greater than or equal to the center pixel gray scale value, binary 1 is assigned otherwise binary 0 is assigned to that neighbor pixel. The obtained binary numbers are aligned starting from the up-left pixel position in a circular trajectory as shown in Fig. 1. Thus, an eight bits binary sequence is obtained. Finally, the procedure is ended with the converting binary sequence to decimal number.

Fig. 20. 2D LBP code of an image patch.

The adaptation of the 2D LBP to 1D case is straightforward [11]. A sliding window with 9 samples length is employed for 1D LBP coding of input signal. An illustrative example is given in Fig. 2. As seen in Fig. 2(a), the samples of the input signal indicated with P_0 to P_7 are in the sliding window coverage. P_C is the interested sample which is in the center of the sliding window.

In Fig. 2(b), all samples in the sliding window coverage are given and the related coding is given in Fig. 2(c). The samples, which have greater value than the center sample, are coded as binary 1 and others are coded as 0. The coded samples are collected from left to right to obtain the 8 bits binary code as shown in Fig.2(c). The last step is converting the binary sequence to decimal number as shown in Fig. 2(d).

III. EXPERIMENTAL WORKS

The dataset, which was used in the experimental works, was collected by Pères-Rosas et al. [12]. The dataset was recorded in courtrooms and contains totally 120 trial video clips. The average length of each video clips in the dataset is 28.0 seconds. 55 video clips contain just female speeches and 41 video clips contain male speeches. The rest video clips, which contain both female and male speeches, are not used in the experiments. The speakers are with ages ranging from 16 to 60 years. Video files were converted into audio files, with a frequency value of 16,000 Hz, a bit rate of 128 kbps, and mono channel specified. Fig. 3 presents a sample time domain speech signal from the dataset.

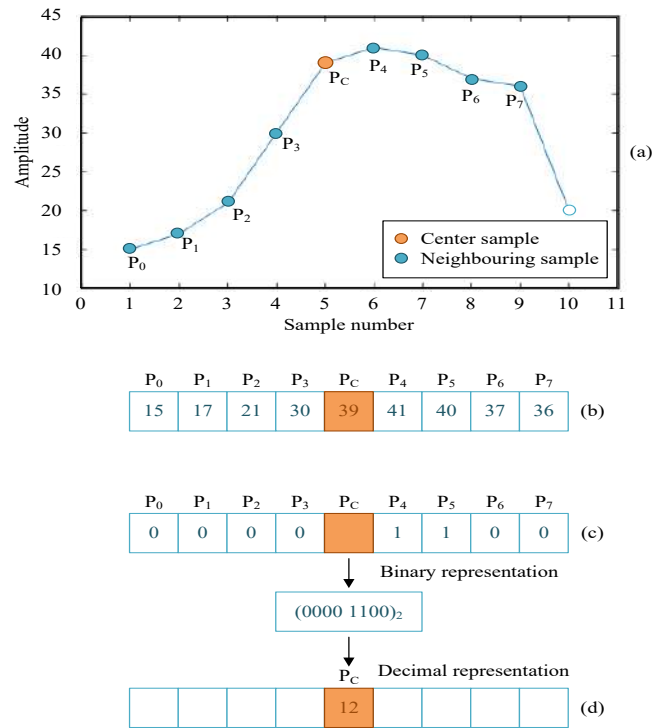

Fig. 21. 1D LBP code of an image patch.

Fig. 22. A sample speech signal from dataset.

A sequence of pre-processing steps was applied to the input speech signals for normalization and noise removal. In this context, min-max magnitude normalization and hamming filtering was applied for noise removal. The hamming window length was selected to 15 ms.

Fig. 23. A sample speech signal after pre-processing.

After pre-processing steps, we applied the 1D LPB to the pre-processed speech signals and histogram of the LPB codes were used as features. The bin size of the histogram was chosen as 50. A sample histogram is depicted in Fig. 5.

Fig. 24. 1D LBP histogram bins.

As we had 96 speakers and for each speaker 50 dimensional feature vector was constructed, totally a 96x50 feature matrix was obtained before classification stage. 70% of the dataset was used for training and the rest was used for performance test of the proposed method. For performance evaluation, the experiments were run 100 times for each classifier and average classification accuracies were recorded for each classifier. For SVM classifier, linear kernel was selected and the C parameter was assigned as 0.1. For ELM, the sigmoid activation function was selected and the number of neurons in hidden layer was chosen as 1,000. The obtained results are tabulated in Table 1.

TABLE III. OBTAINED RESULTS

Classifier	Accuracy	Sensitivity	Specificity
SVM	96.57%	97.28%	95.61%
ELM	98.03%	98.87%	96.95%

The results show that the best accuracy is obtained with ELM. The classification accuracy is 98.08%. In addition, the sensitivity and specificity values are 98.87% and 96.95%, respectively. In addition, SVM yielded the 96.57% accuracy. Sensitivity and specificity values for SVM classifier are 97.28% and 95.61%, respectively. According to the obtained results, ELM classifier highly increases the performance of the proposed scheme. ELM classifier is almost 1.5% better than SVM.

IV. CONCLUSIONS

In this paper, we proposed texture descriptors for efficient classification of gender of a speaker. In other words, speech based gender classification was carried out by LBP. In this

context, 1D LBP structure was employed to extract meaningful features from the speech signals. The histogram of the 1D LBP was used as feature and two classifiers namely, SVM and ELM was adopted. Obtained results are quite good where both classifiers achieved classification accuracy greater than 95%. In addition, both classifiers sensitivity and specificity values were greater than 95%.

Design and Implementation of PID Controller System Based on Android Platform For an Espresso Machine

Ender Oguz and M.Zeki Bilgin
Kocaeli University, Faculty of Engineering,
Kocaeli, Turkey
ender.oguz@gmail.com, bilgin@kocaeli.edu.tr

Abstract – This article suggests an espresso machine design with PID controller and operating principles of the machine. Smart devices are commonly used in daily routine as connectable devices become wider and automation systems are more developed. Especially home control systems and smart home appliances are the main application areas of this field. Coffee machines are widely preferred among fast consumption devices and users choose coffee for their own taste. The high-sensitive cooking process of Espresso is a distinctive property of this coffee type among others. To provide this level of sensitivity, PID control is proposed in this study. Android based operating system is proposed with various criteria for Espresso cooking systems to provide a taste for user preferences. Connectivity is added to the developed control and communication system so that user specific espresso cooking systems can be achieved by connecting this proposed system to common espresso machines in the market. System stages and control methods are stated and experimental results are presented.

Keywords – smart home appliances; PID control; espresso brewing; TDS; Android OS; mobile applications; IoT

I. INTRODUCTION

One of the sectors that is effected by the development of automation systems is smart home appliances. With the increasing number of coffee shops, almost each house has its own coffee machines. The most important proof is that by the year of 2015 more than 76 million coffee machines were sold worldwide and it is expected that the sales figures will exceed 100 million by 2021 [1]. Twelve Turkish coffee machine that has innovation award in 2015 in Turkey has reached over 500.000 sales [2]. Although general structure of coffee machines are similar, factors such as coffee bean, cooking method, brewing time and cooking time can differ. In addition to these factors, personal preferences are the most important factor effecting the coffee devices. In recent years, espresso is one of the widely consumed coffee type. The espresso brewing, originating from Italy, is making hot and pressured water pour over the coffee [3]. Coffee particles dissolves with temperature and pressure, gives the aroma to espresso. The most distinctive property of espresso brewing method is the

balanced and controlled cooking method. Temperature, pressure and flow duration in brewing process increases the quality of espresso. The best way to obtain optimized espresso with bean type, bean grinding and roasting, and personal preferences are empirical methods. If it is considered that each person has different preferences, individual configuration of an espresso machine is a distinctive advantage. Factors such as determining, setting, and saving personal preferences in smart home appliances respond the need of users. Also, the users' involved to the process and this positively contributes to efficiency of coffee and the machine by creating a new experience and increasing product-user interaction. Devices with automation system should also have the connectivity property to commonly use customization option. The largest contribution comes from widely use of internet of things concepts with improved internet and network structures. As the number of connectable objects in the market increase rapidly, application areas have become wider and approximately 500 billion dollar market share is formed [4]. It is inevitable that coffee machines are oriented in this market.

In this paper, design and control method of a smart and connectable espresso machine is proposed. Coffee machine control systems in the literature mainly use fuzzy logic, PID and proportional control methods [5], [6], [7]. PID control system is applied to provide stable and high precision cooking. Thus, according to preferences from smart and Android operating system based device, pressure, temperature, and flow duration is set and brewing process is managed by the user. Suggested reference values are recorded to form user profile. To evaluate the acceptability of the coffee after brewing process, TDS (Total Dissolved Solids) measurement method is used [6]. Thus, TDS method can measure how many coffee particles are dissolved.

Section II of the proposed paper states operating principle of espresso machine. Section III shows design and experimental studies. Section IV indicates the obtained results.

II. OPERATING PRINCIPLE OF PROPOSED ESPRESSO COFFEE MACHINE

Configuration options that can be selected by users for their espresso preferences is shown in Fig. 1. As a result of this configuration options, control system sets temperature, pressure, and cooking time with high-precision and stability.

Fig. 1. Espresso balancing chart (a: lower temperature, b: grind coarser, c: stop the shorter i.e. lower target weight, d: allow the shot to run longer i.e. increase target weight, e: grind finer, f: increase temperature, g: tamp harder, h: stop the shot shorter i.e. lower target weight, i: use fresh coffee ground on demand, j, k: allow the shot to run longer i.e. increase target weight) [8].

Espresso machines fundamentally operate as shown in Fig.2. Water heated in the chamber is poured on milled coffee from portal filter mounted on ground head with a pump and coffee particles are dissolved in hot water. When operating system of espresso machine is considered, pressure and flow duration are the main steps of brewing process. Control of these steps affects the taste of coffee. Since temperature, pressure, and flow duration effects the taste of the coffee, certain control algorithm should be used on these variables to provide the customized tastes for individual users. Fig.4 shows cooking diagrams for different aroma and stiffness. When ideal duration and high precision is changed according to the diagram, the taste of the coffee will improve. To enhance this improvement and to obtain a high-performance device, proposed system implemented a PID control structure. Effects of PID parameters are stated in Fig.4 and Appendix for the given flow.

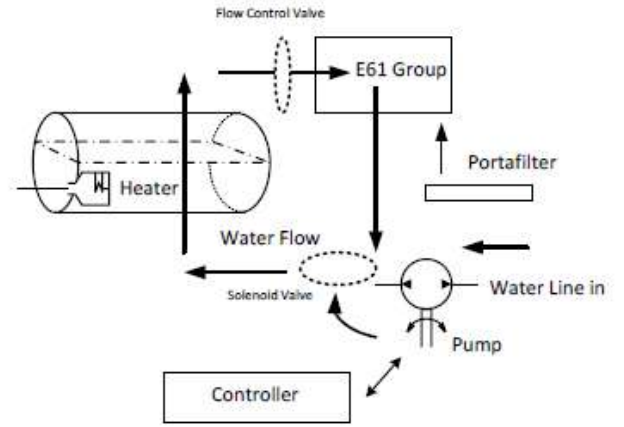

Fig. 2. Espresso machine working principle.

PID control system measures error between feedback and reference value and aims to provide a stable improvement [9]. Both applicability and fast adjustment for the process and time constants, this type of controller is selected in the study.

Fig. 3. Espresso control diagram.

In the control method with proportional, integral and derivative effects, proportional gain, integrator and derivative coefficients can be adjusted and control system can be arranged for cooking method. Control method in Fig.3 is separately applied for temperature, pressure, and flow duration. Transfer function of PID controller is shown in Eq. (1).

$$G(s) = K_p \left(1 + \frac{1}{T_i s} + T_d s \right) \quad (1)$$

Equation shows K_p proportional gain, T_i as integral time constant, and T_d as derivative time constant. Integral gain $K_i = K_p / T_i$ Integral gain is stated as $K_i = K_p / T_i$, derivative gain is stated as $K_p T_d$ [9].

$$e(t) = r(t) - x(t) \quad (2)$$

When the effects of the component on the system are investigated, these effects are shown in Eq. (2) - (4) separately. Where Eq. (2), $e(t)$ is error shows the difference between reference value $r(t)$ and sensor feedback value $x(t)$.

$$P = K_p e \quad (3)$$

$$I = K_I \int_0^t e(t) dt \quad (4)$$

$$D = K_D \frac{de(t)}{dt} \quad (5)$$

Proportional (P) expression in Eq. (3) provides a proportional decrease of error. Integral (I) expression decreases steady-state error. In this study, a low frequency integrator is selected. Derivative (D) expression controls the transient state response. Control algorithm with D uses high frequency differentiator.

Fig. 4. Coffee brewing control chart (A: strong, B: strong bitter, C: bitter, D: weak bitter, E: weak, F: weak underdeveloped, G: underdeveloped, H: strong underdeveloped, I: ideal) [10]

III. DESIGN & EXPERIMENTAL STUDIES

Control block diagram of designed espresso machine is shown in Fig. 6. The designed system should brew 10 glass of espresso with 1500 Watt power and 1.3 L volume. Prototype device is selected as a product on the market. This product and experiment mechanism is shown in Fig.5. Control strategy of the machine consists of three main parts. Selection and placement of sensors, communication and addition of IoT properties and forming control algorithm. The application has a database and user-friendly interface for Android based control. General control structure of the system is shown in Fig.6. User can adjust related interface parameters as shown in Fig.7. These parameters are transferred to coffee machine using Bluetooth communication protocol. The references are arranged with embedded PID control algorithm in microcontroller and data from the sensors provide feedback. If the coffee has the desired taste after brewing process, user records the data and a personal coffee taste archive is obtained.

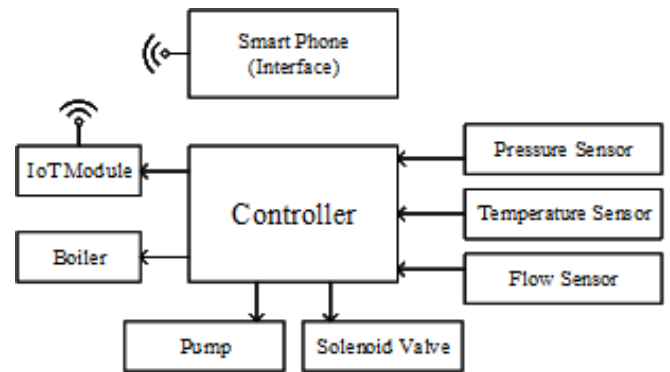

Fig. 5. Overall block diagram.

Fig. 6. Prototype coffee machine.

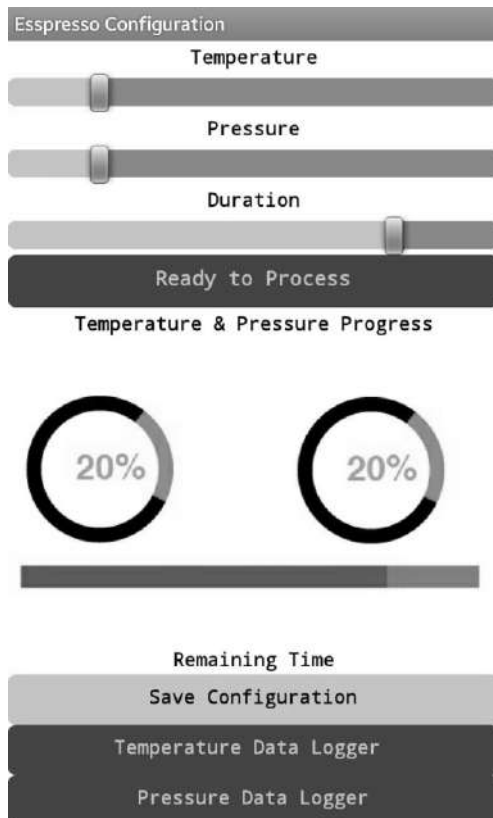

Fig. 7. Android based application's user interface.

Proposed device consists of Atmel Mega 2560 processor, YF-S201 pressure sensor, 100k NTC temperature sensor and HC-05 Bluetooth module. Tests for developed system are conducted according to ideal espresso settings. Fig. 8 and Fig. 9 shows the test results. To show the device performance in the experiments, temperature and pressure change and stability are presented. Fig.8 shows change of temperature and pressure by sampling period. Temperature value is set to 94 °C and pressure reference value is set to 9 Bar. In Fig.9 using an oscilloscope, integrated reference value tracking is presented. Here each noise and disturbance effects are considered and changes in temperature, pressure and cooking duration are monitored. The results show that a control algorithm with desired stability is achieved.

Fig. 8. Heat and pressure variation of cooking process.

Fig. 9. Integrated settlement graphic of cooking process.

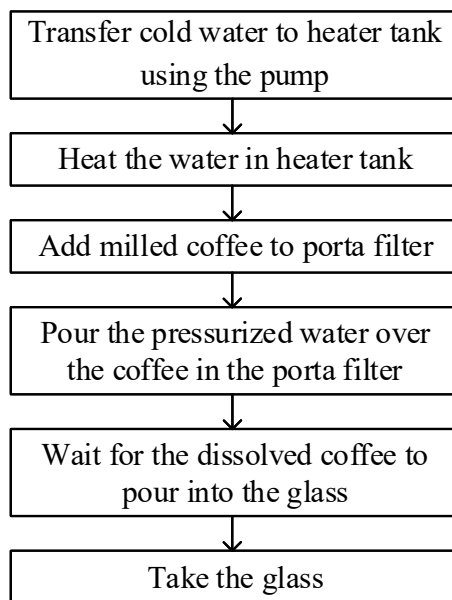

IV.

CONCLUSION

As connectivity properties are added to smart devices in fast moving consumer goods sector, high level of sales figures are achieved in the market. The most important reason is that these devices provide manufacturing custom products for the preference of the user. In this study, customized Android controlled espresso machine is designed. Precise temperature and pressure control are the distinctive properties of espresso. To provide this level of sensitivity, PID control method is applied in this study. Ideal level of espresso is prepared with obtained results and design process and experimental results are presented in the study.

Abstract— In this study, DSP controlled a single-phase bridgeless AC-DC rectifier with low total harmonic distortion (THD) and high power factor (PF) is proposed. Bridgeless converters remove the input bridge the conventional Buck PFC converters to reduce complexity and improve overall efficiency. Moreover, some additional advantages such as zero-voltage cutoff in power switches, zero-voltage conduction in the output diode, and continuous input current are provided by the proposed system. Therefore, electromagnetic noise (EMI) emissions are minimized and high power factor is obtained with low total harmonic distortion (THD) in the input current. The performance of the proposed system is evaluated using simulation studies performed with PSIM and embedded codes are obtained for the TMS320F28335 DSP processor.

Keywords— Power factor correction (PFC); total harmonics distortion (THD); DSP; PSIM

I. INTRODUCTION

Electronic devices cause harmonic currents in power systems. Non-sinusoidal magnitudes occur when passive components such as inductors and capacitors are connected to the power system. However, these harmonics cause various problems such as voltage distortion, heating and noise as well as reducing the line capacity to provide energy [1]. To improve the PF, to decrease the AC current harmonics, to reduce noise and electromagnetic pollution, to use the minimum number of components and to increase the current efficiency are required [2].

The converters used to obtain the enhanced power factor are called power factor correctors (PFC). PFCs are divided into two classes as active or passive. Using active PFC converters, the power factor of the grid is approached to 1 and the power quality can be corrected by drawing currents close to the sinus with reduced harmonic content from the grid. In the world, any device connected to the grid must provide input line current harmonic limit values given in EN 61000-3-2.

According to this standard, the limitation of the input current harmonics is sufficient, so it is not necessary to provide the unit power factor. However, it is important to understand the standard, to evaluate the PFC techniques in accordance with the standard, and to optimize the total cost and performance by some changes in the standard [3].

In this respect, the standards force PFC circuits to be used as rectifiers in power systems. Single phase PFC circuits are widely used in applications ranging from low to moderate power due to simple circuit construction, low current and voltage stresses, low number of components, ease of control, etc. [4]. The commonly used PFC converters are Boost [5], Buck [6], Boost-Buck [7]. Boost PFC converters are often preferred in practical applications, such that the input current can be brought to a sinusoidal waveform in a suitable manner to obtain a unit power factor. However, the Boost PFC converter has a limited capacity because it requires a higher voltage than the AC input of the DC output [8]. Moreover, high voltage stress is produced by Boost PFC converters in wide input voltage range for adjustable electronic devices especially for high voltage input condition. As a result, it becomes very difficult to choose the circuit elements and the energy storage capacitor.

On the other hand, the Buck converter's DC output voltage is lower than the peak value of the AC input voltage, thereby reducing component values and cost [9]. A Buck PFC converter appears as an alternative to lower voltage applications such as 48V DC bus. In addition, when the Buck PFC exceeds the limits specified in IEC 61000-3-2, high efficiency can be achieved in the entire input voltage range [10].

In this study, to evaluate the performance of the proposed control, simulation studies were performed with PSIM software and embedded codes were obtained for the TMS320F28335 DSP processor.

II. BRIDGELESS CONVERTER TOPOLOGY

The output voltage of a Buck PFC is always lower than the grid voltage. The output voltage for 220V grid voltage is usually set to 48 VDC. Figure 1 (a) shows the conventional Buck PFC. The conventional Buck PFC consists of a full bridge diode rectifier and a buck converter. When the switch is closed, the energy is stored in the inductor and the capacitor is discharged through the resistor. By controlling the duty ratio of the output voltage to the desired value, a value lower than the input voltage can be obtained. The disadvantage of this circuit is the occurrence of high conduction losses in the direction of the bridge [11].

The Buck topology of the two active switched bridgeless (Q1 and Q2) is shown in Figure 1 (b).

Figure. 1.(a) Conventional Buck PFC (b) Bridgeless Buck PFC.

L_1 and L_2 inductors must be small enough to reduce the phase shift between the line voltage and the input current to be minimum. Furthermore, L_1 and L_2 inductors must be large enough not to resonate with the input capacitors C_1 and C_2 ;

$$L_1 = L_2 < \frac{(1-D)^2 T_s}{4\pi C_1 f_l} \quad (3)$$

$$L_1 = L_2 > \frac{1}{C_1} \left(\frac{(1-D) T_s}{2\pi} \right)^2 \quad (4)$$

where; f_l represents the line frequency. L_0 coil in the output must be chosen in accordance with the maximum point (peak) I_m of the converter input current;

The same control signal can be controlled by both switches. As a result, the control cycle becomes simpler. During the positive half-line cycle, L_1 , C_1 , Q_1 , L_0 , D_0 and D_p are active. During the negative half-line cycle, L_2 , C_2 , Q_2 , L_0 , D_0 , and D_n are active.

Compared with a conventional buck PFC converter, the bridgeless topology uses an additional inductor and a capacitor and this causes disadvantage because of size and cost. However, compared to a single inductor, better heat performance can be achieved with two inductors. In addition, the return diodes D_p and D_n always provide a low impedance current path for the return current. Thus, higher efficiency is achieved compared to conventional Buck PFC converter by reducing conduction and heat losses [12].

Multi loop fashion as the inner current loop and outer voltage loop are used at the proposed control. The reference current through innovative filtering and signal processing is calculated to outer control loop. PWM switching signals through the PI controller are generated to inner control loop.

III. DESIGN OF BRIDGELESS BUCK CONVERTER

There are many factors in the design of single-phase bridgeless PFC [13]. Input capacitors C_1 and C_2 can be calculated from Equation 1;

$$C_1 = C_2 = \frac{KT_s}{2R_l} \quad (1)$$

where, T_s represents the switching period. K constant should be chosen as follows;

$$K < \frac{D^2(1-D)}{\eta} \quad (2)$$

where, D is the switching rate, η is the efficiency.

$$L_0 = \frac{1}{2I_m f_s} (V_m - V_o) \frac{V_o}{V_m} \quad (5)$$

where; V_m is the maximum value of the converter input voltage, V_o is the output voltage, f_s is the switching frequency and I_m is the maximum value of the input current. On the other hand, output compensator is chosen in accordance with the desired frequency fluctuation value ($\theta\%$) of the output voltage.

$$\alpha + \beta = \chi. \quad (1) \quad (1)$$

$$\theta\% = 2 \cos^{-1} \left(\frac{V_{des}}{V_m} \right) \frac{1}{\pi} \quad (6)$$

$$C_o = \frac{P_L(1-\theta\%)}{V_o^2 \Delta V_{des\%} 2f_L} \quad (7)$$

where V_{des} is the desired output voltage, P_L is the output power of the converter, $\Delta V_{des\%}$ is the fluctuation frequency of the output voltage.

IV. PSIM SIMULATION RESULTS

Two active switched bridgeless buck PFCs are simulated using the parameters shown in Table 1. In the simulation, one voltage control loop and one current control loop are used. Higher PF and lower THD values are obtained by using the current and voltage control loop in the control of the proposed PFC system. The controller can control the output voltage at the desired value.

Table 1. Parameters of Simulation

Parameters		Value
Input Inductors	L_1, L_2	3 mH
Output Inductor	L_o	50 μ H
Input Capacitors	C_1, C_2	47 nF
Output Capacitor	C_o	3000 μ F
Input Voltage	V_{rms}	220 V
Output Power	P_o	100 W
Output Voltage	V_o	48 V
Grid Frequency	f_L	50 Hz
Switching Frequency	f_s	75 kHz

Figure 2 shows the simulation circuit for current and voltage control of the two active switched bridgeless PFCs. Figure 3 shows the simulation results for the input current and voltage of the proposed system. The input current is in the same phase as the input voltage. The output voltage is regulated around 48 V with a frequency fluctuation of 100 Hz. PFC is operated at 75 kHz switching frequency, 220V input voltage and 100 W output power. The PF and THD values were measured as 0.9993 and 4.0195%, respectively.

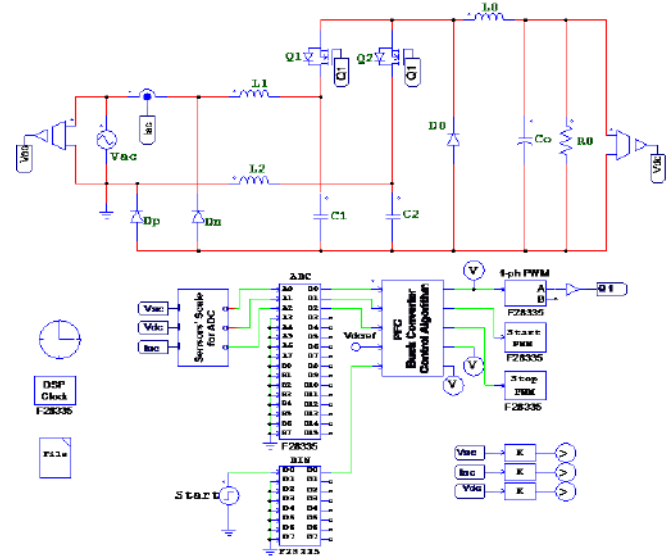

Figure 2. The simulation circuit of the two active switched bridgeless buck PFC

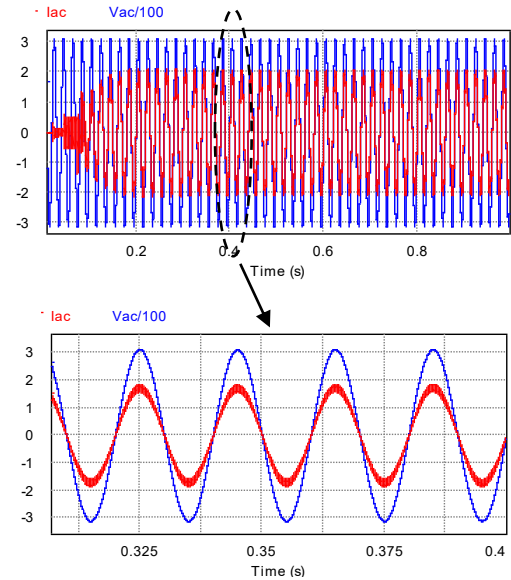

Figure 3. Simulation results of the input current and input voltage

The voltage stress on the capacitor and the switch is around 560V as shown in Figure. 4. Therefore, when selecting the capacitor and the switch, it is necessary to take these voltage values into consideration.

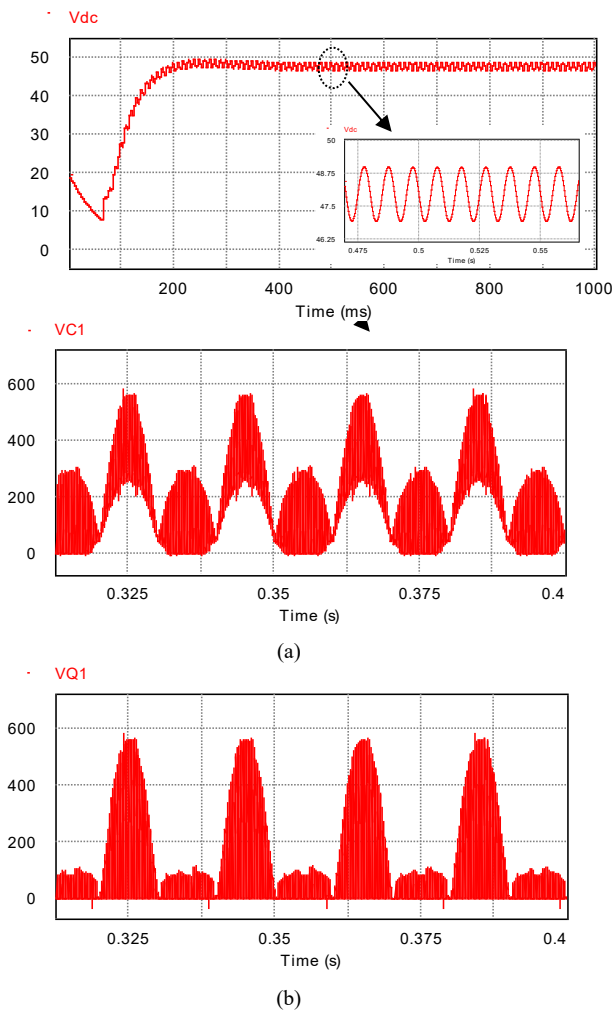

Figure 4. Simulation results of (a) the capacitor (C1) voltage and (b) the switch (Q1) voltage

As it is seen in Figure 5, the output voltage oscillates from 47 V to 49 V at a frequency of 100 Hz, fixing at the desired value of 48 V in a short period of time. The amount of oscillation can be adjusted with the output capacitor.

Figure 5. Simulation results of the output voltage (Vdc)

V. CONCLUSION

In this study, the control of the proposed single phase bridgeless PFC buck converter system is implemented using DSP control. Electromagnetic interference noise emissions are minimized by continuous input current and switching at zero voltage. In addition, total low harmonic distortion and high power factor are obtained by the current and voltage control loop. Therefore, EN61000-3-2 international standards have been provided in the proposed system. To evaluate the performance of the system, simulation studies were performed with PSIM software and embedded codes

were obtained for the TMS320F28335 DSP processor. As a result, the application studies of the proposed system will be more practical in the future.

Abstract— the characteristic parameters of the lightning electromagnetic pulse (LEMP) current have been investigated for many years on the basis of the isolation coordination by scientists studying in the field of electricity and physics. The necessity of studying in this area has arisen in order to protect the electrical and electronic equipment inside the power transmission lines and electrical installations against the harmful effects of the harmonic current of the lightning electromagnetic pulse. The Heidler function is used as the LEMP model used in this study. Analyses of the over-voltages that occur because of the lightning strike to the protection conductor on the top of a grounded pole or one of the pole conductors of the pylon are carried out. In this study, the voltage insulators of the power transmission lines used in Turkey were tested. Furthermore, the behavior of surge arresters against LEMP induced surges and currents of surge arresters used in low voltage (LV) systems was investigated.

Keywords—Lemp, Isolator Protection, Surge Arrester Protection, Voltage Distribution

I. INTRODUCTION

The energy breakdowns and interruptions in power transmission lines and power plants have mainly emerged from research conducted by weather conditions. Currents flowing in the direction of lightning electromagnetic pulses

(LEMP) can lead to high pulsating voltages in power plants [1]. In power transmission lines, when the LEMP strikes on the protection conductor and the phase conductors, the voltage on the insulators may rise due to the voltage increase. This causes the breakdown of the isolators, the deterioration of the insulation of the transformers, and the explosion of the surge arresters in the power plants [2].

Fig. 25. Lightning electromagnetic pulse and time relation [1]

(Fig. 1), the natural lightning LEMP runs at about 1000-1100 μ s, while the simulated orange curve at the LEMP discharge shows that the LEMP of 50 kA reaches its peak value in the time of 0-10 μ s and the time of 10-350 μ s it falls to half the value in my language. The LEMP current resistance characteristics of the protection elements are determined by the discharge current capacity in the range of 10-350 μ s [3]. In this study, the absorber test simulation programs performed the over voltages of the LEMP insulators used in poles and the surge arresters in the power plants, which are used as the result of dropping to the protection conductor of the power transmission lines. Since these tests are expensive in practice and experiments are difficult to repeat, programs such as MATLAB and ATP-Draw, which are designed with numerical methods using modern electronic technology, are used [4].

Many studies have been carried out to investigate the model of surge arresters on 150 kV Hellenic transmission lines, protection against over voltages in low voltage transmission lines, analysis of over voltages generated by LEMP due to type of the utility pole, and modeling of energy systems in simulation programs [5- 6-7].

II. MODELING AND THEORETICAL ANALYSIS OF THE SYSTEM

Using the appropriate mathematical equations that make up the LEMP, a voltage test was performed in MATLAB depending on the breakdown voltage of the isolators at the high voltage (HV) level and the change of the breakdown voltage of the isolators and phase angle. Furthermore, the protection behavior of surge arresters used at the low voltage (LV) level has been examined. 380 kV energy transmission lines prototype models were created and the insulators were tested for voltage. In another analysis, prototypical models of surge arresters were constructed in places with LV level such as workplaces, dwellings, and the behavior of surge arresters against over voltages and currents caused by LEMP was investigated.

A. LEMP Model:

LEMP is modeled as parallel resistance and current source with lightning path impedance in ATP model (Fig. 2). In numerical analysis, Heidler function (Equation 1) is used as LEMP numerical model [8].

Fig. 26. The current waveform of the LEMP used in the studies

$$i(t) = \frac{I_0}{\eta} \frac{(t - \tau_1)}{(t / \tau_2)^n + 1} e^{-t/\tau_2} \quad (1)$$

$$\eta = e^{\left[(\tau_1 - \tau_2) \left(\frac{\tau_2}{\tau_1} \right)^n \right]^{\frac{1}{n}}} \quad (2)$$

Where,

I_0 : Peak value of LEMP current,

τ_1 : Time constant dependent on current rise time,

τ_2 : Time constant dependent on the current delay time,

N : The steepness factor of the current.

The parameters of the Heidler function used in the study are $V = 800$ kV, $\tau_1 = 1.6$ μ s, $\tau_2 = 50$ μ s and $n = 4$, respectively. For the analysis made for the surge arrester, $I_0 = 10$ kA, $\tau_1 = 8$ μ s, $\tau_2 = 20$ μ s and $n = 2$ respectively.

B. Voltage Distribution and Protection Method on Isolators in Power Transmission Lines

In power transmission lines, in case insulators acting as insulation do not have protection armatures, the voltage distribution is not smooth.

$$U_x = \frac{U_n}{C'_E + C'_H} \left[C'_E + C'_H \cdot \frac{sh \gamma x}{sh \gamma h} - C'_H \cdot \frac{sh \gamma (h - x)}{sh \gamma h} \right] \quad (3)$$

Where,

C'_E : Capacity against soil,

C'_H : Capacity against transmission line,

U_n : The voltage at the ends of the conductor-connected isolator element,

H : Isolator height

The voltage distribution for an isolator below a certain voltage level is shown in (Equation 3). If the LEMP pulse is in a falling energy transmission line, the impact voltage will jump back to the conductors via the pole jump when the HV isolator reaches a value greater than 170 kV, which is the impact resisting voltage, causing the insulators to be damaged. That is why the grounding resistance of the poles must be reduced to the point that prevents this backlash. In the case of a voltage drop across the isolators, if the voltage that is blown during the passage of the LEMP current through the grounding conductor is smaller than the breakdown voltage of the isolators used in the overhead lines.

Insulators used in the study have a voltage lower than the voltage level of 170 kV. Therefore, it is determined that they are suitable for the line [9].

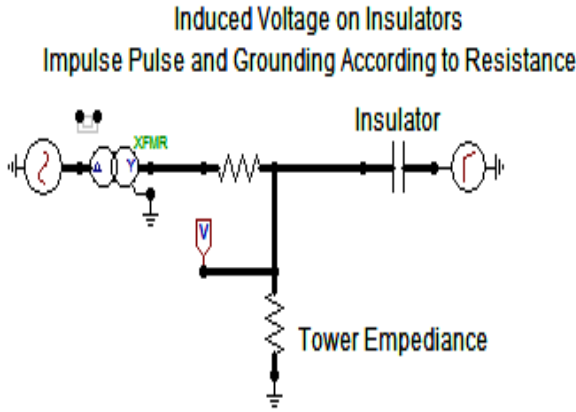

Fig. 27. Isolator voltage test circuit

The structure of the isolators and the angle between the conductor and the conductor (Fig. 4).

Fig. 28. Structure of isolators

In this study, the voltage test for the insulators was performed using the ATP model shown in Fig. 3. In a further analysis, the load voltage at the isolators due to the different openings occurring when the impulse voltage is lowered is calculated according to the form shown in (Equation 4) [10].

$$U_{load} = U_m \cdot \sin(\theta) \quad (4)$$

C. Voltage Surge Protection in Low Voltage Systems

The surge arresters are made according to the pulse discharge current of 5-10 kA. In areas where the atmospheric discharges are intensive, 10 kA, where the

lightning currents are infrequent, 5 kA paraphrase selection is appropriate. When the low voltage windings exposed to impulses, the tests showed that the low voltage windings have been damaged under the surge exceeding 34.5 kV level [11-12]. The other occasion was that the high voltage windings have been damaged under weak impulses (as low as 3 kV) but with long duration applied on low voltage windings. For the transformer connected to the overhead line with length more than 100 m, it is recommended to fit surge arrester with the transformer. However, in case of overhead line less than 100 m, there is no need for fitting the surge arrester. Under the condition that the line length is less than 100m, the applied voltage on the low voltage windings is decreased in addition to the frequency is decreased by factor 10 where in this case the overhead line capacitance is less than the winding capacitance. The surge arrester is as any device has a definite lifetime where it is impossible for its life to be infinity. The lifetime of metal oxide varistor depends on the magnitude and number of strokes. The lifetime can increase other factors by increasing the number of varistors, the varistor size or these two factors together. The surge arrester can be damaged when it is subjected to surge strokes exceeding the maximum voltage or current rating. The ideal surge arrester has the same lifetime of the power distribution network where it is installed [13].

The required conditions for any used surge arrester are [14]:

- Not to absorb current (energy) at the power frequency voltage,
- To operate correctly based on its setting designed based on the electric power system rating,
- To work in the same environment of the protected equipment.

In the study, surge arrester type is selected according to the following data:

Continuous operating voltage (U_c): 280 V,
Nominal discharge current (I_n) 8/20 μ s: 5 kA,
Maximum discharge current (I_{max}) 8/20 μ s: 25 kA,
Voltage protection level (U_p) at I_n : 1100 V,
Voltage protection level (U_p) at I_{max} : 1500 V,
Voltage protection level at long lasting surge 2ms: 850 V

This selected surge arrester is modeled and simulated in the ATP-Draw environment where the above mentioned data in accordance with Pinceti et al. model are used in order to verify the model parameters as discussed in the following section.

$$L_1 = 0.03 \cdot U_n \quad (5)$$

$$L_2 = 0.01 \cdot U_n \quad (6)$$

In this work, Pinceti et al. model is used because of its simplicity. However, its inductance parameters are calculated using relations (Equation 5) and (Equation 6) [14], where U_{r1}/T_2 is not available in the data sheet. So, L_1 and L_0 are found equal to $0.0084 \mu H$ and $0.0028 \mu H$ respectively. The nonlinear characteristics of the two elements A_0 and A_1 are given as the per-unit data (Table I).

TABLE IV. SURGE ARRESTER CHARACTERISTICS OF A_0 AND A_1 [15]

V-I Characteristics of A_0 and A_1		
$I (kA)$	$A_0 (PU)$	$A_1 (PU)$
2×10^{-6}	0.81	0.623
0.1	0.974	0.788
1	1.052	0.866
3	1.108	0.922
10	1.195	1.009
20	1.277	1.091

The surge arrester model is simulated and tested using ATPDraw circuit shown in (Fig. 5). A discharge current $8/20 \mu s$, 5 kA and 25 kA for nominal and maximum conditions respectively are injected to the surge arrester that its parameters are defined above. Adding $1 M\Omega$ resistance is used parallel with the current source in order to avoid the numerical instability of the combination of the current source and non-linear elements. Regularly, it is recommended to add high resistance parallel with the current source in the field of EMTP or ATP/Draw programs [10].

Fig. 29. ATP-Draw circuit model for the surge arrester.

III. RESULTS

In this study, the voltage test of the isolators was done in ATP and Matlab programs. In this analysis, the insulators are represented as capacitors in the analysis performed in the ATP draw program (Fig. 3). These capacitors have a capacitance value of $500 pF$, which is equivalent to the value chain insulators.

Fig. 30. ATP-Draw Voltage test on insulators

The instantaneous voltage rise in L1 phase in an isolator with a LEMP pulse is shown in (Fig. 6). In the surge analysis, the Heidler wave model was used as the voltage type. One of the surge models of low voltage systems was used for analysis. This simulation test was also implemented in the ATP program Fig. 5 and Fig. 7.

Fig. 31. ATP-Draw surge arrester type injected current (maximum discharge current).

Fig. 32. ATP-Draw Surge arrester type injected current (nominal discharge current).

In the same model, the measured current value between the A_0 and A_1 surge arresters is shown in Fig. 8.

Fig. 33. ATP-Draw Model surge arrester type residual voltage.

The model shown in Fig. 5 is also shown in the voltage value measured at point A_2 (see Fig. 9). In the Matlab analysis, the voltage distribution in the isolators (see Fig. 10) is denoted as a result of the LEMP pulse striking to the L1 phase due to the angle change in the L1 phase.

Fig. 34. Voltage waveforms measured at different inception angles θ .

IV. CONCLUSION AND DISCUSSION

Overvoltages due to LEMP, damage power transmission lines, underground cables, distribution transformers, isolators, cable glands, and even AG receivers. In this study, the analysis of the ATP application leads to investigate the overvoltages on the isolator and the protection conductors in the case of LEMP strokes in the energy transmission lines. The proper isolator was specified for energy transmission lines. The phase shifts due to lightning electromagnetic pulses and the corresponding voltage distributions on each isolator were determined. Moreover, the surge arrester behaviors in LV systems were analyzed. The results of the

LEMP analysis may lead to use more realistic pole models and may help to determine the degree of protection and isolation against overvoltages in power transmission systems. If the construction and operation of the facilities are carried out by taking into consideration the existence of LEMP's and corresponding overvoltages which cause short or long term interruptions in the electricity facilities, the uninterrupted and economical high quality power network can be maintained continuously.

TiO₂ Memristor Modelling With LabVIEW

Muhammet Emin SAHIN, Hasan GULER
Firat University, Turkey
memnshn@gmail.com, hasanguler23@gmail.com

Abstract— The fourth fundamental circuit element-Memristor, was mathematically modelled by Prof. Leon Chua in 1971. After about four decade, researchers at the Hewlett-Packard (HP) laboratories submitted the development of a new basic circuit element that completes the missing link between charge and flux linkage, which was suggested by Chua. Though a physical memristor device was not discovered then, many unique simulation applications are executed totake advantage of memristor feature which is different from other circuit elements by many researchers. In this paper, we use TiO₂ memristor model which has different mathematical equations in literature on account of its simplified expressions and the same ideal physical behaviors. Firstly, we obtained the mathematical equations of TiO₂ memristor. Then, this equations are created with LabVIEW and results are submitted. Finally, results of this system's behavior and stability analysis of are submitted.

Keywords— *Memristor, LabVIEW, modelling and simulation, physical behavior*

I. INTRODUCTION

Leon O. Chua published his work where the fourth passive two-terminal electrical component – memristor was described in 1970s [1]. Current, voltage and magnetic flux are the basic elements in circuit theory. There is a relationship between them. Three of them define the three basic devices which are resistor, capacitor, and inductor. They showed that memristor should represent the relation between electric, charge (q) and magnetic flux (φ),

$$d\phi = M dq \quad (1)$$

Memristor was developed for several times, but the scientists did not realised, that they developed a new component– memristor [2]. R. S. Williams who is leader of HP team invented this item, while they have been searching for a device which is a resistor with a state and not for a device, which has charge – magnetic flux relation. This work was published in [3] and it include the first relations for memristor modeling. Memristor has drawn the worldwide attention after HP released its invention. After then many researchers focus on this element. Owing to different properties, memristors are being found out for many potential applications in the areas of nonvolatile memory very-large-scale integrated (VLSI) circuit, digital image processing, artificial neural networks, and pattern recognition and signal processing [4].

In this paper, we focalize the memristor modeling with LabVIEW. We submitted memristor model with different mathematical statement. Similar works have not founds up to, thus we assume that this is a different publications of the models and simulations described below. In methods, our nonlinear model of the memristor is presented and a formula is given in order to infer model parameters used physical parameters. In methods, measurements of simulation are defined. Final part of methods contributions of this paper are summarized.

II. MEMRISTOR

A. HP TiO₂ Memristor Model

In 2008, R. Stanley Williams of Hewlett Packard was submitted an experimental solid state version. A semiconductor device was either use magmatic field as flux or keeps charge as capacitor, memristor which has memory feature used chemical mechanism. One of the film slide depletion of oxygen atoms. The absence oxygen act as carriers it mean that the depleted layer has lower resistance than the non-depleted layer. Meanwhile the resistance of the film as all is dependent on how much charge has been went through it, in a particular direction, which is convertible by changing the direction of current. [5-7]

Figure 1. Memristor

A memristor device is essentially a two-terminal passive electronic element with memory capacity. Its memristance state is affected from amplitude, polarity, and duration of the external applied power. The physical model of the HP memristor from [7], shown in Figure 1, consists of a two layer thin film (thickness $D \approx 10\text{nm}$) of TiO₂ sandwiched between two platinum electrodes. One of the layers, which is described

as TiO_2-x , is doped with oxygen vacancies and thus it exhibits high conductivity. The width w of the doped region is modulated depending on the amount of electric charge passing through the memristor.

Figure 2. HP's memristor model

Fig. 2 exhibits HP's memristor model. We see that total memristance is made of w and D regions. The total resistance of the memristor,

M , is a sum of the resistances of the doped and undoped regions:

$$M(t) = R_{on} \left(\frac{w(t)}{D} \right) + R_{off} \left(1 - \frac{w(t)}{D} \right) \quad (2)$$

where R_{on} and R_{off} are the limited values of memristance for $w=D$ and $w=0$. We selected internal state as $x = w/D \in [0,1]$ then we rewritten as

$$M(t) = R_{off} + (R_{on} - R_{off})x(t) \quad (3)$$

When $t=0$, the initial memristance is

$$M_0 = R_{off} + (R_{on} - R_{off})x_0 \quad (4)$$

Resistance of doped area affects the movement speed of the boundary between the doped and undoped regions.

$$\frac{dx}{dt} = ki(t)f(x), \quad k = \mu_V R_{on} / D^2 \quad (5)$$

where $\mu_V \approx 10^{-14} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$ is the average ionic mobility parameter. As for a memristive device, these nonlinearities are manifested particularly at the thin film edges, especially at the two boundaries [8].

This phenomenon, called nonlinear dopant drift, can be simulated by multiplying a proper window function (x) on the right side of (5). We use this window function for increasing the nonlinearity.

Figure 3. Joglekar window function for $P=1$, $P=3$ and $P=5$

$$f(x) = 1 - (2x - 1)^{2P} \quad (6)$$

where P is a positive integer called the control parameter. Fig. 3 shows the behaviour of the Joglekar window function for different values. Nonlinearity changes with value of P integer. As the integer P increases, the model tends to the linear. Based upon this, we selected $P=1$.

$$f(x) = 4x - 4x^2 \quad (7)$$

Substituting (7) into (5),

$$\int_{x_0}^{x(t)} \left(\frac{1}{x(\tau)} - \frac{1}{1-x(\tau)} \right) dx(\tau) = \int_0^t 4ki(\tau) d\tau \quad (8)$$

Where the internal state variable satisfies $x(\tau) \in [x_0, x(t)]$ and the integration time is $0 \leq \tau \leq t$.

Assume $q_0=0$; we can get

$$\frac{x(t)}{1-x(t)} = \frac{x_0}{1-x_0} * e^{4kq(t)} \quad (9)$$

Then the expression of $x(t)$ can be calculated as

$$x_0 = \frac{R_{off} - R_0}{\Delta R} \quad (10)$$

Then, the expression of (t) can be calculated as

$$x(t) = 1 - \frac{1}{Ae^{4kq(t)} + 1} \quad (11)$$

where A is a constant and its value is determined by R_{off} , R_{on} , and R_0 :

$$A = \frac{R_{off} - R_0}{R_0 - R_{on}} \quad (12)$$

This mathematical statements are used for modelling memristor. They are made control and simulation block in LabVIEW.

III. MEMRISTOR MODEL WITH LABVIEW

We developed a behavioral model of a memristor at device level using the LabVIEW programme by following the mathematical equations presented before. The reason of preferring the LabVIEW program is its graphic based structure and the ease provided to user in constituting interface. [9] We examined TiO_2 memristor model to make it easy to comprehend and ready to be used in memristive systems.

We used LabVIEW programme which is a graphics-based software platform. The usage of program is going up in engineering applications for making this model [9]. We used mathematical equations which are given previous part. Model depicted control and simulation block in LabVIEW. Fig.4 shows the memristor model of LabVIEW front panel.

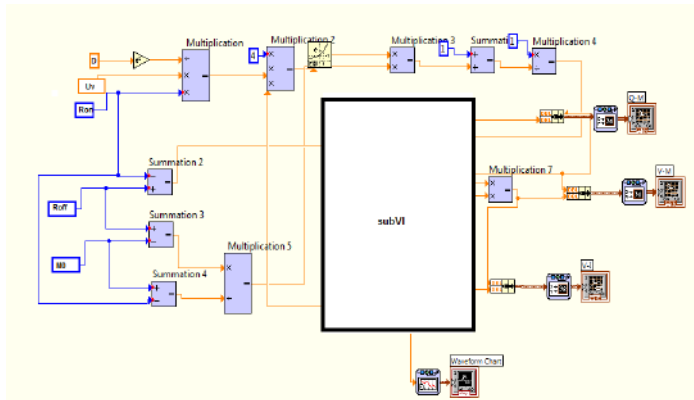

Figure 4. Memristor model of LabVIEW

The parameters of the model are $R_{on} = 100\Omega$, $R_{off} = 20\text{k}\Omega$, $M_0 = 10\text{k}\Omega$, $D = 10\text{nm}$ and $\mu v \approx 10^{-14} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$. [7-8] Moreover, the simulation results in Figure 6.

IV. RESULTS

In order to show memristor characteristics, values of passive elements, and, are chosen to work firstly 0.5mA input current at 5 Hz . Memristor model was simulated to examine the behavior via using LabVIEW program. The simulation results are exhibited in Fig. 5, 6, 7 and 8.

Figure 5. Memristor's current graph

Fig. 5. shows that input current graph to time. The value of this is 0.5 mA sinus flowing through the memristor in this model.

Figure 6. Relationship between memristor's current (I) and voltage (V)

The typical hysteresis loop in figure 6 shows its switching characteristic; that is, the memristance can switch between low resistance and high resistance.

One of the most important memristors' observed specialty is the existence of a pinched hysteresis that effect could be represented by the $i-v$ pinched hysteresis loop characteristic, as Chua highlighted that 'If it's pinched, it's a memristor' [11].

Figure 7. Relationship between memristor's voltage and memristance

Figure 7 illustrates that the memristance is a nonlinear function of the flow of charge. Figure 8 shows the relationship between the memristance M and the charge q . Especially, in the part of the higher memristance state, the change ratio of the memristance is low, while, in the part of the lower memristance state, the change ratio of the memristance is high.

Figure 8. Relationship between memristor's charge and memristance

If we increase input signal frequency, memristor behave as linear resistor. Fig.9 shows signal frequency is at 20Hz and fig.10 shows that memristor's loop turns the line chart at 200 Hz.

Figure 9. Relationship between memristor's current (I) and voltage (V)

Figure 10. Relationship between memristor's current (I) and voltage (V)

V. CONCLUSION

Although HP workers has invited to memristor physically, it is not submitted to the market yet and it will be probably not available for at least some years. Hence, memristor studies are still going on theoretically and based simulation. This paper is one of them. Since memristors have a natural nonlinear behaviour, they can be used in chaotic circuit systems and other different systems such as secure communication and cryptology. The main aim of this study is to show the possibility of application of memristor based circuits. LabVIEW environments were used to achieve simulation and real time application.

Abstract— We report a low cost, field-deployable, reflection based smartphone spectrometer to detect dyes in a body of water. Exploiting built-in flash and camera of smartphones, a customized cradle is fabricated for reflectance based spectroscopy with no requirement for additional electrical parts. First, we evaluated the success rate of the designed spectrometer in identifying methylene blue (MB) reflectance in water with a limit of 0.1 ppm. Then we contrasted our design with that of a commercial spectrometer for reflectance spectra. The resulting condensed, less-costly and high-speed platform could facilitate remodeling the science of measurement for sustainable water management.

Keywords—*smartphone spectrometer; reflection spectroscopy; environmental sustainability.*

I. INTRODUCTION

Dye accumulation in water is harmful to humans and environment and optical spectroscopy is a major measurement method for detection of dyes [1, 2]. Field portable measurement devices offer great advantage to their bulky laboratory counterparts due to similar performance and ability to detect at the location of interest. Smartphones with their embedded hardware are great candidates for spectroscopy instrumentation [3]. By using the flexibility of 3D printing, smartphones can be converted to colorimetric plate readers for ELISA (enzyme-linked immunosorbent assay) immunoassays [4], to absorbance spectrometers for biomarker analysis [5], or to a fluorimeter to detect mRNA sequences [6]. On the other hand, a smartphone without a 3D apparatus is enough to analytically analyze color test strips [7, 8]. For smartphone based spectroscopy, the wavelength range is limited to visible range (400-700nm) owing to the simple optical filters for ultraviolet and near-infrared. A dispersive element placed at a certain angle is used right before the camera to obtain color spectrum image, which is later used to extract absorbance value. Recent work on smartphone spectrometers integrating fiber optical cables aimed to monitor food quality [9]. Moreover, smartphone spectrometers with no external active components (i.e. LEDs, lasers, incandescent sources) were reported for

surface plasmon resonance based refractive index sensing [10], and simultaneous glucose and troponin I detection [11].

Recently, an ultra-low cost plastic fiber based smartphone spectroscopy system was proposed for detection of dyes in water and contribute to environmental sustainability [12]. It requires no extra optical and electrical components, uses camera flash for optical source and camera for spectrometric detection. Here we report an improved version of the plastic fiber based system in the form of reflection spectroscopy integrated onto a smartphone. To enable reflection measurements, a custom cradle was designed to align plastic optical fibers onto the phone camera and flash. A bifurcated fiber design on a dipping apparatus was used along with a small mirror to allow reflection measurements. The system can be used without any liquid extraction from the water source of interest. Our design is very low cost, ultra-stable and enables smartphone based detection of dyes in water using reflection.

II. EXPERIMENTAL METHODS

A. Spectrometer system for smartphone

The smartphone spectrometer was designed by using LG G4 (1/2.6" sensor size with 5312x2988 resolution, 1.12 μm pixel size). The rear-facing camera of the phone was used in capturing to get high resolution images and to be able to use flash of the smartphone. The cradle design includes a hot-plug apparatus holding a diffraction grating, and a smartphone case holder keeping the whole part compact with reflection measurement apparatus were fabricated from the Acrylonitrile Butadiene Styrene (ABS) polymer using a 3D printer (Zortrax M200). The total polymer usage was about 120 g.

In the cradle design, two pieces of plastic (PMMA) fibers were used as one is a 1.5 mm diameter fiber couples the light from the cellphone flash to the reflection measurement apparatus while the other is a 0.25 mm diameter fiber collects the transmitted light, which passes through a linear

diffraction grating (1000 lines per mm, Rainbow Symphony) at an angle of $\sim 42^\circ$ to the normal to reach the smartphone camera. A photographic image of the dipping apparatus is shown in **Hata! Başvuru kaynağı bulunamadı.** To make the design cost-effective, it was simplified by avoiding usage of any collimating lens or mirror components in the light pathway. The alignment of the smartphone flash and camera was implemented mechanically. The total cost of design is less than \$10 which significant part of it caused by 3D printer material. Besides the cost, the plastic optical fibers have an advantage, as compared with glass-based optical fibers, because of its ability to use them without any special tools for stripping and cutting.

B. Image processing

An image is recorded by a digital camera using a two-dimensional array of pixels. When a pixel receives a light, intensity value increases with the number of photons stored in the pixel. Earlier cameras were designed to generate only grayscale images as the pixels cannot classify the photons with respect to color. After each pixel is covered by the color filter array which allows only red (R), green (G) or blue (B) primary colors, then a color image can be captured since the pixel stores only filtered photons which give the intensity value for the respective color. When light passes through the color filter, each pixel contains one of R, G or B color information. By knowing only one color value of each pixel, a RAW image can be created. However, other two color values are unknown for each pixel. To address this issue, demosaicing method was proposed which calculates missing two color values by interpolating from nearby neighbors where those colors are known. Many methods have been proposed such as white-balance, gamma correction, color space correction and compression to obtain viewable image like JPEG.

Conversion of RAW images into JPEG image formats offers some advantages such as occupying a small size and being instantly displayable. However, this conversion causes loss of information due to the compression, having a non-linear RGB color space [13]. In addition, JPEG image formats provide an 8-bit color depth while RAW images have 10–14 bits color information. RAW images do not have any post-processing and contain original image data. If the post-processing steps are applied to the RAW image, it causes corruption of linearity information. Linear images keep the linear relation between the intensity value and the number of received photons which is essential for quantitative scientific data acquisition as a linear relationship with scene radiance is maintained.

Although the RAW images keep the linearity, the issue with this format is difficulty in using the images. Therefore, there are many attempts to approximate raw (linear) RGB from nonlinear RGB images. In that sense, a series of training images captured under different settings and light conditions as well as ground-truth raw images to model a relation between RAW and nonlinear RGB images [14]. To

simplify this approximation process, it is reported to use just gamma correction [15] to overcome nonlinearity problem which has not been verified by other researchers yet. Here, the images were captured and processed in RAW format due to the limitations of the JPEG format. In addition, using raw

(a)

(b)

Fig. 1 (a) The launch and receive port reflectance based sensor when the camera flash is ON; b) The output spectrum comparing smartphone and commercial spectrometer for fluorescent light. (HSV) means the Value is plotted.

data allows to make precise image analysis in our experiments. The problem arises capturing a RAW image with smartphone. It is usually available to get a RAW image from semi-professional and professional cameras.

Recently, smartphone companies produce the smartphones which provide access to raw image data free from postprocessing. One of three RAW file formats can be chosen to work with RAW data. Nikon and Canon companies released their RAW file formats which are “.NEF” and “.CR2”, respectively. In this study, “.DNG” raw file format was chosen since it is a common open format. After the images were captured using smartphone, they were transferred to a computer to process in Matlab environment. The reliability of the camera was tested by capturing five consecutive images and checked normalized values of the images. It was found $\pm 2.73\%$ difference with respect to the average. To improve the reliability of the results, it was decided to use the average of five consecutive images in processing and analyzing the experiments. In addition, same conditions such as the same shutter speed and ISO were set,

and to avoid any possible post-processing performed by the smartphone, manual mode was selected when the images were captured. After that, they were processed with freely available DCRAW software [16] to convert them to tagged image file format (TIFF) for easier extraction of the R, G, B values. Main advantage of using DCRAW is to keep the linear relationship between RAW images and the radiance scene even after conversion. Then, these RGB values were converted to HSV (Hue–Saturation–Value) due to its robustness to the illumination change. For the further processing steps of the image, the V (value) was employed as it was defined, for this study, the amount of the transmitted light through the solution.

A calibrated fiber-optic spectrometer (HR2000; Ocean Optics, FL, USA) was used with a fluorescent lamp to convert each pixel index in the image into its corresponding wavelength value. The detail description of this method is given in [17] which assumes that there is a linear relationship between the wavelength value and pixel index, and extracted spectral resolution values for different size plastic fibers. A resolution of 0.26 nm per pixel is obtained using a 0.25 mm plastic fiber while larger diameter 0.5 and 1.0 mm fibers gives spectral resolutions of 0.265 nm per pixel and 0.27 nm per pixel, respectively. **Hata! Başvuru kaynağı bulunamadı.b** shows the spectrum with the 0.25 mm plastic fiber which closely resembles the spectrum of the calibrated spectrometer, even though the spectral line shapes obtained from different sized fibers show fluorescent light characteristics with 4 peaks between 400 and 700 nm. It is also noted that the spectral resolution and signal-to-noise ratio are directly related to the fiber diameter.

III. RESULTS AND DISCUSSION

We measured different concentrations of MB solution using the developed reflectance based spectrometer. A stock solution of MB dye (50 ppm) was prepared and diluted to the required initial concentrations from 10.0 ppb to 2.5 ppm.

(a)

(b)

Fig. 2 (a) The photograph of MB solutions from 0.01 to 2.5 ppm. (b) The spectral images of the MB solutions.

The concentration range was designed to achieve a high dynamic range and to observe if we can reach a much smaller limit of detection. The solution color gets darker with concentration and the solutions with PPB concentration are almost transparent color (**Hata! Başvuru kaynağı bulunamadı.a**). Although the color of MB is blue, the absorption band is around 664nm, which corresponds to red spectrum. The **Hata! Başvuru kaynağı bulunamadı.b** shows the spectral images of the MB solutions. The red portion of the spectrum starts to lose intensity (8-bit pixel value) as the concentration gets bigger. The green and blue portions of the spectrum are saturated due to high intensity of light.

(a)

Fig. 3 (a) Absorbance spectra obtained from smartphone and commercial (b) The absorbance at 664 nm with standard deviation.

The calibrated spectrum of smartphone spectral images for MB solutions and the spectrum of commercial optical spectrometer (Ocean Optics) with reflection measurement apparatus are shown in **Hata! Başvuru kaynağı bulunamadı.a**, respectively, with solid line with abbreviation of smartphone (sp) and dashed line with “oo” abbreviation. There is a good agreement between the spectrums. It is important to note that the smartphone spectrometer dipping apparatus has an opening of 1.4cm for liquid entrance while the commercial spectrometer has 0.5cm. Hence, the values obtained from commercial spectrometer were multiplied by a value of 2.8 for all the spectrum data.

The absorbance vs. concentration plots show linear relationship for both systems and the coefficients of determination (R^2) are 0.981 and 0.978 for smartphone and commercial spectrometer, respectively (**Hata! Başvuru kaynağı bulunamadı.b**). The limit of detection (LOD) for smartphone based spectrometer is 109ppb that is 3 standard deviations above the distilled water measurement.

By increasing the optical path length by 1.4 times, we were able to reduce the LOD from ~500ppb in our previous report [12]. The sensitivity of the system was increased from 0.1817 ppm^{-1} to 0.5574 ppm^{-1} . The different slope between the commercial and smartphone spectrometer suggests that the analytes should be characterized by the same smartphone instrument.

IV. CONCLUSIONS

In this paper, we proposed a new smartphone spectrometer in the form of reflection spectroscopy integrated onto a smartphone, which is produced from plastic fiber and therefore has ultra-low cost, to examine MB dye reflection.

The reflection measurements were obtained with a custom designed cradle and the influence of fiber size on the spatial and spectral resolution is evaluated. Images were captured in RAW format to obtain more information about the measurements. With proposed system, we obtain significant reduction in the LOD which leads to an increased sensitivity for detection of dye in the water. Another contribution of our proposed system is to prove that it is not necessary to take a water sample to detect dye; instead it can be measured by simply dipping apparatus.

Abstract— The studies for the visually impaired have slightly progressed with development of technology, even so previously mentioned studies are not yet at the desired level. At the present time, visually impaired persons keep continue to use white cane. When taking into consideration of the complaints and the difficulties encountered of these persons, it is not possible to ignore that situations.

In this study, an electronic smart walking stick has been designed for visually impaired persons. Creating a structure that is for visually impaired persons make themselves feel safe via assembled components which are on the cane has been intended. With this purpose, increasing of their movement ability without being in need an additional component, determining their location and easily contact with them in required situation has been provided via microcontroller. On the whole, this mentioned walking stick has been designed as like giving a warning when detect obstacle, providing them to being noticed when the environment is getting dark, if necessary carrying out process which are calling and sending message via GSM and determining location. In consequence of these features, roaming autonomously and ensuring that they may be more adaptable to society has been intended for visually impaired persons.

Keywords—Disabled People, Visual Impairment, GPS, GSM, Arduino, RF, Walking Stick, Voice Recognition, Pulse, Obstacle Detection

I. INTRODUCTION

Finding direction and mobility is important for both children and adults in terms of changing place in their own world safely and effectively. Mobility is a big problem for people who are visually impaired. According to reports of World Health Organization(WHO), 285 million people are visually impaired and 39 million people are totally blind. Vision defect has a significant influence on life quality and the ability of working and developing individual relationships of people. Although some people make improvement for

those people to go on their daily lives, this is not enough. An obstacle may not be dangerous for everyman, but it endangers for visually impaired people. They hardly perceive ambient conditions, thus they have difficulties while moving [1], [2]. Today many blind people rely on other people, dogs or walking sticks to enter the buildings. The handicapped prefer to sort their works out independently instead of relying others [3]. As the technologies, which are used by everyone, improved, solutions, which are user centered, can be more easily found. Innovative devices become sufficient for the cases which people face around them.

According to World Health Organization, Assistive Technology (AT) is defined as product, tool, equipment, or technology to improve the life of disabled person. AT aims to help disabled people for their needs of special training and rehabilitation, cope with daily troubles and get a better quality of life [4]–[6]. At the same time, to develop devices to support the old people is really important. That provides to demand devices which expand the length of life and improve the health. [7].

Historically, walking sticks and cabinet accessories help and protect the disabled people. Walking sticks are guide to visually impaired people and thanks to them, those people can find their way easily. These rescuers also help the old people while they are walking or working. That they fall is one of the cause of physical injury. Falling causes bone fracture and brain injury [8].

In this study, it is provided that blind or old people's ability of mobility have been increased, so they can feel better while doing something without need of anyone. Also, their location can be found by competent authority in case of any injury via more than one microcontroller.

Determination of obstacle and ability of direction are carried out with various distance sensors, GSM and GPS modules, voice recognition and voice command, MP3 module, micro SD card, RF technology, LDR and LED, sensors of pulse and beat, and Ion and LiPo batteries to provide power to the system.

II. METHODS

A. Assistive Technology

In terms of assistive technology, there are various definitions. All of these definitions, the one, which is the most common, is that a tool or a piece of tool provides the disabled people to include in a society. Among traditional support techniques, there are white canes, narrators, leading strings and something like that. White canes give information about the environment, but they are not to be such as to define the obstacle which is one meter ahead of the level of underbelly. Fig. 1 shows the characteristic movement of a white cane [9].

Fig. 35. The characteristic movement of a white cane [9]

Assistive technologies have the potential that they increase the quality of lives of the disabled people with secure. Also these technologies, which encourage them to go out of their normal environment and direct them to interaction with other people, decrease their fear of social isolation [2].

Assistive technology devices, which visually impaired people use to be warned, are portable electronic devices which are held and worn. Many technology devices use ultrasound techniques to measure the items in terms of their distance. Some of them use an infrared light giver or laser technology to find and warn the obstacle. These devices demonstrate some problems. The most important ones are about the interface which transmits the data of obstacle to the user. Each module of the devices should work independently [10].

B. Arduino Mega 2560

Arduino Mega 2560 is an improving card which is based on ATmega2560 microcontroller. It consists of 54 digital inputs / output pins, 4 UART 16 MHz crystal oscillator, USB connection, power jack, offline serial programming header and reset button. They can be used to improve

interactive tools, to get the inputs from the various toggles and sensors and to control other physical outputs. Table 1 shows specification of the Arduino Mega 2560 [1], [11]. Arduino Mega is shown in Fig. 2.

TABLE I. ARDUINO MEGA SPECIFICATIONS [1]

Microcontroller	Atmega2560	Analog Input Pins	16
Operating Voltage	5V	DC Current for 3.3V output	50 mA
Input Voltage	7-12V	Flash Memory	256 KB
Input Voltage (limit)	6-20V	SRAM	8 KB
Digital I/O Pins	54 (15 PWM)	EEPROM	4 KB
DC Current for Each I/O Pin	40 mA	Clock	16 MHz

Fig. 36. Arduino Mega [12]

C. MP3 Player Shield

In the mold of MP3 Player Shield, there is VS1053B voice handler and that provides decoder for voice folders. VS1053, OGG/MP3/AAC/WMA/MIDI support the types of data and it connects to the microcontroller via SPI. The card gets 5V over Arduino and it reduces 3.3V and 1.8V with regulator and gives energy to VS1053B. On it, there is a socket of 3.5mm headphone and micro SD memory card. Track files, which are downloaded to the micro SD card, are transmitted by decoding by card. Fig. 3 shows MP3 Player Shield [12].

Fig. 37. MP3 Player Shield [12]

D. Voice Recognition Module

Voice Recognition Module is an electronic module used to control anything by using voice. In voice recognition module, 15 voice command can be recorded. Voice recognition module is connected to speaker. After the voice is recorded, the command with the voice of anybody else can not be applied. Operating voltage is between 4.5V-5.5V and operating current is lower than 40mA. Digital interface is about 5V TTL, UART is GPIO. Analog interface is 3.5mm mono channel microphone connector. Fig. 4 shows Voice Recognition Module [13].

Fig. 38. MP3 Player Shield [13]

E. GSM/GPS Module

GSM is an open, digital, raster technology used to transmit voice and data. The module of GSM use the technique of TDMA [11]. The module of GGS01 GSM/GPS consists of Simcom with quad-band and SIM900 GSM module matching to RoHS and SIM28 GPS module. Fig. 5 shows GSM/GPS Module.

Fig. 39. GSM/GPS Module

F. E18-D80NK IR Digital Distance Sensor

It is an adjustable, distance sensor. When it perceives an obstacle, its velocity is 0V, if there isn't any obstacle, then it is 5V. Also in logic level, it can be seen as 1 or 0. Its distance can be adjusted between 3-80 cm by an adjusting button. Output current is 100Ma, and reaction time is 2ms. Fig. 6 shows sensor and working principle [14].

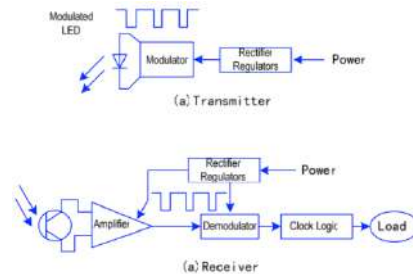

Fig. 40. E18-D80NK IR Digital Distance Sensor [14]

III. RESULTS AND DISCUSSION

The system consists of two main molds as mechanic and electronic. In the part of mechanic, there is a plastic box keeping walking stick, electronic component and equipment. In electronic part, there is LDR, LED, resistor, Arduino Mega, jumper wires, MP3 Player Shield, voice recognition module, NRF24L01 RF module, GSM/GPS module, E18-D80NK infrared digital distance, pulse sensor, LIPO and Li-Ion battery, micro SD memory card, SIM card, on/off switch, microphone and headphone, PL2303HX USB-TTL converter. To carry out software operations, computer, Access Port serial port communication program, C and C++ based software scripts, AVR-GCC compiler, Java based IDE (Arduino IDE) and RF protocol

implementation. Fig. 7 shows a blind user walking with a smart stick.

Fig. 41. Blind user walking with a smart stick.

Seven basic function such as lighting, communication, power supply, determination of obstacle and finding direction, searching, sending of SMS in optional case or in accord with the pulse data and learning location data are observed. In the study, the processing lining up below, are obtained;

-Lighting system composed of LED and LDR steps in, when the Sun sets and gives a warning in the shape of a flasher.

-The system of communication is provided with the model of NRF.

The system of power supply is provided with 7.4V 3000mAh featured Li-Ion battery and 3S 25C 1050m featured LiPo battery. The function of determination of obstacle and finding direction is perceived by IR sensor, a type of E18-D80NK, which has a definite range sensor and it is implemented to give warning with headphone via MP3 module. Searching processing is practiced via GSM module after the voice command is practiced over the voice recognition module. Sending of location SMS in optional case or in accord with the pulse data is practiced, when the obtained location data is transmitted with GSM module via GPS module after filtering the pulse sensor used or voice command is practiced over the voice recognition module. As for learning the data, it is practiced to give warning with headphone via MP3 module after the voice command is practiced over the voice recognition module. Components that used in system are shown in Fig. 8.

Fig. 42. System components

One of the most important characteristics of the study is that visually impaired people use the functions on walking stick by only talking under normal conditions or in any emergency case and that the notification is sent vocally. Use of sensor, which is not sensitive, remain incapable in terms of determination of direction. To prevent that visually impaired person is warned with buzzer system by being determined with the help of sensors in the system. Hence, the accidents, which is possible to occur, are stopped and those people can find their ways more easily. To reduce the conflict of wires, communication is carried out with RF communication without any wire between two Arduino in the system. Because of the fact that there is the system of voice command, no need for any control circuit. If the individuals are thought to use the mechanism in a dark place, a lighting system associated with walking stick, which is to step in, provides the individuals to be recognized by others more easily. Pulse data is used for the purpose of sending the SMS including location data to necessary people, when the pulse endangers. That there are sound control and notifications for all functions provides people convenience in terms of using the walking stick.

After the place of components (sensors, modules, electronic coponents, battery, and plastic box, etc.) has been detected, connections are made by being carried out cabling function. Figure 9 has demonstrated the walking stick, the sensors placed on walking stick, modules, electronic componenets, plastic box in which equipment is placed.

Fig. 43. Smart walking stick and components

TABLE II. ARDUINO MEGA SPECIFICATIONS [1]

1	Pulse Sensor	7	GSM Antenna
2	Voice Recognition Module	8	Arduino Mega
3	Mic	9	NRF24L01 Module
4	IR Distance Sensor	10	LDR
5	LiPo Battery	11	LED
6	GPS Antenna	12	On/Off Switch

The ability of the disabled person who is a walking stick user uses the voice command to learn, search and send the location as a message by the functions of the system. Fig. 10 shows the location notifications that system sends. Functions such as the illumination system for the awareness, the detection of the obstacles and the warning of the user, the acquisition of the pulse data (the user's finger must touch the sensor in order to be able to receive the pulse data) and an automatic location notification message is sent with an indication of the dangerous situation, work without expecting any command from the user [15].

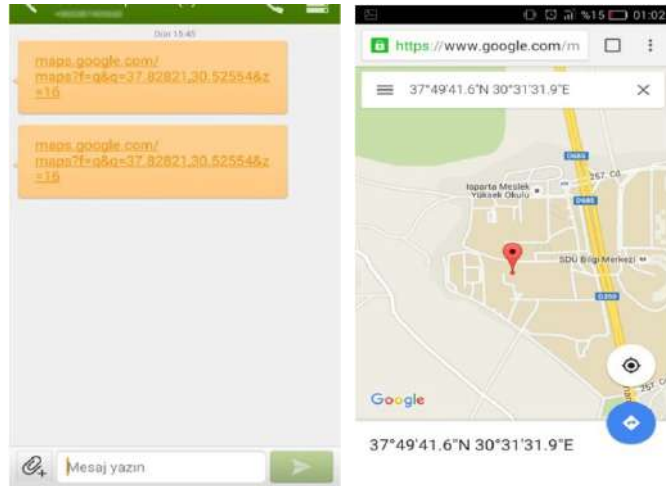

Fig. 44. Send location SMS and Google Maps screen

IV. CONCLUSION

In this study, some problems of visually impaired and elderly people are solved. It is aimed to increase the activities in business and social life of visually impaired people. Visually impaired people are provided with the ability to detect the direction through a walking stick, feel safe, be protected against any danger, find out if they can achieve their goal. It is also aimed to remind them that we have not forgotten the visually impaired people and increase the sensitivity of the society to a certain extent. Considering researchs and experiences in the next years, will increase and develop for the disabled and elderly people.

Abstract— The methods which are used for the production of electrical energy contaminate our nature. Fossil energy sources (coal, oil, natural gas) thermal reactor, hydroelectric power station are commonly used and they are methods which damage our nature so eco-friendly systems should be developed and expanded for a better world. One of the eco-friendly systems which are commonly used is PV (photovoltaic) systems in recent years.

Maximum Power Point Trackers (MPPT) are used to get potential maximum power from Photovoltaic Source Energy Production Systems. Using MPPT, it is aimed to reduce minimal levels the situation of not able to take electric energy which is taken from photovoltaic panels because of load and environmental conditions. In this study, smart playground lighting which powered with solar energy was carried out. Perturb & Observe algorithm which is used to find maximum power point was used. A lighting system which works with solar energy was used to test created Photovoltaic system.

Keywords— MPPT, DC-DC Converters, Energy Efficiency, Photovoltaic Systems, LED lighting.

I. INTRODUCTION

Alternative energy sources are being searched because of the rapid depletion of fossil fuels, and they are also being searched to meet energy demand worldwide. Solar energy technologies are sustainable and clean energy which are important components of the future [1]. Solar energy has an important role to meet the growing demand for electricity with a reduced environmental impact [2]. In recent years, the use of photovoltaic power increased significantly which supports electricity network. Reduction of the cost of photovoltaic solar panels caused development of the big scaled solar energy plants which are connected to medium and high voltage electricity networks [3]. Personal interest in the

photovoltaic solar panels has risen quickly in recent years even the consumers don't abandon using energy by old traditional fossil fuels [4]. Even after obtaining energy from photovoltaic solar panels, green houses which can be combined with agricultural production has started to emerge [5].

Photovoltaic systems convert solar energy directly into electrical energy. Photovoltaic cell is the most important component of a PV system which converts solar energy into electrical energy. PV cells combine to create PV modules. Inverter, battery, electrical elements, installations elements are the most important component of PV modules. PV modules are connected each other in series and parallel configurations because of getting high power. The efficiency of solar panels depend on parameters such as internal resistance, contact patterns, the material that they produced, temperature and solar intensity changes [6]–[8]. In the world, photovoltaic panels, solar energy applications and investments are increasing. Photovoltaic energy trading and the production of photovoltaic cells are promoting [9].

In this study, smart playground lighting which powered with solar energy was done. Perturb & Observe algorithm was used to find maximum power point. The energy stored by this method has been spent using LED lighting elements in places such as parks, walkways, and bicycle paths. The brightness of these LED luminaries was adjusted according to the signal from the ultrasonic distance sensors placed on poles.

The authors acknowledges TUBITAK for the realization of this study, providing financial support within the "2209-A College Students Domestic/Abroad Research Projects Support Program".

II. METHODS

A. Photovoltaic Modules

A solar cell is a p-n junction fabricated in a thin layer of semiconductor. Electricity is being generated by converting the electromagnetic radiation of solar energy through photovoltaic effect. Being exposed to the sunlight, photons with energy greater than the band-gap energy of the semiconductor creates some electron-hole pairs proportional to the incident irradiation. The equivalent circuit of PV cell is shown in Fig. 1 [1].

Fig. 45. The equivalent circuit of PV cell

The total output current and power equation of the parallel and series connected PV modules are expressed in equations (1) and (2) [2]. Parameters in equations (1) and (2) are explained in Table 1.

$$I_{pv} = N_p \left(I_{ph} - I_0 \left[\exp \left(\frac{q(V_{pv} + R_s I_{pv})}{N_s A k T} \right) - 1 \right] - \frac{(V_{pv} + R_s I_{pv})}{N_s R_p} \right) \quad (1)$$

In equation (1), the series resistance R_s value is extremely low and the parallel resistance R_p value is extremely high for silicon in idyllic state. Therefore, the value of R_s and R_p can be neglected and the generated power by PV is calculated with V_{pv} and the simplified I_{pv} in equation (2) [2].

$$P_{pv} = V_{pv} \times N_p \left(I_{ph} - I_0 \exp \left(\frac{q V_{pv}}{N_s A k T} \right) - \frac{V_{pv}}{N_s} \right) \quad (2)$$

TABLE I. EQUATIONS' PARAMETERS

Symbol	Explanation
I_{pv} and V_{pv}	Output current and voltage
R_s and R_p	Series and parallel resistances
N_p and N_s	Number of modules connected in parallel and series
A	P-N junction ideality factor
k	Boltzmann's constant (1.38×10^{-23} J/K)
T	Temperature in Kelvin
I_{ph}	Photon current
q	Electron charge (1.6×10^{-19} C)
I_0	Reverse saturation current

B. DC-DC Converters

DC-DC conversion technology is an important research area in the field of power electronics and has been under development for decades. DC-DC converters are commonly used in applications requiring regulated DC power such as computers, communication devices, battery chargers, switched mode power supplies, and DC machine drive applications [10]. Therewithal, DC-DC converters are being used for applications of smooth speed control of engines applications and have advantages such as high efficiency and dynamic response [11]. DC-DC converters are circuits that generally give steady output and convert DC voltage to another voltage level. DC-DC converters are being used for obtaining stabilized or changing DC voltage(s) by increasing, decreasing or multiplexing from any DC source [12].

Commonly, rectified and unregulated DC voltage obtained from line voltage is used as an input to these converters. So that step-up and step-down processes are being handled a priori as an input to these converters. Unregulated DC voltage levels are regulated by using DC-DC converters [10].

Three fundamental structures of DC-DC converter circuits are buck, boost and buck-boost converters. Other converters are developed from these three main structures [10]. In Fig. 2, DC-DC converter block diagram is shown.

In this system, buck converter was used. Buck or step-down converter regulates the average DC output voltage at a level lower than the input voltage. The circuit diagram of the buck converter is shown in Fig. 2.

Fig. 46. Circuit diagram of buck converter

The circuit diagram of buck converter consists of a controlled switch S , a diode D , a filter inductor L , a filter capacitor C and a load resistance R . In the circuit, V_o is output voltage and V_s is input voltage [11], [12].

The relationship between the output voltage, the input voltage and the duty ratio (D) is given in equation (3).

$$V_o = V_s D \quad (3)$$

C. MPPT Algorithms

Enhancing the performance of the PV installation economically is to consider the balance of system components, particularly the power converter. Researchers developed many MPPT algorithms such as Perturb and Observe method (P&O), incremental conductance method (INC), feedback voltage or current, fuzzy logic method and neural network method. Increasing the efficiency of the MPPT algorithm makes the performance better. MPPT contains software codes that can be embedded within the power converter firmware. The MPPT automatically locates the maximum power point (MPP) that is the desired operating voltage (V_{MPP}) or current (I_{MPP}) in order to achieve the maximum output power (P_{MPP}). Most popular MPPT technique is the perturb and observe (P&O) in literature [13], [14]. The flowchart of the perturbation and observation algorithm is shown in Fig. 3 [15].

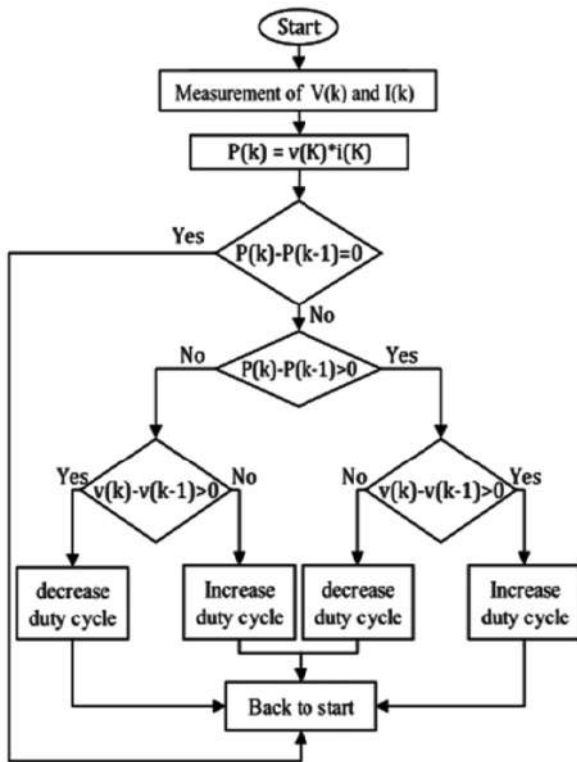

Fig. 47. P&O algorithm [15].

III. RESULTS AND DISCUSSION

DC-DC converter circuits are being used to eliminate the incoordination of the power transfer between the photovoltaic systems and the load or the battery. DC-DC converters have types of buck, boost and buck-boost. The system block diagram is shown in Fig. 4.

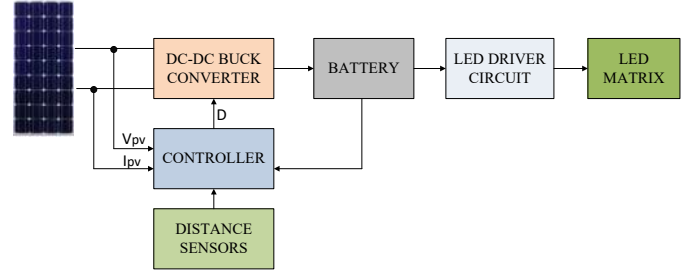

Fig. 48. System block diagram

The PWM signal required by the voltage-down converter must be low enough to reduce the effects of parasitic inductances on the load and must be high enough to provide undervoltage fluctuation without having filter elements in extreme sizes. As a result of the experiments, 50 kHz switching frequency is sufficient[16].

In addition to the main components of the DC-DC converter, there are several other elements in the circuit that allow to drive MOSFET, to measure output voltage and current. TLP 250 optocoupler is used to drive the MOSFET. The power circuit and the ground of the control card are separated at the measuring circuit so that the noise generation is prevented and in case of any short circuit, the controller is protected. Power circuit with MPPT and the battery charge circuit were implemented on the printed circuit by using at least several circuit elements. The power circuit for the system is shown in Fig. 5.

Fig. 49. Power circuit

The Arduino Nano development card with ATmega328p microprocessor, voltage and current sensors to measure voltage and current that MPPT needs for required functions, are used in this study. The voltage sensor is also used for the battery in the system. In addition, an ultra-sonic distance sensor capable of measuring up to 6.5 meters is used to measure the distance of the lighting poles [16].

Armature height connected to poles in the area that needed to be illuminated and the required amount of lighting is calculated in lighting system design.

The MPPT software calculates current power in every 20 μ s and compares it with the previous power. By adjusting the PWM signal according to the power it increases and decreases the voltage and finds the maximum power points. This software runs on Arduino.

Lighting poles were taken out at night to observe and test the operation of the designed system. It has been observed how the LED lighting system works. The amount of light flux obtained for each armature is approximately 5000 lumens(lm). The light flux will change according to the change of light brightness. LED light flux is approximately 1250lm at 25% brightness , %50 2500lm at 50% brightness and 5000lm at 100% brightness.

As coming near to the lighting pole A, the brightness of A armature will be 100% and the brightness B armature will be 50% and the lighting pole C will be at 25% brightness as the distance sensors are out of the detection range [16]. The intensity of the illuminations is shown in Fig. 6. Photographs of the running system are shown in Fig. 7 and Fig. 8.

Fig. 50. Working system illustration

Fig. 51. 25% and 50% Lighting intensity

Fig. 52. 100% and 50% Lighting intensity

IV. CONCLUSION

In this study, an MPPT converter is designed and implemented for effective application of energy conversion in photovoltaic systems, and this application is used in playground lighting. Another advantage of using MPPT is increasing the lifetime of the load that connected to the system by preventing fluctuations in output voltage. The cost of using MPPT in photovoltaic systems is very low as well as the profit generated by increasing the yield and the service life of the loads. The perturb and observe (P&O) algorithm is used in this MPPT. This algorithm seems to have been used in many studies because of its simplicity.

The efficiency of the system can be increased by adding solar tracking system beside MPPT to get more efficiency than solar panels. In addition to the solar tracking system, the efficiency can be further increased by using special coatings that focus the sunlight. By using faster microcontrollers and MPPT algorithms, maximum power points can be found faster. A system can be added to the system that monitors the solar radiation and temperature and a module to estimate the maximum power points. Artificial intelligence techniques can be used by saving the power points, air temperature, panel temperature, solar radiation, etc. to find the maximum power points more quickly.

Abstract—In this paper, control of DC/DC synchronous boost converter for photovoltaic panels with different controllers is simulated in the Matlab/SIMULINK software. Firstly, synchronous boost converter is simulated, and then regarding to the changes in reference and source voltages traditional PI and Fuzzy Logic control is achieved. Results obtained are analyzed and compared.

Keywords—Synchronous; Boost Converter; PI; Fuzzy Logic; Control

I. INTRODUCTION

As the usage of electrical energy continuously increasing this also brings so many problems in together. Problems in providing fossil energy resources, environmental disasters, increasing in energy consumption, in order to stay away from nuclear energy disputes are being the reason of global disagreements and even the wars. Therefore in recent years financial losses as the result of not to providing energy demand properly, regional electricity cut-offs directed people to the renewable energy sources for their clean and reliable energy needs [1].

Approximately 20 % of the energy needs is being provided from renewable energy sources in the world, in Turkey this figure is almost in the rate of 9 % only [2-3]. Electrical energy generated from sun as one of those energy sources is usually obtained by using photovoltaic (PV) panels. While total generated energy from this type of energy was 177 GW in 2014, at the beginning of 2016 this figure reached 227 GW. As in January 2017 in Turkey, this figure has exceeded 860 MW [3]. With regard to the installed power, respectively China, Germany and Japan are the leader countries in this sector [2]. According to the load or systems energy to be provided, whether they are DC or AC, power electronic circuits differ from one to another[4-5].

In order to meet the needs of DC sources, PV systems are in need of boost, buck or buck-boost converters. According

to their circuit structures these converters increase or decrease input voltages, at the same time if they include a diode in their circuit, they are called asynchronous converter, or if they include a switch instead of the diode are called synchronous converters (Figure 1-a and -b).

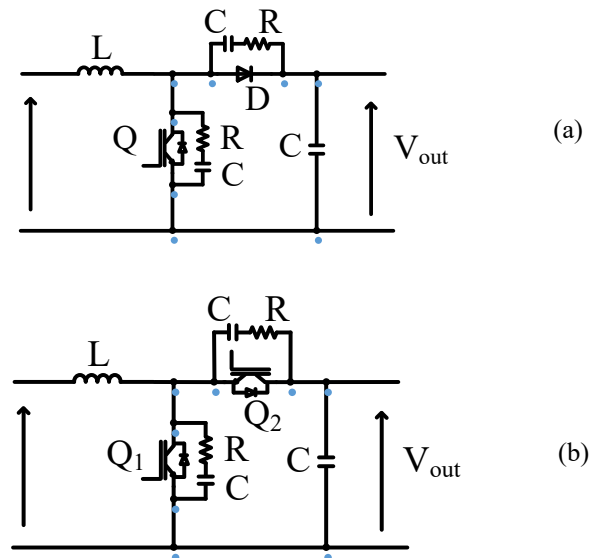

Fig. 1. (a) Asynchronous Boost Converter
(b) Synchronous Boost Converter

In the synchronous converters using a switch instead of diode, as there will not be a voltage drop in forward direction their efficiencies are higher than asynchronous converters[5,6]. Another advantage of synchronous converters output voltage is constant when it is controlled even in no load case. Output voltage in both converter types will be changed with the solar irradiance, temperature and load. In order to fix this output voltage it must be controlled. In the literature there are papers in controlling of

synchronous converter [6,7]. Beside these works, in [8] maximum power point tracking in distributed grids, cost and efficiency analysis are verified for asynchronous and synchronous converters. Efficiency of synchronous type converters reached up to 98 %.

In the controlling of converters are implemented in different ways based on current or voltage. Aims of controlling can be sequenced as maximum power transfer, reactive power control, bus voltage stability and providing load with the quality power supply[9,10]. In [11] fuzzy logic control of buck converter is done for water electrolysis. Beside this in [12], radiant control of synchronous converter is done in case of changing LEDs' status ON or OFF.

In this study, design of a PV panel powered synchronous boost converter is made and then fuzzy logic and PI control under varying source and reference voltage cases, the results obtained are compared and proper control method is proposed.

II. GENERAL DESCRIPTION OF THE SYSTEM

General block diagram of a PV panel powered converter is in Figure 2. System structure includes a PV panel, a synchronous converter, a filter and a control unit.

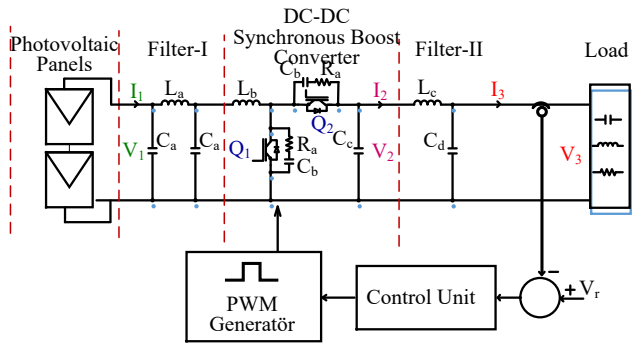

Fig.2. Systems' General Diagram

A. Synchronous Boost Converter

Synchronous boost converter transfer D.C. voltages applied to their inputs by boosting to their outputs according to duty-cycle of switches (Figure 1-b). DC voltage that is generated PV panel will be boosted by synchronous boost converter. Then filtering output filter, this voltage will supply to load

$$\frac{V_{out}}{V_{in}} = \frac{1}{1-D} \quad (1)$$

Where, V_{out} : output voltage, V_{in} : input voltage and D is the duty-cycle.

Output voltage of a synchronous boost converter is basically determined by the duty-cycle of Q_1 switch. Q_1 and Q_2 are opposite switches. When one is ON, the other is OFF. Switching frequencies are 100-1000 times higher than asynchronous converter. Despite in such high frequencies

switching causes to be smaller passive circuit components in greater power systems causes more losses. Therefore faster semiconductor materials and better switching actions are needed.

B. Controller Structure

System controlling depends on synchronous converter control. Classical PI controller and fuzzy logic controllers will be used to stabilize the voltage at the output of converter. Output voltage readings will be compared with reference voltage, the difference between those is the error. In both controllers to decrease the error to the Q_1 and Q_2 switches of converter, Pulse Width Modulation (PWM) will be produced.

$$e(k) = r(k) - y(k) \quad (2)$$

Where, $e(k)$: error signal, $r(k)$: reference signal and $y(k)$: output signal.

1) Fuzzy Logic

Fuzzy logic controller without being in need of a mathematical model adjusts the input signal according to the output signal. System variables is designed for system control. Output voltage of boost converter can be controlled by changing the duty-cycle of switch used. The error in equation (2) and the changing error in equation (3) are inputs of fuzzy logic controller

$$de(k) = e(k) - e(k-1) \quad (3)$$

Where, $de(k)$ change in error is obtained from subtracting previous value of error.

Fuzzy Logic Controller as it is seen in Figure 3 becomes combination of three parts as fuzzification, rule base and defuzzification. Input and output membership functions chosen as a triangle. Two inputs signals, five membership functions by using Positive Greater (PG), Positive Smaller (PS), Zero (Z), Negative Smaller (NS) and Negative Greater (NG).

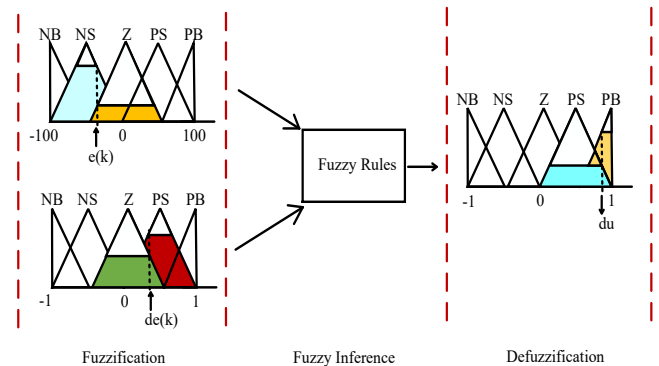

Fig.3. Fuzzy Main Diagram

After the fuzzification process, rules in Table.1 is applied to determine fuzzy memberships of equalized output signal.

Finally, by using the max-min method definite results is obtained. In order to confirm Fuzzy Logic Parameters a better control can be provided by the trial and error method.

TABLE V. RULE BASE

		de				
		NB	NS	ZZ	PS	PB
e	NB	NB	NB	NS	NS	ZZ
	NS	NB	NS	NS	ZZ	PS
	ZZ	NS	NS	ZZ	PS	PS
	PS	NS	ZZ	PS	ZZ	NS
	PB	ZZ	PS	PS	PB	PB

These definite values will be given PWM generator, and according to the duty cycle values PWM will generate two signals inverse of each other, at high frequencies that will be applied to the switches by this mean error will approach to zero.

Fuzzy Logic can be applied to different control systems with fundamental alterations, for detailed information refer to [13,14].

2) PI Controller

In the PI controller, a PI controller is designed to approach to zero the error between the output voltage and the reference voltage such as fuzzy logic controller. In figure 4, a PI controller block diagram is seen.

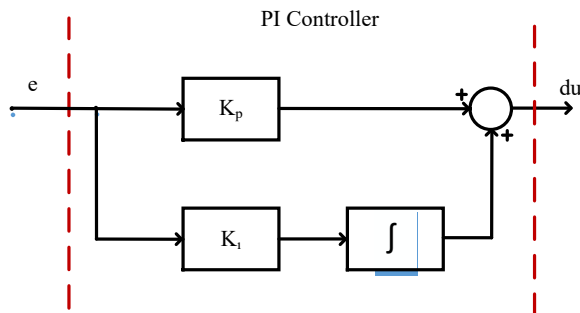

Fig.4. PI Controller Block Diagram

Output of the PI controller like fuzzy logic controller generates PWM signal according to du signal at its output, so the error becomes zero.

III. SIMULATION WORK

In this section, system simulation of a PV panel powered synchronous boost converter with DC loads is done in Matlab/SIMULINK software. Simulation works are accomplished under variable reference and source voltages. Output voltage is controlled by PI and Fuzzy Logic Controllers. Used system parameters are given in Table.II.

TABLE VI. PARAMETERS OF THE SYSTEM

Photovoltaic Panel		Synchronous Boost Converter	
V _{open-circuit}	37.6 V	L _b	2.55 uH
I _{short-circuit}	8.55 A	R _a	33 Ohm
N _{serial}	1	C _b	300 pF
N _{parallel}	2	C _c	1 mF
T _{ambient}	25 °C	f _s	100 kHz
S _{ambient}	1000W/m ²		
Filter-I		Filter-II	
L _a	16.2 uH	L _c	0.338 uH
C _a	33 uF	C _d	10 mF
Load			
P	0.5kW		

Control results of a PV powered high frequency switching synchronous boost converters' PI and Fuzzy Logic controls are shown in Figure 5 and 6 respectively. In the case of synchronous boost converter output voltage changes with a defined reference voltage and changing of source voltage with the light intensity. Therefore indirectly changing in the source voltage, output voltage did not change are shown. In Figure 6 similar situations for Fuzzy Logic controller are valid.

Fig.5. PI Control Results of the System

Fig.6. Results of Fuzzy Logic Control of the System

Fig.7. the Change of the Error in Variable Reference Voltage for Both Controller

Where, V1: PV output voltage, V3: Synchronous boost converter output voltage, REF: Reference Voltage. FLC: Fuzzy Logic Controller

IV. RESULTS

In this study, output voltage of a PV panel powered synchronous boost converter PI and Fuzzy logic control is done. In the simulation work, in case of changing in source voltage and reference voltage, PI and Fuzzy Logic control of output voltage show that it is precisely stabilized. When Fuzzy Logic controller gives faster response to the changings in reference voltage, lesser overshoot rate with respect to PI controller are observed. Both control methods give faster response to any increases in reference voltage but in case of any decrease in reference voltage both methods give slow response. In accordance with these results it is observed that fuzzy logic control is better than PI control.

Because of the developments in power electronics in recent years when switches working at high frequencies will

be commercially available, it is expected that usage of high power synchronous converters will increase, also their efficiencies are higher.

Smart Eyes for Monitoring and Analysis of Human Interactions in Smart Cities

Orhan Yaman, Mehmet Karakose
Firat University, Department of Computer Engineering
Elazig, Turkey
{orhanyaman, mkarakose}@firat.edu.tr

Abstract— Developments in technology are changing the whole area of life. They have led to some changes also in city life and changed people's lives. The concept of smart city has emerged along with the use of developing technological products in city life. In smart cities, applications that will facilitate people's lives in many areas such as transportation and energy consumption have been developed. In recent years, it has become even more difficult to live in cities along with the migrations to large cities. Many conveniences have been provided in many areas such as transportation and energy consumption along with smart city applications. In this study, a vision-based method was proposed to facilitate transportation in large cities. It is aimed to plan public transportation vehicles according to the intensity of use of them by people. The numbers of using public transportation vehicles by people will be observed using cameras. A vision-based method is proposed for the planning of the numbers of service by taking into account the bus stations where there is a great number of people using public transportation vehicles, and the intensity hours. Thus, the transportation of people using public transportation vehicles will be carried out in a more controlled way. With this method, it is aimed to reduce the time people spend in transportation.

Keywords— *computer vision; image processing; smart city; smart cameras; smart devices.*

I. INTRODUCTION

Transportation in smart cities is associated with the buses, rail systems, traffic systems, cameras, traffic lights, road information systems, traffic signal optimization systems, electronic communication systems and car navigation systems that are used in the city's public transportation systems [1-2].

Smart cities should have integrated systems that provide infrastructure and transportation convenience, protect energy, increase water and air quality, quickly identify the problems and provide solutions [3-4]. The purpose of a smart city, in a sense, is to ensure that the systems that can produce effective projects work in an integrated structure by taking into account the city's demands and resources. In this process, infrastructural issues such as transportation infrastructure systems, water resources viewers, energy saving buildings are the key issues in which city

managements invest. Applications are performed in basic study areas needed for smart city management and liveable cities. Issues like transportation, energy, water and security are addressed as smart city solutions.

Traffic problems arise in cities along with transportation, today's increasing population and increasing number of cars. Due to the lack of existing transportation structure, the time of people's daily basic journeys increases and this negatively affects the quality of life. Besides, transportation expenses and environmental pollution are also increasing. It is aimed to facilitate people's transportation by developing many applications for transportation in smart cities.

Luca et al. [1] carried out a study by establishing a smart camera network to monitor traffic in cities. The density of traffic was determined by placing cameras on the electricity lines in the city. Mustafa [2], in his master's thesis study, developed a public transportation information system for transportation in Istanbul. The data kept in public transportation institutions were combined in a standard format and on a common platform and made accessible to mobile devices. The developed method was written as an android application. In the application, users get the most appropriate directions by choosing the location information of the places they want to go and the type of transportation. In addition, the developed application contains information such as times of services of transportation vehicles. It also contains information about station locations of transportation vehicles.

Narol [4] developed an application for public transportation vehicles using NFC technology. In the study, a business model was proposed for a safe and practical ticketing system by giving examples from the projects where NFC technology was used.

Saglam [5], in his thesis study, developed positional decision support tools for transportation services in smart city management. Within the scope of the thesis, the legislative analysis was performed for the city information system and the relevant responsibilities were examined. Maria et al. [6] proposed drone-based image processing system for vehicle identification in smart transportation infrastructure. The aim is to provide useful information automatically, such as available parking spaces and level of

vehicle intensity on the street. The system was tested both on a desktop computer and on an embedded system. A cascade classification was used in the vehicle identification method. The block diagram of the system architecture is presented in Figure 1.

Figure 1. Block diagram of the system architecture [6]

Robin et al. [7] developed a smart parking system, which is a parking occupancy monitoring and imaging system, for smart cities. A prototype for smart parking system using wireless sensor technology and networks is presented in this study. By using a wireless Sensor network, full or available space in the parking space are determined and transmitted to a database. Then, this information is reached by the users through the website or mobile application to get real-time updates. Along with the successful implementation of smart parking, economic and time costs associated with traffic congestion and the costs associated with wasted fuel are decreased. In addition, the time elapsed to search for free parking space will significantly be reduced. A general system model for the smart parking system is presented in Figure 2.

Figure 2. A general system model for the smart parking system [7]

Energy sources have become a symbol of power for countries at the present time. The emission rate of toxic gases is also very high in cities with high energy consumption over the world. Today, it is known that half of the world's population lives in cities. This rate is expected to increase further within the next years [8]. Smart methods are developed to carry out energy consumption in a planned way.

Kiral [9], in his thesis study, developed a smart power socket for energy management in smart networks. A wireless sensor network was created using wireless communication devices. The existing power sockets in the house are remotely controlled. All power sockets are monitored and controlled by the central unit used. In this

study, it is aimed to ensure the efficient and economic use of energy by taking into account the consumers' demands.

Nowadays, water resources are one of the most important life sources for people. Water consumption is increasing rapidly along with the increase in population. Drinking water and wastewater infrastructures are not only insufficient in cities but also cause energy consumption. Water transportation and recycling should be performed using environmentally friendly systems. Studies have been carried out for the efficient use of water in recent years. These studies have become a part of smart cities.

Celik [10], in his thesis study, carried out a study for the modeling of e-management process in the water management administrations of smart cities. In this thesis study, general information about e-applications in water and sewage administrations in Turkey has been given in smart city managements. Studies that would speed up the citizens' transactions were proposed in the light of the existing e-applications that Istanbul water and sewerage administrations have.

First aid and security services are very important concepts for a smart city. First aid services should work concurrently with infrastructure services to be carried out effectively. Today, the increasing population problems as well as the crime scene response services are also affected. Therefore, databases with a dynamic infrastructure and transportation vehicles supported by decision-making tools should be used. More rapid intervention can be performed by using geographical information systems based products in crime scene response. In addition, cameras can also be used in follow-up and investigations. Tokta [11], in his thesis study, developed abnormal situation detection in the crowds through security systems. People's movements were monitored using image processing methods in cameras placed in crowded environments. The abnormal situation detection was performed by taking into account the behaviors of the people identified. In this thesis study, algorithms were developed using optical flow and effect map approach.

In this study, human detection is performed using image processing based methods. The arrangement of service plans is ensured by taking into account the density of people using public transportation vehicles, the hours of use and the locations of stations. It is aimed that the people using public transportation vehicles will be able to travel more easily.

II. DATA SHARING AND MANAGEMENT IN SMART CITIES

A lot of information about our daily life can be reached by means of the information technology that has further increased in recent years. For instance, satellite images and aerial photographs can be obtained and can be used in smart city applications. Nowadays, dynamic vehicle tracking can be performed by GPS systems in vehicles and on the phones thanks to geographic information systems and satellites. The lives of people are made easier with the applications such as

driving directions as well as vehicle tracking. In particular, directions are given by taking into account traffic density with the applications developed on mobile phones.

Millions of data are gathered in a single center using sensors, and real-time traffic, temperature and moisture data are obtained and used in smart city managements. In recent years, there have been developments within the scope of transforming the data obtained using many sensors into open data serving the public. While data production and management studies are carried out in cooperation with the private sector, studies are carried out for the development of internet based software providing open services to the public with these data. The private sector provides information about services to cities, traffic and navigation directly to the users with dynamic data as in official institutions. In applications provided to people, location-based information sharing can be performed through cloud-based systems where users are stakeholders. The relationship between data management and sharing in smart cities is presented in Figure 3.

Figure 3. Data management in smart cities [5]

The management and sharing of data obtained for smart cities is very important in terms of data accuracy. Nowadays, numerical data of almost every place in daily life are obtained using many sensors. Many network structures are used to store the obtained data in specific centers. Information obtained from the sensors are transmitted to base stations using wireless modules or to certain data centers via internet line. A sample wireless configuration developed for a smart city is presented in Figure 4.

III. THE PROPOSED APPROACH

It is aimed to implement the method proposed in this study in many public transportation vehicles. Timetable planning can be made by placing the structure developed for the proposed method in the desired public transportation vehicles. Camera and GPS sensor are used to obtain the necessary information. The cameras are placed on the doors of public transportation vehicles and images are received. The placement of the cameras in a sample public transportation vehicle is presented in Figure 5.

Figure 4. Smart wireless systems [5]

Figure 5. Placement of the cameras in a sample public transportation vehicle

The placement of cameras in a bus is presented in Figure 5. Transportation vehicles for the proposed method are not different. The same system can also be used in public transportation vehicles such as metrobus, tramway and metro. Human detection is performed by using image processing methods on the images received from the cameras. Today, image processing methods are used in almost everywhere [12-21]. An optimization was made by taking into account the number of passengers getting on and getting off public transportation vehicles and the locations of public transportation vehicles. The general architecture of the proposed method is presented in Figure 6.

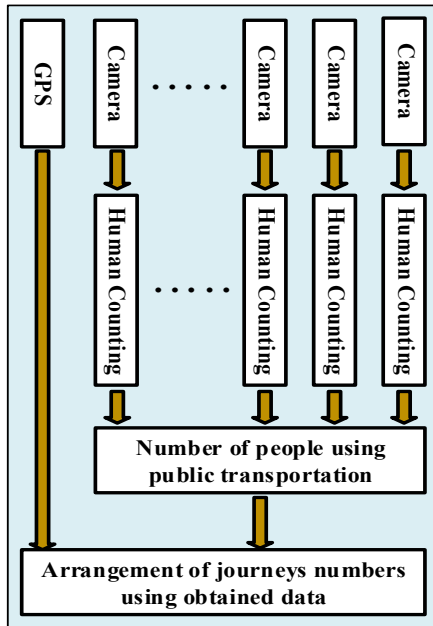

Figure 6. General architecture of the proposed method

According to the architecture in Figure 6, cameras are placed on all the doors of the public transportation vehicle. The cameras placed are connected to an embedded system. The images received from the cameras are used for human detection with algorithms developed on the embedded system. The flow chart of the proposed algorithm for human detection and counting is presented in Figure 7.

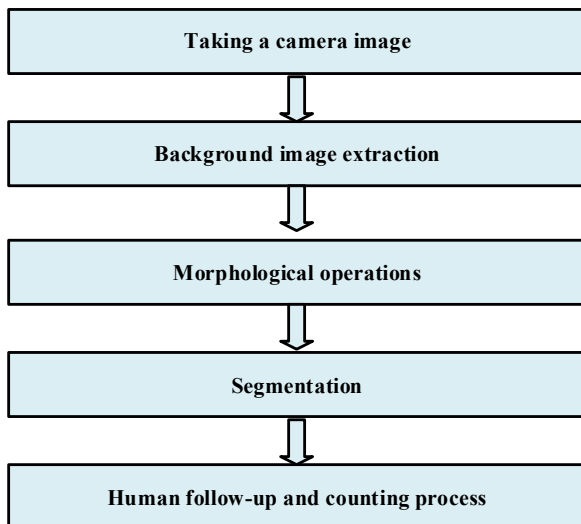

Figure 7. Flow chart of the algorithm proposed for human detection and counting

After the human detection process, it calculates the number of people who get on and get off transportation vehicles by monitoring people's movements. The number of people at all doors is combined on a single module. The

obtained data are combined with the position information received from the GPS device and transmitted to the data collection center. The data collected from public transportation vehicles throughout the day are analyzed using an optimization method. As a result of the analyses, arrangements can be made on the timetable by detecting the hours of intensity in the bus stations. Thus, people using public transportation vehicles will be able to travel faster.

In this study, a sample test data was created to clarify the proposed method. In the sample test data created, the numbers of people who get on and get off a public transportation vehicle going from 1st to the 10th stop are presented in Table 1.

When the test data presented in Table 1 are examined, there were greater numbers of passengers especially between the 1st and 4th stop in the services performed at 07:00, 08:00 and 09:00. It can be concluded that the passengers waited for the public transportation vehicle for more hours. When the numbers of passengers are taken into account, 50 passengers, 66 passengers, 115 passengers and 81 passengers used this vehicle in the services at 06:00, 07:00, 08:00 and 09:00, respectively.

As it can be understood from the numbers of passengers, the number of passengers is quite high in the services at 07:00 and 08:00. In this case, the problem can be solved in the case of increasing the number of services at 07:30 and 8:30 or it is possible to plan different public transportation lines that pass by 1st and 4th stops.

IV. CONCLUSIONS

In this study, a method was proposed for the smart transportation system, which is the most important part of smart cities. In the proposed method, the use of cameras and GPS modules was planned and the number of passengers carried by public transportation vehicles and the information that passengers get on and get off was obtained. The numbers of services or hours of public transportation vehicles can be rearranged by using these data obtained. Image processing methods were used to detect passengers who get on and get off public transportation vehicles. Many applications can be developed for smart cities by using these methods. People at certain points can be counted using cameras. Traffic intensity can be calculated by counting the vehicles in the traffic. The quality of life of people can be increased by using image processing methods in many similar applications. Cameras are indispensable devices for people. Effective applications can be developed for smart cities using cameras and image processing methods.

Table 1. Sample test data used in the study

	Number of passengers descending and arriving via public transportation from 1st stop to 10th stop (Getting on: Getting off)

Abstract— A hardware implementation of a quadratic map through FPGA platform is proposed in this paper. Firstly, a chaotic quadratic map is modeled by using Matlab/Simulink programming and then implemented into the FPGA (Field Programmable Gate Array) to be used for key generation for cryptographic applications. When the quadratic map is in chaotic mode, its output is unpredictable and aperiodic. Besides this, the map has a uniform output distribution and sufficient randomness. These characteristics make the chaotic quadratic map a suitable key generator for cryptography. This paper also reveals the successful real-time implementation of the quadratic map using FPGA for practical applications. Experimental results confirm that the feasibility of the quadratic map is verified under a digital hardware environment.

Keywords— chaos; quadratic map; implementation; FPGA

I. INTRODUCTION

Chaos theory in complex systems has been cited increasingly in several different scientific areas especially in engineering science such as secure communication and cryptography. For example, chaos is used for analog and digital communication systems in [1-6]; for image cryptosystems in [7-12] and is applied in electrical power systems in [13-16]. Chaotic systems have similar properties such as sensitivity to initial conditions and control parameters, pseudo-random behavior and mixing with modern cryptography. These fundamentals characteristics can make the chaotic systems a good candidate for the key generation in data encryption algorithms. Many cryptosystems based on the generation of pseudo-random sequences using chaos have been proposed recently for mixing clear messages in information security [17].

Chaos generation in discrete time systems is very easy and simple due to the low complexity, but having high efficiency comparing with analog chaos generators [18]. In fact,

analogue chaotic systems typically exhibit some practical difficulties since the component conditions are varying with age, temperature, etc. Furthermore, analog circuit implementations generally require a large chip area for realization. Hence, hardware implementations of the discrete chaotic systems can be a solution to overcome these problems. Many digital realizations of chaotic systems have been reported to be used as key generators in cryptographic applications. For instance, in [19], Henon map as a chaotic generator is implemented in real-time on a FPGA to obtain high frequency at output for chaotic communication. In other study [20], a chaotic map is used as a bit generator and its FPGA implementation is performed successfully for cryptographic applications. Generally, chaotic system is used to generate pseudo-random sequences as key streams to mask information. Key streams should be generated randomly and contain enough entropy in order to prevent the key from being guessed. Key sensitivity is also required by secure cryptosystems [21].

In this paper, we consider a quadratic map and present direct real-time implementation into the FPGA as well as hardware co-simulation structure in Simulink. Xilinx ISE (Integrated Synthesis Environment) design software including system generator tool is one of the efficient software technologies, is used to design and implement the chaotic Quadratic map. Firstly, the map equation is modeled by using Xilinx blocks in MATLAB/Simulink and then Xilinx system generator (XSG) performs the compilation of the design.

The rest of the paper is structured as follows: Section II briefly introduces the Quadratic map with its dynamical behaviors and some statistical analyses of the map are performed. In Section III, we realize the digital implementation and hardware-co simulation of the Quadratic map on FPGA. Finally, Section IV concludes the whole paper.

II. CHAOTIC QUADRATIC SYSTEM

A. Quadratic Map

Quadratic map is a simple discrete system exhibiting chaos and defined by [22],

$$x_{n+1} = r - x_n^2 \quad (1)$$

where $0 < r \leq 2$ is called control parameter and $x_n \in (-2, 2)$ is the state variable of the system. Quadratic map can show rich dynamic behaviors from a stationary system to a chaotic state. When $r \in (0, 0.74)$, the map behaves in steady state and if $r \in [0.74, 1.5)$, then the map has periodic behavior. When $r \in [1.5, 2]$, the Quadratic map is capable of very complicated behavior which means that the output of the map is aperiodic, non-convergent and very sensitive to initial conditions. Hence, the value of the control parameter specifies the dynamical behavior of the system.

B. Lyapunov and Bifurcation Analyses

Lyapunov exponent checks a sensitivity criterion of the initial condition for a nonlinear dynamical system [23]. In discrete systems, Lyapunov values are given by the following equation.

$$\lambda = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} \ln |f'(x_i)| \quad (2)$$

A positive Lyapunov exponent indicates that the orbit of a dynamical system is unstable and chaotic. The dynamical behaviors of a system from a fixed point to a chaos as a function of its control parameter are shown by a bifurcation diagram. Fig. 1 shows the Lyapunov spectrum and the bifurcation diagram of the Quadratic map.

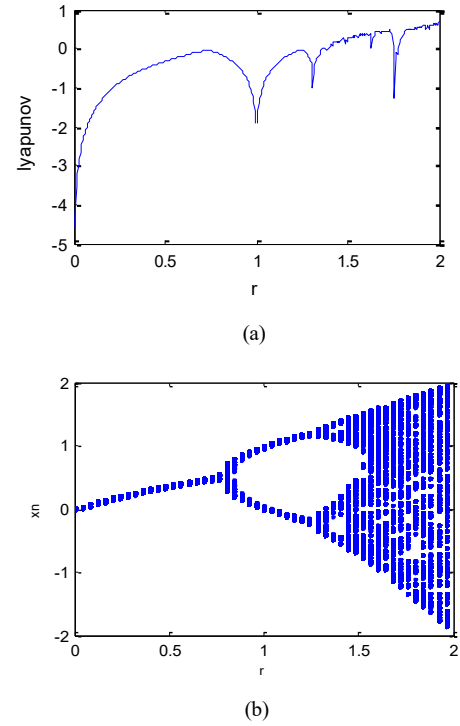

Figure 1. (a) Lyapunov spectrum of the Quadratic map
(b) Bifurcation diagram of the Quadratic map
 $\alpha + \beta = \chi$. (1) (1)

As it is easily observed that when the control parameter is close to 2, then the Lyapunov values are positive and the bifurcation diagram displays complex behavior resulting chaos.

C. Histogram Analysis

Histogram is a graphical display for the frequency distribution of a set of data. A distribution having constant probability for each data is known as uniform distribution. Fig. 2 shows the histogram distribution of the x_n series generated from the Quadratic map with different control parameters. From the graphical results, Fig. 2(a), Fig. 2(b) and Fig. 2(c) demonstrate steady, periodic and chaotic behavior of the Quadratic map, respectively. It is obvious that the histogram has an excellent symmetric property and better uniform distribution when the map behaves chaotically as in Fig. 2(c).

(a) $r = 0.4$

(b) $r = 1$

(c) $r = 2$

Figure 2. Histogram of x_n series with different control parameter (a) $r=0.4$ (b) $r=1$ (c) $r=2$

D. Checking chaotic output

When the Quadratic map is in chaos state, it exhibits complex behavior and generates chaotic sequences at output. Firstly, chaotic output will be checked for homogeneity through central tendency analysis and then the randomness of these sequences will be evaluated by using NIST test. Finally, the entropy of the Quadratic map as a number generator will be determined to measure its uncertainty. If a key generator is used in a cryptosystem, these properties need to be confirmed. In this paper, we chose as $r=2$ to make the system chaotic and perform the following statistical analyses by using Matlab programming.

a) Homogeneity Analysis

In order to check the chaotic output of the Quadratic map, the following two propositions are considered. First of all, the mean value of the output sequences spreading between $(-2,2)$ should be

$$x_{mean} = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{k=1}^N x_k = 0 \quad (3)$$

and second, the self-correlation of these sequences should be zero as given in the following equation.

$$s(\beta) = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{k=1}^N (x_k - x_{mean}) \cdot (x_{k+\beta} - x_{mean}) = 0 \quad (4)$$

According to the above equations, based on 50 simulations with different initial conditions, we have performed 10^6 iterations to get sufficient number of chaotic sequences from the Quadratic map. Then, we got the average mean value 0.000174 and the self-correlation is calculated to be 0.001598. These results are quite good, because both are very close to zero.

b) Randomness Analysis

Randomness means unpredictability and does not follow an intelligible pattern in a sequence of symbols [24]. NIST test is used to determine the degree of randomness of the Quadratic map outputs. NIST includes fifteen tests [25] and each test produces a real p -value in $[0,1]$. If the p -value is greater than a significance predefined level such as $\alpha = 0.01$, then the test is passed successfully. When the all statistical tests are passed, then the map is considered as random generator with 99% confidence. NIST uses binary series to test the randomness, but the output of the chaotic Quadratic map is floating-point value. Therefore, the following transformation is used for the output of the map in order to get sequential bit streams.

$$b_n = \begin{cases} 1, & x_n \geq 0 \\ 0, & x_n < 0 \end{cases} \quad (5)$$

Here, a threshold level of 0 is selected to produce a bit value "1" or "0" from x_n . We preferred the initial value as $x_0 = 0.123$ to obtain 1,000,000 bits to proceed NIST suite. The results are listed in Table 1.

Table 1. Results of the NIST test

Test Name	p-value	Result
Frequency	0.8524	Passed
Block frequency	0.3093	Passed
Runs	0.4939	Passed
Long runs of ones	0.7852	Passed
Rank	0.9912	Passed
Spectral DFT	0.7204	Passed
Non-overlapping templates (m=9; B=000000001)	0.7659	Passed
Overlapping templates (m=9)	0.7819	Passed
Universal (L=7; Q=1280)	0.1201	Passed
Liner complexity	0.9138	Passed
Serial-1 (m=5)	0.5875	Passed
Serial-2 (m=5)	0.6469	Passed
Approximate entropy (m=5)	0.4142	Passed
Cumulative sums forward	0.4086	Passed
Cumulative sums reverse	0.5553	Passed
Random excursions (x=+1)	0.3511	Passed
Random excursions variant (x=-1)	0.8741	Passed

It is concluded that the chaotic Quadratic map is very stochastic that represents random process and generates output sequences having enough randomness according to the NIST results.

c) Uncertainty Analysis

We use information entropy to determine the uncertainty or disorder of the Quadratic map. Entropy is a measure of uncertainty related to a random event [24, 26]. If $H(X)$ is a random source with N length, then its entropy is

$$H(X) = -\sum_{i=1}^N p(x_i) \cdot \log_2 p(x_i) \quad (6)$$

where $p(x_i)$ represents the probability of x_i . For instance, in a uniform bit stream having equal probability '0' and '1', the entropy will be 1 which is a theoretical result. When the output is certain, then the entropy is zero. The entropy of an practical information source is smaller than the ideal one. Generally, the more uncertain or random the event is, the more entropy it will contain [11].

We have used different initial values and number of iterations in order to generate bit streams using the Eqn. (5) from the chaotic Quadratic map. The entropy results for different conditions of the map are listed in Table 2.

Table 2. Entropy results

Initial value	Iterations	# of '0'	# of '1'	p(0)	p(1)	Entropy
0.2	100	52	48	0.52	0.48	0.9988455
-0.315	1000	490	510	0.49	0.51	0.9997114
1.27	10,000	4,967	5,033	0.4967	0.5033	0.9999685
-0.88354	100,000	49,829	50,171	0.4982	0.5017	0.9999916

From the results, when the number of iteration is increased, then the entropy value closes to 1 which means that the uncertainty of the map is becoming greater. Generated for all bit streams, number of zeros and ones are very close to each other resulting uniform distribution in the sequences.

d) Sensitivity Analysis

Quadratic map is highly sensitive to initial value. Thus, arbitrarily small change in the initial value will cause significantly different future output. This property is also acceptable while the map is used as a bit generator. To perform the sensitivity analysis, firstly, we randomly choose an initial value $x_0 = 0.123456788$ and iteration of $n = 50$ to generate a bit sequence (b_1) from the map. Then, a very slight change of 10^{-9} is applied to the first initial value, such as $x_0 = 0.123456789$ to generate another bit sequence (b_2). The last ten elements for both sequences are shown in Fig. 3.

Figure 3. Generated different bit sequences with a slight change of initial value

Fig. 3 states that when a tiny change occurs in the initial value of the chaotic Quadratic map, generated bit sequences are completely different.

III. DIGITAL IMPLEMENTATION

This section describes an approach to the real-time implementation as well as hardware simulation of the chaotic Quadratic map on FPGA. FPGA is a type of programmable chip that can be completely reconfigured for various field applications. Using prebuilt logic blocks and programmable routing resources, FPGAs can be reprogrammed to the required functionality and customized by loading the related configuration data into its internal memory cells. The stored data in these cells determine the logic blocks and reconfigurable interconnects in FPGA. We have used Spartan 3E-XC3S1600E family from Xilinx for the hardware simulation and implementation of the Quadratic map.

Xilinx System Generator (XSG) is a high-level design tool and fully integrated in MATLAB/Simulink that enables the use of the model-based Simulink environment for FPGA design. It allows compilation of the design that is captured using Xilinx blocks and generates synthesizable VHDL (Very High speed integrated circuit Hardware Description Language) codes for FPGA programming. All of the downstream implementation steps including synthesis, place and root processes are automatically performed to generate the programming file via XSG. The Quadratic map model has been designed by Matlab/Simulink with XSG which offers the library of fixed-point arithmetic blocks that can be directly implemented into the FPGA. Fig. 4 shows the Quadratic map model created by Xilinx blocks under the Simulink.

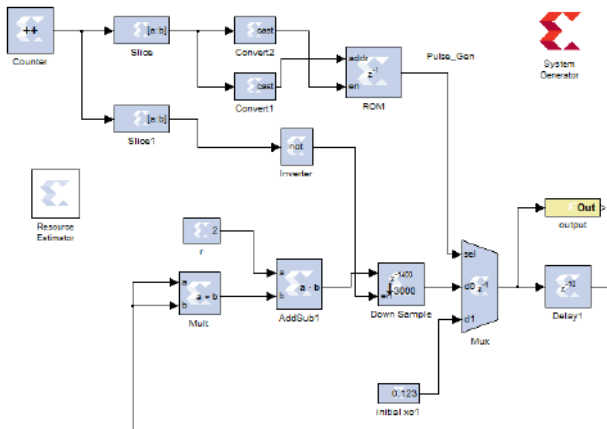

Figure 4. Chaotic Quadratic map model using Xilinx blocks

XSG enables hardware into a simulation, called hardware co-simulation structure that allows incorporating a design running in an FPGA directly into a simulation. Hardware co-simulation compilation targets automatically generate a bit streams and associate it to a block. When this block is simulated in Simulink, then the results for the compiled part are calculated in the hardware. Hence, hardware co-

simulation is used to verify that the design actually works in FPGA platform.

The bitstream download step is performed by using a JTAG cable. We performed the real-time implementation with a fixed-point data type and the real data are represented on 128 bits. Fig. 5 shows the simulation results of the chaotic Quadratic map design with hardware and software in Simulink. It is observed that the hardware-co simulation result is same to the Simulink simulation which means that the realization of the map is performed successfully and the map design actually works in FPGA.

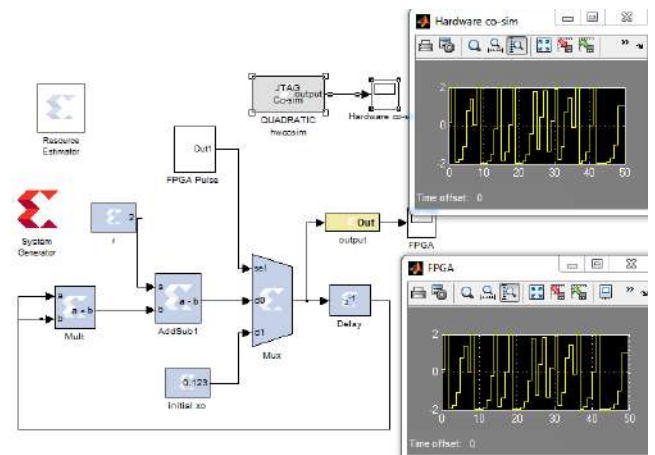

Figure 5. Hardware co-simulation of the Quadratic map

The generated output depends on the initial value of the map that can be directly entered into the design model before the generator starts. We randomly chose the initial value as $x_0 = 0.123$ for the real-time FPGA implementation.

XSG tool automatically generates a synthesizable VHDL codes associated with the design and the created file can be opened with the Xilinx ISE software. PlanAhead tool in ISE is used to assign input and output pin locations in the design. After assigning pins for input and output, then the design is ready to be synthesized in ISE. Successful synthesis creates the programming file of the design. IMPACT tool is used to load the programming file into the FPGA. For real-time implementation of our design, we use the chaotic Quadratic map as an 8-bit number generator to observe the numbers at LED output of the FPGA. First, the output of the map needs to be converted to 8-bit decimal number between 0 and 255. Hence, the following equation is applied to the output of the map.

$$number = \text{mod}(\text{round}(x_n \times 10^9), 256) \quad (7)$$

Here, *round* operation is used to get the nearest integer value and *mod* limits the output between 0 and 255. We assigned 8-bit number for the implementation because our FPGA has

eight LEDs at output. Transformation module is also added to the Quadratic map design. For example, if the initial value of the map is 0.123, then the second number generated from the Eqn. (7) will be 88 in decimal or 01011000 in binary. Fig. 6 shows this value at LED output of the FPGA.

Figure 6. Display of 88 in binary at LED output of the FPGA

Table 3 shows the numbers generated from the chaotic Quadratic system by using MATLAB and FPGA with the same initial value of the map.

Table 3. Generated 8-bit numbers from MATLAB and FPGA

MATLAB (Software)	FPGA (Hardware)
192	192
88	88
137	137
189	189
57	57
133	133
12	12
220	220

The amount of FPGA resources and the required by the Quadratic map can be determined by using Resource Estimator block. They are listed in Table 4.

Table 4. Mapping report of the Quadratic map design

Device	Spartan3E-XC3S1600E				
Resource Type	Slices	Flip-Flops	RAMB 16S	LUTs	IOBS
Available	14,752	29,504	36	29,504	250
Used	10,160	10,922	1	18,843	9

IV. CONCLUSION

This paper presents a chaotic Quadratic map and its implementation on a digital hardware. The results of the statistical analyses confirm that the output of Quadratic map can be used as cryptographic keys when the map behaves

chaotically. In practice, chaotic Quadratic map can be used as a generator in all scientific fields where the pseudo-randomness and chaos are required. The design of the map as well as hardware co-simulation and real-time implementation are successfully applied to the FPGA platform that encourages its usage for practical applications. This paper can be used as a good guide for anyone who wants to implement digital designs on FPGA without knowing VHDL codes.

Abstract— The rapid increase in data traffic exposes the limitations of using only radio frequency (RF)-based mobile communications whose spectrum became so much congested and scarce. The advances made in solid-state lighting technology in the past few years witnessed a growing research in visible light communication (VLC) that can supplement the RF-based mobile communication. Visible light spectrum made up of hundreds of terahertz bandwidth capacity that is licensed free and relatively unexploited. This paper reviews the advent of VLC technology, its transceiver structure, some important challenges and the recent advances made by researchers to address some of these challenges.

Keywords— *Visible light communication, radio frequency, solid-state lighting, spectrum, transceiver and challenges.*

I. INTRODUCTION

The interior lighting in our buildings is undergoing a dramatic change. The widely used incandescent bulb for lighting since its invention about a hundred years ago is becoming obsolete. This is due to the inefficiency of the product as only about 10% of the electrical energy is being converted to light [1] while the remaining 90% is dissipated as heat. In the 1990s compact fluorescent bulbs were introduced. These bulbs provide better efficiency in terms of lighting compared to incandescent bulbs. Although the fluorescent bulbs performs relatively well, but recent advancement in solid state technology gave rise to the introduction of light emitting diodes (LEDs). LEDs prove to have excellent efficiency and longer lifespan. On the average, LEDs luminous efficacy was observed to be as high as 113 lumens/watt in 2015 [2] and it is expected by the year 2020 to be around 200 lumens/watt. These values by far exceed the luminous efficacy of the fluorescent and incandescent bulbs of 60 and 15 lumens/watt respectively [2]. In addition, the longer lifespan of LEDs is of the order of 25,000 to 50,000 hours compared to about 10,000 hours of the compact fluorescent bulb. The LEDs have other advantages apart from high efficiency and longer lifespan of lower heat generation even after excessive usage, low power consumption, non-physiological effects as usage of harmful materials in the design is reduced. Owing to the

forementioned benefits, the adoption of LED luminaries is on the increase and it has been projected that by the year 2030 nearly all lightings will be LEDs [2].

The most important advantage of the LED is its fast switching ability to different levels of light intensity. The rate at which the LED switches is very fast that a human eye cannot notice. This unique characteristic enable LED to have dual purpose, that is, to be used for communication in addition to lighting. The dual ability of LEDs to provide lighting and communication gave rise to interesting applications in home networking, high speed data transfer using the luminaries in offices, traffic light management, communications in airplane cabins and trains and other applications too numerous to mention [3]. VLC researches have shown that very high data rates can be achieved (about 100Mbps in IEEE 802.15.7 standard and up to multiple Gbps in research) [2]. VLC utilizes LED luminaries as transmitters and photodiode or image sensor (a matrix of photodiodes) as a receiver. VLC communication is regarded an emerging area that possesses important characteristics in comparison to other existing wireless communications. Although the history of visible light communication can be traced back to 1880 with the invention of photo-phone by Alexander Graham Bell, the idea of using LEDs for communication in addition to lighting started in the year 2000 by Japanese researchers from Keio University [2]. Japan is therefore regarded as the pioneer hub for research in VLC. Researches in VLC were further ignited as a result of the success recorded in Japan with the formation of visible light communication consortium (VLCC) in 2003 [4]. In 2006, a proposal was made by the center for information communication technology research (CICTR) which is based in the United States to come up with a novel indoor broadband access by combining power line communication (PLC) with LED [4]. The most interesting of all these findings as far as VLC technology is concerned over the past years is that of Herald Haas from the University of Edinburgh United Kingdom referred to as Light Fidelity (Li-Fi). These activities witnessed a growing research in VLC with researchers all over the world paying attention to different aspects of the technology such as light source arrangements (transmitter) to reduce signal to noise ratio (SNR) fluctuations, the receiver position and

orientation, handoff strategies, multiple input multiple output (MIMO) systems, single input single output (SISO) systems and others too numerous to mention.

The rest of the paper is organized as follows: Section II dealt with the transceiver structure, channel models and

modulation techniques. Some important challenges were discussed in section III. Advances made by researchers to address these challenges were discussed in section IV. This is followed by conclusion in section V.

Figure 1. LEDs used for lighting and communication [5].

Figure 2. Methods of producing white light [3].

II. VLC TRANSCEIVER STRUCTURE

A. Transmitter

A VLC system employs LED luminaire as transmitter. The LED bulb can contain one or more LEDs to form an array usually used for lighting purposes. Apart from the LED lamps the bulb also contains the driver circuit which controls the amount of current flowing which in turn controls the brightness. For communication purpose the driver has to be modified to use two different intensity levels of light. It should be noted that the primary purpose of the LED lamp is the provision of lighting, therefore designing an LED luminaire to serve the function of communication without compromising the lighting requirement in addition to the ability to mitigate any noticeable flickering by the users is the most crucial design requirement. VLC transmitters should be able to meet these two requirements simultaneously as depicted in Fig.1. In practice, white light is the most commonly used for both indoor and outdoor illumination as a result of its excellent color rendering. The white light is usually produced by either combining blue LED with a Phosphor layer or via a mixture of red, blue and green light referred to as RGB combination. This is illustrated in Fig. 2. Although, the first method is cheaper to implement and the most widely used, but has a switching limitation to few MHz due to the phosphor coating. The RGB combination is the most preferred for communication.

B. Receiver

Two types of receivers are employed for VLC systems. The photo-detector (PD) (also called photodiode) referred to as non-imaging receiver and the imaging sensor which is essentially a matrix of photodiodes used as camera sensor. The imaging sensor is a good device used for VLC signal reception which is readily available on smart phones, tablets and laptops even though the frames per second (fps) on smart

devices is limited due to the control number of photo detectors that is commonly not more than 40 fps [2]. The basic architecture of a VLC receiver consists of a concentrator, optical filter, amplifier and an equalizer. The rays initially pass through the concentrator and optical filter before being captured by the detector. The complete architecture is shown in fig 3.

Figure 3. VLC receiver configuration

C. VLC Channel Model

The space between the transmitter and the receiver is referred to as the channel in communication. A measure of performance of any communication channel is its ability to transmit the carrier signal under the influence of many factors that includes attenuation, interference and noise. The space between the LED transmitter and Photo detector in VLC is the channel, mathematically represented as the response H . Two major types of channels are considered in VLC. The single VLC channel involving single transmitter and a single receiver referred to as single-input single-output (SISO) system, and a multichannel VLC referred to as multiple-input multiple-output (MIMO) system where there are multiple transmitters and

multiple detectors. In any case, the channel model is either line-of-sight (LOS) or non-line of sight (NLOS).

LOS

Figure 4. Line-of-sight (LOS) propagation

In an optical wireless communication, the DC channel gain due to the directed light propagation as studied in the literatures [5], [6], [7] and [8] as shown in Fig.4 can be written as:

$$H(0) = \left[\frac{(m+1)A}{2\pi d^2} \right] \cdot \cos^m(\varphi) \cdot T_f(\alpha) \cdot g(\alpha) \cdot \cos(\alpha) \quad (1)$$

Where the incident angle φ takes the values: $0 \leq \varphi \leq FOV$. It should be noted that the gain $H(0)$ will be null when $\varphi \geq FOV$. $T_f(\alpha)$ is the transmission filter while $g(\alpha)$ is the concentrator gain. The distance between the transmitter and receiver is d and A stands for the physical area of the detector. The concentrator gain is expressed as:

$$g(\alpha) = \frac{n^2}{\sin^2(FOV)} \quad , \quad 0 \leq \varphi \leq FOV \quad (2)$$

$$0, \quad 0 \geq FOV$$

Where n is the index of refraction.

The power received P_r can be derived from the transmitted power P_t as:

$$P_r = H(0) \cdot P_t \quad (3)$$

NLOS

Figure 5. Non Line-of-sight (NLOS) propagation

Fig.5 shows the NLOS configuration where the effect of reflections due to the walls is taking into consideration. In this case the received power is computed from the DC channel gain of the directed path (LOS) $H(0)$ and that of the reflected paths (NLOS) $H_{ref}(0)$.

$$P_r = \sum_{LEDs} \{ H(0) \cdot P_t + \int_{walls} H_{ref}(0) \cdot P_t \} \quad (4)$$

Where $H_{ref}(0)$, is the DC channel gain due to reflections.

D. Modulation Techniques

Presently, four modulation techniques are adopted for VLC in the literatures. These techniques are (1) On-Off Keying (OOK), (2) Orthogonal Frequency Division Modulation (OFDM), (3) Pulse position modulation (PPM) and (4) Color shift keying (CSK). Of these techniques OOK is the simplest and most widely utilized but only suitable for a single light source [9]. Table I gives the characteristics of these modulation techniques.

TABLE I: MODULATION TECHNIQUES USED IN VLC

	Techniques			
	OOK	PPM	OFDM	CSK
Data Rate	Low	Moderate	High	High
Dimming Support	Yes	Yes	No	Yes
Flickering	High	Low	Low	Low
Comment	Simple Design	Max. spectral Efficiency with MEPPM	Complex design, support MIMO system	Utilizes RGB LED enhanced multi-user access

III. CHALLENGES

For effective deployment and commercialization of VLC technology a number of challenges need to be addressed. The visible light spectrum needs to be organized and the standardization of this novel discovery needs to be given the required attention in order to move the technology forward.

Although, the working group IEEE 802.15.7 provides a set of rules guiding the technology and the consortium in Japan, VLCC provides few working standards that can support VLC deployment but a number of issues need to be addressed for effective deployment and commercialization of this technology.

Based on reviews of some current literatures on VLC, some important challenges that required attention are outlined as follows:

A. LED Arrangement in VLC

It was observed that indoor LED arrangement has a direct effect on SNR variations in a room which affects the performance of a VLC system. Most studies provide a suitable LED arrangement for square layouts that minimizes the fluctuations of received power and luminance distribution in the layout. Further research is necessary to design LED arrangement that can optimize communication performance while meeting the illumination constraints for different layouts such as Hospitals, Shopping malls, etc.

B. Shadowing

Although there was a preliminary study on shadowing effect on the performance of a VLC system, however, shadowing in VLC has not been studied separately in the literatures. Since VLC exhibits different characteristics than Radio Frequency signals, it is therefore desirable to model VLC shadowing in indoor environment in order to fully understand how to mitigate its effect.

C. Optical Beam-forming

Optical beam-forming can significantly improve the performance of a VLC system, but unfortunately there are a very limited number of studies done towards that. Performing beam-forming while meeting the illumination constraints is an important direction for future research in VLC MIMO systems.

D. Inter-cell Interference and Hand-over Issues

Since the primary function of an LED luminaire is to provide illumination, it is not clear whether the resultant cell topology in use is interference optimal for communication purposes or not. Further research is needed to determine interference optimal cell topology by efficient hand-over strategies.

E. Receiver Position and Orientation

Because of users movement within a room there are cases where LOS propagation cannot be collected by the receiver. In such cases reflected light has to be taken into consideration during channel modeling. Most studies consider static receiver situation and does not account for receiver orientations and positions.

F. LED to internet connectivity

Most present literatures consider the downlink design only. Connecting the large number of LEDs to internet via wired infrastructure (E.g. Ethernet etc.) will attract huge additional cost which may cancel the expected benefit of reusing the

LEDs for communication. Uplink design consideration for VLC is therefore another area for future research.

IV. SOME ADVANCES IN VLC TECHNOLOGY

A. Light source Arrangement

Authors in [10] successfully analyzed the performance of a new light sources arrangement for indoor VLC. In the study, the authors proposes a new light sources arrangement which involves placing individual LEDs spaced at 0.5m apart as against the traditional LED arrays typically used in buildings. A total of 121 LEDs were used in the research and the performance of this new arrangement shows significant improvement in the luminance and SNR fluctuations in the room as compared with that of a four (4) LED arrays centered on the ceilings. The illumination in the room also met the ISO standard of 300lx – 1500lx. A novel LED arrangement that is applicable to a square layout was proposed in [11]. The authors compare the performance of 16 LEDs placed in the center of a square layout (5m*5m*3m) with that of a 12 LEDs arranged in a circle of radius 2.2m + 4 LEDs one at each corner of the room. The proposed arrangement significantly reduced the SNR fluctuation in the room and the Q-factor was also improved.

B. Hand-Over Strategies

Hand-over strategies is another aspect that is directly linked to LED configuration in an indoor layout. In an effort to address hand-over issues Thai-Chien Bui et al [12] in 2014 proposed a configuration for supporting hand-over in a rectangular layout. The study suggested that to deal with mobility issues in indoor VLC the overlap area between two adjacent LEDs must be large for a successful handover while maximizing illumination and SNR distribution. To overcome ISI the research suggested that the various LEDs should be modulated using different frequencies and the receiver should be a photo-detector with multiple lenses to distinguish between signals.

C. Receiver Position and Orientation

In order to maximize signal reception in an indoor VLC system, the receiver position and orientation needs to be taken into account. The receiver might not necessarily be stationary but mobile as in the case of a smart phone or a tablet being carried by a user in the room. Also, the orientation of the receiver changes with time, it is not always perpendicular as previous studies assume. To deal with such situations authors in [13] demonstrated the impact of receiver orientation and position on VLC link performance. The study considers a square layout with four LEDs as transmitters and analyses a scenario where the receiver is assumed to be a smart phone or a tablet being carried within the room. Although the analysis uses only four transmitters but result shows that the ISI contribution due to receiver orientation variation has a stronger impact compare to the case where the receiver is perpendicular which shows that ISI needs to be taken into consideration for channel modeling.

D. Shadowing

The effect of shadowing is directly linked to the user carrying the receiver in an indoor VLC; this depends on the body posture and varies according to the data rate. In a study carried out by [14], where the performance of two body models having different reflectivity were investigated using a mobile receiver with random orientation to account for varying body postures. The result shows that under the assumption of low data rate, a 2D body model with perpendicular receiver orientation provides a suitable performance. But for high data rates when the 2D body model was used, the result shows link-efficiency deterioration depending on the receiver orientation variation.

V. CONCLUSION

Visible light Communication technology is a novel research area with potential to compete with other existing optical wireless communication systems. In this review a general overview of the technology with emphasis on the transceiver structure, modulation techniques and some important challenges were presented. It should be noted that for effective implementation of VLC technology, the existence of appropriate regulations is paramount. And these regulations and standards are lacking. Also, most of the researches on VLC are simulations based; therefore further research needs to be done on practical implementation of various aspect of the technology. In order to address some of the VLC technology challenges such as Uplink internet connectivity more studies need to be conducted, this further portrays VLC technology as a hot research area with a lot of future scope and potentials.

Abstract— The aim of this paper is to develop a smart security system for remote control using a small computer. In this paper, it has been proposed a comparatively inexpensive security system which has the capability to automatically initiate capture a picture by Raspberry Pi Camera Module when any movement is detected by PIR sensor and the Raspberry Pi device will send that picture to the user's smartphone device via Wi-Fi using application. Also, the system will light up the light bulb and LEDs when motion is detected. In addition, this system can be counted the number of moving objects located with the help of the infrared PIR sensor and will be sent that number with notification message "Motion Detection" to smartphone alongside the picture. The proposed system is very effective and crucial choice for energy save and security for home or service buildings. Nowadays, in electronic markets, there are many expensive solutions. However, low-cost solutions are very important for spreading between all people. Knowing that the Raspberry Pi 3 device and Telegram application were used in this proposed system.

Keywords—Raspberry Pi 3; PIR Sensor; Raspberry Pi Camera Module; Relay; Smartphone

I. INTRODUCTION

Security is the first attention in everywhere, every time and for everyone. Each person who wishes to be his home and service buildings in safety (PRIYANKA and REDDY, 2015). The heart-dominant in this system is the small computer is Raspberry Pi 3. Obviously, Raspberry Pi 3 is a single board which, when it is interfaced with the screen, keyboard, mouse and installed the operating system to be able to achieve the functions for any computer. The Operating System (OS) is the collection of programs and instructions that make the Raspberry Pi 3 run. In addition, the operating system whose works in Raspberry Pi 3 based only on Linux operating systems such as Raspbian OS and NOOBs (Narkhede and Khadke, 2016). It is worth to mention that, in this system, Raspbian OS version Jessie with PIXEL is installed in the Raspberry Pi 3 and the python programming language was

used to programming the project program. This project describes a smart security system for all homes and service buildings that can monitor any place. The system has been able to detect any object movement, turn ON/OFF light bulb and LEDs when an object moving in light day or darkness, take a picture, count the object moving number and automatically send the data to a smartphone via Wi-Fi using Telegram application. The data include the picture and notification message "Motion Detection" with moving object number located. The advantage of using this system is very crucial choice for energy save and home security. Also, another advantage is that it is a simple circuit and able to work at any time in the light day or darkness (Ahmad, Studiawan and Ramadhan, 2014). The other major advantage is that it is very economic system and it can be placed anywhere (Zafar and Carranza, no date).

II. DESIGN AND IMPLEMENTATION OF PROPOSED SYSTEM

The design and implementation of a low-cost system monitoring based on Raspberry Pi 3, a single board computer which interfaced with PIR Sensor, Raspberry Pi Camera Module, LEDs and relay and controlling them by implementing program written in python language in software implementation. The block diagram of this system is illustrated in Figure 1 below.

Figure 1. Block Diagram for the proposed system

To improve and facility the algorithm for the proposed system, the algorithm is separate into two parts which are motion detection part and lighting part. The system implementation begins when connecting the Raspberry Pi 3 and relay to the power supply. Knowing that the starting number for image counter is 1. Firstly, if there is no motion detected by the PIR sensor, the program will turn OFF the LEDs and suspends the program for 1 second and directly return back to check the motion detection. Secondly, if the motion is detected by PIR sensor the program will turn ON the lighting part and then the camera module will capture the picture and stores it in micro SD card. After that, the program will send the picture taken and notification message "Motion Detection" with the object number located directly to smartphone by Telegram application every time a motion is detected to alert the owner which having a smartphone and then the program will increment the counter image by 1 and subsequently turn OFF light bulb to energy save after that the program will suspend for 10 seconds before return one more time to check the object movement. The lighting part consists of LEDs and light bulb. Besides that, the security system will stop when separating the power supply. The flowchart for the proposed system is shown in the Figure 2 and the block diagram of the lighting part is shown in Figure 3.

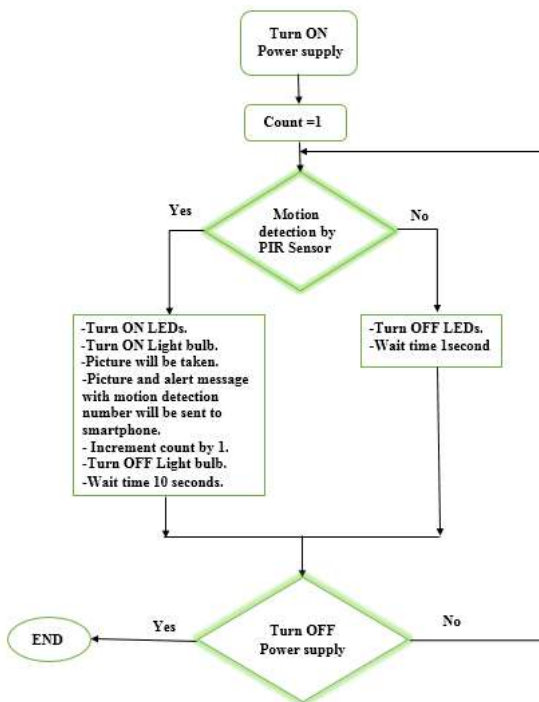

Figure 2. Flow Chart of proposed system.

Figure 3. Lighting part

III. SYSTEM COMPONENT DESCRIPTION

The major components of the proposed system are Raspberry Pi 3 Model B, Passive Infrared (PIR) Sensor, Raspberry Pi Camera Module, Relay, Power supply, LED (Light Emitted Diode), Telegram Application on smartphone and GPIO pins configuration. The block diagram for the proposed system illustrated in Figure 1.

A. Raspberry Pi 3 Model B

Raspberry Pi is a small credit card sized, single-board computer. It was more useful for projects which require very low power and used for computer science education. The amazing new version of raspberry pi is Raspberry Pi 3 Model B. This third generation model developed by the Raspberry Pi Foundation Company in the UK (Chandana, Jilani and Javeed Hussain, 2015).

The proposed system used Raspberry Pi 3 Model B that consists of the key specifications as illustrated in Table 1 and Raspberry Pi 3 board in Figure 4.

Table 1. Specifications of Raspberry Pi3 Model B

Specification	Description
SoC (System on Chip)	Broadcom BCM2837
CPU	64-bit, ARMv7, Quad cortex A53 @ 1.2GHz
GPU	400 MHz video Core IV 3D graphics Core
RAM	1GB SDRAM
SD Card Slot	Micro SD Card Slot (Push-Pull)
GPIO	40 Pin
USB 2.0	4 Ports
Bluetooth	Bluetooth 4.1, BLE(Bluetooth Low Energy)
Wireless LAN	802.11n Wi-Fi
Ethernet Port	10/100 LAN Port
HDMI Output	Full-Size HDMI Video Output
Power Supply	5V and Up to 2.5 Amps
Audio Output	3.5 mm, 4-track composite video and audio output jack
Dimensions	85.6mm x56mm x21mm
Price	35\$

Figure 4. Raspberry Pi 3 Model B board

B. Passive Infrared (PIR) Sensor

PIR sensor is an essential part of this proposed system. The object will emit infrared (IR) radiation through his movement. PIR is an electronic sensor that used to detect the object motion by receiving the infrared (IR) radiates light from the external environment. Hence, the sensor compares the intensity of the infrared radiation from time to time. If there is an object movement in the room, then the intensity changes, it causes detecting the object movement. Knowing that the range for PIR sensor can up to 5-7 meters (Ahmad, Studiawan and Ramadhan, 2014). The PIR Sensor is small in size, inexpensive in price, used low-power, easy in use and connectivity. They are often referred to as PIR, Passive Infrared, Pyroelectric, or IR motion sensors (Patel *et al.*, 2016). In this proposed system the HC-SR501 PIR Sensor Module is used.

Figure 5. PIR Sensor

C. Raspberry Pi Camera Module

The Camera Module Rev 1.3 is a camera that created specifically for Raspberry Pi model A and B. It is manufactured by the Sunny company. It provides high sensitivity, very small PCB design, price almost 25\$, lightweight design and 5-megapixel resolution image. The camera module connects to Raspberry Pi 3 by CSI (Camera Serial Interface) connector using a 15cm ribbon cable to the 15 pin CSI connector (Million, 2013).

Figure 6. Raspberrv Pi Camera Module

D. Relay Card

A relay is an electrical switch that is used to control high voltage by using very low voltage and as an input (GPIO pins). It is used to control several circuits by one signal (Vigneswari *et al.*, 2015). The relay card consists of two parts. The first part of the right side in Figure 7 below, it consists of a ground, a control pin to switch ON/OFF depending on the state and a 5V power pin for the relay card itself. The second part on the left side, will be connected to the load device, it contains 3 cards:

- NC means (Normally Closed): this indicate to that when the relay card has 0 on the control pin (no input signal), the connected circuit active COM is connected to this thing when the relay coil is off.
- NO means (Normally Open): this indicate to that, on the reverse, when the relay card has 1 on the control pin (value of 5V applied to the relay card) will switch off the circuit and vice versa. COM is connected to this thing when the relay coil is on.
- COM means (Common): always connected, it is the moving point of the switch.

Besides that, only two relay plugs will be used in accordance with the selected operating mode. The Raspberry Pi sends a low current on its GPIO pins whether at 0 or 1. This a weak current is enough to excite the relay. In this proposed system the SRD-05VDC-SL-C sainsmart 2 relay module are used and the light bulb is load used for relay card. The light bulb was worked like the flashlight for the camera module

Figure 7. Relay Card

E. Power supply

The proposed system needs of two power supplies. The first one used for Raspberry Pi3 board is Micro USB connector that supplied at least 5V at up to 2.5Amps is main for the proposed system. It is worth to mention that, many smartphone chargers are appropriate for Raspberry Pi (Pi, 2012) as shown in Figure 8 below. The second one used for the light bulb is 220V.

Figure 8. Power supply adapter for Raspberry Pi

F. LED (Light Emittied Diode)

Electronic pieces resemble small lamps work to convert electricity to light and are available in different colors. In this system, the 5MM white LEDs are used to improve lighting for an image which captured by the camera module.

Figure 9. White LED

G. Telegram Application on a Smartphone

The telegram is a cloud-based mobile and computer messaging application with a focus on security and speed. The telegram-cli is a private library for telegram application which provides a possibility to send any file type from Raspberry Pi to smartphone and from the smartphone to the Raspberry Pi.

Figure 10. Telegram Application on Smartphone

H. GPIO Pins Configuration

The Raspberry Pi 3 has two rows of pins that called General Purpose Input Output (GPIO) connector which includes 40 pin connector.

Figure 11. GPIO pins layout for proposed system

The Raspberry Pi 3 allows the peripheral devices such as sensors, LEDs...etc to connect directly to GPIO pins. Also, the GPIO pins allow control and interact directly with the Raspberry Pi processor (Antony and Gidveer, no date). In addition, the Raspberry Pi 3 needs to install the libraries such as Rpi.GPIO that allows access to the GPIO pins using a programming language such as python. Besides that, the Rpi.GPIO library is used to install these pins as an input or output. The GPIO pins which used in the proposed system are mentioned in Figure 11.

IV. RESULTS

The security system is developed which result is represented in Figure 12 and Figure 13.

Figure 12. The security system at the moment of take the picture if motion is detected.

Transmission of Image, Message and The number of persons located via Wi-Fi internet to a smartphone.

Figure 13. The result of proposed security system in smartphone.

V. CONCLUSION

This paper presents a new smart security system that able to monitor any movement in the room .Besides that, this movement will be detected by using PIR sensor. The smart security system able to give monitoring information (image, a notification message with the numbers of people sites) in real time to alert the user through Telegram Application .Hence, the Raspberry Pi 3 has two basic components interacting with each other: one is the Telegram Application that executes on

the smartphone device's browser and server side scripts that run by the Raspberry Pi 3 Hardware tool component. This security system works immediately when turning ON the power supply for the system and no need for the user to execute the smart security system .Additionally, this system is the very effective and crucial system choice for several reasons belong to inexpensive, consumes low power, simple circuit, and advanced system.

A Study of Multistage Network Expansion Planning by Using DC-Lossy and Linearized-AC Models

Mehmet Fatih Cankurtaran, Engin Karatepe
Department of Electrical-Electronics Engineering,
Engineering Faculty, Dokuz Eylul University
Izmir, Turkey

mfatih.cankurtaran@gmail.com, engin.karatepe@deu.edu.tr

Abstract

— As the world's electrical consumption increases rapidly, the network expansion planning becomes a crucial issue for power system planners. In that manner, the transmission expansion planning (TEP) and the reactive power planning (RPP) should be performed in order to meet the growing demand in economically and securely. This paper presents a multistage network expansion planning; in the first stage the TEP is performed by using DC-lossy network model, in the second stage the RPP is performed by using linearized-AC network model in order to improve the voltage profile. Finally, the obtained network in planning stages is tested for long term performance by using Power World Simulator. The effectiveness of proposed method is demonstrated by using IEEE 24-bus reliability test system.

Keywords — *Transmission Expansion Planning, Reactive Power Planning, Multistage Network Expansion Planning, Voltage Profile*

I. INTRODUCTION

Over the last decade, network expansion planning has gained great importance due to the fact that the consumption of electricity in the world has been increasing rapidly [1], because the generated power should be transmitted to the loads in economically and securely. In that manner, transmission expansion planning (TEP) and reactive power planning (RPP) are of capital importance for power system planners [2].

In literature, the different network models have been developed for TEP problems [3-6]. In general, the DC network model is used because of its simplicity and less computational burden [3-4]. On the other hand, the AC network models have been introduced in power planning problems [5-6]. But in this case, the problem becomes more complex because of increasing variables and constraints. In addition, although the reactive power issue and voltage

magnitudes can be included in AC network models, it can be result in oversized investment on transmission lines [7] for maintaining the voltage levels within allowable range by adding more lines. Due to these reasons, the RPP is usually performed after the TEP problem where the main aim is to allocate the reactive resources with a minimum cost in order to improve the voltage profile.

In this paper, a multistage network expansion planning is performed. In the first stage, the TEP is performed by using DC-lossy network model. In the second stage, the RPP is performed by using linearized-AC network model in order to improve the voltage profile. The annual peak load is considered during the planning stages. In order to demonstrate the effectiveness of the planning results for a long term performance, the AC optimal power flow (OPF) including voltage and line constraints is performed under the hourly test load profile of a year. Thanks to ability of Power World Simulator (PWS) program [8], the IEEE 24-bus system is constructed with obtained expansion planning and then the long term simulation is performed through this environment.

This paper is organized as follows. In Section II, the planning procedures and the mathematical formulation of TEP and RPP are given. Section III presents the results of the planning stages using IEEE 24-bus test. In Section IV, the long term performance of the planning results is investigated by using PWS program. Finally, some concluding remarks are presented in Section V.

II. PLANNING PROCEDURE AND FORMULATION

In this paper, the planning procedure consists of two stages. In the first stage, TEP is applied by using DC-lossy network model for the purpose of dealing with the congestion on the lines. In the second stage, RPP is

This study was supported by the Scientific and Technological Research Council of Turkey, TUBITAK-114E514.

performed by using linearized-AC network model and it is aimed to find the location and size of capacitors by using the obtained network in the first stage in order to get the voltage levels in acceptable range and enhance voltage profile of system.

A. Transmission Expansion Planning

The DC network model considering power loss is used to solve TEP problem and the formulation is given as follows;

$$\text{Min} \quad C_{line} = \sum_{(i,j) \in \Omega^c} c_{ij} n_{ij} \quad (1)$$

Subject to

$$\sum_{(i,j) \in \Omega^o \cup \Omega^c} P_{ij} + PG_i = \sum_{(i,j) \in \Omega^o \cup \Omega^c} PL_{ij} + PD_i \quad (2)$$

$$PL_{ij} = g_{ij} \theta_{ij}^{sqr} \quad \forall (i,j) \in \Omega^o \quad (3)$$

$$0 \leq PL_{ij} - g_{ij} \theta_{ij}^{sqr} \leq (1 - n_{ij})M \quad \forall (i,j) \in \Omega^c \quad (4)$$

$$0 \leq PL_{ij} \leq n_{ij} g_{ij} (\bar{\theta}_{ij})^2 \quad \forall (i,j) \in \Omega^c \quad (5)$$

$$P_{ij} = b_{ij} \theta_{ij} \quad \forall (i,j) \in \Omega^o \quad (6)$$

$$-\bar{P}_{ij} \leq P_{ij} \leq \bar{P}_{ij} \quad \forall (i,j) \in \Omega^o \quad (7)$$

$$-(1 - n_{ij})M \leq P_{ij} - b_{ij} \theta_{ij} \leq (1 - n_{ij})M \quad \forall (i,j) \in \Omega^c \quad (8)$$

$$-n_{ij} \bar{P}_{ij} \leq P_{ij} \leq n_{ij} \bar{P}_{ij} \quad \forall (i,j) \in \Omega^c \quad (9)$$

$$\underline{PG}_i \leq PG_i \leq \bar{PG}_i \quad (10)$$

$$\theta_{ij}^{sqr} = \sum_{l=1}^L s(l) \Delta \theta_{ij}(l) \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (11)$$

$$\theta_{ij} = \theta_{ij}^+ - \theta_{ij}^- \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (12)$$

$$\sum_{l=1}^L \Delta \theta_{ij}(l) = \theta_{ij}^+ + \theta_{ij}^- \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (13)$$

$$0 \leq \theta_{ij}^+ \leq \sigma_{ij} \bar{\theta}_{ij} \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (14)$$

$$0 \leq \theta_{ij}^- \leq (1 - \sigma_{ij}) \bar{\theta}_{ij} \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (15)$$

$$-\bar{\theta}_{ij} \leq \theta_{ij} \leq \bar{\theta}_{ij} \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (16)$$

$$0 \leq \Delta \theta_{ij}(l) \leq \frac{\bar{\theta}_{ij}}{L} \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (17)$$

$$\Delta \theta_{ij}(l+1) \leq \Delta \theta_{ij}(l) \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (18)$$

$$\frac{\bar{\theta}_{ij}}{L} - \Delta \theta_{ij}(l) \leq [1 - \varepsilon_{ij}(l)] \frac{\bar{\theta}_{ij}}{L} \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (19)$$

$$\Delta \theta_{ij}(l+1) \leq [1 - \varepsilon_{ij}(l)] \frac{\bar{\theta}_{ij}}{L} \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (20)$$

$$s(l) = (2l-1) \frac{\bar{\theta}_{ij}}{L} \quad \forall (i,j) \in \Omega^o \cup \Omega^c \quad (21)$$

Ω^o and Ω^c denote the set of existing and candidate lines, respectively. The objective function is presented in (1) which includes total line investment cost. In (2), the real power balance equation is given. While the real power loss for existing lines is represented in (3), constraints (4) and (5) represent the real power loss for candidate lines where θ_{ij}^{sqr} denotes the square of bus voltage angle difference. In order to represent this quadratic term as in linear form, the piece-wise linearization technique [9] is used and corresponding equations are given in (11)-(21). In (6) and (7), the real power flows and its limits for existing lines are presented, respectively. In (8) and (9), to calculate the real power flows for candidate lines, disjunctive method is used in order to overcome the nonlinearity term which come from product of binary variable and continuous variable. The real power limits of generators are given in (10).

B. Reactive Power Planning

The linearized-AC network model is used to solve RPP problem by using obtained network in first stage. The formulation of this problem is given as follows.

$$\text{Min} \quad C = \sum_{i \in \Omega^L} (\Delta V_i^{set} - \Delta V_i)^2 \quad (22)$$

Subject to

$$\left\{ \begin{array}{l} \text{Constraints (1), (7), (10)-(21)} \end{array} \right.$$

$$\sum_{(i,j) \in \Omega^{up}} Q_{ij} + \sum_{k \in \Omega^{cap}} QC_i^k + QG_i = \sum_{(i,j) \in \Omega^{up}} QL_{ij} + QD_i \quad (23)$$

$$P_{ij} = (\Delta V_i - \Delta V_j) g_{ij} - b_{ij} \theta_{ij} \quad \forall (i,j) \in \Omega^{up} \quad (24)$$

$$PL_{ij} = g_{ij} \sum_{l=1}^L s(l) \Delta \theta_{ij}(l) \quad \forall (i,j) \in \Omega^{up} \quad (25)$$

$$Q_{ij} = -(\Delta V_i - \Delta V_j) b_{ij} - g_{ij} \theta_{ij} \quad \forall (i,j) \in \Omega^{up} \quad (26)$$

$$QL_{ij} = -b_{ij} \sum_{l=1}^L s(l) \Delta \theta_{ij}(l) \quad \forall (i,j) \in \Omega^{up} \quad (27)$$

$$(1 - d_i^k) \underline{QC}_i^k \leq QC_i^k - (1 + 2\Delta V_i) b_i^{cap} \leq (1 - d_i^k) \bar{QC}_i^k \quad \forall i \in \Omega^L \quad (28)$$

$$d_i^k \underline{QC}_i^k \leq QC_i^k \leq d_i^k \bar{QC}_i^k \quad \forall i \in \Omega^L \quad (29)$$

$$\sum_{k \in \Omega^{cap}} d_i^k \leq \bar{d}_i \quad \forall i \in \Omega^L \quad (30)$$

$$\underline{\Delta V}_i \leq \Delta V_i \leq \overline{\Delta V}_i \quad (31)$$

$$\underline{QG}_i \leq QG_i \leq \overline{QG}_i \quad (32)$$

The objective function is given in (22) where the aim is to improve the voltage profile and ΔV_i is the voltage deviation. Ω^u and Ω^L denote the set of updating network lines (obtained from TEP result) and set of load buses, respectively. The reactive power balance equation is given in (23). The real power flow and power loss are presented in (24) and (25), respectively. Similarly, the reactive power flow and power losses are presented in (26) and (27). In (29), the installation of capacitor k at bus i is determined by d_i^k which is binary variable, i.e. when d_i^k is equal to 1, capacitor k is installed at bus i , otherwise it is not installed. When the capacitor k is connected at bus i , the value of reactive power injection is calculated in (28). In this equation, the linear approximation technique is used to linearize the square of voltage (i.e. $V_i^2 \approx 1 + 2\Delta V_i$). The installation limits of capacitors at bus i is given in (30). In (31) and (32), upper and lower limits of voltage magnitude and reactive power limits of generators are given, respectively.

III. CASE STUDY

The presented method is performed on the IEEE-24 bus reliability test system (RTS) which has 24 buses, 35 existing lines, 32 generators at 10 buses, and 21 loads. The system parameters and line investment cost can be found in [10]. In order to create contingency, the total system load is increased by 50% and the maximum power flow limit of line is decreased by 50%. The system peak load which is at the 51th week on Tuesday from 5 to 6 P.M. is used for TEP and RPP stages. The capacitor used in this paper has 0.2 per unit susceptance value with a cost M\$ 0.05 each [11].

All results are obtained on the computer which has Intel(R) Xeon(R) CPU E5-2650 @ 2.3 GHz with 64 GB of RAM by using CPLEX under GAMS. While the mixed integer linear programming (MILP) is used to solve TEP problem, the mixed integer quadratic programming (MIQCP) is used to solve RPP problem.

TABLE VII. TEP RESULTS FOR THE IEEE-24 BUS SYSTEM

Candidate Lines	Expansion Plan

15-21	
15-24	
16-17	1
17-22	
20-23	1
Investment Cost (M\$)	202.65

The candidate lines and expansion plan of TEP problem are given in Table I. There are 15 candidate lines and as an expansion plan, totally 8 lines are required to be built with a cost M\$ 202.65 in order to run the system in efficient manner. Then, the RPP is performed to find the location and number of capacitors by using the updated network and the results are given in Table II.

As seen in Table II, the all load buses are selected as a candidate bus and totally 6 capacitors are required to be connected at 4 buses. The IEEE-24 bus test system has two regions considering voltage levels which are lower region with 132kV and the upper region with 230kV. At upper region of system, there are strong buses because the bulk generators are placed and there are generation surplus. On the other hand, the buses at the lower region of system are weak buses because of the generation deficits. Thus, as it is expected, the locations of the capacitors were found at lower region of system in the RPP stage.

TABLE VIII. RPP RESULTS FOR THE IEEE-24 BUS SYSTEM

Candidate Buses	Expansion Plan
3, 4, 5, 6, 8, 9, 10, 11, 12, 17, 19, 20, 24	3(1), 6(2), 9(2), 10(1)
Investment Cost (M\$)	0.3

To demonstrate the effectiveness of the RPP, the voltage levels of load buses before and after RPP are illustrated in Fig. 1. These values are obtained from AC power flow solution for annual peak load. As seen in this figure, the voltage violations are observed at some buses before the RPP. After the RPP, the voltage magnitudes can be maintained within the range of required levels and the voltage profile of system is improved.

Fig. 1. The voltage levels for before and after performed RPP stage

IV. LONG TERM PERFORMANCE OF PLANNING RESULTS

The results of TEP and RPP stages are obtained according to maximum load condition. In this section, the long term performance of obtained expansion plan by using proposed method is investigated. In that manner, the hourly 8736 real and reactive load data are generated as seen in Fig. 2 according to annual peak load for IEEE 24-bus system [12].

Power World Simulator (PWS) is a user friendly program and it facilitates to understand what happens in the power system visually. Moreover, it is an interactive simulation program designed to simulate the power system operation on a time frame ranging from several minutes to several days [8]. Thus, PWS is used in order to perform AC-OPF for 8736 hours and the IEEE 24-bus test system is shown in Fig. 3.

Fig. 2. The generated hourly real and reactive load data

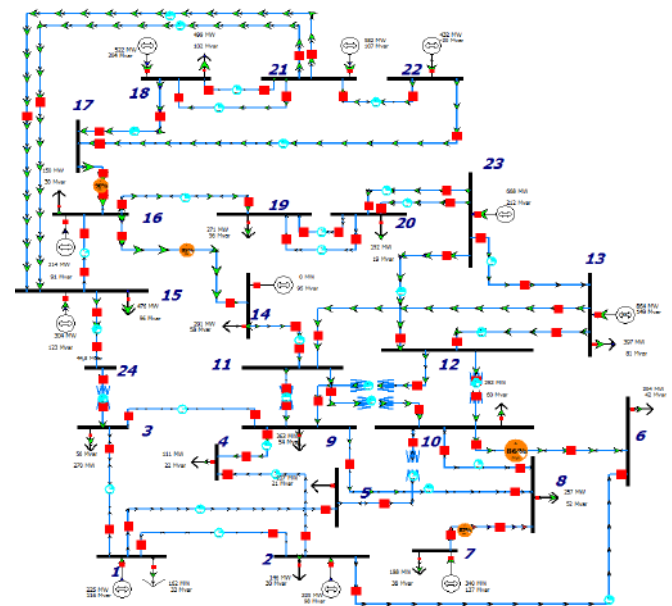

Fig. 3. The IEEE 24-bus test system in PWS

The IEEE 24-bus test system is constructed according to planning results in order to investigate the long term system performance. Voltage levels and line flows for each hour are obtained and it is observed that there is no violation on lines and voltage limits. The mean and standard deviation of the voltage at load buses are given in Table III for 8736 hours. As seen in table, the mean of the most of bus voltages are around 1 per unit and the standard deviations are within acceptable range. As a result, besides no violation, a good voltage profile is obtained for long term load profile by using presented planning procedure.

TABLE IX. LONG TERM PERFORMANCE OF VOLTAGE PROFILE

Load Buses	Mean	Standard Deviation
3	1,0098	0,0159
4	1,0001	0,0132
5	0,9997	0,0129
6	0,9949	0,0126
8	0,9845	0,0151
9	1,0049	0,0116
10	0,9909	0,0126
11	0,9745	0,0105
12	0,9851	0,0135
17	1,0400	0
19	1,0200	0
20	1,0388	0,0012
24	1,0079	0,0102

V. CONCLUSION

In this paper, a multistage network expansion planning is presented. In the first stage, DC-lossy network model is used in TEP problem for minimizing line investment cost. Then, in the second stage, the linearized-AC network model is used in RPP problem to improve the voltage profile of system. The effectiveness of the proposed method is demonstrated by using IEEE 24-bus reliability test system. The planning results are tested for long term operation by using Power World Simulator. The results show that the planning procedure is capable of long term operation without any violation and also improvement on voltage profile.

Abstract— In this study, a method has been used to classify the short circuit faults. In this method, the current values of three phases and zero, positive, and negative sequence current component values obtained through the application of modal transformation on the line currents have been used in order to obtain the classification features. In each case of fault, in order to ensure that the classification features remain within specific range of values, the current values of the three phases for one cycle after fault occurrence are reduced being divided by the biggest peak value among the current values of again these three phases. Similarly for each case of fault, the sequence current components for one cycle after fault occurrence are reduced being divided by the biggest peak value among the sequence current components. After the signals are reduced, the classification features are obtained using Root Mean Square (RMS) values of the three phase current signals, RMS values of the sequence current component signals and the proportions of these RMS values to each other. The classification features obtained are used with Naive Bayes and J48 machine learning methods to classify the short circuit faults occurring in transmission lines. While the Alternative Transients Program (ATP/EMTP) is used to model the transmission lines, the Waikato Environment for Knowledge Analysis (WEKA) program is used for Naive Bayes and J48 machine learning algorithms.

Keywords—*fault classification; naïve bayes; j48; root mean square; transient current signals*

I. INTRODUCTION

With several literature studies, fault classification is one of the significant issues worked on in order to treat short circuit faults faster and better. Half Cycle Discrete Fourier Transform (HCDFT), Full Cycle Discrete Fourier Transform (FCDFT) and Fuzzy Logic (FL) are used in order to define different types of faults (Das and Reddy, 2005). HCDFT and FCDFT are applied on current signals to obtain different features for classification. Although in the study it is emphasized that the use of FCDFT will bring about better

classification features, HCDFT and FL combination is recommended for fault classification as HCDFT is faster (Das and Reddy, 2005). Multi Resolution Analysis (MRA) and Fuzzy Interference System (FIS) are used in order to develop a method to determine the location and type of fault in transmission lines (Reddy and Mohanta, 2007). Wavelet transform is applied on line currents in order to obtain MRA coefficients, then the type of fault is determined by applying the sum of these MRA coefficients on a certain rule base. In the study, fault types have been determined for approximately 1000 individual cases and phase angle at fault instant has been claimed to have a significant influence on line currents and phase angle at fault instant has been kept between (0-180°) degrees (Reddy and Mohanta, 2007). Discrete Wavelet Transform (DWT) and Multiclass Support Vector Machine (MCSVM) are used in order to develop a method to determine the type of fault in transmission lines (Ekici, 2012). Consisting of half cycle before and half cycle after fault a total one cycle of current and voltage signals have been used for DWT feature extraction (Ekici, 2012).

In this study, one-cycle current signals have been used in order to obtain classification features. Modal transformation has been applied on current signals in order to increase the number of features to be used in classification. Each line current is divided by the biggest peak value among the line currents of the three phases in order to ensure that the classification features in various fault cases remain within the specific range of values. Similarly, each of the three sequence components are divided by the biggest peak value of the three sequence current components. Then, RMS values of the line currents, RMS values of the sequence current components and the proportions of these RMS values to each other are used in order to obtain classification features. After the classification features are obtained, Naive Bayes (NB) and J48 machine learning algorithms are used in order to classify short

circuit faults. While the ATPDraw (Meyer and Liu, 1987) program is used to model the transmission lines and to obtain transient current, WEKA (Hall, Frank, Holmes,

II. OBTAINMENT OF CLASSIFICATION FEATURES

Extraction of classification feature from current or voltage signals has mostly been one of the most significant issues in the studies conducted. Varying line and fault parameters might influence the classification features obtained. Consequently, classification features must be clear and consistent for several states of faults. In this study, RMS values of one-cycle line currents occurring after fault, RMS values of zero, positive and negative sequence current components obtained after modal transformation of these line currents and the proportions of these RMS values to each other are used in order to obtain the classification features.

Equation 1 is used in order to apply modal transformation to line currents. Here, I_m indicates the modal current vector and I_p indicates the phase domain current vector. Transformation matrix T and T^{-1} is given in Equation 2.

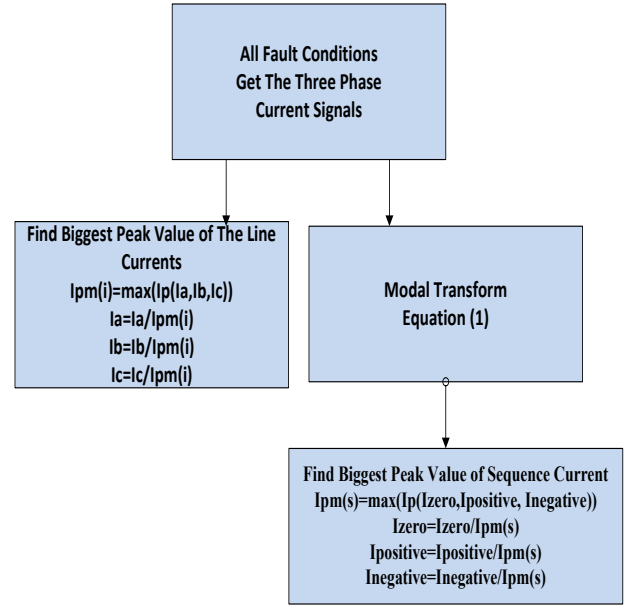

$$I_m = T^{-1}I_p \quad (1)$$

$$T = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & -1 & -1 \end{bmatrix} \text{ and } T^{-1} = \frac{1}{3} \begin{bmatrix} 1 & 1 & 1 \\ 2 & -1 & -1 \\ -1 & 2 & -1 \end{bmatrix} \quad (2)$$

RMS values of line current signals are affected by different states of faults. In order to minimize this effect, line current signals and sequence components of current signals at each case of fault are reduced through a certain method before getting RMS values. To do this, each line current is divided by the biggest peak value of the three phase currents and so the line current signals are reduced. Similarly, each of the three sequence current components is divided by the biggest peak value of these components to reduce the sequence current component signals. Figure 1 presents the method used to reduce the signals at each case of short circuit fault.

Figure 2 presents the wave forms obtained after the reduction of the line currents formed by the Symmetrical Three-Phase Fault (LLL) occurring in the middle of the 600 km long transmission line with 25 mH source inductance. As it can be seen here, the biggest peak value of the three phase line current is +1 A. Figure 3 presents the wave forms obtained after the reduction of the sequence current components for the same fault. As it can be seen in this figure, the biggest peak value of the sequence current components is +1 A. With this method, the signals are reduced in such a way that the peak values of the biggest

Pfahringner, Reutemann, Witten, 2009) program is used for classification algorithms.

line current and the biggest sequence current component will be either -1 A or +1 A in each case of faults.

Figure. 1. The method used for each case of short circuit fault to reduce three phase currents and sequence components of the currents

In this study, 12 features in total have been used for classification after reducing signal. While RMS values of each line current (RMS (Phase (A)), RMS (Phase (B)), RMS (Phase (C))) and the proportions of these values to each other (RMS (Phase (A))/RMS (Phase (B)), RMS (Phase (B))/RMS (Phase (C)), RMS (Phase (C))/RMS (Phase (A))) are used in the first six features; RMS values of the zero, positive and negative sequence current components obtained after the application of modal transformation on current signals (RMS (Zero), RMS (Positive), RMS (Negative) and the proportions of these values to each other (RMS (Zero)/RMS (Positive), RMS (Positive)/RMS (Negative), RMS (Negative)/RMS (Zero)) are used in the other six features.

Here, the RMS value of a vector is calculated as;

$$X_{RMS} = \sqrt{\frac{1}{N} \sum_{n=1}^N [X_n^2]}$$

(3)

The Bayes Theorem determines the probability of the occurrence of an event by considering the probability of another event that occurred in the past (Vijayarani and Muthulakshmi, 2013; Khoshgoftaar, Golawala and Hulse, 2007). NP classifiers are very fast for learning and applying. The classifier is called “naïve” as all predictor variables are assumed to be conditionally independent. Although the assumption of independence is typically inaccurate for the real world data, the classifier is reported to have shown

Figure. 2. The wave forms obtained after the reduction of the three phase line currents

Figure. 3. The wave forms obtained after the reduction of the sequence current components

III. NAÏVE BAYES AND J48 MACHINE LEARNING ALGORITHMS

After the classification features are obtained, NB and J48 machine learning algorithms are used in order to classify the types of faults. WEKA program is used in order to apply NB and J48 algorithms. WEKA is a JAVA program having graphical tools and algorithms necessary for data analysis. WEKA is able to perform several standard data mining applications such as pre-processing, clustering, classification, integration, visualization and feature selection (Aher and Lobo, 2011).

A. Naïve Bayes

NB algorithm depends on conditional probabilities. This machine learning method uses the Bayes Theorem, which is a formula that calculates a probability by counting the frequency of the past data values and value combinations.

good performance even in the presence of strong feature dependencies (Khoshgoftaar, Golawala and Hulse, 2007).

B. J48

Ross Quinlan (Quinlan, 1993) developed C4.5 algorithm which is used to create a decision tree. In this technique, a tree is created in order to model the classification process. Once the tree is created, the method is applied to each data group inside the database and that data group is classified. When creating a tree, J48 ignores the missing values. The value of that matter can be predicted based on the feature values of other records. J48 allows for classification through decision trees or through rules that are made depending on those (Patil and Sherekar, 2013)

IV. SIMULATION STUDY

Transmission line parameters selected in the study are presented in Table 1. Figure 4 presents the ATPDraw model of LLL fault.

Table 1. transmission line parameters

Line length	600km
Voltage	380kV
Frequency	50Hz

Figure. 4. ATPDraw model used in the simulation for LLL fault

Table 2. short circuit fault parameters used in the simulation

	Database 1	Database 2	Database 3
Fault Distance (km)	20,40,60,80...580	30,50,70,90...570	100,200,300...500
Fault Resistance (Ω)	1,25,50	15,30,45	15,30,45
Source Inductance (mH)	1,25,50	15,30,45	15,30,45
Phase Angle (Degree)	0	0	30,90,150,210,270,330
Number of Fault Types	10	10	10
Number of Different Fault Types	10	10	10
Total Data	7830		

Table 2 presents the short circuit fault parameters selected for creating the faults in different conditions. As it can be seen from this table, 7830 individual short circuit faults were created using ATPDraw program. 10 different types of fault, namely, Line-to-Ground-(LG)(a), Line-to-Ground-(LG)(b), Line-to-Ground-(LG)(c), Line-to-Line-(LL)(a-b), Line-to-Line-(LL)(a-c), Line-to-Line-(LL)(b-c), Double Line-to-Ground fault (LLG)(a-b-g), Double Line-to-Ground fault (LLG)(a-c-g), Double Line-to-Ground fault (LLG)(b-c-g) and LLL short circuit fault, were used in this study. 10 different types of classification were appointed in NB and J48 classification algorithms for these 10 different types of faults.

In the study, the classification method created in three different ways was tested using WEKA program. First, randomly chosen 20% of the database (1556 data) was used

for training and 80% (6264 data) was used for testing. Then, randomly chosen 30% of the same database (2349 data) was used for training and 70% (5481 data) was used for testing. Finally, k=10 cross-validation was made in database in order to test the classification success of the method. Table 3 presents the results of the simulation.

Table 3 shows that J48 machine learning algorithm ($S \geq 98.83\%$), which is based on tree structure, is more successful in fault classification compared to the NB machine learning method ($S=90.93$) which is based on probability. This is similar to the results of [10]. In study [10], NB and J48 algorithms were compared in terms of

classification in certain datasets and J48 algorithm was reported to be more successful in classification. In Table 4, literature studies and the recommended method are compared in terms of certain aspects. Values given in the Table 4 show that, the recommended method ($S \geq 98.83\%$) is as successful as the methods used in literature. However, number of test data used (6264) in this study is more than

Table 4. fault classification studies completed in literature

	The signal used	Feature extraction	Classifier	Number of tests	Success %
Das and Reddy	Line Currents	MRA, FIS	Some detected rules	T \approx 1000	100

number of test data used in literature.

V. CONCLUSIONS

Fault classification is one of the significant issues worked on in transmission lines. In this study, several different short circuit faults were created using ATPDraw program in order to obtain transient current signals. In order to ensure that the classification features remain within certain value range in different fault conditions, three phase currents of after-fault were divided by the biggest peak values of three phase current. Similarly, sequence components of line currents were divided by the biggest peak values of sequence components of line currents. Then, RMS values of the line current signals, RMS values of sequence current component signals and the proportions of RMS values to each other were used in order to obtain classification features. Once the features were obtained, Naive Bayes and J48 machine learning algorithms were used in order to classify the types of short circuit faults. Results of the simulation showed that J48 machine learning algorithm based on the tree structure was more successful for the database used in classification. Similarly, these simulated results show that combination of the classification feature extraction method used in the study and the J48 classification algorithm are successful for determining the short circuit faults.

Abstract—A metamaterial based sensor is designed and demonstrated numerically and experimentally for the detection of microfluids. The structure consisting of a single circular split ring resonator (CSRR) has a simple geometry and can be adjusted to any desired frequency depending on the material to be characterized. In this study, two different chemical liquid sensor applications have been investigated. First, a liquid sensor application which can successfully achieve the alcohol content of the ethanol water mixture. Second, application of chemical liquid sensor to distinguish branded and unbranded diesel samples from each other are designed. The results show that the proposed structure is especially applicable to liquid sensor applications in biochemistry.

Keywords—metamaterial; biochemical sensor; liquid sensor; microwave

I. INTRODUCTION

Sensor applications have always attracted the attention of many scientists. In this work, a novel sensor technology recently interested by many scientists is being investigated. This technology is based on metamaterials (MTM) exhibiting unusual electromagnetic behaviors. Using these extraordinary materials, it is possible to achieve negative permeability and permittivity at the same time. MTMs [1]-[3] have great potential and wide application prospects in perfect absorber [4], perfect lenses [5], invisible cloaks [6], chirality [7], and super definition [8] and so on.

Recently, many MTM-based sensor structures have been investigated in microwave frequencies. Characterization and applications of various sensing devices such as liquid sensing based on a discrete ring resonator was performed by Withayachumnankul et al [9]-[10]. The operating principle of such microfluidic sensing devices depends on the interaction between the samples placed in the sensing layer and the electric field provided by the microstrip lines. A chiral MTM sensor structure has been designed by Karaaslan et al [11] to determine the properties of samples with chiral properties.

Various MTM-based strain sensor applications have been implemented by Melik et al [12] to detect mechanical deformation in microwave frequencies.

In this work, we proposed a metamaterial sensor with the ability to detect ethanol-alcohol mixed liquid detection and branded-unbranded diesel fuels in microwave frequency regime theoretically and experimentally. The proposed structure has a simple circular split ring resonator (CSRR) topology coupled with a microstrip transmission line to investigate the transmitted signal. First, the operating frequency of the structure was investigated numerically and experimentally, assuming that the sensor layer was empty. To perform the liquid sensing application, the dielectric constant and dielectric loss values of the ethanol-water mixture and the diesel samples were measured using the dielectric probe kit at the operating frequency band. The sensing ability of the proposed structure according to the obtained dielectric properties of the fluids was analyzed numerically and experimentally with a simulation program and a vector network analyzer.

II. NUMERICAL AND EXPERIMENTAL DESIGN

The proposed sensor structure is designed and fabricated as a circular split ring resonator (CSRR). A microstrip transmission line, which forms the magnetic coupling effect with the CSRR, is integrated on the structure to observe the shifts in resonance frequency as shown in Fig. 1 (d). The back side of the structure is covered with a metallic plate, which is set as the ground plane. A radial gap was created in the CSRR to measure the sensitivity of the samples by monitoring the shifts in resonance frequency, which is an important parameter for the sensor applications. Typical dimensions of the CSRR and microstrip line obtained from parametric studies are given in Table 1.

Table 1. Typical dimensions of the proposed structure

r1	r2	sr1	sr2	rg	rd
7.0 mm	5.0 mm	4.35 mm	3.85 mm	2.0 mm	7.30 mm

Numerical studies were carried out with electromagnetic simulator software based on finite integration technique. As shown in Fig. 1 (c), two separate connection points are integrated at both ends of the microstrip transmission line to monitor the transmission coefficient S_{12} . Electromagnetic properties of the ethanol water mixtures and diesel samples were measured with the Agilent 85070E dielectric probe kit and these mixtures and diesel samples are defined as new materials according to the values measured in the simulation program.

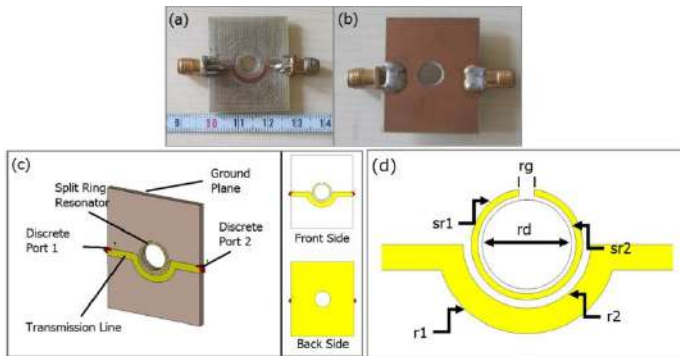

Figure 1. (a) The front side of the proposed structure, (b) the back side of the proposed structure, (c) The simulation model of the sensor structure, and (d) the geometrical dimensions of the proposed structure.

The metamaterial-based sensor structure was fabricated by the LKPF E33 Protomat PCB prototyping machine as shown in Fig. 1 (a) and (b). The dielectric substrate used in simulation and production is FR4 with a thickness of 1.6 mm, relative permittivity of $\epsilon_r = 4.3$ and loss tangent of $\tan \delta = 0.02$. The metal plates on the dielectric substrate is copper with a thickness of 35 μm and an electrical conductivity of $\sigma = 5.80001 \times 10^7 \text{ S/m}$. In addition, 50 Ω connectors are soldered on both sides of the transmission lines.

Experimental study of the sensor was performed with the PNA-L Agilent vector network analyzer (VNA) with operating frequency up to 43.5 GHz. The experimental setup is shown in Fig. 2. Before connecting the sensor structure for measurement, the VNA was calibrated using the appropriate calibration kit.

Figure 2. The experimental setup

The structure was then connected to the VNA and measured without the sample to be measured in the sensing layer. The corresponding simulation and test results for the sensor structure without any sample placed in the sensing layer are shown in Fig. 3. It is observed that the proposed sensor structure has a resonance frequency of about 4 GHz. There was a slight difference between the measurement and simulation results, due to calibration errors and manufacturing errors.

Figure 3. Simulation and experimental results of the transmission coefficient

III. ETHANOL-WATER MIXTURE SENSING APPLICATION

An ethanol water mixture was used for liquid detection application. The dielectric constant and dielectric loss factor values of the mixtures were determined with Agilent 85070E dielectric probe kit based on the percentage of ethanol in the mixture. After the dielectric probe kit was calibrated, the ethanol ratio of the mixture was increased by 20% each time, and the measurements are carried out at the operating frequency of 4.1 GHz. Table 2 shows the dielectric properties of the alcohol content in purified water measured at 4.1 GHz by means of a dielectric probe connected to the network analyzer. The dielectric properties given in Table 2 are those obtained at 4.1 GHz.

Table 2. Dielectric and loss tangent values of the ethanol-water mixture at 4.1 GHz

Ethanol Content (%)	ϵ'	ϵ''	Loss Tan.	Sim. Res. Freq. (GHz)
0	78,64	11,34	0,144	3,897
20	69,42	11,03	0,159	3,911
40	52,85	10,03	0,190	3,924
50	45,03	9,27	0,206	3,930
60	37,66	8,16	0,217	3,943
80	25,35	6,99	0,276	3,987
100	8,96	5,22	0,583	4,057

In this section, the application of liquid sensor for specific ethanol and water mixture ratios of the CSSR sensor structure has been investigated. The observed transmission coefficient values are obtained numerically and experimentally as shown in Fig. 4. Examining the simulation results given in Fig. 4 (a), the resonance frequency is found to be at about 3.897 GHz for pure water content. When the percentage of ethanol in the mixture increases by 20%, the resonance frequency shifts to the right to new value of 3.911 GHz. As the amount of ethanol content in the mixture increases, the shift in the resonance frequency of the proposed sensor appears to be approximately linear as shown in the simulation results in Fig. 4 (a). Such linear variation is also observed in the experimental results as seen in Fig. 4 (b). The experimental results have the resonance frequencies obtained for 0%, 20%, 40%, 50%, 60%, 80% and 100% of the ethanol content of the mixture at 4.024 GHz, 4.029 GHz, 4.033 GHz, 4.035 GHz, 4.038 GHz, 4.043 GHz, and 4.0, respectively. Numerical and experimental results demonstrate that the proposed CSSR based sensor structure has the potential to be used as a liquid sensor.

Figure 4. (a) simulation and (b) test results for the liquid sensor with respect to ethanol content

IV. BRANDED AND UNBRANDED DIESEL SENSING APPLICATION

In this section, an experimental study was conducted to distinguish branded and unbranded diesel fuels. First, the dielectric properties of the diesel samples were determined with the Agilent 85070E dielectric probe kit as shown in Table 3. Although the values are close to each other, the sensor structure of the proposed sensor has different capacitive effects on the sensor layer.

Table 3. Dielectric and loss tangent values of branded and unbranded diesel samples at 4.1 GHz

	ϵ'	ϵ''	Loss Tan.	Meas. Res. Freq. (GHz)
Branded Diesel	2.642	0.584	0.221	4.082

Unbranded Diesel	2.689	0.614	0.228	4.091
-------------------------	-------	-------	-------	-------

The experimentally obtained resonance frequencies for branded and unbranded diesel samples are shown in Fig. 5. It has been observed that the branded and unbranded diesel samples placed in the sensor layer shift the resonance frequency of the CSRR. The resonance frequency was obtained at 4.082 GHz for the branded diesel sample and 4.091 GHz for the unbranded diesel sample. A difference of about 9 MHz has occurred between the resonance frequencies of the two samples. When the results are examined, it is understood that the proposed sensor structure has the ability to separate two samples from each other.

Figure 5. Experimental results for branded and unbranded diesel samples

V. CONCLUSION

A CSRR type sensor structure with a metamaterial base exhibiting chemical liquid sensor characteristics has been analyzed both numerically and experimentally at microwave frequencies. In the study, first, the dielectric properties of the ethanol water mixture and diesel samples were determined. The samples are then tested both experimentally and numerically. When the findings are examined, it is understood that the proposed sensor structure works well as a chemical liquid sensor.

Abstract—We present a Metasurface (MS) polarization converter to transform linearly polarized signals into circularly polarized signals. The unit cell of the proposed structure consists of two metallic patches placed in the cross corners of a rectangular loop. Polarization conversion quality referred to axial ratio is kept below 3 dB. The axial ratio is obtained numerically and experimentally by the division of cross-polar and co-polar responses of the antennas. Quite good axial ratio bandwidth, 260 MHz, is achieved experimentally which supports the simulation results. The proposed MS structure can be fabricated and configured easily for any desired frequency range due to its simple design. It can be used efficiently in many applications such as weather radar, airport surveillance radar and satellite communications.

Keywords—axial ratio; axial ratio bandwidth; metasurface; polarization conversion

I. INTRODUCTION

Metamaterials (MTMs) are artificial materials having unusual electromagnetic properties which cannot be found in nature. First theoretical study about double negative material (DNG) was carried out by Veselago in 1968 [1]. In the late 20th century, Pendry et. al. produced materials which have negative value of dielectric permittivity [2] in 1996 and magnetic permeability [3] in 1999. In 2000, Smith et al. realized the first DNG material which consists of a split ring and wires providing negative permittivity and negative permeability, simultaneously [4]. In recent years, many researchers study MTMs and its application areas and this attention gradually increases [5]–[7].

Metasurfaces (MSs) are the two dimensional equivalent of MTMs. MSs take up less volume and they can be less lossy structures comparing to the three dimensional MTMs [9]. There are many potential application areas concerning MS structures such as controllable smart surfaces [10], wave guide

structures [11] and absorbers [12]. In addition to these topics, MSs are also configured as polarization converter structures. Many radar and satellite systems need circularly polarized signals rather than linearly polarized ones, because circular polarization keeps signal constant at bad weather conditions.

In this study, we present a polarization converter MS structure to transform linearly polarized signal into circularly polarized one, numerically and experimentally. In order to show the conversion feature, the axial ratio (AR) of the proposed MS is calculated by dividing cross and co-pol responses. In the design, metallic patches placed in cross corners of rectangular loops are provide phase difference to obtain circular polarization. The proposed MS has two dip points which provide perfect polarization conversion activity at 2.85 GHz and 3.10 GHz. It has also 260 MHz of axial ratio bandwidth (ARBW) at two separate frequency ranges. The polarization converter can be efficiently used in S-band applications such as weather radar, airport surveillance radar, and satellite communications and so on.

Furthermore, in antenna industry, you must design two separate antennas if you need both linear and circular polarization. It is not only costly and time consuming but it also requires more physical space which is extremely important in the sector. Physical space for the antenna integration is generally limited meaning that the engineers mostly faced up the problem shrinking the antenna to fit the limited space on the radio transmitter or receiver structures. Therefore, there are many studies and researches concerning about the miniaturization of antennas. This problem can be overcome by using the proposed structure, having an antenna which is capable of radiating both linearly and circularly polarized waves will be possible. In other words, designing a linear polarized antenna will be enough to work with in any application requiring both linearly and circularly polarized

signals. In addition, the structure only contains a single layer which makes it possible for us to integrate the structure on any traditional radomes of antennas. Thus, no extra space will be used and radiation in a desired polarization can be achieved by a simple radome change which can be considered another advantage of the proposed model. Using multilayer structures may give good results in polarization conversion but it will most probably ruin the radiation pattern as well as the gain and directivity.

II. DESIGNING OF THE METASURFACE POLARIZATION CONVERTER

The unit cell of the proposed MS polarization converter consists of two metallic patches placed in crossed corners of a rectangular loop. The construction of MS structure is arranged by 16 unit cell in 4X4 layout. Rogers RT 5870 is used in the structure substrate with a thickness, loss tangent and relative permittivity of 1.575 mm, 0.012 and 2.33, respectively as shown in Fig. 1(a). The unit cell of the periodic structure is shown in Fig. 1(b) with a strip line whose thickness is $w = 0.48$ mm while the width and length are $x = 14.68$ mm $y = 14.90$ mm, respectively connecting the metallic patches. Dimensions of each metallic patches are $R_x = 4.90$ mm, $R_y = 4.64$ mm.

The goal of the study is to obtain circularly polarized signals from linearly polarized signals that can be investigated by the axial ratio (AR) which can be simply written in dB as;

$$AR(dB) = \text{Mag}(20 \log(AR(\omega))) \quad (1)$$

Figure 1. (a) Linear to circular polarization converter MS (b) unit cell dimensions of MS

AR is;

$$AR(\omega) = \frac{T(\omega)_{cross-polar}}{T(\omega)_{co-polar}} \quad (2)$$

III. NUMERICAL AND EXPERIMENTAL STUDY

Numerical study of the proposed MS structure is realized by CST Microwave Studio which is a commercial simulation software and 3D full wave electromagnetic solver based on finite integration technique. Periodic boundary conditions and floquet port mode are chosen for this study. To obtain efficient

circular polarization, AR is kept below 3 dB. The proposed MS has two dip points at 2.95 GHz and 3.15 GHz which give perfect polarization activity in the simulation results of AR as shown in Fig. 2(b). About 300 MHz of ARBW is also obtained between the frequencies of 2.92 GHz and 3.22 GHz.

Figure 2. (a) Fabricated MS sample (b) simulated and measured AR results of proposed structure

Experimental study is achieved by Rohde & Schwarz ZVL6 vector network analyzer (VNA) with two linearly polarized microwave horn antennas. Fabrication of MS is realized by using LPKF E33 Protomat as shown in Fig. 2(a).

To obtain transmission values ($T(\omega)$), VNA is calibrated by using free space measurement. Both co-pol and cr-pol responses should be measured in order to obtain AR for the working frequencies. To measure co-polar response, the MS is placed between two horn antennas whose E-fields are in the same direction and for cross-polar response measurement, one of the horn antennas is simply rotated by 90° and the scattering parameters for the transmission (S_{21}) is measured and recorded. Finally, AR is calculated by the division of these two responses as in Eq. (2). There are two frequency bands below 3 dB which is optional to choose operating frequency range of MS as shown in Fig. 2(b). First band is between at 2.82 GHz and 2.88 GHz with a ARBW of 60 MHz. The second one is occurred between at 2.98 GHz and 3.16 GHz with a ARBW of 200 MHz. Since we have dual working frequency band, the proposed MS polarization rotator can be used with dual band antennas, either. Another dip points are also obtained at 2.85 GHz and 3.10 GHz for the proposed structure.

Although there is a small mismatch between numerical and experimental results as shown in Fig. 2(b), AR dip points and ARBW of these results are almost at the same level and agree well with each other. The deficiencies are originated by not having ideal measurement conditions in the laboratory and the manufacturing defects of MS sample.

IV. CONCLUSION

A metasurface polarization converter which transforms linearly polarized signals into circularly polarized one is realized in this study. Simulated and measured results are compared to each other and it shows that the results are in a good agreement. AR is kept below 3 dB for polarization

conversion quality. The perfect polarization conversion activities are obtained at frequencies of 2.83 GHz and 3.10 GHz and the ARBW of 260 MHz is also obtained at two frequency bands when the measured results are considered. Since circularly polarized signals are not affected by the weather conditions, the proposed MS can be used effectively in S-band radar and satellite systems. In addition, this design can be used on the existing linearly polarized antennas without using any extra space on the enclosures on which antennas are mounted. Furthermore, the proposed MS structure can be easily fabricated, integrated and reconfigured for any desired frequency range.

Abstract—This paper deals with a comparative study between the control of three to three phase matrix converter feeding a star-connected three phase induction machine and the control of three to three phase dual matrix converter feeding an open-end winding induction machine. The control strategy used in both cases is based on a proposed direct transfer function control approach of Venturini algorithm which allows to obtain a unity power factor at the input side to boost the output phase voltage up to 150% compared to the input phase voltage, while keeping the main advantage of the matrix converter by providing a fully bidirectional power flow operation. The main objective of using the open-end winding topology is to ensure the minimization of the common mode voltage which is clearly observed in the case of star-connected winding. Simulation results are presented under both control strategies, where both matrix converters are supplied from the same three-phase power source. Whereas; the two output voltage system of the dual matrix converter are shifted with 180 degrees. Based on the obtained results the performances of the both control approaches are technically discussed.

Keywords: Matrix converter, Dual matrix converter, Direct transfer function approach, Simulation Model, Open-End Induction Machine Drive.

I. INTRODUCTION

Recently, dual-matrix converter feeding open-end winding induction motor drives have attracted great interest due to their inherent advantages compared to the standard star or delta connected induction machine drives. The main characteristics of open-end winding induction machine are [1,2]: Since the machine is powered from both ends of the winding, each matrix converter has half of the machine power rating and therefore each stator phase current can be controlled individually. Consequently, depending on the modulation strategy, possibility of doubling the effective switching frequency is caught. The matrix converter (MC) is

a forced commutated converter which can achieve varying amplitude and frequency at the output side. Indeed in recent years, significant research efforts have focused on direct matrix converter where it is increasingly used in several applications due to some implicit advantages comparing to their analogue indirect power electronics conversion using two stages power conversion, DC-AC and AC-AC. Main outstanding advantages of the matrix converter can be summarized as follows [2,3]:

1. Direct conversion (no dc link);
2. Sinusoidal input and output currents can be achieved;
3. The easiness of the input power factor control for any kind of load;
4. Bi-directional power flow capability;
5. Simple and compact design;

On the other side, due to the high integration capability of the semiconductor structures, the matrix converter topology is being recommended for several extreme and critical applications. However, the topology of the matrix converter itself has pushed the researchers to run after more favorable control strategies. In this context several modulation techniques have been developed to fulfil the requirement of the matrix converter control. Among these techniques two main control approaches are being used, the scalar approach such as; the direct transfer function approach (DTF) proposed by Venturini [4,5], and the space vector approach such as; direct and indirect space vector modulation (DSVM and ISVM) [6,7].

In this paper, the direct transfer function control approach is applied to the matrix converter for feeding an

open-end three-phase load topology to overcome the main problem of the common mode voltage and to achieve a more flexible control and the operation reliability [8,9]. The both sides of the three-phase load are supplied using dual three-phase to three-phase matrix converters. The dual matrix converter has the same topology as shown in Fig. 1. The load is an open-end winding induction machine supplied by a dual matrix converter.

In this paper, a comparison between the applications of the same induction machine supplied by a single matrix converter and a dual-matrix converter is presented. Simulation tests were performed to demonstrate the effectiveness of the used topology and control approach for both single and dual matrix converter applications for the same induction machine.

C_f limits the voltage distortion between the terminals of the converter.

L_f limits the current distortion of the supply.

R_f limits the overshoot on turn-on and avoids the resonance excitation by the supply or converter.

II. THE MATRIX CONVERTER TOPOLOGY

The topology of a three-phase input - three-phase output matrix converter is presented in Fig.1. The voltages V_{i1} , V_{i2} and V_{i3} are the input-voltages and V_{o1} , V_{o2} and V_{o3} are the output voltages. Each leg has three bidirectional power switches to ensure the connection between one phase of the input and one phase of the output at any instant [8]. These switches are operating under the two main constraints which are: The input side is not short-circuited and the output side cannot present an open-circuit at any instant. These are the two main important constraints that they are imposed by the normal operation of matrix converter to protect both of the matrix converter and the load [9-11].

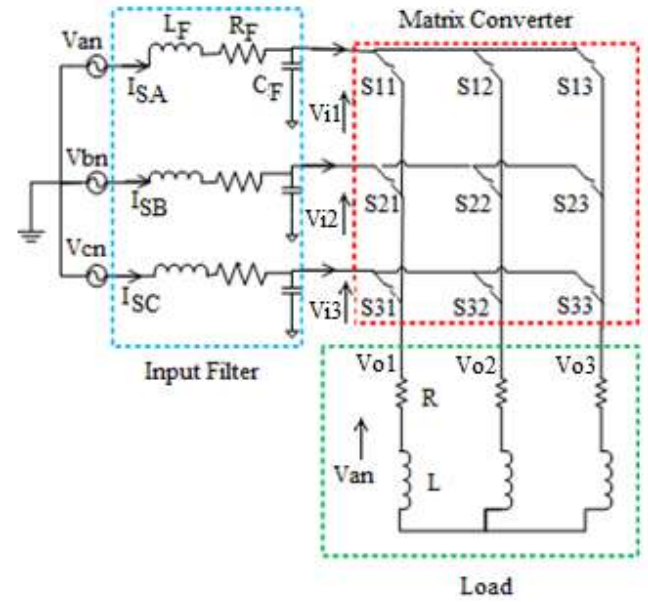

Fig.1 Three-phase matrix converter with input filter

The vector of the input voltages is given as follows:

$$\begin{bmatrix} V_{i1} \\ V_{i2} \\ V_{i3} \end{bmatrix} = V_{im} \begin{bmatrix} \cos(\omega_i t) \\ \cos(\omega_i t + 2\pi/3) \\ \cos(\omega_i t + 4\pi/3) \end{bmatrix} \quad (1)$$

The vector of the output voltages is given as follows:

$$\begin{bmatrix} V_{o1} \\ V_{o2} \\ V_{o3} \end{bmatrix} = V_{om} \begin{bmatrix} \cos(\omega_o t) \\ \cos(\omega_o t + 2\pi/3) \\ \cos(\omega_o t + 4\pi/3) \end{bmatrix} \quad (2)$$

A. The Switching Equations

The symbol S_{ij} represents the ideal bidirectional switches, where i ($=1, 2, 3$) represents the index of the output side and j ($=1, 2, 3$) represents the index of the input side. The relation between the output voltages and the input voltages can be achieved via an intermediate matrix M , which is known as the modulation matrix, hence the relation between the input and output voltages can be expressed as follows:

$$[V_o] = [M] \cdot [V_i] \quad (3)$$

The relation between the input current $[I_i]$ and output current $[I_o]$ can be deduced:

$$[I_i] = [M]^T \cdot [I_o] \quad (4)$$

Where $[M]^T$ represents the transposed matrix of $[M]$.

Equation (3) can be presented in a developed manner as follows:

$$\begin{bmatrix} V_{o1} \\ V_{o2} \\ V_{o3} \end{bmatrix} = \begin{bmatrix} m_{11} & m_{12} & m_{13} \\ m_{21} & m_{22} & m_{23} \\ m_{31} & m_{32} & m_{33} \end{bmatrix} \begin{bmatrix} V_{i1} \\ V_{i2} \\ V_{i3} \end{bmatrix} \quad (5)$$

where the elements of the modulation matrix representing the modulation coefficients are expressed as follows:

$$m_{ij} = \frac{t_{ij}^k}{T_s} \quad (6)$$

During the switching process, the bidirectional switches can connect or disconnect the phase i of the input to the phase j of the output which is connected to the load. In general, the modulation coefficient must provide the following rules [12]:

- At any instant, only one switch S_{ij} ($i = 1, 2, 3$) conducts in order to avoid short-circuit between the input phases.

$$\sum_{i=1,2,3} S_{ij}(t) = 1; j = \{1, 2, 3\} \quad \forall t \quad (7)$$

- At any instant, at least two switches S_{ij} ($j = 1, 2, 3$) conduct to ensure a way to the inductive load current.
- The switching frequency $f_s = \omega_s / 2\pi$ must have a higher value than the maximum of f_i, f_o ($f_s \gg \max f_i, f_o$).
- During the period, T_s which is known as the sequential period, the sum of the conduction times of switches being used to synthesize the same output phase, must be equal to T_s .

The time t_{ij} , which is called the time of modulation, can be defined as:

$$t_{ij} = m_{ij} \cdot T_s \quad (8)$$

III. MODIFIED DIRECT TRANSFER FUNCTION APPROACH

The modified direct transfer function approach [4,5] permits to control the switch, S_{ij} , whereas the output voltage, V_{oij} and the input current, i_{ij} are sinusoidal with the same values of the output frequency, the input amplitude, the input frequency and the displacement factor.

The maximum voltage output is obtained by the injection of the third harmonic of the output and input waveforms. The mean values of the output voltage over the sequence K^{th} are then given by:

$$\begin{aligned} v_{o1}^{(k)} &= v_{i1}^{(k)} \frac{t_{11}}{T_s} + v_{i2}^{(k)} \frac{t_{12}}{T_s} + v_{i3}^{(k)} \frac{t_{13}}{T_s} \\ v_{o2}^{(k)} &= v_{i1}^{(k)} \frac{t_{21}}{T_s} + v_{i2}^{(k)} \frac{t_{22}}{T_s} + v_{i3}^{(k)} \frac{t_{23}}{T_s} \\ v_{o3}^{(k)} &= v_{i1}^{(k)} \frac{t_{31}}{T_s} + v_{i2}^{(k)} \frac{t_{32}}{T_s} + v_{i3}^{(k)} \frac{t_{33}}{T_s} \end{aligned} \quad (9)$$

The conduction time is modulated with the ω_m while T_s is constant, such as $\omega_m = \omega_o - \omega_i$, these times are defined as follows:

1. In the first phase, we have:

$$\begin{aligned} t_{11} &= \frac{T_s}{3} (1 + 2q \cos(\omega_m t + \theta)) \\ t_{12} &= \frac{T_s}{3} \left(1 + 2q \cos(\omega_m t + \theta - \frac{2\pi}{3}) \right) \\ t_{13} &= \frac{T_s}{3} \left(1 + 2q \cos(\omega_m t + \theta - \frac{4\pi}{3}) \right) \end{aligned} \quad (10)$$

2. In the second phase, we have:

$$\begin{aligned} t_{21} &= \frac{T_s}{3} \left(1 + 2q \cos(\omega_m t + \theta - \frac{4\pi}{3}) \right) \\ t_{22} &= \frac{T_s}{3} (1 + 2q \cos(\omega_m t + \theta)) \\ t_{23} &= \frac{T_s}{3} \left(1 + 2q \cos(\omega_m t + \theta - \frac{2\pi}{3}) \right) \end{aligned} \quad (11)$$

3. In the third phase, we have:

$$\begin{aligned} t_{31} &= \frac{T_s}{3} \left(1 + 2q \cos(\omega_m t + \theta - \frac{2\pi}{3}) \right) \\ t_{32} &= \frac{T_s}{3} \left(1 + 2q \cos(\omega_m t + \theta - \frac{4\pi}{3}) \right) \\ t_{33} &= \frac{T_s}{3} (1 + 2q \cos(\omega_m t + \theta)) \end{aligned} \quad (12)$$

Where θ is initial phase angle.

The output voltage is:

$$[V_o^{(k)}] = [M^{(k)}] \cdot [V_i^{(k)}] \quad (13)$$

$$[M^{(k)}] =$$

$$\begin{bmatrix} 1 + 2q \cos(A) & 1 + 2q \cos\left(A - \frac{2\pi}{3}\right) & 1 + 2q \cos\left(A - \frac{4\pi}{3}\right) \\ 1 + 2q \cos\left(A - \frac{4\pi}{3}\right) & 1 + 2q \cos(A) & 1 + 2q \cos\left(A - \frac{2\pi}{3}\right) \\ 1 + 2q \cos\left(A - \frac{2\pi}{3}\right) & 1 + 2q \cos\left(A - \frac{4\pi}{3}\right) & 1 + 2q \cos(A) \end{bmatrix} \quad (14)$$

Where:

$$\begin{cases} A = \omega_m t + \theta \\ \omega_m = \omega_o - \omega_i \end{cases} \quad (15)$$

This mathematical development shows that the matrix converter with modified direct transfer function approach generates three-phase sinusoidal voltage waveforms at the output.

IV. MODELLING OF THE OPEN-END WINDING INDUCTION MACHINE

The open-end stator winding induction machine presented in Fig. 2 is supplied by two three-phase voltage systems and these systems are defined as:

The three-phase systems supplied by the first matrix converter: $[V_{s1}] = [V_{s11} \ V_{s12} \ V_{s13}]^T$;

The three-phase systems supplied by the second matrix converter: $[V_{s2}] = [V_{s21} \ V_{s22} \ V_{s23}]^T$;

Hence, the voltage vector applied on the stator winding of the machine is:

$$[V_s] = [V_{s11} - V_{s21} \ V_{s12} - V_{s22} \ V_{s13} - V_{s23}]^T$$

The mathematical flux model is defined in (d-q) reference frame, and described by the following state equations representation:

$$\frac{dX(t)}{dt} = [A(\omega, \omega_{dq})][X(t)] + [B] \cdot U(t) \quad (16)$$

$$Y(t) = [C] \cdot Y(t) \quad (17)$$

where:

$X(t) = [\phi_{sd} \ \phi_{sq} \ \phi_{rd} \ \phi_{rq}]$ is the state vector;

$U(t) = U_1(t) - U_2(t) = [V_{sd1} - V_{sd2} \ V_{sq1} - V_{sq2}]$ is the control vector;

$Y(t) = [I_{sd} \ I_{sq} \ I_{rd} \ I_{rq}]$ is the output vector;

The principle diagram of the system is shown in Fig. 2:

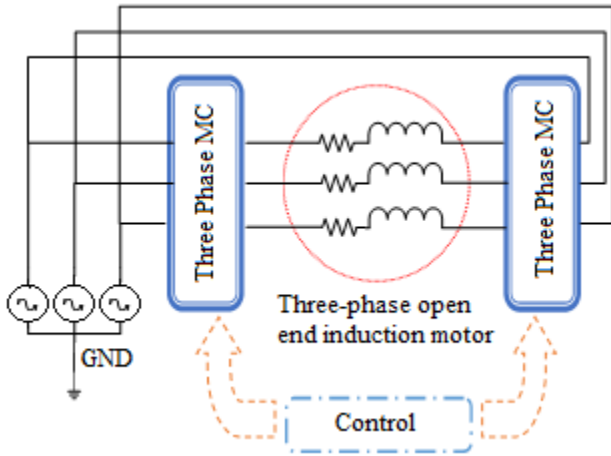

Fig.2 Three phase open-end winding induction motor fed by dual matrix converter

Fig.3 Block diagram of the open-end winding machine

On the other side the following parameters are taken into account:

$\tau_s = \frac{L_s}{R_s}$ is the stator constant time

$\tau_r = \frac{L_r}{R_r}$ is the rotor constant time

$\sigma = 1 - \frac{M_{sr}^2}{L_s L_r}$ is the coefficient of dispersion of Blondel

R_r is the rotor resistance, R_s is the stator resistance, L_r is the rotor inductance, L_s is the stator inductance, M_{sr} is the mutual inductance between stator and rotor.

The equation for current vector is:

$$[I] = [L]^{-1}[\phi] \quad (18)$$

The matrices [A], [B] and [C] are defined as follows:

$$[A] = \begin{bmatrix} -\frac{1}{\sigma\tau_s} & \omega_{dq} & \frac{M_{sr}}{\sigma\tau_s L_r} & 0 \\ -\omega_{dq} & -\frac{1}{\sigma\tau_s} & 0 & \frac{M_{sr}}{\sigma\tau_s L_r} \\ \frac{M_{sr}}{\sigma\tau_r L_s} & 0 & -\frac{1}{\sigma\tau_r} & \omega_{dq} - \omega \\ 0 & \frac{M_{sr}}{\sigma\tau_r L_s} & -(\omega_{dq} - \omega) & -\frac{1}{\sigma\tau_r} \end{bmatrix} \quad (19)$$

$$[B] = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$[C] = [L]^{-1} = \begin{bmatrix} \frac{1}{\sigma L_s} & 0 & \frac{M_{sr}}{\sigma L_s L_r} & 0 \\ 0 & -\frac{1}{\sigma\tau_s} & 0 & \frac{M_{sr}}{\sigma L_s L_r} \\ -\frac{M_{sr}}{\sigma L_r L_s} & 0 & -\frac{1}{\sigma L_r} & 0 \\ 0 & -\frac{M_{sr}}{\sigma L_r L_s} & 0 & \frac{1}{\sigma L_r} \end{bmatrix} \quad (20)$$

The mechanical equation is given as follows:

$$T_{em} - T_r = j \frac{d\omega}{dt} + f\omega \quad (21)$$

$$T_{em} = \frac{3}{2} p (\phi_{s\alpha} I_{s\beta} - \phi_{s\beta} I_{s\alpha}) \quad (22)$$

where, T_{em} is the electromagnetic torque; T_r is the load torque.

V. SIMULATION

In this work, two simulation tests were performed to prove the advantage of the use of the open-end winding induction machine fed by a dual matrix converter having the same

topology and characteristic. The first simulation presents the induction machine fed by only one matrix converter, where the output voltage is characterized by a fundamental frequency of $f_0=50$ Hz and a magnitude of $V_0=350$ V. The parameters of the input voltage source and the induction machine are presented in Table 1. On the other side, due to the distortion which may occur in the input current and to avoid the propagation of this kind of harmonics pollution toward the source, an LC input filter is inserted as shown in Fig.2 where its parameters can be found in Table 1. [13-15].

A. Induction Motor Fed by A Three-Phase Matrix Converter

In this case, a single three-phase matrix converter is used to feed a three-phase induction motor. The output voltage and the output current of the matrix converter are presented in Fig. 4 and 6, respectively. Total Harmonic Distortion (THD) of the output voltage and current waveforms, which is defined in Eq. (23), are presented in Fig. 5 and 7, respectively. It can be concluded that the harmonic rays are around the switching frequencies ($n \times f_s$) where it is taken as $f_s=10$ kHz

$$THD = \sqrt{\frac{V_2^2 + V_3^2 + \dots + V_n^2}{V_1^2}} \quad (23)$$

The fundamental harmonic amplitude of the output voltage is 344.4 V with THD of 99.36% as shown in Fig. 5 and harmonics rays can be remarked clearly around the switching frequency. However, due to the inductive nature of the induction motor, the output current posses a low THD as 2.77%. Figs. 8 and 9 show the decoupling carried out between the flux and the electromagnetic torque. The decoupling between torque and machine speed is remarked clearly especially at the interval between 1.5 s and 2.5 s. The supply current waveform is shown in Fig.10. The result shows great effect of the input filter where the high order harmonics are eliminated by the input filter.

Table 1 Simulation parameters

V_s	Input voltage	350 V
f_s	Input frequency	50 Hz
L_f	Filter inductance	0.03 H
R_f	Filter Resistance	0.5 Ω
C_f	Filter Capacitance	25 μ F
R_s	Stator resistance	4.85 Ω
R_r	Rotor resistance	3.81 Ω
L_s	Stator inductance	0.274 H
L_r	Rotor inductance	0.274 H
L_m	Mutual inductance	0.258 H

B. Dual Matrix Converter Feeding Open-End Winding Induction Motor

In this case, two of three-phase matrix converter feed the both sides of the open-end winding of the same induction machine stated previously. Under this topology the common mode voltage (CMV) will be totally removed and the three-phase load can be controlled independently. Due to the balanced nature of the load, the voltage applied at each load phase is the same except for the eventual required phase shift. Figs.11 and 12 illustrate the voltages between the two

terminals of the three-phase load and the load currents, respectively. It is obvious that the fundamental magnitude of the voltage is 348.5 V with a THD of 75.12 % whereas, the fundamental current is 4.636 A with THD of 3.36 % which means that there is an improved voltage and current quality in comparison with the situation where the machine is fed by a single three-phase matrix converter (Fig. 13 and Fig. 14). In the same time a less harmonic rays can be remarked clearly near the switching frequency $f_s = 10$ kHz. The two level voltage is clearly observed and the three-level voltage at the load terminals is also obviously observed. The effect of the input filter can be seen clearly in Fig. 17. Figs.15 and 16 show the decoupling carried out between the flux and the electromagnetic torque. In the same time, the decoupling between the torque and the speed of the machine can be seen especially at the interval between 1.5 s and 2.5 s.

VI. CONCLUSIONS

In this paper, the main advantages of the dual matrix converter used in open-end structure is proved by simulation results. The results show clear improvement on quality of the voltages enforced to the induction machine drive and elimination of the common mode voltage which is major problem in all three-phase load applications, especially in three-phase electrical machines. On the other side, due to the multilevel nature of the voltage applied at the terminal of the open-end load, the current quality is also improved, where the THD is decreased at nearly 48% compared to the classical topology based on one matrix converter. An important issue is that the use of a dual matrix converter is more reliable in case of fault on one or more switches. This problem can be solved by easily adjusting control signals of the switches. Finally, it can be said that the presented topology can have a large use in electric machines application in industry based on the afore mentioned advantages.

Abstract— A metamaterial absorber (MA) based sensor is designed and analyzed for various important applications including pressure and density sensing. After obtaining a perfect absorption (PA) at around 5.5 GHz and 7.7 GHz, we have achieved 130 MHz bandwidth for the pressure sensing depending on the thickness of the sample, 200 MHz bandwidth for density sensing in different type of materials Arlon type AD 300, AD 350 and AD 450 and 200 MHz bandwidth in the working frequency band. The proposed structure uses the changes on the overall system resonance frequency caused by the sensor layer's dielectric constant which varies depending on the electromagnetic behavior of the sample placed in. This model can be adapted to be used in industrial, medical and agricultural product for sensor applications.

Keywords— *metamaterial, absorber, sensor*

I. INTRODUCTION

Metamaterials (MTMs) are such engineered structures that possessing extraordinary features as backward propagation, negative permittivity and/or permeability. They allow researchers to explore many interesting areas [1-6]. MTM sensors offer higher sensitivity and resolution compared to the traditional structures due to their strong localization of fields. They also reduce the sensor size compared to a regular structure that is less proportional to the operating frequency. For this reasons, For the past decade, MTMs have been extensively used in sensor applications. For example, Schueler et al. [7] reviewed the MTM inspired composite right/left-handed transmission line microwave sensors. Chen et al. [8] examined MTMs application in sensing with an emphasis on split ring resonator-based sensors. Niu et al. [9] investigated an optical waveguide sensor application. Yang et al. [10] developed a high sensitive sensor based on split ring resonators. In this manuscript, we want to develop a concept study which is covering both MA and MTM sensor studies in C band to provide high resolution sensing in temperature, humidity, pressure and density.

II. NUMERICAL DESIGN AND EXPERIMENTAL SETUP

Proposed MTM The main subject of the study is to design a MA, therefore, firstly absorption configuration of the proposed structure is introduced and investigated. Designed MTM as introduced in Fig.1 composed from consists of two resonators; one of them is a square and the other one is a ring shaped inclusion which incorporates two splits. There are dual splits placed on both of them as shown in Figure 1.a. Resonators are made of copper elements with the conductivity of $5.8 \times 10^7 S/m$, Arlon DiClad 5.27 type material is used as a substrate whose thickness is 1.6mm and dielectric constant is 2.50. Square and ring resonators have a thickness of 0.8 mm and the distance between the square resonator and the unit cell edge is also 0.8 mm. split width on the resonators The gap width were chosen as 1.6mm to ensure the best numerical results. The proper dimensions of the unit cell are evaluated by using parametric studies. Design is produced by using CNC controlled machine and experimental tests are realized by using horn antennas and a 42.5 GHz VNA as shown in Figure 1.b As it is explained in the following sections, proposed design is tested numerically and experimentally for absorber and sensor applications. For absorber configuration, copper plate is used behind the dielectric substrate that supports resonators. For sensor configuration copper plate is not used behind the resonators' substrate and sensor layer is put behind the substrate. In order to show the absorption characteristics, a dielectric substrate (DiClad 5.27) which is backed by copper is placed behind the sensor layer as shown in Figure 1.a and Figure 1.b.

III. METAMATERIAL ABSORBER AND SENSOR APPLICATIONS

Since proposed MTM sensor application based on an absorber, we physically produced, numerically and experimentally verified the absorber application. For absorber application, copper plate is placed behind the dielectric back of resonators and by using horn antennas experimental verification is of absorber is tested. Numerical verification is realized by using CST microwave studio under periodic boundary conditions. It is known that the essential

requirement of an absorber is to confine the penetrated energy in the structure. The reflected and transmitted waves have to be minimized ($R(\omega) \& T(\omega) \rightarrow 0$) so that these waves should be as small as possible in order to realize perfect absorption. Numerical and experimental results obtained for the mentioned dimensions of the structure are given in Fig. 3. As shown in figure, there are two resonances that occur at 6.46 GHz and 7.68 GHz which are resulted from two coupled resonators. Resonant frequencies are located in the upper half of the C-band and dual resonance characteristics are good for absorbing electromagnetic energy. When numerical results are compared with the experimental results, a tiny shift is seen in the resonant frequency which is due to calibration, fabrication errors and non-ideal measurement conditions. Measured absorption level is also smaller than that of the simulation due to the same reasons.

Fig. 3 Numerical and experimental results for absorber configuration of the proposed structure showing double resonances around 6.5 and 7.7 GHz.

First sensor application by using the sensor configuration defined in Fig. 2 is pressure sensor. It is simulated and experimentally tested by changing the sensor layer's thickness up and down which correspond a pressure increase and decrease. gives the opportunity to build different sensor applications. One of these sensors is a pressure sensor. This type of sensor is realized by changing the sensor layer thickness. It should be noted that as the pressure decreases, the thickness of the layer expands. On the other hand, an increase in the pressure leads to a decrease in the thickness of the sensor layer. Three different air cushion have been taken as sample which are 1mm, 1.5mm and 2mm to show reflection coefficient both numerically and experimentally as compared in Fig.4. In this application, a sensor layer which is composed of air having a relative dielectric constant of 1 is used. Numerical and experimental results for three different sensor layer thicknesses (1, 1.5, 2 mm) are presented in Fig.5. Three different air cushions are especially chosen to show linearity. This is because of the fact that, resonance frequency behaves according to $1/\sqrt{LC}$ formula, capacitance is inversely proportional with plate distances as the distance increases capacitance value decreases and resonance frequency increases. When the thickness

decreases, the resonance frequency shifts downwards as shown in Figure 4 due to the coupling effects of the sensor layer. Capacitive effect is responsible for this shift, because it is inversely proportional to the layer thickness. Absorption ($A(w)$) term is the main criteria for all sensor applications in this study, since air is an isolating material, its' thickness is affecting $A(w)$ term. Figure 4 shows that the absorption frequencies for sensor layer with the thicknesses of 1, 1.5, 2 mm sensor layer are 5.92 GHz, 6.00 GHz and 6.05 GHz, respectively. The corresponding absorption values are 0.77, 0.97, 0.99 at 5.92, 6.00 and 6.05 GHz respectively. As shown in Figure 4, the best results for absorption values are obtained when the layer thicknesses are 1.5 and 2 mm. Fig. 4 also shows that 1mm change in the sensor layer thickness results in a shift of 130 MHz in the resonance frequency which proves that the sensor application based on this absorber is very sensitive to the changes in the sensor layer thickness

Fig.4 MA Based pressure sensor application for 1mm, 1.5mm and 2mm.

Sensor layer can be used to detect the density of a material if it is properly configured. In this part of numerical and experimental study, sensor layer is assumed to be filled with such materials that have different density values. Sensor layer thickness is again 1.6mm for numerical and experimental parts of this illustrations. As a beginning, Since the resonance frequency of the absorber based sensor changes with respect to the capacitance of the structure, sensor layer is assumed to be compromised of a material having different dielectric constant permittivity with respect to the density. Inductance term of the absorber based sensor is kept constant during the density sensor application, since it is only affected by metallic path dimensions and wavelength of the incident electromagnetic wave. Mutual inductance between the front and back side structures does not change due to the constant substrate and sensor layer thicknesses. Three different materials known as Arlon AD300, Arlon AD350 and Arlon AD 450 are used in the sensor layer for simulation and experimental validation. Sensor layer thickness is also 1.6 mm as in the previous study. Numerical and experimental results are presented in Figure 5. Resonance frequencies are 8.44, 8.36, 8.23 GHz for

AD 300, AD350 and AD450, respectively. When AD450 type material is used in the sensor layer, as the sensor layer, the maximum absorption value of 0.97 is obtained. The dielectric constants are 3.3, 5.4, 5 for AD 300, AD350 and AD450, respectively. As seen from Figure 8, when the dielectric constant of the material used in the sensor layer as a sensor layer increases, the resonance frequency of the absorber based sensor shifts downward. The total shift is about 210MHz which shows that the absorber based sensor is very sensitive to the changes in the dielectric constant of the sensor layer.

Fig. 5 MA Based density sensor numerical and experimental result comparison for Arlon type AD300, AD 350 and AD450 materials.

IV. CONCLUSION

This study focuses on multi-functional sensor applications based on MA. The sensing properties of the suggested sensor design are presented for pressure and density. In order to show the sensor quality of the proposed design, pressure and density sensor applications are also experimentally tested. It can be seen that the numerical results are in a good agreement with the experimental ones. The linearity of the sensing frequency changes depending on the dielectric constant of the proposed structure. For this reason, more applications can be developed.

Abstract— Metamaterials are attractive media for scientific society for their potential multi-functional and a wide range of applications due to their unusual electromagnetic properties. In this paper, we present pressure and bulk material type sensing applications with different permittivity values. Pressure and material sensing applications are carried out experimentally and numerically. The model is based on a split ring resonator (SRR) topology and the sensing layer sandwiched between the SRR and a rectangular copper layer located at the background. . Since sensor layer affects the resonance frequency of the system, the proposed model can be used for chemical, agricultural, medical and biological sensing applications in the microwave frequency band

Keywords— metamaterial, absorber, sensor

I. INTRODUCTION

Metamaterials with their extraordinary electrical and magnetic behaviors offer a wide range of application areas, such as sensing, absorption, polarization rotation, source shifting or imaging, perfect lenses and many more applications attracting an increasing number of researchers in this field [1-5]. In the case of sensing applications, micro and nano size metamaterial structures started to be built with the new and continuously growing technology. For example, Schueler et al. [6] worked with metamaterial inspired composite right/left-handed transmission line microwave sensors. Chen et al. [7] developed a sensor application by using split ring resonator. In this study, we have proposed a sensor based on metamaterial absorber which is different from traditional sensor designs. This is realized by placing sensor layer between resonator and metallic layers as an absorber which is explained in the next section. Although changing resonant frequency due to the environment has been studied previously by different scientists. Difference of the proposed study from the others is being metamaterial absorber based study for X band waveguide operation and having unique design features. Sensor layer's thickness and permittivity value of material inside the layer affects the resonance frequency of sensor system. Several sensor applications can be developed by this design approach from medical to food industry.

II. NUMERICAL DESIGN AND EXPERIMENTAL SETUP

In this study, we created a MA based sensor. The proposed design consists of a Roger RT 5870 type dielectric material which has a thickness of 0.76 mm and a dielectric constant of 2.33 which is chosen as a substrate as seen from Fig. 1. The suggested structure has five parts, resonators, a substrate, sensor layer, another substrate and a copper plate, respectively. Back side of this sensor design is completely plated with copper type metal which is supported by an RT 5870 material. In numerical analysis, PEC boundary conditions for x- and y-directions and open boundary condition for z-direction are applied to simulate waveguide measurements. Sensor layer is realized in order to use for multi-functional applications. It can be adapted for different sensor applications such as density, pressure, temperature and humidity sensing. In this study, density and pressure sensor applications are numerically and experimentally realized and discussed. In Fig.1, the proposed MA based sensor design and waveguide boundary conditions are given.

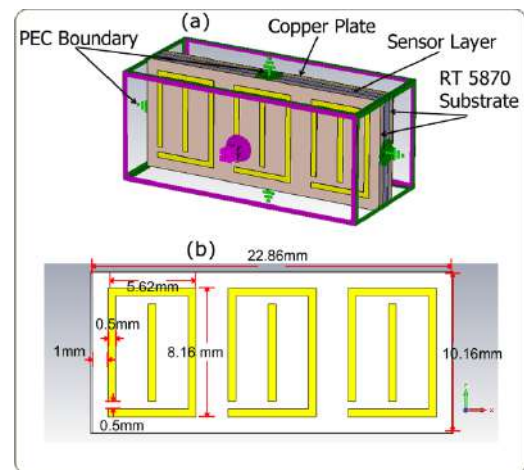

Fig. 1. (a) The proposed MA based sensor design, (b) Dimensions of the suggested MA based sensor design.

III. SENSOR APPLICATIONS

Different materials together with different version of the same materials have different density values and different permittivity values. In this part of the study, change in the permittivity used for density sensing. In the first part of density sensing demonstration, three different samples which are Roger RT5870, Arlon AD350 and Arlon AD450 are used for numerical simulation and experimental testing. Other density sensor applications are realized numerically by using published data about density and permittivity values because of the laboratory possibilities.

In this part of the study, sensor layer thickness is 0.76mm which is same as substrate thicknesses. When one of the given materials are placed in the sensor layer, overall reflection coefficient of the unit cell reacts according to the placed materials' properties. Densities of RT 5870, AD 350 and AD 450 are 2.2 g/cm³, 2.40 g/cm³ and 2.45 g/cm³, respectively. Absorption which is related to the angular frequency can be represented as $A(\omega)$ and it can be defined as $A(\omega) = 1 - |S_{11}|^2 - |S_{22}|^2$ and the absorption values of different materials are given in Fig. 2. The term (ω) given here refers to the angular frequency. As it can be seen from Fig. 2(a), the resonance frequencies shift depending on the material densities to the resonance frequencies of 9.68, 9.46 and 9.33 GHz, respectively. Furthermore, the resonance frequencies are measured experimentally as 9.70, 9.44 and 9.34 GHz for the materials of RT5870, AD 450 and AD 350, respectively as shown in Fig. 2. Linear relation between the material densities and the resonance frequencies is presented in Fig. 2. One can see from Fig. 2. that the absorption level is decreasing according to the material densities. Obtained results show that the numerical values of the sample are in a good agreement with the measured ones. According to Fig. 2, resonance frequency shifts backward as the permittivity values of the material inside the sensor layer increases. Because, capacitance and permittivity are directly proportional with each other, resonance frequency shifts backward according to $1/2\pi\sqrt{LC}$.

Fig. 2. Simulated and measured absorption values for density sensor application based on MA design,

One of the other important sensor parameters of MA based sensor design is the pressure sensor application which is realized both numerically and experimentally. In this part, the suggested sensor layer is assumed to be filled with air and the thickness is assumed to be loosened or tightened according to the pressure as seen from Fig. 3. Pressure is affecting the system resonance directly due to the capacitive effect which is directly related with the thickness of the air gap. Numerical simulation and experimental test results are compliant with each other, there are small resonance frequency and absorption level differences due to calibration and configuration errors as testing. As shown in Fig. 3, when sensor layer leaves empty (only air placed inside), and thickness of sensor layer has been changed, resonance frequency of the metamaterial absorber based sensor system changes accordingly. As generally known, capacitance of the parallel plates is inversely proportional with plate distance, as it shown in Fig. 3, when the distance increases, resonance frequency of the split ring resonator increases according to $1/2\pi\sqrt{LC}$. Three distance values have been taken as sample which are 0.4, 0.8, 1.2mm to show pressure increase and decrease application, resonance frequency of them 10.04, 10.24 and 10.32 GHz, respectively. According to figure, every 0.1mm change, in the pressure results with 35MHz change in the resonance frequency which can be noticed by vector network analyzers easily.

Fig. 3. Pressure sensor application of MA based density sensor

IV. CONCLUSION

This study focuses on the multi-functional sensor applications in X band. Unique design is obtained by numerical study which also experimentally tested to obtain sensitive metamaterial absorber based sensor. The sensing properties of the suggested sensor design are presented for different material and pressure sensor applications. It can be seen that the numerical results are in a good agreement with the experimental ones.

Abstract— This paper details a Single-Phase Multilevel Inverter based STATCOM for reactive power compensation. STATCOM is very important in any generation and distribution system because it plays a major role in supporting the reactive power, whenever the reactive power compensation takes place. Two controllers PI and Fuzzy Logic are used in this paper, PI controller for producing the modulation index and fuzzy controller for getting the delta(which is used to generate the reference signals from the change in phase angle). Sinusoidal Pulse Width Modulation then uses the modulation index and delta for producing the switching signals for the inverters. In this research we used two full H-bridges.

Keywords— STATCOM; PI controller; Fuzzy Logic controller; Sinusoidal Pulse Width Modulation; H-bridge Multilevel Inverter

I. INTRODUCTION

In every power system, the reactive power improvement and harmonic compensation have always been very important areas of discussion. This is because of the fact that it has a very strong impact on the power loss, voltage stability and power quality of the power system. As we know that the total power in any power system is the sum of the active and the reactive power and therefore the improvements in the reactive power means improvements in the overall power of the system. Many methods (Peng and Adams, 1998) have been employed in the past for the compensation of the reactive power which includes the use of reactors and capacitors. But these methods are not very good and efficient as they tend to become more complicated when non-linear loads are applied which leads to higher implementation and maintenance cost. Therefore, extensive research has been going on in this area and new techniques are developed in order to get better results. These techniques make use of Active Power Filter (APF), Static Synchronous Compensator (STATCOM) and other Flexible AC Transmission System (FACTS) devices which shows a quite fast response and good performance for harmonic compensation and reactive power improvement (Prakash, Mahalakshmi and Karpagam, 2016). There are a variety of control techniques in electronics which can be used for this purpose with their own merits and demerits.

STATCOM is used for injecting and absorbing reactive power, so it will improve the power system. It belongs to the FACTS device family. The basic aim of a STATCOM is to absorb or inject reactive-power in the power system and the output of the converter is controlled by changing the amplitude of the output voltage (Cheng, Qian, Crow, Pekarek and Atcity, 2006). The cascaded H-bridge multilevel topology for inverter is used here and the cascaded H-bridge multilevel topology offers several advantages over other inverter topologies in such cases (Paserba, Reed, Takeda and Aritsuka, 2000). There are many different cascaded topologies for STATCOM application and the one which is implemented in this work is the cascaded transformer multilevel topology. The inverter in this work consists of two full H-bridges and two capacitors are used, i.e. one for each bridge. Also, two controllers are used, fuzzy logic controller produces change in phase angle by comparing the reference DC voltage with the obtained DC voltage and the other PI controller outputs the modulation index from the inputs which is the reference reactive power and the obtained reactive power. These two parameters along with the capacitor voltages, carrier signals and current are given to the Sinusoidal Pulse Width Modulation as an input and the switching or gating signals are generated by the Sinusoidal Pulse Width Modulation as the output which is used to drive the inverters.

II. STATIC SYNCHRONOUS COMPENSATOR (STATCOM)

In power systems to compensate reactive power STATCOM device is often used. The basic purpose of STATCOM is to maintain stable reactive power to the power system by absorbing or supplying reactive power as required. STATCOM is the member of FACTS controller's family. A typical STATCOM contains following components such as voltage source converter with capacitor on DC side as energy storage element, a coupling transformer and an inductor for AC side. A basic STATCOM configuration is shown in (Figure 1) which is directly connected to the main power line.

A. Components of STATCOM

A STATCOM consists of following components:

a). Voltage Source Converter (VSC)

i. Square Wave Inverters

In square wave inverters, the output waveform usually contains multilevel steps. The inverter's fundamental component is directly related to DC voltage. The inverters generally use insulated gate bipolar thyristor for switching. The IGBTs are used because of its high frequency switching and high power rating. Furthermore, to reduce the harmonic contents of square waves generated by each inverter a transformer is used along with passive filter.

ii. PWM Inverters

The most prevalent method of controlling cascaded h-bridge multilevel inverter is sinusoidal pulse width modulation (SPWM). The main working principle of sinusoidal PWM modulation scheme is to compare a reference sine wave signal with a triangular waveform in order to produce the controlling signals for switches

The pulse width modulation (PWM) scheme is used by voltage source converter (VSC) to convert a dc voltage at the input into sinusoidal waveform at the output. The frequency of PWM is few kHz used to drive the IGBTs. There is a difference between these types of inverters as compared to the GTO type. These inverters rely on modulation index to change their ac output voltages. Also, a shunt filter is employed on the AC side to reduce the harmonic content in the output waveform.

b). Coupling transformer

STATCOMs cannot be linked directly with the high voltage power systems. These high voltages can damage the system components. Therefore, a transformer is needed to reduce these voltage levels. Transformer steps down the high grid voltages to appropriate levels for further processing by the system. But there is a drawback related to the use of transformer; the power losses are increased mainly due to reactance.

c). DC Capacitor

DC capacitor is an essential component of STATCOM as it provides the necessary voltage for inverters and also stores energy.

d). Inductive Reactance

This inductive reactance is due to the leakage inductance of coupling transformer. It is connected with the output of inverter and power system.

e). Harmonic Filter

The harmonic filter is located at the AC side. It is mainly used for removing harmonic content present in the output waveforms of each inverter. To remove the harmonics we used inductor.

B. Operation Modes of STATCOM

Following are the two ways to operate STATCOM.

a). Voltage Regulation mode

In voltage regulation mode, the main operation of STATCOM is to compensate for reactive power in the power system. It will either absorb or supply the reactive power using voltage source converter. A DC capacitor is used for voltage regulation. At point of Common Coupling, multiple electric loads are connected. Following are some of the functions performed by the STATCOM during reactive power compensation:

When PCC voltage is higher than its reference, STATCOM absorbs reactive power from PCC.

When PCC voltage is lower than its reference, STATCOM injects reactive power into PCC.

b). VAR Control mode

In this mode, irrespective of other system parameters the reactive output of STATCOM remains constant. In VAR control, reactive power of the STATCOM injected or absorbed is controlled. Generally a closed loop control scheme is used to control the reactive power generated or absorbed by STATCOM.

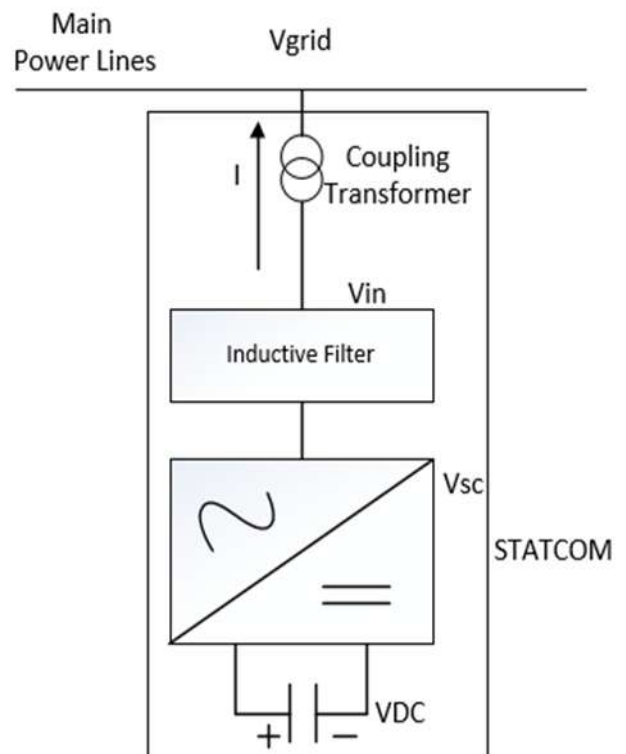

Fig.1 The Grid Connection of STATCOM with power line

III. MODELLING OF SINGLE PHASE CASCADED H-BRIDGE MULTILEVEL INVERTER

The basic construction of five level ($2N+1=5$) cascaded H-bridge inverter consisted of two ($N=2$) full-bridges is shown in Fig. 2. Since there are two capacitors, there usually happens a voltage imbalance between capacitor voltages that should be minimized or practically eliminated with a number of techniques. Furthermore, capacitor voltage ripples can be reduced by active power control for each bridge (Lipo, 2000). Various methods are discussed in to remove the ripples in DC voltages. This topology involving cascaded H-bridge multilevel inverters is used in many applications for reactive power compensation. Low-frequency modulation scheme is used in (Haque, 2004). Due to the switching losses of IGBTs. According to (El-Moursi and Sharaf, 2005). The frequency of line and commutation are almost similar.

Fig.2 A basic construction of H-Bridge Multilevel Inverter

Each h-bridge consists of four switches and four diodes connected in parallel with switches. These diodes which are connected in anti-parallel fashion act as full-bridge rectifier and together they are used for charging the DC capacitor. The charging energy comes from the coupling inductor. The output of h-bridge contains three levels namely positive, negative and zero level. These voltage levels when summed up form a sinusoidal waveform. The AC output of h-bridge is given as:

$$V_{ca} = V_{ca1} + V_{ca2} + V_{ca3} + \dots + V_{caM} \quad (1)$$

Where: M represents the number of inverters per phase.

The proposed topology of cascaded multilevel inverter is modular meaning the output AC waveform can be improved by simply adding more h-bridges in the circuit. The conduction time for each h-bridge varies for example, for the first level the DC capacitor will charge less and discharge more and for the last level the DC capacitor charges more and discharges less. To solve this problem, we select suitable switch pattern swapping method which will

swap the angles of switching for every half cycle as mentioned in (Shukla, Ghosh and Joshi, 2007). The rectified energy accumulated in the inductor is stored in a capacitor that is linked on the DC side of the h-bridge multilevel inverter. The circulation of current and non-stop charging and discharging of inductor can cause voltage ripples. To remove these ripples and smoothing the voltage DC capacitor is used. Below figure further demonstrates the process:

Fig.3 Fundamental components DC voltage, Capacitor current and capacitor voltage

As can be seen in the figure above the VDC is either maximum or minimum at $\pi/2$. The area under the I_c gives us the total reactive power. Capacitance is calculated as given by the equation:

$$C = \frac{i_c}{f_{rp} * \Delta V_{Dc}} \quad (2)$$

Where: f_{rp} here represents the ripples frequency which is twice the fundamental frequency

The RMS value of I_c is:

$$i_c = \frac{Q}{V_{pcc}} \quad (3)$$

Where Q: maximum power (reactive) produced by STATCOM

The voltage ripples can be further reduced by using a high value capacitor as given by the equation for capacitance. But increasing the value of capacitor will also increase the time constant RC. With increase in value of time constant it may lead to large current flows from the switches. The large current flows in on state can damage the switching devices. For coupling of reactive power between STATCOM and PCC an inductor is used. Its inductance depends on the modulation index of multilevel inverter and harmonic content. The inductance is calculated using the following equation:

$$L_{fmax} = \frac{V_{pcc}}{2 * \pi * f * i_c} \quad (4)$$

Where: V_{PCC} is the voltage at PCC and f represents the fundamental frequency

i_c : maximum current that inverter can produce or absorb

Using the above equation, we can calculate the maximum size of inductor to be used. Using a large size inductor will improve harmonics at PCC and will help minimize current ripples. But it will also lead to less current flows through capacitors. To solve this issue phase shift between the V_{pcc} and V_c is increased which results in active current flows through capacitor but it also increases the V_L across the inductor. This effect is reduced by increasing the voltage produced by multilevel inverter. It is accomplished by increasing the h-bridges or size of DC capacitors.

In (Mynavathi, Chinnaiyan, Venkatesh and Balamurugan, 2015) on the electric transmission lines STATCOM was utilized for the reactive power compensation. It discusses the compensation and its conventional way using STATCOM. Its implementation, the circuit configuration, switching technology along with the operating principle has been discussed.

The reactive power control has been presented in (Gultekin and Ermis, 2013) of an Autonomous Wind-Diesel Hybrid Power Systems (AWDHPS) with a real time environment in which the STATCOM helps supplies and absorbs the reactive power which has been controlled by the proportional plus integral controller.

A proposed design has been discussed in (Singh, Murthy and Chilipi, 2014) for a STATCOM which is for the cascaded multilevel converter (CMC) based transmission. It discusses the details of the system along with the number H-bridges used in the CMC for each of the phase along with its voltage ratings and other important aspects.

(Rao and Yang, 2000). Proposes a system which uses a 3-phase induction generator which is self-excited (SEIG) which is being utilized by a power generation of a single phase. They both work in conjunction with a STATCOM (3-phase). The single-phase loads which create the unbalanced currents are compensated by the STATCOM.

The distinct feedback control strategies have been compared with the PI control conventional method in (Mosobi, Chichi and Gao, 2014). The LQR control is discussed along with its superior terms (control effort and the response profile) which has been used in order to be applied on the voltage control applications of the power systems.

IV. SINUSOIDAL PWM MODULATION SCHEME

In determining the harmonic content and efficiency of a multilevel inverter, choosing the modulation scheme used for the semiconductor switching plays a major role. The sinusoidal pulse width modulation (SPWM) is the most prevalent modulation scheme for cascaded H-bridge multilevel inverter. The working principle of Sinusoidal pulse width modulation is to compare a reference sine wave

with a triangular waveform in order to produce the control or gating signals of semiconductor switches. The phase shifted SPWM modulation scheme has several advantages such as easier implementation, reduced switching loss and lower level of harmonics. The magnitude of the output inverter voltage is controlled by the modulation index m

Fig.4 Sinusoidal Pulse width modulation

V. CONTROL SCHEME OF STATCOM

The PI and fuzzy controllers are used in this research work. Fuzzy controller is used to get the phase angle or delta. PI controller is used to get the modulation index. The single-phase STATCOM designed in this work is based on two cascaded H-bridges that produce five voltage levels at the output. STATCOM is proposed to be operated under VAR control mode in which the reactive power of the STATCOM is expected to follow its reference value with a high dynamic performance both in inductive and capacitive modes of operation.

The block diagram of the STATCOM location is shown in (Figure 5).

Fig.5 Block diagram of the proposed system

The control method presented here consists of two controllers namely fuzzy logic and PI. The delta (δ) or change in phase angle is generated using fuzzy controller from DC voltage. The PI controller is used for generating modulation index using the difference between measured and reference reactive powers. The delta, modulation index, capacitor voltages and carrier signals are then fed to the modulator which produces control signals for driving IGBTs. The block diagram of the overall control method is shown in (Figure 6):

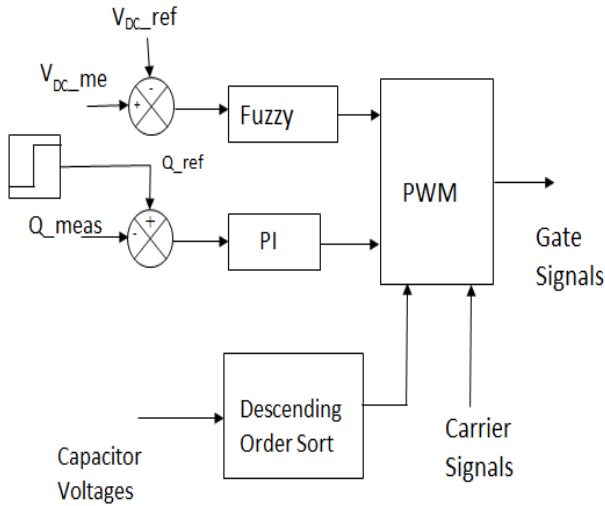

Fig.6 Control Scheme using Fuzzy Logic and PI Controllers

The reactive power is given by the following equation.

$$Q_s = \frac{E_c^2 - E_c E_s \cos \delta}{X} \quad (5)$$

This is the reactive power which STATCOM transfers to the line.

Where

X: represent the modeled reactance

E_s: is the RMS Voltage of line

E_c: is the RMS voltage of STATCOM

By changing the voltage level of STATCOM the reactive power can be controlled. Following is the relation between the STATCOM voltage and DC voltage.

$$\frac{V_{out}}{E_{Dc}} = m \quad (6)$$

Equation for reactive power is now

$$Q_s = \frac{E_s^2 - m E_{Dc} E_L \cos \delta}{X} \quad (7)$$

This equation represents the working of STATCOM. Modulation index is changed in order to control the reactive power of STATCOM. It is the main manager of STATCOM.

The control block contains two controllers PI and Fuzzy Logic. PI controller generates the modulation index. It takes difference of measured and reference reactive power as an input. Reactive power is controlled using this modulation index. Fuzzy logic controller is used for producing delta (δ). It takes difference of reference and measured DC voltage as an input.

In a fuzzy logic system, there are three stages namely; Fuzzification, Rule assessment and De-fuzzification. The first stage or fuzzification involves the mapping of variables between 0 and 1. This is done using the membership functions at the input. The rule assessment is important stage where all the processing takes place. Each rule is evaluated and then result is compiled which is then used in next stage. In last stage of de-fuzzification crisp variables are obtained by converting the fuzzy variables into non-fuzzy. As a membership function we have used triangular function. The rules used are negative big, negative medium, negative small, zero, positive big, positive medium and positive small. In the figures below the input error, change of error and output is shown separately.

The control block Simulink diagram is shown below:

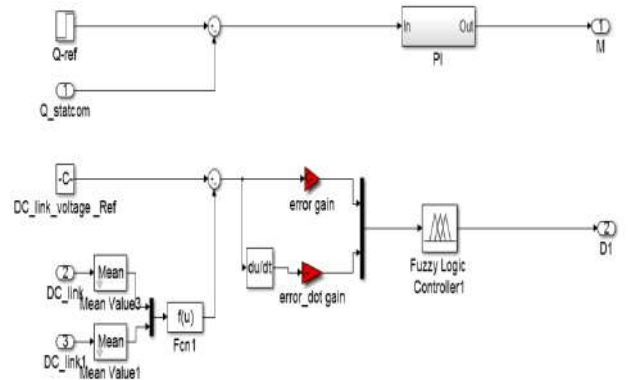

Fig.7 PI Control block diagram in Simulink

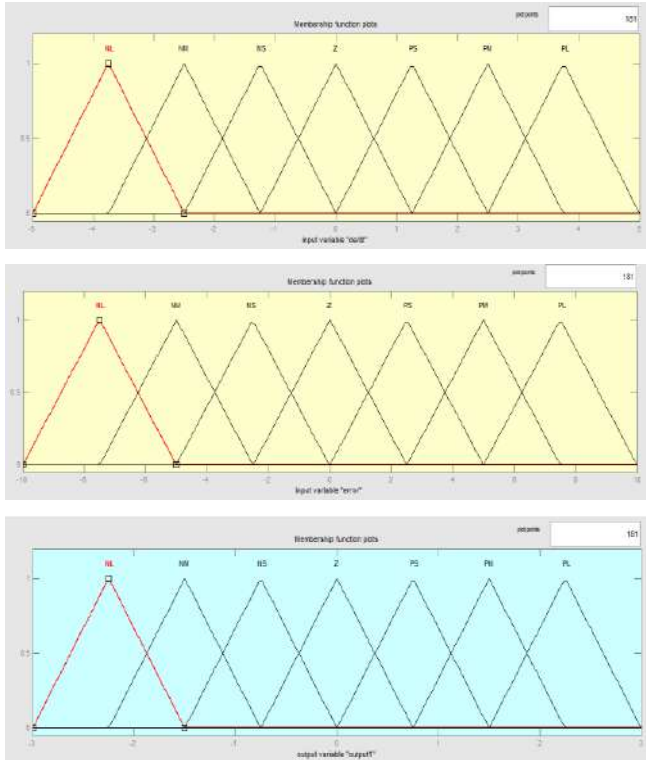

Fig.8 Membership functions for error (Top), change in error (Middle) and change in output (Bottom)

a. Phase Locked Loop Block

Shown below is the block diagram of phase lock loop or PLL. It is used for tracking of voltage. The PLL outputs the angle as it tracks the voltage signal.

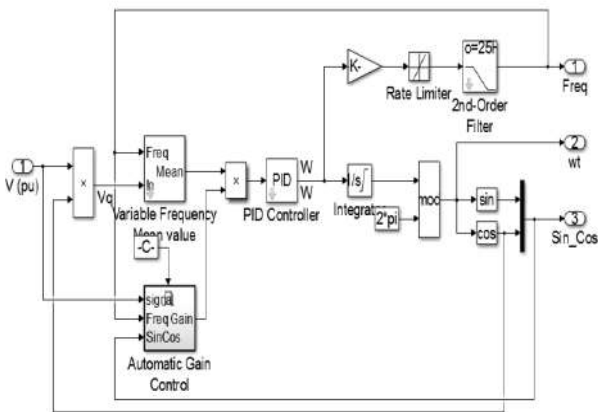

Fig.9 Simulink block diagram of PLL

A. Modulation Block

The modulation block is used for producing control pulses to drive the switches of inverter. The inputs given are carrier signal, delta and modulation index. Shown below is the Simulink block diagram of modulation scheme.

Fig.10 Modulation block in Simulink

The output of this block generates the pulses to drive switches. Equation (5) is used for the calculation of reactive power of STATCOM. Equation (6) is used for calculation of the modulation index. It is deduced from above equations that it is possible to control reactive power by varying the voltage levels of STATCOM. Using this relation of modulation index in the equation for reactive power we get equation (7) as shown, we can directly control the reactive power by varying the modulation index.

B. Inverter Block

Following block consists of the inverter and switching circuitry. The modulation block produces the control pulses which are compared with triangular wave to give a resultant pulse signal. This pulse is then inverted and given to h-bridges to perform switching. Shown below is the diagram for inverter block:

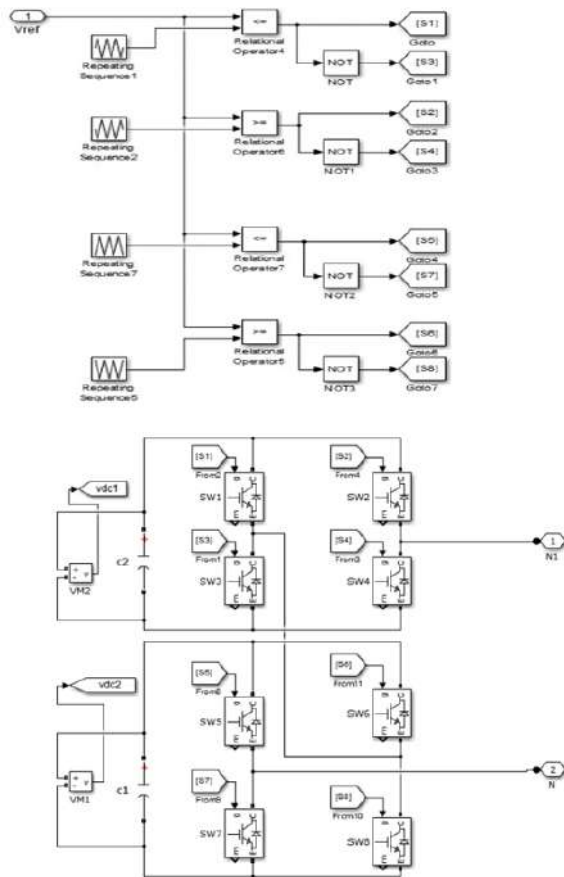

Fig.11 Simulink block diagram of inverter

There is no need for extra STATCOM or capacitor for the power factor regulation on feeders.

VI. SIMULATION RESULTS

The proposed system is designed and simulated using software with libraries for electrical components and systems. The block presented in software of complete system is shown in the following figure:

Fig.12 Simulink block diagram of complete system

In this case, we have considered a purely sinusoidal waveform as source voltage and a non-linear load. The IGBTs are used as switching devices in the h-bridge circuit. The system is simulated for 10 sec. During the first five seconds the system supplies 200 VAR reactive power and in the next five seconds it absorbs 200 VAR reactive power.

Table 1. Detail of System Parameters

	Parameters	Values
Source	Peak Amplitude (Volts)	311.12 V
	Frequency (Hz)	50 Hz
	Phase (Degree)	0 °
Load	Nominal Voltage (Volts)	220 Vrms
	Nominal Frequency (Hz)	50 Hz

VII. CONCLUSION

In this study, we designed and simulated two effective techniques to compensate for reactive power. The results suggest that using PI and Fuzzy Logic controllers together can maintain the reactive power flow in the power system. This is done with the help of STATCOM which is connected with the grid for controlling the reactive power. The proposed system is able to supply and absorb the reactive power in inductive and capacitive mode respectively. The simulation ran for 10 s. providing reactive power for 5 s and absorbing for the next 5 s.

Abstract—This paper presents a class AB amplifier with enhanced transconductance and slew rate using adaptive biasing technique and new drivers. Adaptive biasing configuration provides a tail current dependent on the input signal to increase the slew rate during slewing phase. In addition, the new structure benefits from new drivers to enhance the transconductance which are supported by adaptive biasing configuration. These enhancement techniques lead to the input and output class AB structures for fast settling applications. The proposed structure is simulated in 65-nm CMOS technology which shows a 16.2-dB enhancement in DC gain and a 72% reduction in settling time compared to the conventional structure.

Keywords—landfill; municipal slurry; bottom layer; geolayer; permeability

I. INTRODUCTION

Development of data converters and analog filters lead circuit designers to improve operational transconductance amplifiers (OTAs) as the block that consumes the most power. The accuracy, speed and input noise of such circuits are directly dependent on specifications of the OTAs [1, 2]. Therefore, enhancing their specifications is still one of the important design challenges. Folded cascode (FC) structure is the most commonly used owing to its advantages over the other structures [1, 3]. The FC structure provides more output voltage swing and it does not have the input to output connection problem in comparison to the telescopic structure, besides, the FC amplifier consumes more power. Therefore, to optimize the power consumption, the recycling folded cascode (RFC) structure has been presented in [1, 2]. This structure employs load transistors as new drivers to enhance transconductance and consequently enhance the specifications of the amplifier. Besides, some transconductance enhancing techniques such as current shunt [4, 5], extra paths [5, 6], positive feedback [6], additional drivers [6, 7] and self-biasing configurations [8, 9] have been recently applied on the RFC structure to get more efficiency. In addition, a design methodology based on Gm/Id characteristics to reach the maximum efficiency and decrease the input referred noise has been reported in [3] that is dedicated to the FC structures.

There are other techniques which their main objective is increasing the slew rate to get smaller settling time. Adaptive biasing technique presents a structure that its tail current is

dependent on the input common mode voltage [10-12]. Therefore, such structures can provide more DC current to charge and discharge load capacitors during slewing phase when the input voltage has a large swing. Moreover, creating extra paths from the input node to the output node transfer more DC current into the load capacitors to charge and discharge them in a shorter time [13, 14]. In the most cases, in addition to increase the slew rate, the extra paths will also result an enhancement in the transconductance [5]. Therefore, to reach higher speed (smaller settling time) and higher accuracy (larger DC gain) employing such enhancing techniques are necessary in the FC structures.

In this paper, the conventional FC structure is somehow re-configured to provide a class AB structure with enhanced transconductance and slew rate. The proposed structure uses new input to output paths and adaptive biasing technique to increase the slew rate and transconductance. The paper is organized as follows: Section 2 illustrates the enhanced structure and compares it with the conventional structures based on mathematical analyses for frequency and transient characteristics. Section 3 reports the simulation results of the designed amplifiers and finally, the conclusions are given in Section 4.

II. ENHANCED RFC

Fig. 1 shows the conventional FC amplifier. In this figure, transistors M3a and M4a play role of the load in a cascode structure. To improve its efficiency, load transistors can be employed as common source amplifiers. The RFC structure which uses transistors M3a and M4a as new drivers is shown in Fig. 2. In this structure, the input signal is applied to the gate terminals of the new drivers through transistors M1b-M6b [1, 2]. Therefore, the RFC structure includes two different amplifiers: one folded cascode amplifier (M1a-M6a) and one current mirror amplifier (M1b-M6b) with a current gain of (k). Thus, the transconductance of the RFC structure is summation of gm_{1a} and $k(gm_{1b})$ [2, 3]. To have the same current consumption for the FC and RFC structures, the current gain factor k is typically set equal to 3 or less. Note that the DC current through M1a_{RFC} is half of that through M1_{FC}, the transconductance of the RFC is two times over the FC that leads to higher DC gain and gain bandwidth (GBW). In addition, due to the existence of the extra paths from the

input node to the output node, the RFC structure charges and discharges load capacitors by more DC current compared to the FC during slewing phase [1, 5]. Besides, both of the FC and RFC amplifiers include a flipped voltage follower (FVF) cell as the tail current to have an internal class AB operation.

Fig. 1. The conventional FC amplifier

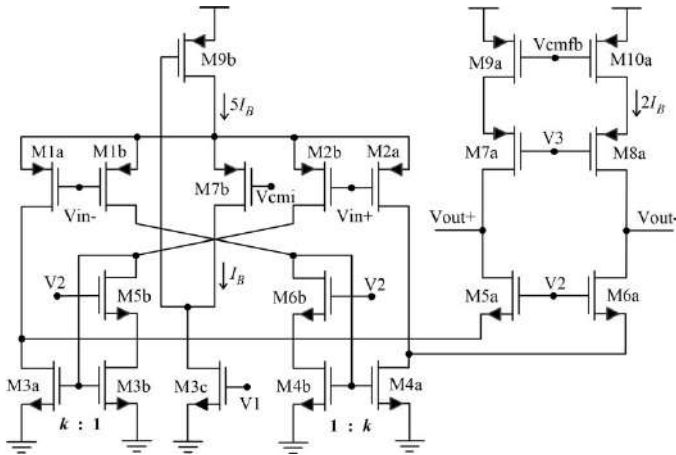

Fig. 2. The RFC amplifier

A. Small Signal Analysis

Fig. 3 shows the enhanced recycling folded cascode (ERFC) structure. By adding the adaptive biasing technique and employing new drivers (M9a and M10a), the RFC structure in Fig. 2 is re-configured in Fig. 3. To implement the adaptive biasing technique in the enhanced structure, two FVF cells (M7b-M10b) are employed as two matched tail currents [8, 15]. In the small signal operation, the input signal applies to the source terminals of the input drivers (M1a-M2b) through adaptive transistors M7b/M9b and M8b/M10b. On the other hand, the input signal is connected to the gate terminals of the input drivers. Based on the superposition theorem and analysis in [11], the total transconductance of these transistors is concluded from two amplifiers: one common source amplifier and one common gate amplifier. In addition, load transistors (M9a and M10a) in the cascode structure are employed as new drivers similar to M3a and M4a. The input

signal which passes through the adaptive biasing transistors (M9b and M10b) is applied to the gates of M9a and M10a to enhance transconductance. The transistors M3d and M4d with smaller current than M3a and M4a are used to control output common mode voltage by using a simple switched-capacitor common mode feedback. According to the above discussions, and also $gm_{1,FC} = 2gm_{1a,RFC}$, $gm_{9a} = 2gm_{1a}$, $k=3$ and $m=2.5$ the small signal transconductance of three structures can be given by

$$Gm_{FC} = gm_1 \quad (1)$$

$$Gm_{RFC} = (1+k) gm_{1a} = 2Gm_{FC} \quad (2)$$

$$Gm_{ERFC} \approx 2(1+m) gm_{1a} + gm_{9a} = 4.5Gm_{FC} \quad (3)$$

Equation (3) shows a 350% and 125% enhancement in the transconductance of the ERFC structure compared to the FC and RFC structures, respectively, which leads to the DC gain and GBW improvement. However, because of the added transistors to implement the adaptive biasing technique, the enhanced transconductance will not significantly decrease the total input referred noise in comparison with the RFC amplifier.

Fig. 3. The enhanced RFC amplifier

B. Large Signal Analysis

The adaptive transistors (M9b and M10b) perform as variable tail currents that their gate voltages are dependent on the amplitude of the input signal. On the other words, the DC current of these transistors will significantly change for a large input signal. Therefore, the DC current of all transistors that charge and discharge load capacitors will increase. In addition, the new drivers (M9a and M10a) are biased by adaptive transistors (M9b and M10b) and their gate voltages and consequently their DC currents can change during slewing phase to enhance the slew rate. Therefore, the adaptive biasing technique and new drivers provide an input and output class AB operation for the ERFC amplifier that leads to a significant enhancement in the slew rate.

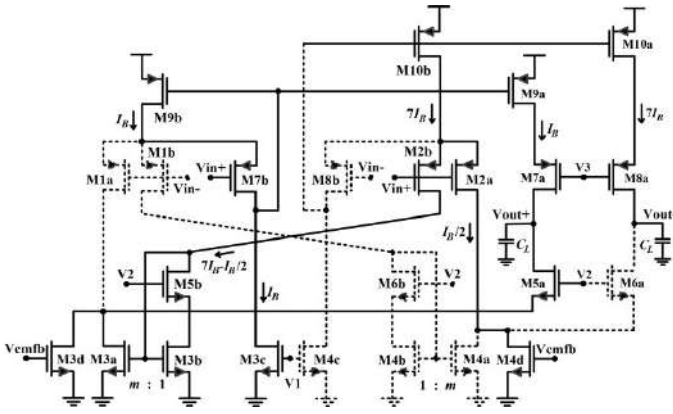

Fig. 4. The large signal model of the ERFC structure during slewing phase

Fig. 4 shows the enhanced structure during slewing phase when a large positive voltage is applied to the v_{in-} . Therefore, transistors M1a and M1b enter the cut-off region that force M4b, M4a and M6b to cut-off and M6a to deep triode region. Under this situation, M9b wants to pass a large DC current through M7b, but this current is limited by M3c. Consequently, the drain voltage of M7b rises to set the DC current through M9a and M9b equal to (I_B) . On the other hand, transistor M8b turns off which forces M4c to deep triode region by decreasing its drain voltage. Given that the gate voltages of M10b and M10a are connected to the drain voltage of M4c, the drain currents of M10b and M10a increase approximately to $(7I_B)$ for an input amplitude equal to the maximum output swing.

The gate voltage of M4d is controlled by a constant voltage which sets the drain current of M2a equal to $(I_B/2)$. For better illustration, the turned off transistors are shown in Fig. 4 by dash lines. It can be seen that the load capacitor at the negative output is charged by $(7I_B)$ and the load capacitor at the positive output is discharged by $[m \times (7I_B - I_B/2) - I_B/2]$. By considering $k=3$ and $m=2.5$, the differential slew rate ($SR_{Diff} = SR^+ + SR^-$) of three structures can be calculated by

$$SR_{FC} = \frac{4I_B}{C_L} \quad (4)$$

$$SR_{RFC} = \frac{k(4I_B)}{C_L} = 3(SR_{FC}) \quad (5)$$

$$SR_{ERFC} = \frac{(13I_B/2) \times (m+1)}{C_L} = 5.7(SR_{FC}) \quad (6)$$

Equation (6) shows a 470% and 90% enhancement in the slew rate of the ERFC structure compared to the FC and RFC structures, respectively, which leads to the settling time reduction.

III. SIMULATION RESULTS

Three structures FC, RFC and ERFC are designed in 65-nm CMOS technology while drive a $2 \times (2\text{pF})$ load at 1.2V supply voltage. Table 1 reports the transistor sizes of the three

structures. To obtain high DC gain and low input referred noise, the channel length of all transistors are chosen to be $0.3\mu\text{m}$. Fig. 5 presents the open loop frequency response of the designed amplifiers which shows a better performance for the ERFC amplifier over the others. The DC gain of the FC, RFC and ERFC are 39.9dB, 48dB and 56.1dB, and their GBWs are 32.6MHz, 82.6MHz and 180.5MHz, respectively. Therefore, the ERFC amplifier shows a 154% and 118% improvement in the DC gain and GBW over the RFC, respectively, which confirm theoretical analyses. Besides, the added new transistors as adaptive biasing technique and the new drivers lead to more poles and consequently worse phase margin. The ERFC amplifier has a phase margin about 62.5° that shows a reduction of 26.5° and 22.5° compared to the FC and RFC amplifiers, respectively.

Table 1. Transistor sizes (μm)

Parameters	FC	RFC	ERFC

Fig. 5. Open loop frequency response of the designed amplifiers

Fig. 6 shows the total input referred noise versus frequency for designed amplifiers. The input referred noise of the FC, RFC and ERFC at 100kHz are respectively 17.9nV/ $\sqrt{\text{Hz}}$, 14.1nV/ $\sqrt{\text{Hz}}$ and 13.6nV/ $\sqrt{\text{Hz}}$ that ERFC shows a 4.3nV/ $\sqrt{\text{Hz}}$ reduction compared to the FC. Besides, the ERFC does not show a significant input noise reduction in comparison with the RFC due to the existence of more elements.

Fig. 6. Input referred noise for designed amplifiers

In order to consider the settling time and the slew rate, three structures are configured as a unity gain capacitive buffer that has been presented in [1]. A large step of 1V at 10MHz is applied and the results are shown in Fig. 7. It indicates that the average slew rate of the FC, RFC and ERFC are respectively 25.9V/ μs , 60V/ μs and 128V/ μs . The ERFC shows an enhancement of 102.1V/ μs and 68V/ μs over the FC and RFC. The enhanced slew rate and GBW of the ERFC result a 72% and 46% reduction in the 0.1% settling time compared to the FC and RFC, respectively. In addition, this figure shows a better final value for the ERFC due to its higher DC gain.

Fig. 7. The large step response of the designed amplifiers

During fabrication process the mismatch and variations directly effect on the specifications of the circuit. Monte-Carlo and corner analyses are considered to show their influence on the important specifications of the ERFC amplifier. The results are reported in Table 2 that shows the considered factors of the ERFC amplifier do not experience substantial changes over process variations. The Monte-Carlo analysis was performed for 1000 runs.

Two figures of merit (FOM) are defined by equations (7) and (8) for better comparison between ERFC amplifier and the others. Finally, the comparison results are summarized in Table 3.

$$FoM_1 = \frac{(GBW)(C_L)}{(Power\ dissipation)} \quad (7)$$

$$FoM_2 = \frac{(SR)(C_L)}{(Power\ dissipation)} \quad (8)$$

Table 2. Important specifications of the ERFC amplifier in Monte-Carlo and corner analyses

IV. CONCLUSION

In this paper, an enhanced class AB amplifier based on the RFC structure is presented. The enhanced structure uses the adaptive biasing technique and new input to output paths to enhance transconductance and slew rate. Simulation results in 65-nm CMOS technology show 16.2dB, 144.3MHz and 102.1V/ μ s improvement in the open loop DC gain, GBW and slew rate over the conventional one, respectively, with just 8% expense in power dissipation.

Abstract- Handwriting character recognition can be used to seek texts in big documents, take notes on tablet or decide whether or not internet user is a human or a computer in terms of Web security. In this study, a handwriting recognition system is studied by using fuzzy rules. The system includes 4 parts, namely image processing, feature extraction, fuzzification of the inputs, and defuzzification. In the first stage, image processing based on morphological operations are used to perform the handwriting recognition under the same conditions. The feature extraction process is employed to find the total number of white pixels in each column. Then these pixel numbers are assigned to arrays. The next step is to find the local maximum and minimum values by considering this arrays as an increasing-decreasing mathematical function. Therefore, it is observed that the handwritten letters of these values are divided into various groups. In the next operation, fuzzy classification membership functions and rule tables of text groups are generated by using extracted feature data. For a better recognition performance, the letters group have to be known in order to use image fuzzy logic algorithm. Consequently, this group of letters was successfully classified with fuzzy logic rules.

Keywords — Handwriting recognition, character recognition, fuzzy logic approach, image processing algorithms.

I. INTRODUCTION

Nowadays, studies on handwriting recognition have found numerous application area in technological development. Handwriting recognition systems can greatly facilitate human life by speeding up many operations such as reading tax statements, directing mail, reading bank checks and so on and so forth. On the other hands, these systems may reduce the need for human interaction. Therefore, the academics and commercial studies about handwriting characters have recently become an important research topic in pattern recognition. The human handwritings have been tried to be recognized by many artificial intelligence methods such as Artificial Neural Networks (ANN) [1], K-Nearest Neighbors (KNN) [2], and Linear Differential Analysis (LDA) [3]. One of the methods in application is Fuzzy Logic approach. Fuzzy logic is very suitable for handwriting recognition systems because of its capability for processing of uncertain data. The difficulty in handwriting recognition systems is that handwriting characteristic varies greatly from person to person. For this reason, handwriting recognition systems are quite complex.

In this study, we have studied on the set of images containing big handwritten letters with straight lines. Image processing and feature extraction algorithms in the system were coded in C++ environment. Fuzzy logic algorithms have been constructed and tested in MATLAB environment for handwritten letters. Once the fuzzy logic algorithms were tested in MATLAB to check the recognition performance, then they are written in C++. In the final stage, all the algorithms are combined in a single software, and, therefore handwritten characters are recognized with a reliable performance.

II. IMAGE PROCESSING

Most of the images require preliminary image processing algorithms before applying any recognition technique. In order to increase the accuracy of the classification, it is very important to include descriptive features

when extracting features. The steps of image processing algorithms used in this study are explained as in the following subsections.

A. Convert the Image into a Binary Image

The image to be classified in this section is converted from RGB space to gray space by using *OpenCV* in C++ environment. The grayscale histogram density is automatically calculated and converted to a binary image with the applied threshold value. In the obtained binary image, all the pixel values above the threshold value are assigned to 1 (white) value and all the pixel values below the threshold value are assigned to 0 (black) value. Thus, the image to be classified is divided into two parts that are 1 and 0 with the threshold value. Since feature extraction is related to the number of pixels that have value of 1, the division of parts must be done properly. For this, the Otsu Method, which has a library on *OpenCV* that automatically calculates the threshold value, is used. This method assumes that the image is composed of only two color classes, namely, the background and the foreground. The variance values for all threshold values for these two color class is calculated. The threshold value, which has the smallest variance value, is determined as the optimum threshold value

B. Finding More than One Character in the Image

In this section, binary image applied with threshold value is used as input. The binary image can have more than one character. Firstly, the characters must be separated from the whole image and considered as single image, and each process referred to in this work must be applied. As a first step, the boundary lines is found by the *findContours* function in *OpenCV* library [7]. The boundary lines are stored in an array with two memory files. The first memory of the array is the object and the second is the point of the object boundary line. The object boundaries are dropped to an array by using a simple for loop. Then, the smallest rectangles surrounding these boundary lines are found with the help of *OpenCV* rectangle as in Fig. 1 [7]. This rectangular image is cropped sequentially from the left of the image, and each cropped rectangle is regarded as an image to be classified.

Figure 1. The handwriting image divided into character groups

C. Image Standardization

The last step of image processing procedure is the size standardization of the image characters. Since character images are in different sizes from each other, they need to be reduced to the same size for comparison and recognition of images adequately. By means of this algorithm, the images to be classified in different sizes are standardized to (40 × 30) pixel dimensions.

D. Feature Extraction

In feature extraction stage, the approach is to scan all the columns of the digitized image respectively and keep the total number of white pixels in each column in a string form. Then classification of the characters is performed by comparing the total number of white pixels in this column. Figure 2 shows the 'A' letters drawn with different handwriting and Table 1 lists the column pixel data after image processing procedure is applied to these characters. Note that the pixel values of the characters are different according to each column in Table 1. The main reason of the characters' difference is that they are written by different handwritings.

Figure 2. The characters 'A' written by different handwriting

As the columns are observed carefully, even if the characters look like in the form of a different character, the Table 1 gives a hint about classification scheme. In all four cases, the column data shows that the values of pixels increase to nearly 21, decrease to nearly 11, increase nearly 39 again, and finally decrease to 0, respectively. For this reason, a mathematical function can be evaluated according to the local maximum and local minimum values of the data in Table 1. The difference between the current local maximum (or minimum) and the previous local minimum (or maximum) gives us the transition values. These transition values will form the inputs of the fuzzy system. It is possible to verbalize these pixel values in the column with fuzzy logic. Then, the characters can be defined by these verbal statements with fuzzy rules.

TABLE I. S₁, S₂, S₃ and S₄ PIXEL DATA

Column	S ₁	S ₂	S ₃	S ₄

1) *Finding extreme values:* In this process, the program takes into account the data in the column and compares it with the previous data set in order to see whether or not it extracts a local maximum or local minimum

point. Figure 3 shows the flow diagram of the algorithm for computing the extremum (transition) values written in C++. In Table 2, the transition values are listed for the letter 'A' with this block diagram. In the diagram, CD is the current state data and PD is the data in the previous column. Outputs of this algorithm is a transition number and a transition value associated with it. For instance, the parameters $T_1 = 23$ indicates that the transition number is 1 and the transition size is 23. The algorithm also includes determining directional change. When a directional change (transition value) is determined, there must be more difference than ± 3 value between CD and PD. Negative DIT (-DIT) (Direction of transition) means incrementation and positive DIT (+DIT) means the decrementation. If there is a difference equal to 2 or less between CD and PD, the big one is selected. If CD is big, the direction sign is considered. If the direction sign is positive, then L_{max} is equal to CD, otherwise the algorithm will search the next column. If PD is big and the direction sign is negative, then L_{min} becomes as CD. If the direction sign is positive, the other column is passed.

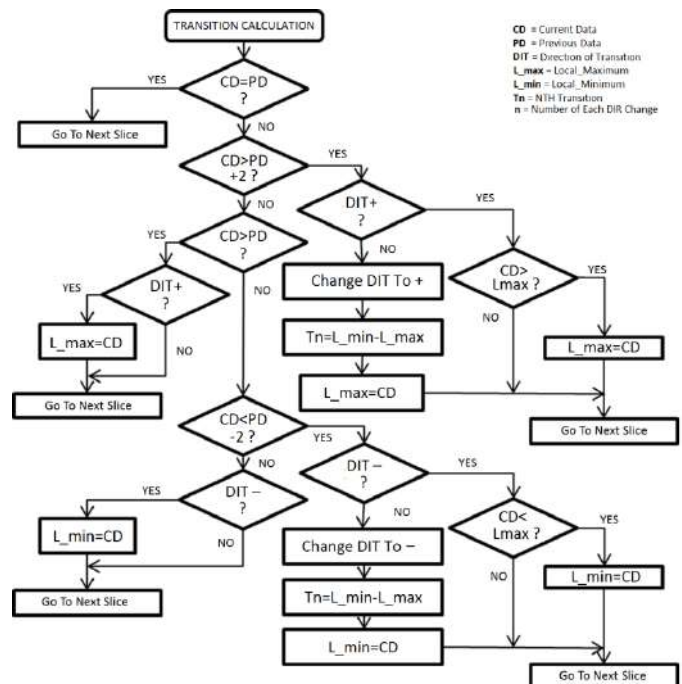

Figure 3. Transition value calculation algorithm

The transition values of the character A (S₁) found using the algorithm in Fig. 3 are shown in Table 2. As shown in Table 2, there are 4 transition points of character A ($T_1 = 23$, $T_2 = -12$, $T_3 = 28$, $T_4 = -39$). The feature extraction in order to characterize each character is applied to all the letters. In feature extraction operations, characters are divided into 3 character sets with 2, 4, or 6 transition values. B, E, G, S have six transition values; A, C, F, J, O, P, R, Z, D have four transition values and H, I, K, L, M, N, T, U, V, Y letters have two transition values character sets, respectively. Firstly, the character to be recognized is determined by which of these letter class, and so this operation facilitates decision of classes with and also flow of the system. These transition values can not provide sufficient accuracy in each character set in order to recognize the characters. For this reason, the total number of pixels, the first maximum and minimum column number, and the characteristic length specific for the character set are extracted by the software to increase the accuracy of the program.

2) *Finding total pixel data:* In this process, the pixel of images that are standardized and considered to be drawn in certain dimensions are scanned in C++ in order to find the total number of white pixels. The total number of pixels is not used because it does not vary much in the class which has only 4 transition values. The total number of pixels found is written in the fuzzy logic rule table and in the membership functions with TPS abbreviation.

3) *Finding the first maximum and minimum points:* It was observed that the column numbers in which the first and maximum transition values were found during the observation of the data differ between the letters and that the same letter has close values even in different handwritten letters.

The first maximum and minimum column numbers found differ in letter sets with 2 transition and 4 transition values. They are not used since these values do not vary sufficiently in the 6-pass value set.

4) *Feature extraction of a set of letters with four transition values:* In this process, the character lengths of this set of letters shown in Fig. 4 are determined to increase the accuracy of the system. The logic of the written algorithm is to count the number of black pixels remaining between the first white pixel and the next white pixel. To find the length between the vertical and horizontal red lines, the scan operation is performed from (20,0) to (20,30), and from (0,28) to (40,28), respectively. The accuracy of recognizing letters has been increased thanks to differences in letters (C, F, J, P, Z) that do not have horizontal length (HU), and the letters (C, F, J, P, Z) do not have vertical length (VU).

Figure 4. The characteristic length extraction

5) *Feature extraction of a set of letters with two transition values:* Characteristic length extraction in the case of two transition values is to determine the length between the horizontal and vertical red lines shown in Fig. 5. The reason for obtaining these lengths is the same as in the previous feature extraction process. The difference only in the scanning process is that the scanning direction is from (33,0) to (33,30) for the vertical lengths, from (12,3) to (28,3) for horizontal lengths. In this letter set, only the letter K is recognized by using fuzzy logic with the length of the letter K in the vertical direction, the differences in the horizontal length between the letters with the transition values, the first maximum column number, and the total pixel values.

E. Fuzzification of Data

Fuzzification is the process of converting information received from the system into symbolic values, which are linguistic qualifiers. By taking advantage of the membership process, it determines the fuzzy set and membership level to which the input information belongs, and assigns numerical values to the entered numerical values such as "small, smallest". In order to determine each verbal expression, firstly the intervals where the values of the data change must be found. In this study, many different handwritten characters have been evaluated for each character; feature data were examined, and variation intervals of values were found. Each variable interval is divided into sub-regions and each sub-region is labeled with verbal expression. The rule tables of each character group are determined via the MATLAB FIS Editor interface by using the variable data found in C++ software in order to find the membership level of these verbal expressions. Then the variable data are labeled as verbal expressions; fuzzy clusters and membership functions are created in the most accurate way by trial and error method. The fuzzy clusters and membership functions that have been verified by MATLAB program are created in C++ and integrated into image processing and fuzzy logic software. The fuzzy sets in the system consist of 3 membership functions that are small (S), medium (M) and large (L). These membership functions are defined as triangular and trapezoidal functions as shown in Fig. 6. The trapezoid membership function consists of 4 points, n_1, n_2, n_3 and n_4 , and the triangular membership function consists of 3 points, n_1, n_2 ve n_3 . Points of triangular and trapezoidal functions of all letter sets are given in Table 3, Table 4 and Table 5.

F. Fuzzy Inference

Fuzzy inference is the process and inference of the fuzzy concepts in a way similar to the ability of people to make decisions and make inference. In fuzzy inference, there are several methods such as min-max, max-prod and Tsukamoto. Min-max was used in this study. The number of transition values of the letter and the letter set given above will be evaluated according to in the rule table. In the rule table, the number of the transition values of the image to be recognized and the character set of letters given above is found. For each letter rule in the rule table, the membership function value of the fuzzy set which the letter is the member is found, respectively. The minimum values of the membership degree of each rule found are stored in an array. The maximum value obtained between these minimum ratings specifies which letter is the image.

III. TESTING OF HANDWRITING RECOGNITION SYSTEM

Figure 7 shows the output of the program with the image of the letter S handwritten to be classified. The letter S image was first converted to binary image by thresholding method, and then the boundary points were found in the OpenCV library. The character to be recognized is regarded as a separate image by the smallest rectangle formed by these boundary points, and this image has been translated into (40 × 30) pixel dimensions for standardization data in the program. As shown in the program output, this character is a member of a set of letters with 6 transition value. The fuzzy logic inputs in this set of letters are the transition values and the total number of pixels. The total pixel values and transition values found and the membership degree of the fuzzy clusters are calculated. In the next step, the membership degrees as shown in Figure 8 are placed in each letter rule table as in Table 6. The minimum membership degree between the membership degrees listed in rule table is found. As shown in Figure 8, S character has 0.2, B character has 0, the character G has 0 and the character E has a membership rate of 0.1. based on taking into account the maximum membership level between these minimum membership degree, it can be determined which letter rule is the Max degree member of the image to be classified. As seen from the Min values, this character belongs to two rules. The letter E is a member with a membership level of 0.14 and the letter S is also a member with a membership level of 0.2. As mentioned before, the

maximum value (0,2) between these two membership levels indicate the letter S.

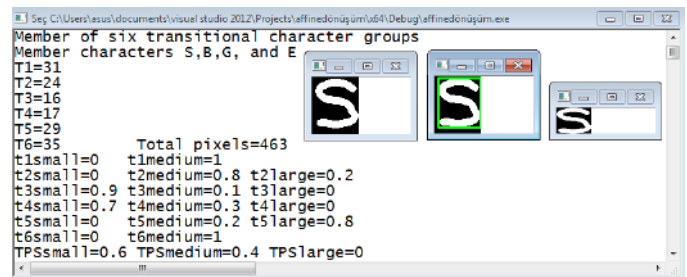

Figure 7. C++ program output

Figure 8. C++ program output

IV. CONCLUSION

In this study, a handwriting recognition system is realized by using image processing, feature extraction and fuzzy logic algorithms in C++ environment. Character images written in different handwriting, image processing algorithms, feature extraction are examined. The accuracy of the system has been increased by examining more than one samples for each letter. As a result of this examination, it is found that the same data in each letter does not vary, that each letter does not have the same number of variable data numbers, and that each letter does not contain the same variable data. Therefore, letters are separated into character groups and fuzzy logic algorithm is created by using variable data of each group of letters. Handwritten letters are successfully classified by using fuzzy logic algorithm. In this study, the dotted letters (ö, ü, i) were not classified due to the uncertainties of the data. In future work, the authors will be concentrated on a recognition system based on more advanced intelligent algorithms such as artificial neural networks, neuro-fuzzy inference system and support vector machines.

Abstract — Bearings are generally used as rolling elements in rotation machines. Faults in the rolling elements causes breakdown, and this may lead downtime and huge damages in rotating machines. On the other hand, bearings are often employed under high load and high running speed conditions. In this study, artificial faults are created on bearing inner rings by a laser beam in certain size namely 0.15 cm, 0.5 cm, 0.9 cm diameter. Vibration signals are collected by a data acquisition device in a shaft-bearing test setup. Before classifying the data, feature extraction is performed to characterize the signal. Statistical features are calculated and they are used as input to classification method. SVM classification model is employed to diagnose the size of the faults. The SVM model developed in this study classify the size of bearings faults with no prediction error. In addition, 0.1 mm error band is determined to eliminate minor bugs.

Keywords- Support vector machines; bearings; diagnosing

I. INTRODUCTION

A bearing element is composed of an inner ring, an outer ring and certain number of rolling balls. Bearings are also one of the most important elements of mechanisms such as motor-shaft which is rotating with the least friction. Nowadays, there are usually bearings on the wheel and on the hub of everything that turns. The first manufacturer of bearings is the FAG Company and its founder Friedrich Fisher invented the first bearing in 1883. There are nearly three hundred thousand types of roller bearings used in the industrial applications. Hence, the usage areas of the bearings are a lot. They are used in many different areas and sectors as a transitional element between mechanisms such as aircrafts, subways, coaches, buses, trains, engines, conveyor lines, gears, patters, washing machines, microscopes, telescopes, wind power plants, pumps [1].

A fault on the roller bearings may cause damage in the whole mechanical system. Moreover, faulty bearings can lead to downtime in whole plant. This is undesirable case especially for the big and expensive systems. For this reason, the bearings must be checked at periodic intervals; and repair or replacement must be carried out before fault occurs. To prevent these faults, many diagnostic studies carried out.

There are numerous research studies in the literature related to diagnosing of bearing elements. For example, Liu

et al. [2] developed an expert system that can detect faulty conditions by examining the vibration signals measured in the radial direction before bearing faults occur. This system can classify bearing faults by using fuzzy logic model with various time domain features such as kurtosis. The authors also calculated the success of the diagnosis methods and they claimed that the fuzzy logic method can detect fault with 100% success. The developments in fault diagnosis by using artificial intelligence strategies are summarized by Frank and Koppen –Seliger [3]. They pointed out that the artificial intelligence methods play an important role in the control of faults together with analytical methods.

Along with the developing classification methods, Abdulshahed et al. [4] employed ANN and ANFIS model to detect warming points by friction, corrosion etc. They recorded the thermal warming areas that occurred during spindle motor rotation on the CNC machine tools. The correctness of the positioning of these thermal faults that is very important in terms of machine stability. ANN and improved c-averages fuzzy method achieved valid classification rate. Under different operating conditions, the ANFIS model carried out 98.6% successful classification rate.

Zhang X. et al. [5] performed fault detection and classification of motor bearing by using a hybrid model. The authors calculated permutation entropy (PE) from the vibration signal. They employed the support vector machines (SVM) optimized by inter-cluster distance (ICD) in the feature space in order to classify the fault type and fault severity. They noticed that the developed model obtained effective and robust detection and classification results for motor bearing fault. Fernandez-Francos D. et al. [6] studied on an automatic method for bearing fault detection and diagnosis. They employed a one-class v-SVM to classify normal and faulty conditions. The authors used band-pass filters and Hilbert Transform to obtain the envelope spectrum of the original raw signal. To compare the performance of the method, they used two different data sets are used that are real data from a laboratory test setup and a fault-seeded bearing test setup. They claimed they determined not only the failure in an incipient stage but also the location of the defect.

In this study, a classification method based on Support Vector Machine (SVM) was developed for various faulty bearing elements. For this, bearing faults were created by a laser beam artificially in different sizes. The faulty bearing elements were made run in the experimental setup under various operating conditions. Vibration data was collected from a shaft-bearing setup, then time domain statistical features were calculated. These features were employed as input parameters to a SVM classification method to predict the different fault sizes of the bearings.

II. SUPPORT VECTOR MACHINES

The aim of Support Vector Machines is to estimate the most appropriate function for separating two classes with the help of the optimal hyperplane by the binary classification logic. Since multiple planes can be calculated when the data are classified, it is necessary to obtain the most appropriate hyperplane. The optimal hyperplane is obtained by maximizing the distance between the support vectors of the different classes with the separation of the state of interest. The Support Vectors are the closest vectors on either side of the hyperplane. SVM minimizes the empirical classification error while classifying.

Burgess noted that he needs to maximize the distance from the boundary of the hyperplane which passes through the two classes for a good classification in his studies. SVM classifiers are basically separate two groups according to the linearity of the data set [7].

Let $\{x_i, y_i\}$ $i = 1, 2, \dots, N$ the set of N elements is used for training of Support Vector Machines. Where $x_i \in R^p$ p is the input vector number and $y_i \in \{-1, 1\}$ is output values. In case of linear separation, the two field output values can be separated by a direct hyperplane.

When $S = \{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$ is given to training set consisting of $\{x_i, y_i\}$ pairs, the appropriate weight vector w and threshold value b for this training set will determine whether the training set is linearly separated.

$$Y_i (wx_i + b) \geq 1 \quad i = 1, 2, \dots, N \quad (1)$$

If the (1) is generalized, $w x + b = 0$ is obtained. With the help of this equation, the bounds are determined in order to obtain the most appropriate hyperplane between the two vectors.

Figure 1. Optimal hyperplane and support vectors [8]

In Fig. 1, the green lines and the red line represent border and the most appropriate hyperplane, respectively. The marked points on the green lines indicate the support vectors. The most appropriate hyper polarity is located at the midpoint of the boundary lines. The distance between these boundary lines is called d distance [8].

The main philosophy of Support Vector Machines is to maximize the d distance. The distance between two sample classes, namely the distance between the boundaries can be calculated from $d = 2/\|w\|$ formula. The maximum distance between these two bounds is obtained by minimizing the $\|w\|^2$ value.

$$\text{Objective Function} = \text{Min} \frac{1}{2} \|w\|^2 \quad (2)$$

$$\text{Constraint} = y_i (wx_i + b) \geq 1 \quad (3)$$

To find the maximum limit, the nonlinear optimization problem must be solved by the objective function as in (2) with the constraint in (3). The Lagrange Multipliers method should be used to solve this problem. The Lagrange function found in Cortes, Vapnik and later Burgess's work is used in

$$(4) \cdot L_p(w, b, \alpha) = \frac{1}{2} \|w\|^2 - \sum_{i=1}^n \alpha_i [y_i (wx_i + b)] + \sum_{i=1}^n \alpha_i \quad (4)$$

In (4), each $\alpha_i \geq 0$ is a Lagrange multiplier.

L_p is a function that maximizes the Lagrange multipliers, w is the weight vector, and b constant is a function that is minimized. According to this method, the derivatives of the function w and b are obtained and equalized to zero. Karush-Kuhn-Tucker (KKT) conditions are calculated as seen in (5) and (6).

$$w = \sum_{i=1}^n y_i \alpha_i x_i \quad (5)$$

$$\sum_{i=1}^n y_i \alpha_i = 0 \quad (6)$$

The obtained KKT conditions are substituted in (4) and the optimization problem becomes dual problem of the maximization type.

$$L_D(w, \alpha, b) = \sum_{i=1}^n \alpha_i + \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j (x_i x_j) \quad (7)$$

$$\sum_{i=1}^n \alpha_i y_i = 0 \quad (8)$$

When the model in (7) is solved under the constraint given in (8), one Lagrange multiplier is obtained for each training data. Gunn named his support vectors as Lagrange multipliers which values greater than zero in his studies in 1998. Those that are non-zero are those that are above the borders, and those that are equal to zero are those that remain on the other side of the borders. These non-zero Lagrange multipliers are located above the boundaries and those equal to zero remain on the other side of the bounds.

III. METHOD

A. The Test Platform

The experimental data used in this study is collected from a bearing-shaft assembly which is consist of an AC servo motor as shown in Fig. 2.

Figure 2. The experimental setup

The data is collected by National Instruments 6211 data acquisition card (DAQ) via MATLAB environment. The piezoelectric vibration sensor (352C65) is used for transmitting vibration signals to electrical signals. Signal conditioners is employed in order to eliminate noise and to amplify the vibration signal.

Bearing faults in specific size are formed by laser beam artificially on inner ring for this study. Faults are formed in

micron precision to inner ring for this experiment in the size of 0.15 mm, 0.5 mm and 0.9 mm diameter. Fig. 3 a microscopic fault formed by laser beam can be seen. Laser beam is very sensitive in terms of diameter size error.

Figure 3. A sample microscopic fault image

B. Raw Vibration Data and Feature Extraction

Vibration data at a sampling frequency of 24 kHz is separated into 20 pieces with 1 second. These data packet are calculated and stored in computer environment. A sample raw vibration data can be seen in Fig. 4.

Figure 4. Raw vibration data

Time domain statistical features are obtained from data packets. The features must represent data packets accurately. Otherwise, it is very hard to classify the fault size. 9 different feature are utilized to create feature data. That are:

- RMS
- Kurtosis
- Standard Deviation
- Skewness
- Maximum
- Minimum
- Average
- Median
- Crest Factor

C. Building of Support Vector Machine Model

The 9 type feature is extracted from the data packets divided into 20 part. This procedure is applied for each data in different size. Therefore, the feature matrixes were stored in 9x60 sizes. These feature matrixes are given as input to developed SVM model. As in Fig. 5, SVM model and its feature inputs can be seen.

Figure 5. Bearing fault size classification model

A target output matrix of 1x60 that meets the input matrix was created. The target matrix consists of 3 different matrices that are 1x20 small size, 1x20 medium size, 1x20 large size. The hypothetical values that are 0.15, 0.5, and 0.9 mm are determined as small, medium and large size, respectively. In Table I, faults size and target output size are illustrated.

TABLE I. FAULT TYPES

Fault Types	Target Output (mm)
Small	0.15
Medium	0.5
Large	0.9

The SVM model actually distinguishes objects into 2 groups. Thus, the classification process is performed in the form of steps as in Fig. 6. First, the small faulty bearing was separated from the other faulty bearing. In the remaining group, medium and large defective bearings were distinguished from each other by the 2nd stage classification process.

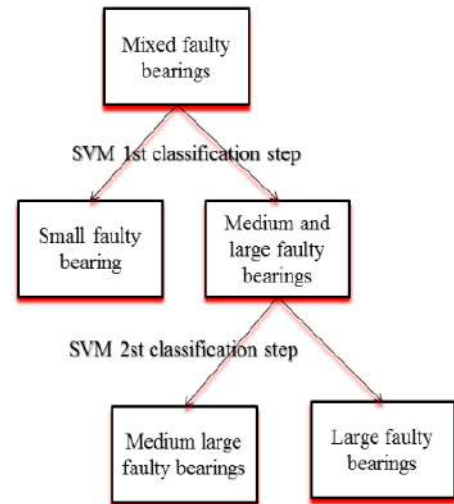

Figure 6. SVM classification model steps

IV. EXPERIMENTAL RESULTS

The simulation results obtained were evaluated according to two different performance criterion. Equation (9) and (10) were taken into consideration when evaluating the results.

$$Actual\ Error\ (\%) = \frac{1}{N} \times \sum_{i=1}^n \left| 100 \times \frac{(a_i - p_i)}{a_i} \right|$$

$$(9) \text{ Error Band Success } (\%) = \frac{1}{N} \left(\sum_{i=1}^n \left(\left| (a_i - p_i) \right| > 0.1 \right) \right) \times 100$$

(10)

a and p values are respectively the actual and predicted values. n is the number of output values not included in the error band, and N is the total number of inputs used. The actual error equation indicates how far the prediction results of the classification models from the actual test data. It is aimed to estimate the bearing fault dimensions more precisely by observing the small faults by the 0.1 mm error band.

For classification via Support Vector Machine, MATLAB Statistics and Machine Learning Toolbox is used. The Radial Basis Function (RBF) was selected as the appropriate kernel function. These parameters were selected by trial and error according to their accuracy performance. In addition, quadratic programming was selected as a solver algorithm, subsampling heuristic procedure is used.

50% of the data set were used to train the SVM network, and remaining 50% were used for testing. The train and test data is randomly assigned for each trial. As the SVM classifies the classes according to the assignment process, the results of the classification process are estimated as exact 0.15, 0.5 and 0.9 values. Therefore, deviations from the average were not observed.

A successful classification was achieved in the SVM model thanks to the hyperplane technique. The classification is performed by the assignment between them according to hyperbolic lines. In Fig. 7, blue points are target output and the red values show estimated results by an SVM model. By the SVM model, the bearing fault dimensions are classified correctly and the bearing error dimensions are determined with 100 % success.

Figure 7. The predicted and the target output

V. CONCLUSIONS

In this study, artificial faults on bearing were created by laser beam on inner ring. The vibration signal was acquired from the experimental setup. The features were extracted through raw vibration data in the time domain and they were given as input to SVM model for classifying fault sizes in the bearings. In order to avoid small classification errors, an error band function was employed in the diagnosing approach. The fault sizes are determined with a %100

success by the classification model. It is observed that SVM model is very useful for detection fault size. In the future work, a multi-decision algorithm will be employed for inner, outer and ball faulty bearings.

ACKNOWLEDGEMENT

The work presented in this paper has been done at Sensor Laboratory of Mechatronics Engineering Department and was supported by TÜBİTAK under the project code 106M280. Authors of this paper thank to the Middle East Bearing Industry (ORS) for granting bearings. They also thank to Laser Technologies Research and Application Center (LATARIUM) for contributing to make the artificial defects on bearings.

Abstract—This work reports a modelling method of functionally graded materials (FGM) using ANSYS APDL. ANSYS, as many other analysis software packages, does not provide a direct way to model variation in material properties as a function of position. However, ANSYS offers the option of temperature dependent properties; and ANSYS also offers the ability of assigning temperature values according to the position; joining these two abilities offered by ANSYS, the material properties would be position dependent. In this work, using ANSYS APDL, dummy thermal loads are used to obtain FGM distributed properties. The presented modelling method is explained and then applied to some case study of static analysis to verify its accuracy by comparing its results with the analytical solution from the case study source. The main advantage of such a method is its simplicity and ease; it does not require deep knowledge of mathematical models of FGM and delivers high accuracy. Although in this study ANSYS APDL is used, one can apply it in ANSYS Workbench Mechanical or any other analysis package that has coupling capabilities of structural and thermal studies. The presented method is already mentioned in the literature, but no single documentation about it is found. This paper presents a complete representation of the method.

Keywords—Functionally graded material; ANSYS; modeling; Dummy thermal loads method.

I. INTRODUCTION

Functionally graded materials FGMs are defined as “materials that comprise a spatial gradation in structure and/or composition, tailored for specific performance or function” [1]; i.e. functionally graded material properties at any point at the structure differ according to the position of the point. So we can say that Functionally Graded Material (FGM), a revolutionary material, belongs to a class of advanced materials with varying properties over a changing dimension [2]. This distributed properties are achieved by composing the microstructure using different materials, at least two. The microstructure is designed in such a way that leads to gain certain desired properties for the whole structure. For example, ceramics have high strength and high thermal properties, but lack toughness, so they could be

compounded with metals as FGM to gain the desired toughness.

As in FIG-01, the structure is ranging from one material phase, i.e. ceramic to another material phase, i.e. metal. The properties transition from one phase to another occurs gradually according to the design equation of the microstructure. Typically, properties variation could be linear, exponential, some power equation, etc. as a function of some dimension i.e. position.

Figure 1 FGM microstructure. [3]

FGM properties variation could be modeled as microstructure changes, layers change, continuous changing, as shown in FIG-2.

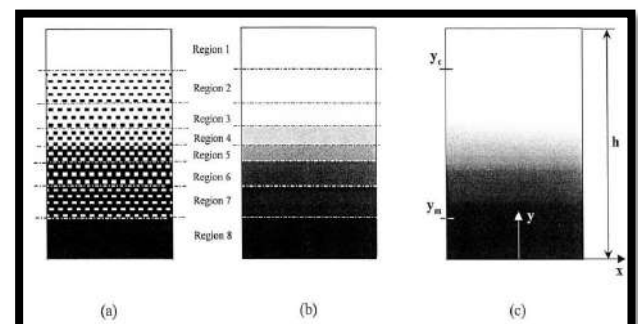

Figure 2 FGM modeled by: (a) micro-structure, (b) layers and (c) a continuously changing structure. [4]

The three models have the same concept of dimension dependent microstructure, and so the properties. The microstructure change and layer change models have

additional concept of intervals for properties (regions). The selection of one model represents the manufacturing technique, i.e. the design of the microstructure, or the simplicity level desired in the model.

These models have been the subject of many studies.[3] It requires a solid knowledge of mathematics, elasticity, mechanics, etc. to model, solve, or even use these models.

ANSYS and analysis packages offer obtaining solutions and results without the must of neither the knowledge of mathematical model nor the solution methods of them. The only requirement is to express the problem correctly to the software. ANSYS has wide range options and capabilities that makes it easy to communicate with it; i.e. express the problem and extract results.

II. THE CASE PROBLEM DESCRIPTION

An application problem is selected to illustrate the presented modelling way. It is a static analysis problem of FGM solid cylinder with radius (b) m, subjected to external pressure (P₀) Pa. The goal is to obtain the normalized radial displacements, radial stresses and hoop stresses. There are two material properties in concern here, Elasticity modulus (E) and Poisson's ratio (ν). Poisson's ratio is considered fixed in this problem, while elasticity modulus of the cylinder varies exponentially through its radius according to the following equations:

$$E(r) = E_0 e^{-nR^n}, \quad n = \ln\left(\frac{E_0}{E_{out}}\right), \quad R = \frac{r}{b}$$

where,

r = radius at given point.

E(r) = the elasticity modulus at points at radius r.

E₀ = Elasticity modulus at the cylinder center.

n, η = material parameters.

E_{out} = Elasticity modulus at the cylinder outer surface.

R = rational radius.

b = Radius of the cylinder.

Radial displacements, radial stresses and hoop stresses are obtained for different values of (n) and (η), while the values of (b) and (E₀) are arbitrary assumed; their values has no importance because the comparison is between the normalized outputs. (E_{out}) is directly related to (E) through the value of (n). Normalized outputs follows the following equations:

$$U = \frac{uE_0}{bP_0}, \quad \sigma' = \frac{\sigma}{P_0}$$

where:

U = normalized radial displacement.

u = obtained radial displacement (m).

σ' = normalized stress, applicable to the radial and hoop stresses.

σ = obtained stress, radial or hoop stresses (N/m²).

For this particular problem, it can be modelled as 2D plane strain problem. Due to the symmetry of the cylinder cross

section shape (circle) and the symmetry of the load, only quarter of the cross section is needed.

The following values are used:

B = 200 mm

E₀ = 120 GPa

P₀ = 1000 Pa

n = [-1.0, -0.5, 0.0, 0.5, 1.0]

ν = 0.3

η = 0.9

III. METHOD OVERVIEW

The main goal is to obtain dimensional dependent properties, which is not directly available in ANSYS. The idea is to make the desired distributed property as a function of other value which is a function of position only; which makes the desired property depends only on dimensions.

ANSYS offers the ability of temperature dependent properties; and ANSYS offers the ability of assigning temperature value at any point (node) according to the point's position; joining these two abilities offered by ANSYS, the material properties would be position dependent.

The general steps can be summarized as:

- Define the material properties as a function of temperature; and make sure the expansion is set to zero to eliminate any thermal stresses.
- Create and mesh the geometry to obtain the nodes (points).
- Apply thermal loads, i.e. temperature values, for each node of the structure as a function of position (dimension). This makes material properties depend only on temperature, and temperature depends only on position, so material properties depends only on position. The temperature value will represent the dimension; i.e. replace the dimension.
- Apply problem's loads and constraints
- Run the simulation and obtain results.

IV. METHOD APPLICATION BY STEPS

Here is the detailed step-by-step illustration:

A. Selection of GUI filtering:

This case problem is about static analysis, so select structural analysis filter. In addition, thermal loads are used in this method; so thermal analysis has to be selected as well. Selection of GUI filters is at:

Main Menu > Preferences

B. Selection of the element type and its options

i. Element Type

Selection of the element type depends on the specific problem as it may be planer 2D elements or solid 3D. Since the problem includes thermal and structural studies and since it is decided to be a 2D analysis, a coupled field element could be selected. Exactly "Quad 8 nodes 223" is selected as the element type. It is a planer 2D element which has the ability of performing coupled thermo-structural analysis. Select element type at:

Main Menu > Preprocessor > Element Type > Add/Edit/Delete > Add..

ii. Element Options

Since this is a plane strain problem, element behavior has to be set as plane strain. Set element options at:

Main Menu > Preprocessor > Element Type > Add/Edit/Delete > Options...

C. Create part geometry

Create the problem geometry. Here for this example case study, create an area of a circle quarter, with radius of 200 which its center is at (0,0).

Main Menu > Modelling > Areas > Circle > Partial Annulus

D. Meshing

Main Menu > Preprocessor > Meshing > Mesh tool

Modify meshing options as to have a fine mesh, which leads to more real representation of the FGM material. Here Smart Size is used, and its value is set as 1 (Fine Mesh).

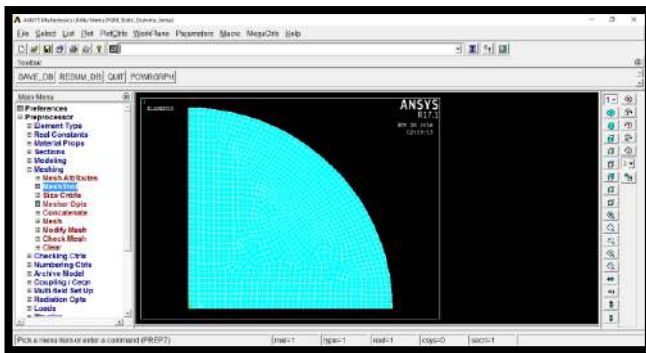

Figure 3 Meshed Shape

E. Material properties

We want to distribute the elasticity modulus across the cross section as a function of the radius, using a linear distribution of nodes temperatures. ANSYS allows us to express the elasticity as a function of temperature by assigning points of (Temp, Elasticity) in the material model window.

Figure 4 Material Properties

If the material property varies linearly, we have to put only two points to express the straight line. But with nonlinear variation of the property, as in this case problem (exponential distribution) we have to assign more the two points; and it is better to have as much points as possible to present the curve of distribution. ANSYS allows up to 100 points to be assigned to express the curve. This is tedious to

be achieved manually. We can use other program like MS Excel to obtain these points, or we can use MACRO. MACRO is the name of subroutines in ANSYS. We can make a MACRO that automates the process of assigning these points of temperature-Elasticity relationship. Here MACRO is used.

From: Pull Down Menu > Macro > Create Macro, give it a name end with (.mac).

Figure 5 MACRO Creating

Then open it from the directory using any text editor. In the .mac file write this command series; i.e. program:

```

PREP7                                ! allows preprocessor commands
E0 = 120                              ! GPa
n = -0.5                              ! v = 0.3 constant ... Poisson's ratio
mu = 0. 3
*DO,j,1,100,1                         ! loop of 100 points
  R = (j-1)/99                        ! R ranges from 0 to 1
  T = 0 + (100-0)*(j-1)/99            ! T ranges from 0 to 100
  Er = 1000*E0*exp(-n*R**mu)          ! E(r) ranges from E0 to Eout
  MPTEMP,j,T                          ! assign the (j)th temperature
  MPDATA,EX,1,,Er                     ! assign the (j)th Elasticity (E)
  MPDATA,PRXY,1,,0.3                  ! assign the (j)th v, Poisson's ratio
*ENDDO
!the following lines of code: Assign expansion to zero,
!conductivity to arbitrary value i.e. 60
MPTEMP,,,,,,,,
MPTEMP,1,0
UIMP,1,REFT,,
MPDATA,ALPX,1,,0
MPTEMP,,,,,,,,
MPTEMP,1,0

```

This MACRO loops through temperature and calculates E(r) as a function of R and T, finally in each loop it assign the calculated values to the material properties.

Run this macro by calling it with its name from the command line

Figure 6 Calling created MACRO

Then check the material properties. The material properties should be filled with points.

Figure 7 Checking Material Properties

We can check the variation of elasticity modulus through the temperature range by clicking on “Graph” button in the above figure

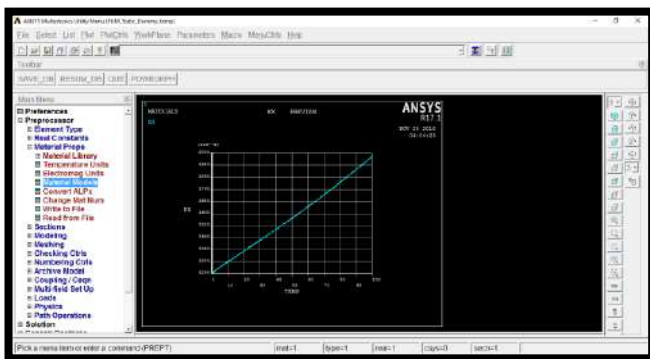

Figure 8 Graph material properties

F. Loads

In this step we will apply the thermal loads, and for this case problem we have to apply the external pressure. So we have two loads to apply. In addition we will express the symmetry of the shape.

i. Thermal loads

Thermal loads are applied as assigning temperature value at each node. The range of temperature has to be the same as the temperature range used in assign properties in Step 5. The range of 0-100C was selected, as the center point has 0C and the outer radius has 100C. Temperature varies linearly across the radius. To assign these values of temperature we use Function capability offered by ANSYS.

Pull Down menu > Parameters > Functions > Define/Edit..

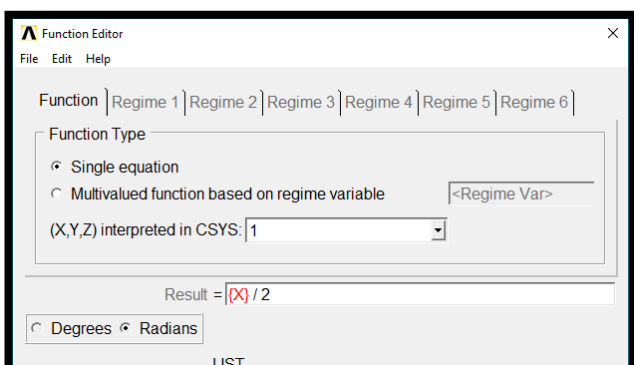

Figure 9 Function Creating

- Modify the coordinate system (CSYS) to be polar system (value 1); now (X) means the radius. Since we want to range the temperature between 0C and 100C, and our radius range from 0 to 200, so the result must output the value of $(X / 2)$. Save the function; and then call it from:

Pull Down menu > Parameters > Functions > Read From File

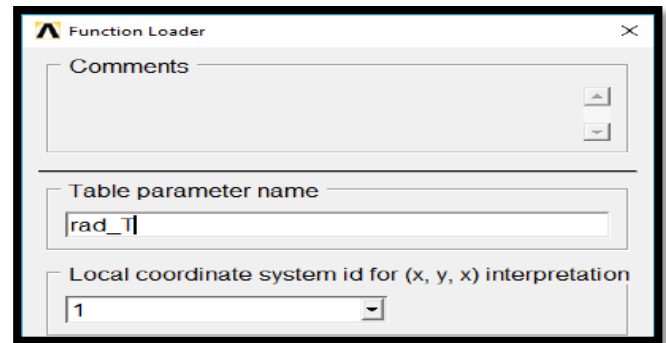

Figure 10 Creating table from function

- Give it a name at “table parameter name”. Here we named it as “rad_T”. Now we can finally apply the thermal load.

Main Menu > Preprocessor > loads > Define Loads > Apply > Temperature > On Nodes

Select all nodes by choosing “pick all” in the selection window. Select TEMP as DOF to be constrained, and apply as “existing table”

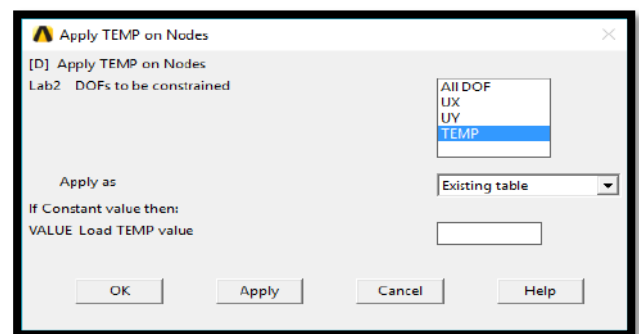

Figure 11 Apply TEMP on Nodes using existing table option

- Select the table name previously created “RAD_T”

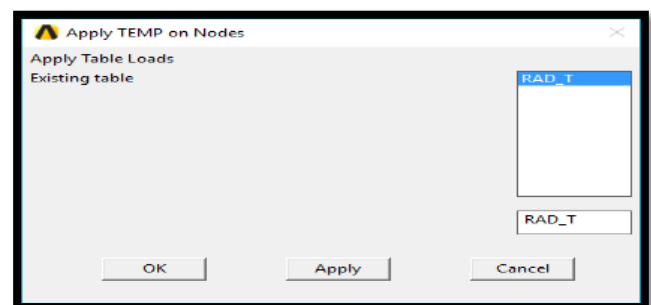

Figure 12 Calling The created Table

The temperature load applied, and will appear as follows:

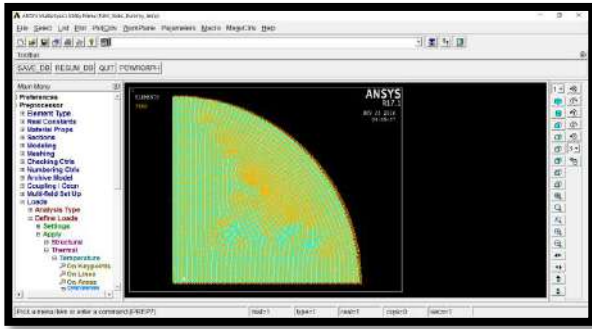

Figure 13 Temperature applied to nodes

ii. Structural load

Apply the external pressure at the outer radius of the quarter. Main Menu> Preprocessor > Loads> Structural > Pressure > On Lines, and select the outer arc line of the shape. Assign the value of the pressure as given 1000 Pa.

iii. Symmetry boundary condition

From: Main Menu> Preprocessor > Loads> Structural > Displacement > Symmetry B.C. > On Lines, select the two straight lines of the circle quarter.

G. Solve

Run the analysis from: Main Menu> Solution > solve > Current L.S

V. RESULTS

The analysis has been done with different values of proposed material constant (n). The output files of our ANSYS analysis are then processed in Excel to obtain the normalized values, and compared with the analytical solutions. The obtained values from ANSYS are compared to those obtained by the formulae in [5]. The comparison plots are shown in figures 14,15 and 16. The obtained values from analytical solution and ANSYS are shown in tables 1 and 2 respectively. Table 2 also contains in its last column a comparison between the analytical and ANSYS solution expressed as percentage relative error (ERROR%).

VI. CONCLUSIONS AND COMMENTS

From the obtained results comparison with the analytical results the validity of this method is justified. As seen in the results section in Table-2, there is a very small relative error in the results; sometimes the error vanishes to zero. The main advantage of such a method is its simplicity and ease; it does not require deep knowledge of mathematical models of FGM and delivers high accuracy.

In this paper a static loads problem is solved successfully but other certain types of analysis will not work. The first problem with the illustrated method is the lack of ability of performing thermal studies on FGM. Because thermal properties and loads are already used to present the dimension change. So, if thermal study is needed other methods of modelling FGM in ANSYS have to be used. The second problem is that it cannot be applied to obtain normal modes, since this kind of studies simply ignores the thermal and all other loads.

This method is not the only method to model FGM in ANSYS; i.e. one can build the model as layers stacked in the changing dimension, then assign different properties to each layer while making sure each adjacent layers are somehow connected i.e. glued. This later method is also effective and can solve all kinds of analysis but it will need much more MACRO programming skills especially if the change in properties is in more than one dimension.

Abstract— In this investigation, a three dimensional, single-phase proton exchange membrane (PEM) fuel cells with triple-serpentine and straight flow channel was studied numerically, evaluating reactant gas humidification, water management and cell performance. The structured grid scheme was employed which was built with a pre-processing software, GAMBIT 2.4.6. Then, the grid was imported into finite volume based commercial software, ANSYS-FLUENT 16.2. The PEMFC Module is an add-on module based on FLUENT CFD package for computations. These 3-D models with $19 \times 50 \text{ mm}^2$ same active layer used to investigate the performance of fuel cell by determining the current density, oxygen, hydrogen and water molar concentration distributions took into account the mass, momentum, energy, species, charge conservation equation as well as combines electrochemistry reaction inside the fuel cell. The simulation results of comparison of triple-serpentine and straight channels were illustrated polarization curves including I-V and I-P curves which were obtained by varying the cell potential with a 0.1 V steps. From the results, analyzing the polarization curve of the different flow field design it can be said that maximum current and power density was obtained from straight channel. For lower operating voltages, as the cathode and anode relative humidity increases, the cell performance is enhanced because the cell performance is mainly dependent on the cathode mass transport limitations due to the liquid water blockage effect. As decreases, the oxygen concentration in the reactants increases and the water concentration on the cathode side decreases, this reduces flooding and improves the cell performance.

Keywords— Fluent; PEM fuel cell; performance; simulation

I. INTRODUCTION

PEM fuel cells are one of the most promising clean energy technologies in many applications like portable, automotive and stationary due to their high power density at low operating temperatures. Besides, flow field design is one of the most important considerations in the development of PEM fuel cell components. A good flow field design cannot only provide optimum reactant gas supply but also reduce the overall cell weight and cost. Generally; modelling is preferred instead of

costly experimental works in order to reduce project costs, to try different working conditions more quickly and to be able to make the necessary corrections in a much shorter time by seeing the negativities that may occur. Therefore, modeling plays a very significant role in determining the way the new materials developed, the best configuration for the reactant transport and the optimum operating conditions of the fuel cell in order to improve the performance.

The proton exchange membrane fuel cell (PEMFC) is considered one of the most promising alternative clean power generators for mobile and stationary applications because of its low to zero emissions, low-temperature operation and high power density. The performance of PEMFC depends on material characteristics, mechanical design (particularly the flow-field design in bipolar plates) and operating conditions [1–6].

The flow plates are an important component in PEM fuel cell. Flow plates contain either a few very long channels or a large number of channels referred to as the flow field. These flow plates account for the bulk of the stack generally between 80% and 90% of the total weight of the stack. For this reason, an optimal flow plate design is critical for obtaining high power density in fuel cell. Since the early development of PEM fuel cells there have been many varieties of flow field designs. Early designs of flow fields generally consisted of parallel or straight channels. In literature, several modelling and experimental work has been investigated in order to understand the effect of channel geometries in bipolar plate including, serpentine flow channels, parallel flow channels, interdigitated flow field, flow field with pins and the influence of these parameters to the fuel cell performance.

Ionescu [1] studied gas flow velocity influence on the cell performance at first then investigated the effect of channel width and channel height on the current density at various cathode gas flow velocities based on Comsol Multiphysics which is a commercial solver. He found that the most uniform variation of local current density was achieved at $0.8 \times 3 \text{ mm}^2$, $1.2 \times 3 \text{ mm}^2$ and $1.6 \times 3 \text{ mm}^2$ gas channel geometries due to more amount of oxygen entering the channel.

Lim et al. [2] investigated a conventional and modified parallel flow field designs split flow into variant channel widths to facilitate even reactant distribution using computational fluid dynamic modeling at their study. They found that multiple stages of flow distribution can achieve an evenly distributed pressure drop with an ideal distribution of reactant among channels.

Xing et al. [3] developed a fully coupled 2D, along-the-channel, two-phase flow, non-isothermal, CFD model. In their results thinner GDL could result in more non-uniform and more significant temperature rise at high current densities. Also a new channel design featured with multi-inlets and outlets is proposed to reduce water flooding improve the cell performance.

Rahimi-Esbo et al. [4] in their paper seven flow fields were analyzed and their performances were investigated at the optimum channel to rib ratio. A novel serpentine flow field design aimed at effective water removal is introduced and examined. The results showed that 2-1-serpentine flow field has the highest performance especially at high current densities. It was founded that for operating voltages over 0.5 V, the geometry of the flow channels did not have a significant effect on performance.

Saco et al. [5] carried out a numerical analysis on scaled up model of PEM fuel cell (225 cm²) with four flow channel models. The study was mainly conducted to find the impact of flow field design on the performance of PEM fuel cell. From the results it was found that the current and power density of the straight zigzag flow channel was quite high compared to all other flow channels due to better consumption of hydrogen and oxygen molecules, better water removal rate in the flow channels.

Rostami et al. [6] studied a three-dimensional numerical model to understand the effect of bend sizes on a PEM (polymer electrolyte membrane) fuel cell in this work. The obtained results showed that as bend size increases from 1 mm to 1.2 mm, not only did the over potential reduce significantly but temperature gradient was also alleviated. Moreover, it was shown that the serpentine flow channels with 1.2 mm square bend size acted successfully in preventing secondary flows internal thereby decreasing pressure drop about 90.6% compared to serpentine flow channels with a bend size of 0.8 mm.

For the objective of this paper, a three-dimensional, single-phase, steady-state model that resolves coupled transport processes in membrane, catalyst layers, gas diffusion layers ,single and double serpentine channel of PEM models which have 70x70 mm² active layer have been developed to investigate performance of fuel cell by determining the current density with different humidity conditions.

II. MODELLING

The PEMFC module is an add-on module based on ANSYS-FLUENT for computations. While the basic governing

equations related to the mass, momentum and energy transport are solved by FLUENT solver as usual, the other constitutive relations unique to fuel cell application, related to electric potential and current as well as electrochemical reactions are computed with additional equations coming with the add-on module.

After the geometry and mesh are generated in GAMBIT 2.4.6, the relevant zones for the modeling domains which are current collectors(bipolar plate) , flow channels, gas diffusion layers, catalyst layers and membrane can be identified easily by using this module

Fig. 1. Example of a figure caption.

TABLE I. GEOMETRICAL PROPERTIES OF MODELS

Parameters	Value	Units
Channel width	1	mm
Channel length	50	mm
Gas diffusion layer thickness	0.2232	mm
Catalyst layer thickness	0.0287	mm
Membrane thickness	0.23	mm
Active area	0.00095	m ²
Number of channels(for two types of PEMFC)	9	-

Fig. 2. Triple serpentine bipolar plate flow channel pattern

Assumptions of the study;

- The PEM fuel cell operates under steady-state conditions.
- Operating temperature is assumed to be 343 K.
- The reactants are hydrogen and air.
- The gas flow is laminar, incompressible.
- The gas diffusion layers, catalyst layers and membrane layer are isotropic materials.

- Therefore gas flow of the anode and cathode channels is in the same directions

The building sector is the leading energy consumer in the worldwide in terms of primary energy consumption. According to the energy technology perspectives 2015 report, 40% of total final energy was consumed by the building sector for the activities such as heating, cooling, air conditioning, and lighting [1]. Up to now, several organic PCMs have been examined as a TES material in buildings due to their desired thermodynamic, kinetic and chemical characteristics. Among the organic phase change materials (PCMs), paraffins are the most recommended PCMs because of their advantages of high heat storage capacity, chemical and thermal stability, lowcost, non-subcooling, congruently melting, non-corrosiveness, odorlessness, chemically inertness and good thermal reliability after repeated thermal cycles [2,3]. However, the high phase-transition temperature of most paraffins limits their use in building TES applications such as energy conservation and indoor temperature regulation. Fortunately, the eutectic mixtures of paraffins can be easily formed and thereby providing PCMs with a proper temperature for their use in building applications. In this work, a gypsum-based composite with the paraffin eutectic mixture was prepared via direct impregnation method to form a novel energy storing composite building material. The structure and thermal energy storage properties of the form-stable composite PCM (FSCPCM) were investigated by The Fourier Transform Infrared (FT-IR) and Differential Scanning Calorimetry (DSC) analysis techniques. The thermal regulating performance of the gypsum plaster prepared with this composite was also evaluated in a small test chamber. The maximum mass percentage of C18–C24 absorbed in gypsum was determined as 18% without the leakage of C18–C24 in liquid state. The FT-IR spectroscopy and DSC techniques were used to characterize the FSCPCM. The FT-IR spectra confirmed that any chemical interaction did not occur among the components of the composite during the impregnation. Besides, DSC analysis showed that the FSCPCM had reversible melting and freezing behavior and quite satisfying thermal properties for building applications. The composite maintained its chemical structure and thermal energy storage characteristics after 1000 melting/freezing cycles. In addition, the gypsum plaster with FSCPCM exhibited excellent thermal regulating performance when compared to that of only gypsum plaster under the same conditions. From all results, it can be deduced that the obtained gypsum based composite plaster is a promising material to control room temperature and to conserve energy in buildings.

Key words: Phase change material, Form-stable PCM, Thermal properties, Thermal performance

Latent heat thermal energy storage (LHTES) using phase change materials (PCMs) is one of the best solar passive techniques used for different type of applications such as thermoregulation of medical and textile products, cooling electronic and medical equipments and space heating/cooling of buildings. The main problem regarding the usage of PCMs is their leakage behavior during phase change from solid to liquid phase. This problem of the PCMs can be solved by encapsulating of them within a capsule with polymeric shell in micro or nano sizes. Moreover, the encapsulation case provides much more surface/volume ratio for heat transfer and also gained direct utility function in actual LHTES systems [1,2]. Fatty acids have been used as solid-liquid PCMs for solar passive heating and cooling purposes due to their good LHTES characteristics [3]. However, the leakage problem mentioned above significantly restricts the usage potential of them. In this sense, the present study is focused on preparation, chemical and morphological characterization and determination of LHTES properties of the micro-nano encapsulated capric acid (CA)-stearic acid (SA) by using polystyrene (PS) shell. For this aim, the eutectic mixture of CA-SA was prepared to decrease the melting temperature of SA and thus expand its practice effectiveness in LHTES applications. PS/(CA-SA) micro/nano capsules were prepared successfully by using emulsion polymerization method. In the fabricated capsules, the CA-SA eutectic mixture as a PCM has LHTES function while the PS has shell action around the eutectic mixture. The experimental parameters, monomer(styrene)/PCM ratio, homogenization rate, temperature, type and amount of surfactant and cross-linking agent were optimized systemically. The styrene polymerization reaction around the eutectic PCM was characterized by FT-IR spectroscopy analysis. The morphology and the particle size distribution of the capsules were investigated by SEM, POM and PSD analysis techniques. The SEM and POM results showed that the prepared capsules were consisted of almost smooth micro and nano sized spheres. However, some of spheres with especially nano-sized were partially agglomerated. The PSD analysis results indicated that the capsules had almost uniform PSD value in the range of 0.01 - 125 μm and the mean diameter of them was 7.6 μm . The DSC analysis results indicated that the fabricated capsules, PS/(CA-SA)Ö(2:1), PS/(CA-SA)(1:1) and PS/(CA-SA)(1:2) had a melting temperature of 16.19, 17.33 and 22.29 °C and a latent heat of 56.21, 77.31 and 114.25 J/g, respectively. The thermal cycling test revealed that the prepared capsules had long-term LHTES performance after 5000 melting/freezing process. Moreover, The TGA results exhibited that the prepared capsules had good thermal stability until 200 °C. Furthermore, based on all findings, it was concluded that the synthesized PS/(CA-SA) micro/nano capsules were considered as promising PCM for solar passive LHTES applications for heating and cooling targets.

Abstract—In this study, the machining times of the cycloidal gears in a CNC milling machine were examined according to the radial machining method. In order to determine these times, the CAM program, which was prepared according to the parametric tool path equations of the cycloidal gear in the previous studies of the authors, was taken into account. In this program, the design and cutting parameters of the gear were changed and simulations of the cycloidal gears were performed for final machining. Then, gears with different numbers of teeth were manufactured in Dyna 4M CNC machine and their manufacturing times were determined. As a result, it was observed that the CAD/CAM parameters of the cycloidal gear significantly affected the production times of the gear.

Keywords—cycloidal gear; CAD/CAM parameters; CNC milling machine; machining times

IV. INTRODUCTION

There is a great deal of manufacturing data involved in process planning, such as the identification of machines, tools, features, parameters and operations [1-3]. All this data has to be evaluated in order to select the sequence of operations that will make up what is known as the route sheet. The sequence is generally obtained to conform to particular objectives, such as, the shortest time and /or the minimum cost.

A method is described for calculating the optimum cutting conditions, in turning for objective criteria such as maximum production rate. The method uses empirical models for tool life, roughness and cutting forces. The method consists on explaining the feed in relation to the roughness which depends on the cutting speed. Then, the cutting speed which gives the minimum production times was calculated [4]. To minimize the cost of workpiece machining, cutting parameters must permit to minimize production time and obtain specified specifications such as roughness [5,6]. In another work was discussed the

influence of the tool path strategy on the cycle time of high-speed milling operations. Experiments and predictions were focused on pocketing operations with a zig-zag tool path, quantifying the significant discrepancy between the programmed feed rate and the actual average feed rate [7, 8]. Maropoulos, P.G. et al. was discussed the estimation of machining times necessary to assess the tools selected using machining performance related criteria [9]. Boogret et al. was designed reliable NC programs to generate tool path and cutting condition algorithm [10]. An alternative method devised by Ou-Yang and Lin uses assumptions about the operations carried out and the likely cutting conditions of the tool in order to determine machining times of common milling features such as those implemented within VITool [11]. Malakooti and Deviprasad formulate at metal cutting operation, specifically for a turning operation, as a discrete multiple objective problems. The objectives are to minimize cost per part, production time per part, and roughness of the work surface, simultaneously [12]. Panwalkar and Rajagopalan consider the static single machine sequencing problem with a common due date for all jobs in which job processing times are controllable with linear costs. They develop a method to find optimal processing times and an optimal sequence to minimize a cost function [13].

The effects of the CAD parameters on the tooth profile errors of the cycloidal gears manufactured with an end mill in CNC milling machines were examined [14]. In other studies, spur and bevel gears were manufactured in CNC milling machines and then, the manufacturing times and tooth profile errors of these gears were examined [15-17].

In this study, while cycloidal gears were machined in a vertical machining centered CNC milling machine according to

the radial machining method, the effects of the parameters in the tool path equations of the gear on the machining times were examined.

II. RADIAL MACHINING OF CYCLOIDAL GEARS IN CNC MILLING MACHINE

For machining the cycloidal gear in a vertical-machining-centered CNC milling machine, the gear blank was connected to the machine table with the help of bolts and wedges as follows (Figure 1) [14]:

Figure 1. The clamping of the cycloidal gear blank

In the previous study, it was stated that the end mill cut the gear blank along the Z-axis, in the planes parallel to the X-Y plane as follows (Figure 2) [14].

Figure 2. Tool paths for radial machining

Where, h_n and H_{max} heights show the chip cutting thickness and tooth length of the gear, respectively.

A. Tool Path Equations for the Tooth Profiles of the Cycloidal Gear

As is known, the tooth upper profile of a cycloidal gear is an epicycloid curve. The epicycloid curve is a curve formed by any point P on a circle (roulette) that rolls on another circle without slipping (Figure 3).

Figure 3. The formation of an epicycloid curve (top view)

While the end mill cuts the gear in a CNC milling machine, the trajectory followed by the center of the cutter is the equidistant curve of the epicycloid curve. An equidistant curve is expressed as the geometric location of the points at equal and perpendicular distances from a curve (Figure 4).

Figure 4. The relation between the end mill and epicycloid curve (top view)

The tool path equations for the epicycloid tooth profile were derived as follows by taking the location of the cutter centre according to the X and Y axes (Figure 4).

$$X_{e_n} = x_{e_n} + \Delta x_{e_n} \quad (1)$$

$$Y_{e_n} = y_{e_n} + \Delta y_{e_n} \quad (2)$$

Where, x_{e_n} and y_{e_n} were defined as the coordinates of any point on the epicycloid curve. The coordinates of this point were written as follows (Figure 3 and 4) [14].

$$x_{e_n} = (R_c + r_e) \cdot \cos \psi_n - r_e \cdot \cos \left[\frac{(R_c + r_e)}{r_e} \cdot \psi_n \right] \quad (3)$$

$$y_{e_n} = (R_c + r_e) \cdot \sin \psi_n - r_e \cdot \sin \left[\frac{(R_c + r_e)}{r_e} \cdot \psi_n \right] \quad (4)$$

Where, r_e and R_c are the radii of the roulette and rolling circle, respectively. Δx_{e_n} and Δy_{e_n} were derived as follows (Figure 4).

$$\Delta x_{e_n} = r_c \cdot \cos \lambda_n \quad (5)$$

$$\Delta y_{e_n} = r_c \cdot \sin \lambda_n \quad (6)$$

λ_n and γ_n are defined as the normal and tangent curves, respectively. Where, slope of the tangent was written as follows.

$$m_t = \tan \gamma_n = \frac{dy_{en}}{dx_{en}} \quad (7)$$

The relation between the curves can be written as follows.

$$m_t \cdot m_n = -1 \quad (8)$$

In this case, λ_n angle is derived as follows.

$$m_n = \lambda_n = \tan^{-1} \left(-\frac{dx_{en}}{dy_{en}} \right) \quad (9)$$

Where, the derivatives of dX_n and dY_n (3) and (4) equations were taken according to ψ_n angle and were calculated as follows.

$$\frac{dX_n}{d\psi_n} = -(R_\zeta + r_e) \cdot \sin \psi_n + (R_\zeta + r_e) \cdot \sin \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right) \quad (10)$$

$$\frac{dY_n}{d\psi_n} = (R_\zeta + r_e) \cdot \cos \psi_n - (R_\zeta + r_e) \cdot \cos \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right) \quad (11)$$

λ_n angle was derived as follows.

$$\lambda_n = \tan^{-1} \left(\frac{-(R_\zeta + r_e) \cdot \sin \psi_n + (R_\zeta + r_e) \cdot \sin \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right)}{(R_\zeta + r_e) \cdot \cos \psi_n - (R_\zeta + r_e) \cdot \cos \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right)} \right) \quad (12)$$

As a result, the tool path equations for the epicycloid tooth profile were derived as follows.

$$Xe_n = xe_n + r_c \cdot \cos \left[\tan^{-1} \left(\frac{-(R_\zeta + r_e) \cdot \sin \psi_n + (R_\zeta + r_e) \cdot \sin \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right)}{(R_\zeta + r_e) \cdot \cos \psi_n - (R_\zeta + r_e) \cdot \cos \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right)} \right) \right] \quad (13)$$

$$Ye_n = ye_n + r_c \cdot \sin \left[\tan^{-1} \left(\frac{-(R_\zeta + r_e) \cdot \sin \psi_n + (R_\zeta + r_e) \cdot \sin \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right)}{(R_\zeta + r_e) \cdot \cos \psi_n - (R_\zeta + r_e) \cdot \cos \left(\frac{R_\zeta + r_e}{r_e} \cdot \psi_n \right)} \right) \right] \quad (14)$$

$$Ze_n = H_{\max} \text{ (constant)} \quad (15)$$

Similarly, the tooth bottom profile of the cycloid gear is a hypocycloid curve. The hypocycloid curve is a curve formed on the inner side of the rolling circle by any point on the roulette rolling without slipping. Where, r_h is defined as the radius of the roulette (Figure 5).

Figure 5. Formation of the hypocycloid curve (top view)

Similarly, while the end mill cuts the hypocycloid profile, the trajectory followed by the centre of the cutter is the equidistant curve of the hypocycloid curve (Figure 6).

Figure 6. The relation between the end mill and hypocycloid curve (top view)

The tool path equations for the hypocycloid tooth profile were also derived similarly to those of the epicycloid profile as follows (Figure 5 and 6) [14].

$$Xh_n = xh_n + r_c \cdot \cos \left[\tan^{-1} \left(\frac{-(R_\zeta - r_h) \cdot \sin \beta_n - (R_\zeta - r_h) \cdot \sin \left(\frac{R_\zeta - r_h}{r_h} \cdot \beta_n \right)}{(R_\zeta - r_h) \cdot \cos \beta_n - (R_\zeta - r_h) \cdot \cos \left(\frac{R_\zeta - r_h}{r_h} \cdot \beta_n \right)} \right) \right] \quad (16)$$

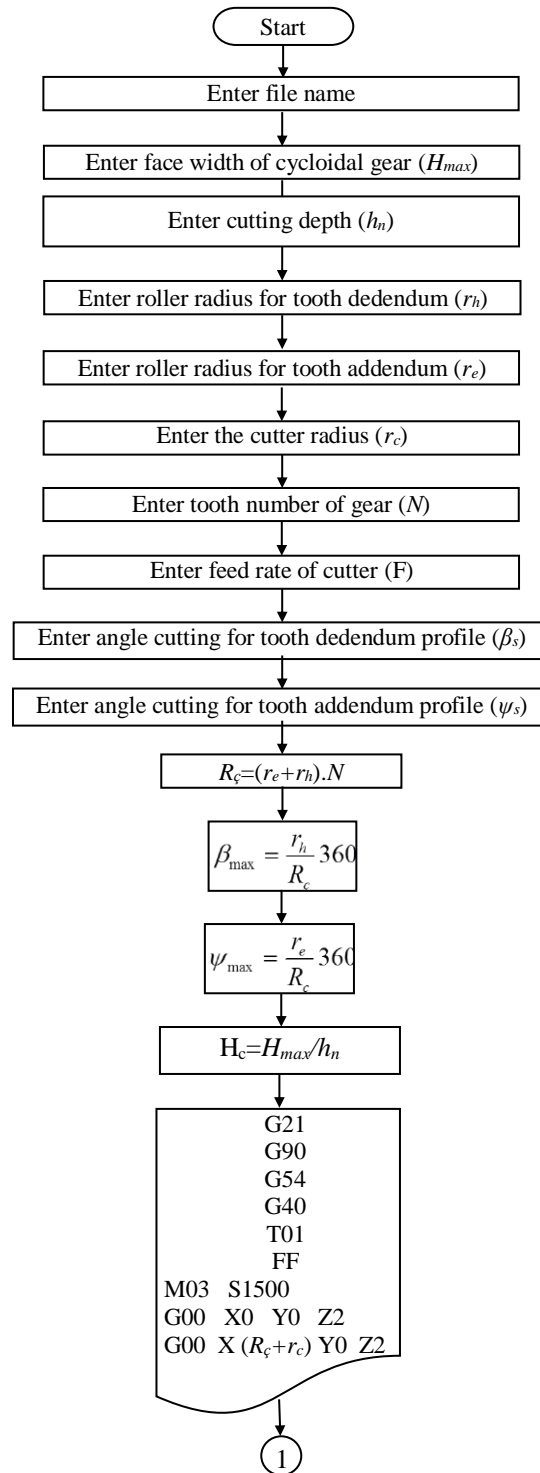

$$Yh_n = yh_n + r_c \cdot \sin \left[\tan^{-1} \left(\frac{-(R_\zeta - r_h) \cdot \sin \beta_n - (R_\zeta - r_h) \cdot \sin \left(\frac{R_\zeta - r_h}{r_h} \cdot \beta_n \right)}{(R_\zeta - r_h) \cdot \cos \beta_n - (R_\zeta - r_h) \cdot \cos \left(\frac{R_\zeta - r_h}{r_h} \cdot \beta_n \right)} \right) \right] \quad (17)$$

$$Zh_n = H_{\max} \text{ (constant)} \quad (18)$$

It is observed that while the end mill machines the cycloidal gear according to all these equations written above, parameters such as β_n , ψ_n , R_ζ , r_e , r_h and H_{\max} in the equations will affect the machining times of the gear.

III. CAD/CAM PARAMETERS OF THE CYCLOIDAL GEAR AND MACHINING TIMES

According to the equations written above, the C++ program prepared to derive the CAM codes of the cycloidal gear works according to the CAD/CAM parameters such as the sensitivity of hypocycloid profile cutting (β_s), sensitivity of epicycloid profile cutting (ψ_s), feed rate of the end mill (F), tooth number of the cycloidal gear (N), roulette radius of the tooth addendum (r_e), roulette radius of the tooth dedendum (r_h), and cutting depth (h_n) (Figure 7) [14].

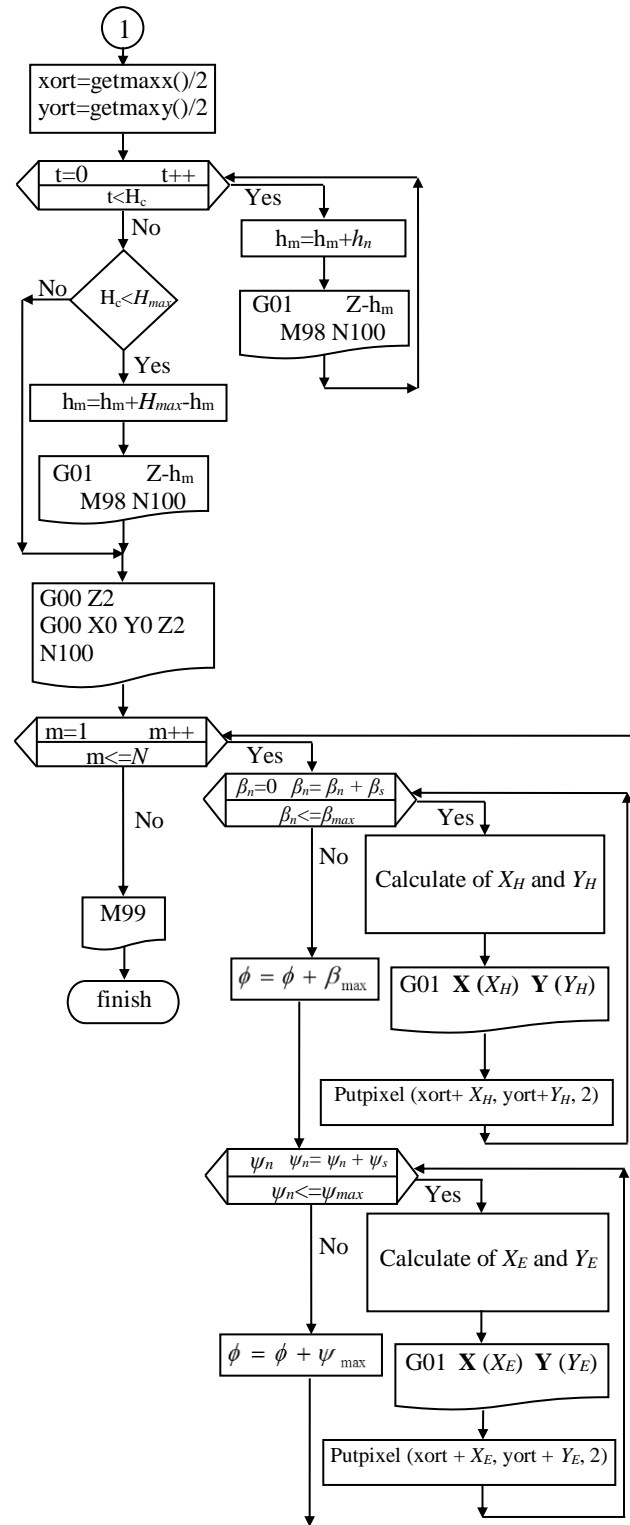

Figure 7. The algorithm used to derive CAM codes

In this study, C++ program was operated according to various values of these parameters and the CNC codes were derived for the cycloidal gears. The simulation of the gears was performed using these codes in Dyna 4M CNC program (Figure 8).

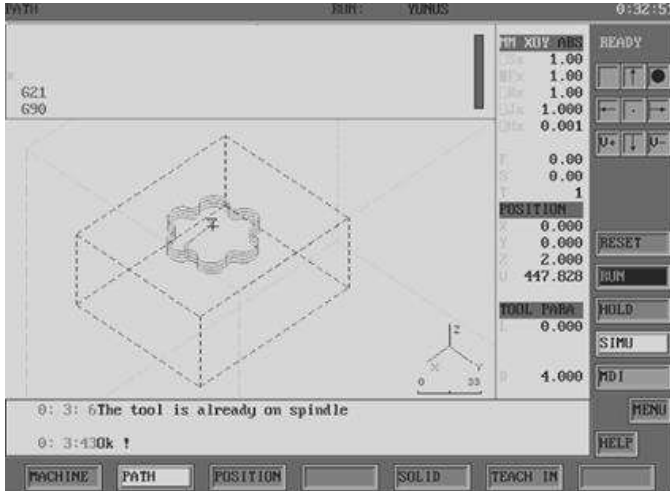

Figure 8. Simulation of a cycloidal gear

Then, cycloidal gears with different tooth numbers were manufactured (Figure 9) and the manufacturing times of the gears were determined.

Figure 9. Manufactured cycloidal gears

These times were determined for the $H_{max}=1$ and $h_n=1$ values of the cycloidal gear. To find the actual machining times of the cycloidal gear, the values in Table 1 can be obtained by

multiplying by the number of layers (H_{max}/h_n) in the X-Y plane along the Z-axis (Figure 2). In this study, the machining times (t) for the cycloidal gear with $N=4$ teeth are given in Table 1.

In this study, the machining times were also determined for a cycloidal gear with 8 teeth. However, these results were not presented in the form of a table so that the paper would not be too long. These results are shown in the graphical form only (Figure 10 and 11).

Figures 10. Machining times for $N=4$ teeth

Figure 11. Machining times for $N=8$ teeth

In order to read the graphs in Figure 10 and 11, three of the machining parameters are kept stable and the change in the machining time is examined depending on the change in the fourth parameter. For example, in Figure 10, it is observed that the machining time of the cycloidal gear in the CNC milling machine decreases with the increase in the feed rate of the end mill if the sensitivity of machining, minor roulette radius and major roulette radius are kept stable (Table 1). In the graphs, the section scaled from 1 to 81 shows the number of experiments.

TABLE I. FINISHING MACHINING TIMES OF THE CYCLOIDAL GEAR ACCORDING TO THE CAD/CAM PARAMETERS

IV. RESULTS AND DISCUSSION

The high values of the cycloidal gear such as N , r_e and r_h prolong the manufacturing time of the gear (Figures 10 and 11). On the other hand, the high values of h_n and F shorten the manufacturing time of the gear. However, in this case, the cutting efficiency of the cutter may decrease. In the case that these values are selected as too small, the manufacturing time prolongs considerably (Figures 10 and 11). The very high values of β_s and ψ_s also shorten the manufacturing time of the cycloidal gear. However, in this case, the amount of error of the tooth profiles (epicycloid and hypocycloid profiles) will also increase. The very low values of β_s and ψ_s prolong the manufacturing time of the cycloidal gear (Table 1).

Abstract— In this study, a gain scheduling PI controller for variable time delay systems is designed. The design is based on finding the weighted geometric center of stabilizing control parameters area and valid for the systems in which variable time delay is measurable or observable. Each of the control parameters of proposed gain scheduling PI controller is a function of variable time delay. These functions are obtained through matching of weighted geometric center points corresponded to different time delays by means of curve fitting method. The simulation results show that the designed gain scheduling PI controller presents good transient responses through overcoming the variable time delay in the system.

Keywords— Gain scheduling; PI control; weighted geometrical center; variable time delay

V. INTRODUCTION

VARIABLE time delay processes pose a challenging problem in control engineering. A time delay of the order of the time constant of the system, combined with a variation of it, requires an inventive control strategy to fulfill certain performance requirements. As there are many practical problems involving variable time delay in industry (e.g. steel rolling processes, paper manufacturing, fuel-air ratio control systems at engines, thermal plants, nuclear reactors), it would be interesting to develop new control strategies on it.

Although several advanced control strategies have been developed, structurally simple proportional-integral (PI) and proportional-integral-derivative (PID) controllers are still widely used in industrial control systems because of their robust performance and simplicity. Because of these reasons, developing better PI/PID design methods still attracts the interest of researchers [1-5]. One of the PI design methods reported in recent years is weighted geometrical center (WGC) method which is presented in [6]. The method is based on calculating the weighted geometric center of stabilizing controller parameters area.

In this study, WGC method was adapted to control of a variable time delay system. Proposed scheduling method is valid in the systems where variable time delay directly measured or observed. For example, variable time delay in fuel-air ratio control systems of engines can be observed by means of their rotation speed [7-11]. The design is based on

calculating the WGC controllers corresponding to different values of variable time delay and following this, associating these values to variable time delay by means of curve fitting method and obtaining the controller parameters (k_p, k_i) as a function of time delay. The simulation results show that the gain scheduling PI controller guarantees the stability of the system against the variable time delay existing in the system and exhibits a good performance.

The paper is organized as follows. The next section represents considered varying time delay system. In Section 3, design of the gain scheduling PI controller is presented. Simulations are considered in Section 4 to illustrate the wisdom of the designed controller. Finally, concluding remarks are given in Section 5.

VI. MODEL

For the method is explained, a FAR control system given in [12] is used. In this system, variable time delay (T_D) can be obtained by using (1) [7-11].

$$T_D = \frac{120}{n} \quad (1)$$

Where n is the rotation speed of the engine. Accordingly, if it is considered that engine speeds typically vary from 600 to 6000 rpm, the time delay in the system will also vary by at least 10:1 [12].

The considered system is a second order system with variable time delay. The transfer function of this system is given in (2), and the controller block with PI controller is shown in Fig. 1. Where, r , y , $C(s)$ and $H(s)$ represents the reference input, system output, transfer function of the PI controller and sensor dynamics respectively. $C(s)$ and $H(s)$ are given in (3) and (4) respectively.

Fig. 7. Control blok diagram

$$G(s) = \frac{25.5 \cdot s + 50}{s^2 + 51 \cdot s + 50} \cdot e^{-T_D s} \quad (2)$$

$$C(s) = k_p + \frac{k_i}{s} \quad (3)$$

$$H(s) = \frac{1}{0.1 \cdot s + 1} \quad (4)$$

VII. GAIN SCHEDULING PI CONTROLLER

Calculating the stabilizing controller parameters area was obtained from the joint solution of (5) and (6) through the stability boundary locus approach [11] according to the variable time delay. The (5) and (6) were obtained respectively, through the separation of imaginary and reel terms of the characteristic equation of the system shown at Figure 1. In these equations, ω is frequency. It was considered that the time delay changed between the range of [0.2, 2] s. The stabilizing controller parameter areas and obtained for ten different values in this value range, are shown at Figure 2.

$$\begin{aligned} &2.04 \cdot k_p \cdot \omega^2 \cdot \sin(T_D \cdot \omega) + 4 \cdot k_p \cdot \omega \cdot \cos(T_D \cdot \omega) \\ &- 4 \cdot k_i \cdot \sin(T_D \cdot \omega) + 2.04 \cdot k_i \cdot \omega \cdot \cos(T_D \cdot \omega) \\ &= 0.488 \cdot \omega^3 - 4 \cdot \omega \end{aligned} \quad (5)$$

$$\begin{aligned} &-2.04 \cdot k_p \cdot \omega^2 \cdot \cos(T_D \cdot \omega) + 4 \cdot k_p \cdot \omega \cdot \sin(T_D \cdot \omega) \\ &+ 4 \cdot k_i \cdot \cos(T_D \cdot \omega) + 2.04 \cdot k_i \cdot \omega \cdot \sin(T_D \cdot \omega) \\ &= 0.896 \cdot \omega^2 - 0.008 \cdot \omega^4 \end{aligned} \quad (6)$$

As it is expected, increase in time delay, limits the stabilizing controller parameter area. It is presented at [11] that, the WGC of the stability region is a special point for the time delay systems with regards to trade-off of the transient response characteristics. The controller parameter values corresponding to WGC of the stability areas obtained at Figure 2 are given in Table 1.

Fig. 8. Stability regions in accordance with different time delay values

TABLE II.
THE WGC
CONTROLLER PARAMETERS CORRESPONDING TO
DIFFERENT TIME DELAY VALUES

T_D	k_p	k_i
0.2	0.6322	3.4710
0.4	0.4644	1.6700
0.6	0.4063	1.0450
0.8	0.3557	0.7358
1.0	0.3060	0.5584
1.2	0.2675	0.4443
1.4	0.2270	0.3693
1.6	0.1976	0.3148
1.8	0.1747	0.2739
2.0	0.1526	0.2432

To obtain the gain scheduling PI controller, by using the values given at Table 1, the controller parameters are obtained as the third degree function of time delay. In (7) and (8), the expressions of controller parameters of k_p and k_i according to time delay are given respectively. In Fig. 3, the change of fitted $k_p(T_D)$ and $k_i(T_D)$ functions corresponding to time delay is shown. In Fig. 3, it is seen that curve fitting at third degree provides enough precision.

$$k_p(T_D) = -0.089T_D^3 + 0.403T_D^2 - 0.738T_D + 0.720 \quad (7)$$

$$k_i(T_D) = -1.874T_D^3 + 7.780T_D^2 - 10.495T_D + 4.993 \quad (8)$$

Fig. 9. Change of controller parameters with time delay

VIII. SIMULATIONS

The simulations performed for two different time delay cases for the efficiency of the proposed gain scheduling PI controller is showed. The Matlab-Simulink block used in simulations is given at Fig. 4. The change of time delay in first case in the different trapeze form, as seen at Fig. 5 and the change of time delay in second case in the sinusoidal form, as seen at Fig. 6 were taken into consideration.

Moreover the closed loop system with classical PI controller was used in the simulations in order to

provide a comparing opportunity. For this purpose, the WGC controller of most interior area remaining in the entire stability areas between the considered time delay value ranges was used as classical PI controller (see Fig. 2). The parameters of this controller are $k_p=0.1526$ and $k_i=0.2432$ (for $T_D=2s$).

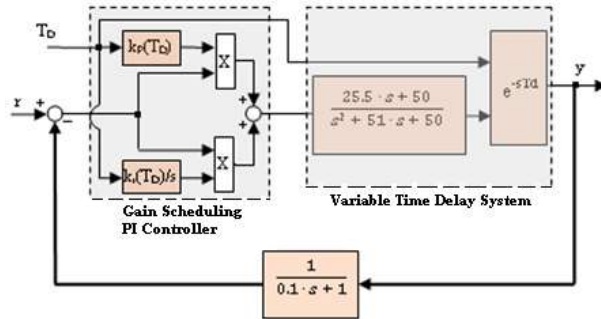

Fig. 10. Simulation block diagram

Fig. 11. Change of time delay in trapeze form

Fig. 12. Change of time delay in sinusoidal form

The unit step responses corresponding to the change in time delay of proposed controller in first and second case are given at Fig. 7 and 8. Numerical values of transient state response characteristics performances of the closed loops are given in Table 2 for comparison. Here, it is seen that the proposed gain scheduling PI controller against the time delay change in the system, provides the system to be stable continuously and presents better transient state responses comparing with classical PI controller. In addition to this, it is seen that the selected classical PI controller for comparison is robust against variable time delay, because it is

WGC controller of area providing joint stability for all values of the time delay value range.

Fig. 13. The unit step reply for the first case

Fig. 14. The unit step reply for the second case

TABLE III. NUMERICAL VALUES OF TRANSIENT STATE PERFORMANCES OF THE CONTROLLERS

	Cases	Rising Time (s)	Settling Time for %2 (s)	Overshoot (%)
Gain Scheduling PI Controller	Case 1	0.94	7.41	9.37
	Case 2	1.84	4.26	1.65
Classical PI Controller	Case 1	7.48	12.65	0
	Case 2	6.46	10.25	0

IX. CONCLUSION

In this study, a new gain scheduling PI controller design method for a second degree system with variable time delay was presented. This method, is based on calculating the weighted geometric center controllers corresponding to different values of variable time delay and following this, associating these values to variable time delay by means of curve fitting method and obtaining the controller parameters as a function of time delay. The proposed system's assuring system steady against the variable time delays in the system is the most important characteristic of the method. But requirement for one more sensor for sensing or observing the varying time delay is a disadvantageous. The results of the simulation show that the proposed method will provide successful results for systems where variable time delay can be observed.

Abstract— Present study explores the impact resistance and energy absorption capacity of intraply Carbon/Aramid/epoxy composite laminates with nano-clay particles. Impact performance of samples was evaluated by assisting charpy impact tests in accordance with ISO 179 international standards. Nano clay particles were used as additive material within the epoxy resin by the weight ratios of 0, 2, 4, 6, 8 and 10. Failure characteristics after the impact tests will be studied over the surface of the samples. Results from this study will be analyzed according to incorporation of nano-clay particles in intraply Carbon/Aramid/epoxy composite in terms of impact and energy absorption capacity according to full samples.

Keywords— Impact, Nano-clay, Carbon, Aramid

XI. INTRODUCTION

Although carbon fiber reinforced composites have high strength and modulus in recent years, their low fracture energy and impact resistance are their limitations due to brittle nature of carbon fiber [1], and impact resistance properties of carbon fiber reinforced composites can be increased by hybridization of aramid fibers [2-3]. Dorey et al. [4] showed that hybridization of Aramid fibers with carbon or glass fibers significantly improved the energy absorption and impact resistance of materials.

Hybrid composites are composed of two or more different types of fibers, and they are extensively used in many engineering applications as like aviation, marine and automotive in order to design the structures as desired specifications. In addition, hybrid type and structure are major parameters influencing load bearing and impact resistance of

hybrid composites [5], and two different hybrid composites are existing in terms of weaving architectures, namely, interplay and intraply, respectively. Even though many studies are available about impact behavior of interplay woven hybrid composites in literature, studies on impact behavior of intraply woven hybrid composites are limited. Pegoretti et al. [6] investigated interplay and intraply woven E-glass and polyvinyl alcohol composite laminates. It was asserted that intraply woven composites exhibited greater mechanical and impact resistance as compared with interplay one. Researchers [7] studied impact behavior of 3D woven hybrid composites, indicating their superior impact resistance compared with 2D woven composites. Besides hybridization of fibers with different weaving architectures, another one of increasing impact resistance of composite materials is incorporation of nano particles within the epoxy. In nano particles, nano clay is one of the best particle that is utilized and is considered one of the multiple functions of clay materials, which are widely utilized in many areas. Several studies [8-10] performed on mechanical characterization of composite laminates with addition on nano clay particles. It was indicated that mechanical performance of the materials was increased at the small amount of nanoclay inclusions by weight ratio. Shishavan et al. [11] explored the influence of nano clay addition and temperature on the tensile strength and toughness of nano-composites using the (Taguchi) mode of design of experiences. Results showed that tensile strength and stiffness of nano clay reinforced composites were significantly affected by injection temperature. Chowdary and Kumar [12] investigated the effect of Nano-clay content on the mechanical and morphological behavior of the S-glass

fiber/polyester resin. Nano-clay contents were 1, 3, 5, and 7 % by weight in polyester resin. The results suggested that the inclusion of Nano-clay has a significant effect on the mechanical behavior of composite materials, resulting highest improvement in addition of Nano clay by 3 wt %.

Results from above studies prove that limited studies are existing about impact and mechanical properties of intraply woven hybrid composites investigating nano particle effects. Present study experimentally investigated the tensile and charpy impact resistance of intraply woven carbon/aramid hybrid composites reinforced with nano clay particles. Tensile, energy absorption and impact resistance of samples were characterized different amount of nanoclay particle loading within the epoxy resin. Their failure mechanisms after impact tests were also recorded.

XII. MATERIALS AND METHODS

A. Production materials

The epoxy (MOMENTIVE-MGS L285), hardener (MOMENTIVE-MGS H285), twill intraply Kevlar/carbon woven fabrics (190 g/m²) were supplied from Dostkimya Company, Tuzla, Istanbul, Turkey. Montmorillonite (NM-MMT) Nano clay was bought from Grafen Chemical Industries in Turkey.

Kevlar/carbon fabric has weight of 190 g/m², weave of 2/2 twill, width of 1000 - 1200 mm and thickness: 0.23 mm. Nano clay particles have lateral width of 0.5-2 μ m, thickness of 1-10 nm and bulk density of 200-500 kg/m.

B. Production of test samples

The laminates were manufactured using hand layup technique with application the epoxy/nanoclay particle mixture on fibers. Samples were prepared 10 layers impregnating fabrics layer by layer. Then, they are subjected to (120 kPa) pressure for 1 h curing time at 80°C temperature, and cooled to room temperature under constant pressure for three hours. Production process and some of produced samples were illustrated in Figure 1.

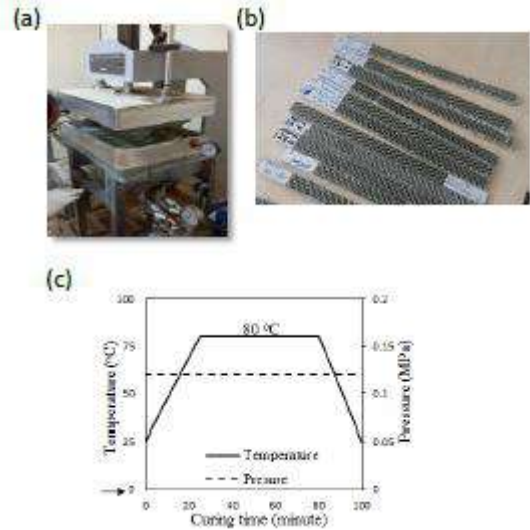

Fig. 15. Production process and test samples. (a) Hot-mold press, (b) Test samples with bulk shapes, (c) Curing procedure

C. Tensile tests

The tensile properties of the composite samples were determined at room temperature utilizing the AG-X series-Shimadzu testing machine (Kyoto, Japan) as illustrated in Fig. 2 (a). After the production process, test specimens were prepared from bulk sheets by cutting to meet desired size as per ASTM standards (D638-00). Fig. 2(b) illustrates the produced tensile test samples. The thickness of tensile specimens was in the range of 2.5 \pm 0.1 mm depending on variation of Nano-clay content. The crosshead speed was set to 2 mm/min for tensile test. Three samples were tested at least for each group, and their average values were recorded.

Fig. 16. Tensile test measurements. (a) Tensile test machine, (b) Tensile test specimens.

D. Impact tests

Charpy impact tests were performed by a Köger 3/70 Charpy impact tester with 15 J hammer (Köger, Germany) (Fig. 3 (a)). Absorbed energy and impact strength of composite samples were calculated using equations 1 and 2 from energy differences after (E_2) and before (E_1) impact tests as illustrated in Fig 3 (b)

$$E = E_1 - E_2 \quad (1)$$

$$U = \frac{E}{bh} \quad (2)$$

where E is the absorbed energy after impact, E_1 is the impact strength, and E_2 are initial and final potential energies, b and h are width and thickness of the samples, respectively. Multiply of b and h shows impacted area of the samples by impact hammer.

Composite samples have rectangular shapes with dimensions of 55×10 mm for impact tests according to the prescriptions of the ISO 179/92 standard [13].

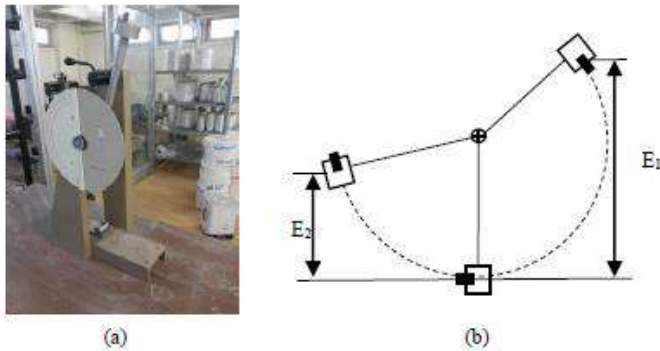

Fig. 17. Impact tests. (a) Charpy impact machine, (b) Illustration of impact mechanism

XIII. RESULTS AND DISCUSSIONS

A. Tensile tests

Fig. 4 shows the variation of tensile properties of test samples according to nanoclay content by weight. From Fig.4, it is observed that Kevlar/carbon/epoxy composite (pure) exhibits a tensile strength of 371 MPa, while Kevlar/carbon/epoxy at 1wt % of Nano clay showed the highest tensile strength as 421 MPa. After the critical value of 1wt %, tensile strength values were decreased while strain values were increasing. This is attributed the agglomeration of nanoparticles after the critical value of 0.1 wt %, leading to decrease mechanical properties of composites. In addition, all the specimens were broken without any necking and the fracture in intra-layered samples, (Fig. 5) which means that specimens fail in a brittle fashion during a tensile test.

Fig. 18. Tensile properties of test samples

Fig. 19. Fractured tensile test samples after tests

B. Impact tests

Impact tests were performed using energy lost by charpy impact tests. Table 1 presents the results on impact tests in terms of absorbed energy and impact strength, and their variations were displayed in Fig. 6. It is observed that impact strength was gradually increased from KFRP to KFRP-NC6%, then decreased as addition of nanoclay content in the epoxy. The increase in impact strength was attributed the good adhesion between fiber and nanoclay particles, providing composite samples efficiently to withstand impact loadings, and usage of nanoclay filler at 6 wt % increases the impact strength by 19.84 % compared to unfilled composite sample (KFRP).

TABLE I. IMPACT TEST RESULTS

Specimen	Absorbed Energy (J)	Impact strength (kJ/m ²)
KFRP	1.23	51.25
KCFRP-NC2%	1.42	57.49
KCFRP-NC4%	1.56	61.42
KCFRP-NC6%	1.64	60.97
KCFRP-NC8%	1.62	57.14
KCFRP-NC10%	1.52	52.65

Fig. 20. Variation of impact test results

Failure surfaces of test samples were displayed in Fig. 7. It is noted here that fiber ruptures and delaminations are observed over the rear side of the samples, and amount of the damages for sample of KFRP-NC6% is much more than those of other samples due to the enhancement of brittle nature as increasing nanoclay content in the epoxy resin.

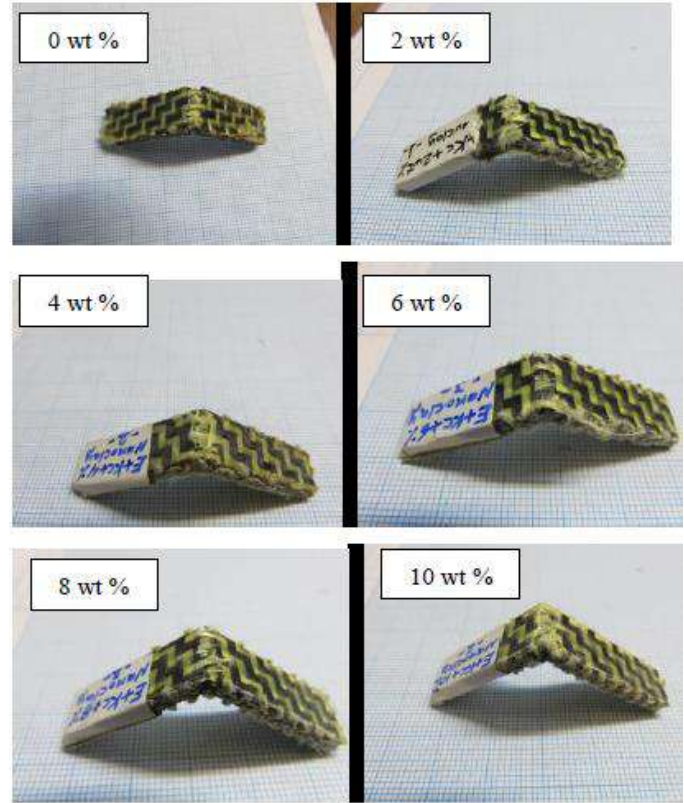

Fig. 21. Fractured test samples after impact tests

XIV.CONCLUSION

Tensile and impact properties of intraply woven hybrid composites were investigated incorporating different weight content of nanoclay particles in the epoxy resin. It is concluded that incorporation of nanoclay filler at 1 wt % and 4 wt % revealed the highest tensile and impact performances, respectively. Further increase in content of nanoclay in the epoxy resin caused the decrease of the mechanical performances due to the poor interphase bonding between nanoclay particle-fibers-epoxy, suggesting the usage of nanoclay particles at the small amounts for enhancement of structural performances during the services.

Abstract—In the past many studies proved that when polymers are laminated with nanofibers there are positive gains in regard of their mechanical properties such as improved impact resistance, ductility, less delamination, less debonding and more. In this work Glass Fiber Reinforced Polymer (GFRP) composite materials have been developed and interleaved with non-woven Nylon 6,6 nanofiber mats which are produced by the electrospinning technique and compared with a corresponding virgin sample by using the Low Velocity Impact tests. Three kind of polymer configurations are generated for the specimens; one virgin configuration where two glass fiber layers are placed in epoxy and two kind of nanofiber interleaved configurations in which one and three Nylon 6,6 nanofiber mats are interleaved in the two glass fiber layered epoxy composition specimens. Then those specimens are considered for their impact resistance and energy absorption capabilities after Low Velocity Impact experiments. The results showed that while nylon 6,6 nanofiber mats resulted in decrease of load carrying capacities of the composite laminates and improved the energy absorption capabilities.

Keywords—GFRP; Nylon 6,6; Low Velocity Impact

XV. INTRODUCTION

In today's world, Fiber Reinforced Polymers (FRP) composites have found themselves many application areas. Glass, Carbon, Aramid and Basalt are among the fibers that are used as reinforcements [1]. Those fibers are often used in polymers. Epoxy resin is one of the most frequently used polymer for composite manufacturing due to its superior abilities and being relatively cheap than other alternatives. FRPs can be used in aerospace, automotive, marine, and construction industries [2].

Glass Fiber Reinforced Polymer (GFRP) is a strong and not so weight material that has many application areas such as aircraft, boats, automobiles, bath tubs and enclosures, swimming pools, hot tubs, water tanks, roofing, pipes, cladding, casts, etc. Compared to Carbon Fiber Reinforced Polymer (CFRP), it might be not so strong still but is less brittle, and its raw materials are cheaper [3,4].

In laminated composite structures, physical disunities and mismatches can cause problems like debonding and/or delaminations. Delamination means separation of laminated plies that stuck together in a composite structure. If one takes into consideration that composites are of anisotropic character and how they performance during external impact forces, even a weak blow might cause enough damage the composite material to fracture thus rendering it defected. To minimize this problem, many methods are developed [5-11] and interleaving nanofiber mats in the composites is one of them [11-16].

Nowadays electrospinning is one of the most frequently used method to produce nanofiber mats [17-19]. Materials like Polyamides, PVC, Chitosan etc. can be electrospun to produce nanofibers as well. [20-26]. Nylon 6,6 is a thermoplastic polyamide that has a high elastic module and also has a compatibility with epoxy so it is often used for generating nanofibers for composite materials [27, 28].

In literature, there are studies that focused on mechanical performances of virgin [29-34] and the nanofiber modified [12-15,36,37] GFRP laminated composite structures as well. Modifying the epoxy resin of the GFRP is also investigated [38]. Some researchers also used Carbon Fiber in studies and by interleaving nanofiber mats to see their effects on the impact resistance of their specimens [13,15,22,27,39]. Modifying the epoxy resin of the CFRPs with interleaved nanofiber mats is also investigated [40].

In this work, Nylon 6,6 nanofiber mats were electrospun and placed into GFRP laminated composite structures in three different configurations. The virgin specimens were also manufactured and Low Velocity Impact tests at an energy value of 6,3 Joule were conducted on the specimens. A comparison was made to determine the effects of the nanofiber mats on delamination as well as impact resistance and energy absorption capabilities of the specimens.

XVI. MATERIALS AND METHODS

The specimens are generated by placing two E-glass fiber layers into epoxy and then interleaving the nylon 6,6 nanofiber mats for the nanofiber modified configurations.

The epoxy resin codenamed H160 which was provided from Dostkimya company was used. Its properties can be found on their website [41]. Epoxy resin and hardness were mixed together in a weight ratio of 60% and 40%, respectively. Dry E-Glass fiber layers were cut in $150 \times 100 \text{ mm}^2$ proportions and the fiber orientations being; $[0^\circ, 90^\circ]$. The specimens were produced in dimensions proposed in ASTM-D-7136 standards [42] by using the hand lay-up method where the iron molds were used for the manufacturing.

Electrospin device was used to generate nanofibers. Nylon 6,6 pellets were provided from Sigma Aldrich and their properties can be found on their website [43]. The pellets were dissolved in a mix of two different acids with a concentration of 10% w/w. The acids were Formic Acid and Dichloromethane and they were put together in 1:1 weight ratio. To assure homogeneity of the solution, it was put in an ultrasonic bath device for about 8 hours. Afterwards the solution was drawn into a 10 mL syringe and then it was placed into a syringe pump system. The electrospinning process was performed in those following conditions: applied voltage 30 kV, distance between the cylindrical collector and the needle 20 cm, feed rate 0,65 mL/hour, temperature 25°C and relative humidity 50-60%. The electrospun nanofiber mats were left in a room for a few days to make sure they were dry enough before used in the specimens. Fig. 1 shows the SEM image of the electrospun nanofibers.

Fig. 1. SEM images of Nylon 6,6 Nanofiber Mats

The laminated composite specimens were produced by the hand lay-up method. Three kind of configurations for the specimens were considered; one kind of virgin one and two kind of nanofiber modified ones. For the virgin one; only two glass fiber layers were placed in epoxy and their simplified cross-

sections are presented in Fig. 2. For the nanofiber modified ones; one nanofiber mat was interleaved in two glass fiber layers and then placed into epoxy and three nanofiber mats were interleaved in two glass fiber layers and then placed into epoxy as well, whose simplified cross-sections are presented in Fig. 3, and Fig. 4, respectively. The nylon 6,6 nanofibers mats are notated as NF mats in those figures.

Fig. 2. Cross-section of the specimens codenamed "G"

Fig. 3. Cross-section of the specimens codenamed "1N"

Fig. 4. Cross-section of the specimens codenamed "3N"

The specimens were left to cure for 24 hours and removed from the mold eventually.

The virgin specimens are codenamed with the suffix G. The nanofiber mat modified ones are codenamed with the 1N and 3N suffixes; 1N is indicating one nylon 6,6 nanofiber mat interleaved two glass fiber layered specimens while 3N is indicating three Nylon 6,6 nanofiber mat interleaved two glass fiber layered specimens.

Afterwards the produced composite laminates have been subjected to Low Velocity Impact tests in accordance with

ASTM-D-7136 standards. Impact tests were conducted with a drop tower in which the impactor has a hemispherical tip with a mass of 5,6 kg and a diameter of 12 mm diameter. The test specimens were placed into a fixture produced for placing and holding the test specimens at the point of impact. The test specimens were tested under impact velocity of 1,5 m/sec which corresponds to impact energy of 6,3 Joules.

The force signals were measured by a force sensor in mili volts scale. The signals were first amplified and filtered by a signal processor and transmitted to the data acquisition card. The variations of interaction force between the impactor and the sample versus time were obtained using NI Signal Express software. The sampling rate of data acquisition system is 25 kHz. As described in the regarding standard, the Newton's second law of motion was used to express the velocity and displacement of impactor versus time. When the impactor first hits the material, the kinetic energy of the impactor is partly transferred to the material. The remaining kinetic energy is used for rebound which makes the impactor to rise. This process continues until the kinetic energy of the impactor is fully consumed. During this process the material is generally subjected to 12-15 impacts. However, the testing machine has an anti-rebound system which allows us to get only one impact.

XVII. RESULTS AND DISCUSSION

Fig. 5 shows the variation of contact force with time for different specimens. It is seen in this figure that the addition of Nylon 6,6 nano fiber mats has resulted in decrease of maximum contact force. This can be explained due to the delaminations that occurred in the specimens. While the nylon 6,6 nanofiber mat modified specimens had the delamination problem, the virgin specimens were better in that aspect.

Fig. 5. Load-Time graphs of the specimens

Fig. 6 shows the load-deflection curves for different specimens. In Fig. 6 it can be observed that the specimens showed tendency to create closed curves which are typical of the load-deflection graphs. Due to the failures (delaminations, penetrations, fiber detachments etc.), the curves weren't fully closed.

It is seen in this figure that delamination take place when contact force reaches to 650-720 N. After that point, a clear decrease in bending stiffness is observed. It is clear that when delamination takes place, the bending stiffness considerable decreases. The virgin specimens do not show a damage formation until contact force reaches about 1200 N. After that point delamination takes plate. So, it can be concluded that nylon nano mats has clearly resulted in decrease of delamination threshold.

Fig. 6. Load-Displacement graphs of the specimens

Fig. 7 shows the variation of energy during contact. It is clearly seen that specimens with nylon 6,6 nano fiber mats absorb much more energy than virgin specimens. It is seen in this figure that all specimens started to consume the kinetic energy of impactor until it is fully consumed at 6,3 Joules. After that rebound period has started. It is clear that rebound energy for virgin specimen is considerably high that that for modified specimens.

Fig. 7. Energy-Time graphs of the specimens

Table I shows the total energy distributions for the specimens. 1N and 3N specimens perform pretty similar in their

energy absorption capabilities. While the absorbed energy of the G specimens was about 68% the total energy, 1N and 3N ones managed to absorb almost 80% of the total energy which correspond to an enhancement about 12% with respect to virgin specimens.

TABLE I. ENERGY DISTRIBUTIONS ON THE SPECIMENS

Specimen Codenames	G	1N	3N
Total absorbed energy (J)	4,29	4,972	5,009
Total rebound energy (J)	2,009	1,327	1,29
Total Energy (J)	6,3	6,3	6,3
Total absorbed energy (%)	68,10	78,92	79,51
Total rebound energy (%)	31,89	21,06	20,48
Total Energy (%)	100,0	100,0	100,0

XVIII. CONCLUSION

In this work, three kind of laminated composite specimen configurations were considered. The first one was the virgin configuration where only two glass fiber layers placed into epoxy. The other two was about nanofiber mat modified configurations where one nylon 6,6 nanofiber mat was interleaved in two glass fiber layers then placed into epoxy for one configuration and three nylon 6,6 nanofiber mats were interleaved in two glass fiber layers then placed into epoxy for the other one to generate laminated composite specimens. The specimens were manufactured with the hand lay-up method and the relationships between them were investigated by putting them through the Low Velocity Impact tests. The results are as follows:

- It has been observed that adding nylon 6,6 nanofiber mats into the specimens caused premature delamination and a decrease in the load capacity.
- There wasn't a significant difference between one and three nylon 6,6 interleaved nanofiber mats in regard to their influence on the load and absorbed energy capabilities and the damage resistance.
- Still specimens with nylon 6,6 interleaved nanofiber mats absorbed more energy than the virgin specimens; absorbing about 12% energy than their corresponding virgin specimens.

Abstract—Water electrolysis is an efficient method to produce hydrogen efficiently. It can be applied to a clean energy storage and conversion system for sustainability of energy production. Especially Proton Exchange Membrane (PEM) water electrolysis which has acidic media, commonly used to produce the big amount of hydrogen in the industry. However, in water electrolysis, there are some obstacles to overcome. Mass transport limitations and bubble coverage on the electrode surface are some examples of these problems. It is aimed that to increase electrolysis performance using the constant magnetic field. When magnetic field positioned with the electric field in a perpendicular direction velocity of the particles enhances remarkably. This effect can be called as “magnetohydrodynamic(MHD)”. In the literature, there are several applications of the MHD. Some of these are related to the observation of the fluids and metallic particles under magnetic field [1, 2]. Shail et.al. [3] investigated laminar two-phase flow using MHD effects. Another important application is in electrochemistry. MHD maintains in an electrochemical cell to the convective movement of the hydrogen and oxygen bubbles and other species from the electrode surface [4, 5] thanks to Lorentz Force. Effect of Lorentz force to the hydrogen production is investigated by many researchers. They generally about the observation of the mass transport effect to the water electrolysis. Matsushima et al. [6-8] investigated water electrolysis under a magnetic field to show how they affect the convection in several electrochemical cells. Lin et al. [4, 9] showed that magnetic field enhances the separation of bubbles to the electrode surface and decreasing the sticking of species to the electrode. Kaya et al. [10] used cost effective electrodes in alkaline solutions to show possibilities of the using lower concentration water electrolysis to produce economical hydrogen production. There is remarkable interest this issue to improve the electrolysis performance using different parameters. In this study, it is investigated that low concentration acidic solutions (0.5 M H₂SO₄) with the Pt anode and cathode electrodes under magnetic field. Two magnets are positioned to these Pt electrodes perpendicularly in the electrolyte solution to obtain upward direction Lorentz Force. Magnetic flux density of the magnets is nearly 0.8 T in this experiment. For the solution bath, acidic resistant Delrin® Polyoxymethylene (POM) material is used and it is specially designed to position magnets, solution and electrodes for water electrolysis. Neodymium magnets are used to produce constant magnetic field. Experiments are conducted using magnetic field and non-magnetic field condition. Electrode distance between anode and cathode is selected the same (25 mm) for both electrochemical cell. Hydrogen production is measured using gas accumulation tubes. In the experiment section; firstly, stability of the Pt electrodes are investigated in 4 V. Afterward, at the same voltage, current density of the cell is investigated with time in magnetic and the non-magnetic cells. During these experiments, 11% increase of current density is observed in magnetic cell. Approximately, 8% increase the rate of hydrogen production is investigated in the magnetic cell. It can be concluded that using Pt electrode and magnetic field; lower energy consumption to produce per mole of hydrogen can be possible during water electrolysis process. Thanks to the constant magnetic field it will be possible to study lower solution concentration and lower current density value. Results of this study can be apply to the other application of the electrochemistry.

Abstract— Hydrogen energy systems are one of the best alternatives to overcome global warming effects from the environment. Because of their energy conversion by fuel cells, they attract researchers to improve this technology. There is a big interest to produce hydrogen and oxygen gasses efficiently in the electrolysis systems. However, there are some challenges to overcome in water electrolysis systems. Mass transport limitations and concentration losses decrease the cell voltage during hydrogen production. This affects the stability of gas outputs and the durability of the system. There is some field effect to overcome these problems. Supergravity field, ultrasonic field and magnetic field. These effects reduce the voltage drop, reaction overvoltage and transferring of bubbles through the electrolyte and electrode surface [1-4]. Under a magnetic field, it is possible to overcome gas bubble separation and convection problems. To provide this, a constant magnetic field should be positioned to the electrical field perpendicularly. This effect called as magnetohydrodynamic (MHD) due to Lorentz Force. It sustains convective movement of water electrolysis species through the electrolyte bath and electrodes. Gas bubbles sticking at the electrode surface and mass transport limitations are the challenging topic to produce hydrogen efficiently. Kaya et al. [5] investigated alkaline water electrolysis under magnetic field and they concluded that magnetic field decrease the sticking of gas bubbles on the electrode surface due to Lorentz Force and that causes the more current density and hydrogen production via time. In the literature, there is very much interest for magnetic field study in electrochemical applications [6-8]. In the experimental studies, it is hard to use bigger than 1 T magnetic flux density in constant magnets due to the working area. It is possible to make a numerical simulation for magnetohydrodynamics to observe different magnetic flux density effects to the water electrolysis. Moreover, numerical studies related with electrolysis are one of the important research tools to show species distribution in an electrochemical cell. But, there is very limited research about the numerical investigation of the MHD phenomena in electrochemistry. In this study, the magnetohydrodynamic effect to the water electrolysis numerically simulated using Comsol Multiphysics software. Firstly, solution bath and electrodes are modeled and electrochemical model is created using the Butler-Volmer equations. Fluid flow in the cell is selected laminar and transport of diluted species phenomena is used to model transport of species in the electrochemical cell. Current density change with different Lorentz force direction and velocity value change of species are studied.

Keywords— Lorentz Force; Magnetohydrodynamic (MHD); Numerical Modeling; Water Electrolysis.

Abstract— Damping and vibration properties of Carbon/Kevlar/epoxy composite laminates were investigated incorporated nanoclay particles in the epoxy resin. Test samples were prepared woven intraply carbon/epoxy fabrics following by hand lay-up procedures. During the production process, different weight content of nanoclay fillers were included in the epoxy resin in the ratios of 0, 1, 2, 4, 6, 8 and 10 % by weight. Results showed that samples have shown the highest damping and vibration responses at the nanoclay ratios of 4% wt and 10 % wt, respectively.

Keywords—Vibration, damping, nanoclay, carbon, aramid

I. INTRODUCTION

In recent years, damping and vibration properties of the structures have become the important issue for fiber reinforced composites since structures of aerospace, automobile and ships may subject to dynamic loadings resulting to vibrate the system. Thus, it is needed to predict the vibration properties of the structures for safety of the structures during the service. Hybridization of fibers is one way of designing of structures as desired properties. For example, carbon fiber has high stiffness and strength properties as well as its brittle nature, and Kevlar fiber has good toughness and impact properties. It is possible to make a new material by hybridization of carbon and Kevlar to obtain good toughness and high strength properties. Several researchers [1-3] investigated the hybridization of different fibers influencing mechanical properties of composite laminates. Two different hybrid composites are existing in terms of weaving architectures, namely, interplay and intraply, respectively. Pegoretti et al. [4] indicated that intraply woven

composites exhibited greater mechanical and impact resistance as compared with interplay one.

One way of another method to increase mechanical properties of composites is inclusion of nanofiller in the epoxy resin. Kireitsey et al. [5] indicated that nanoscale carbon fibers significantly increase the structural damping and stiffness of the materials. Jiua et al. [6] showed that damping ratio of the nanocomposite beams may increase in 200–700% at higher frequencies. Chandradas et al. [7] examined that the vibration behavior in glass fabric/vinyl ester composites with different weight contents (0, 1, 3 and 5 wt%). The highest improvements in damping ratio was obtained with Nano-clay content of 3 wt%. Chowdary and Kumar [8] suggested that the inclusion of Nano-clay had a considerable effects on the mechanical behavior of composite materials, and highest improvement was obtained with 3 wt% addition of Nano clay.

In this study, the influence of nanoclay addition on damping and vibration properties of woven Kevlar/carbon/epoxy composite laminates. Natural frequency and damping properties of test samples were characterized dynamic modal analysis experimentally, and result were compared with each other.

II. MATERIALS AND METHODS

A. Production materials

The epoxy (MOMENTIVE-MGS L285), hardener (MOMENTIVE-MGS H285), twill intraply Kevlar/carbon woven fabrics (190 g/m²) were supplied from Dostkimya Company, Tuzla, Istanbul, Turkey. Montmorillonite (NM-

MMT) Nano clay was bought from Grafen Chemical Industries in Turkey.

Kevlar/carbon fabric has weight of 190 g/m², weave of 2/2 twill, width of 1000 - 1200 mm and thickness: 0.23 mm. Nano clay particles have lateral width of 0.5-2 μm , thickness of 1-10 nm and bulk density of 200-500 kg/m.

B. Production of test samples

The laminates were manufactured using hand layup technique with application the epoxy/nanoclay particle mixture on fibers. Samples were prepared 10 layers impregnating fabrics layer by layer. Then, they are subjected to (120 KPa) pressure for 1 h curing time at 80°C temperature, and cooled to room temperature under constant pressure for three hours. Production process and some of produced samples were illustrated in Figure 1.

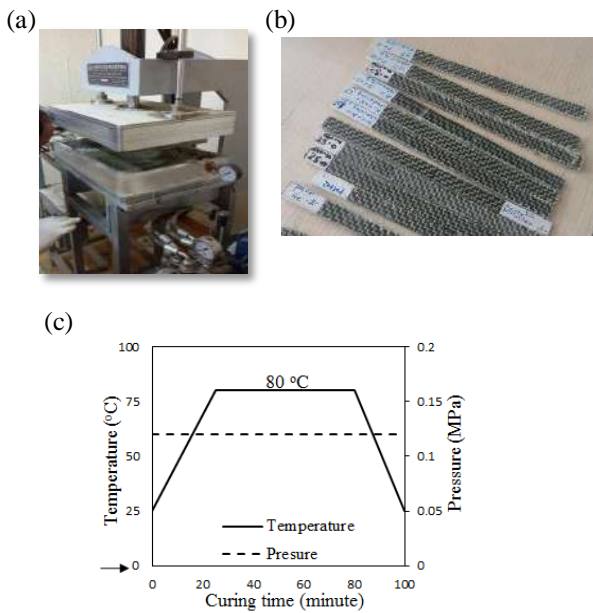

Fig. 1. Production process and test samples. (a) Hot-mold press, (b) Test samples for vibration tests, (c) Curing procedure

C. Vibration tests

Vibration and damping properties of Nano-clay modified CKFRE composite laminates were obtained utilizing test set-up according to ASTM E756 as shown in Figure 2. (Figure 3.12a). In the vibration testing, National Instrument product NI 9234 with LABVIEW software with a general aim PCB 352C03 ceramic shear ICP[®] accelerometer and a PCB 086C03 general purpose modal effect hammer were utilized for output signal acquisition, information acquisition and stimulus force signal, respectively.

Fig. 2. Experimental set-up for vibration tests

Half power bandwidth method was performed to evaluate damping responses of first natural frequency modes of the composite samples using equation 1. Figure 3 illustrates the schematic illustration of half-power method.

$$\xi = \frac{\omega_2 - \omega_1}{2\omega_n} \quad (1)$$

Fig. 3. Schematic illustration of half-power method

The loss modulus (E'') and storage modulus (E') are calculated from in equations (2) and (3).

$$\omega_1 = \frac{1.875^2}{2\pi L^2} \sqrt{\frac{E'I}{\rho A}} \quad (2)$$

$$E''(\omega) = 2E'(\omega)\xi(\omega) \quad (3)$$

Where ω_1 Is the natural frequency of the first mode, L is the free length of the beam, I is the moment of inertia for the given cross-section of the beam, ρ is the density of the beam and A is the cross-section of the beam.

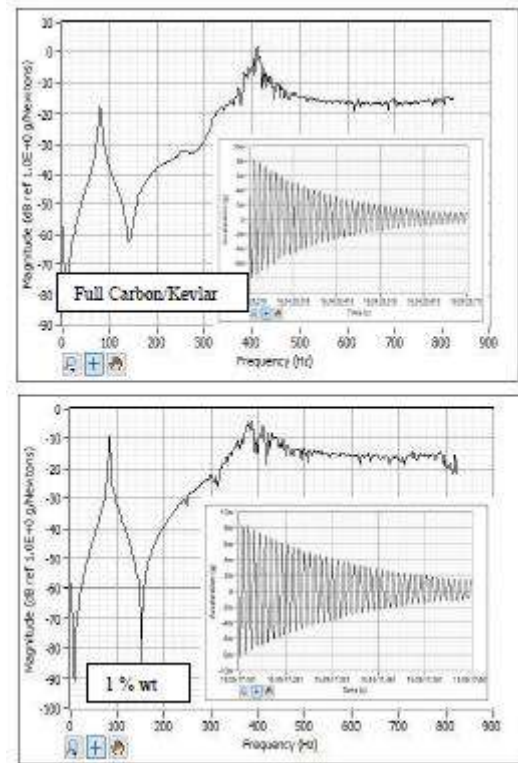

III. RESULTS AND DISCUSSIONS

The results for vibration properties of test samples were presented in Table 1, and their frequency response curves were illustrated in Figure 4. . It is noted here that first mode of natural frequency of the sample is dominantly seen for all Nano-clay particle loadings. The highest increment in maximum amplitude and natural frequency are obtained with 22.7 % at Nano-clay particle content of 10 % wt. The specimens having 1% wt of Nano-clay content exhibited the maximum storage modulus with enhancement of 24.5 %, while specimens with Nano-clay content of 4 wt% have the highest loss modulus with enhancement of 70.0 % compared to full composites composite. Stiffness and natural frequency are directly proportional to each other, suggesting that stiffness of the sample increased while increasing nanoclay content in the epoxy resin. However, further increasing in nanoclay content in epoxy resin resulted the reverse effect decreasing the damping ratio and loss/storage modulus. This may be explained the poor bonding between nanoclay-matrix-fibers interphases.

TABLE I.

TABLE 1. VIBRATION TEST RESULTS

NanoclayC ontent (wt%)	Natural Frequency (Hz)	Damping ratio,	Storage Modulus (GPa)	Loss modulus (GPa)
0	77.62	0.200	30.2	12.1
1	84.23	0.220	36.5	16.0
2	82.58	0.230	36.3	16.7
4	84.99	0.370	31.9	23.6
6	82.58	0.350	30.8	21.5
8	90.83	0.240	27.1	13.1
10	95.23	0.220	25.1	11.2

Fig. 4. Schematic illustration of half-power method

IV. CONCLUSION

Damping and vibration properties of woven kevlar/carbon/epoxy composite laminates were inspected incorporating nanoclay inclusion in the epoxy resin. It is shown that incorporation of Nano-clay particles were improved damping ratio for all Nano-clay contents and reached maximum at 4 weight% with increment of 72.0 % compared to unmodified full composites. In addition, natural frequency values were increased with increase of nanoclay content. The first mode frequency and natural frequency were maximum at the Nano-clay content of 10% wt.

Abstract— In present study, the convective heat transfer and friction factor with using nanofluids in an elliptic channel is investigated numerically in the three-dimensional steady laminar flow conditions. Numerical procedure is solved by SIMPLE algorithm. In the studies, the Reynolds (Re) number, the aspect ratio of elliptic channel (AR), nanoparticle types and volume fraction (ϕ) parameters are changed and the other parameters kept constant for all cases. The change of aspect ratio for elliptic channel effected slightly the heat transfer. Comparison of Nusselt (Nu) number for different nanofluids under the steady flow conditions is presented and numerical results showed that heat transfer significantly increases also due to improve thermal conductivity the use of nanoparticles. It is observed that the heat transfer enhances significantly with increase in nanoparticle concentration at high Reynolds number, but also friction factor increases. The highest thermal performance and friction factor are found for SiO_2 -water nanofluid compared with tested other nanofluids. The obtained results are given as a function of dimensionless parameters.

Keywords—elliptic channel; convection; nanofluids; skin friction; CFD

I. INTRODUCTION

Alternative ways have been investigated to enhance the thermal performance of devices such as refrigeration, compact heat exchangers and air-conditioning applications, one of the most important of these is the use of nanofluids instead of traditional working fluids. It is known that nanofluids have the potential to improve thermal performance. Many researchers have investigated on heat transfer and hydrodynamic characteristics of nanofluids and the results of this researches demonstrated that the nanofluids enhanced the heat transfer performance according to base fluid [1-3]. The single phase fluid model [4-7] and two phase fluid model [8-11] were studied to examine the flow and heat transfer characteristics of the nanofluids for different channel geometries. Beheshti *et al.* [12], investigated numerically turbulent convective heat transfer of Al_2O_3 -water and TiO_2 -water nanofluids inside an annular duct for single phase and two phase fluid models. Findings demonstrated that the Nu number enhanced with increase in nanoparticle concentration and Re number for both nanofluids. Narrein *et al.* [13], performed a numerical study to examine the effect of flow and heat transfer on pulsating laminar flow in a

three-dimensional helical microchannel using Al_2O_3 -water nanofluid for the two phase fluid model. Numerical simulations indicated that the thermal performance enhanced for the pulsating inlet flow condition compared with steady flow conditions and the Nu number increased with increasing the amplitude, frequency and particle volume fraction at high Re numbers.

It is well known that the pressure drop in the elliptical channels is less compared with other circular cross-section channels. Therefore, in the production of heat exchangers is preferred elliptical tubes. There are a lot of studies by using nanofluids for different aspect ratio of elliptic channel. It has been declared that using nanoparticles to the traditional base fluids can lead to heat transfer enhancement with together increase in pressure drop [14].

Rao *et al.* [15], numerically studied the convection heat transfer for laminar flow in short elliptical channels with uniform wall temperature and determined wall heat flux. The Nusselt number for constant wall heat flux was found than constant wall temperature. Velusamy *et al.* [16], numerically examined the heat transfer characteristics for laminar regime in channel of semi-elliptical cross section. They investigated both an isothermal and uniform heat flux conditions on the channel walls for different aspect ratio. Numerical results indicated that the friction and heat transfer coefficients for the uniform heat flux condition increased as the aspect ratio of channel decreased. Sivakumar *et al.* [17], examined numerically the flow characteristics of the two-dimensional steady flow of incompressible power-law fluids over an elliptical cylinder for the different Reynolds number ($0.01 \leq Re \leq 40$), power-law index ($0.2 \leq n \leq 1.8$) and the aspect ratio ($0.2 \leq E \leq 5$). The streamlines and vorticity profiles were obtained and the pressure distribution on the wall of the cylinder was obtained to explain flow kinematics. The results shown that the pressure drop coefficient always decreased with an increase in the power law index, at all events the value of Reynolds number, fluid behaviour, or shape of the cylinder.

Shariat *et al.* [18], investigated effects of the aspect ratio (AR) on the nanofluid flow in elliptic tube. Findings shown that in the elliptic tube with $AR = 0.75$ was obtained the highest heat transfer performance and the lowest friction factor. For this reason, they recommended the usage of the elliptic ducts with

$AR = 0.75$ instead of the circular ducts. Shariat *et al.* [14], in their other studies, researched the effects of volume concentration of nanofluid Al_2O_3 /water under laminar mixed convection flow in an elliptic channel with uniform heat flux for two phase fluid model using the finite volume method (FVM). It was declared that at the constant Reynolds number with increasing of nanoparticles volume fraction heat transfer improved but shear stress increased. Huminic and Huminic [19], effects of parameters such as particle volume fraction, Brownian motions of particles, and Re number on heat transfer coefficient were analyzed by using the flattened tube. Numerical simulations shown that the heat transfer performance enhanced with increase in the particle volume concentration and flattened tubes enhanced significantly the heat transfer coefficients compared to that of the circular and elliptic tubes for the same flow conditions. Dawood *et al.* [20], investigated for three dimensional laminar flow and heat transfer through for different nanofluids in an elliptic annulus channel with uniform heat flux using SIMPLE algorithm. At simulations were performed, four different types of nanofluids Al_2O_3 , CuO , SiO_2 and ZnO , with different nanoparticles size 20, 40, 60 and 80 nm and different volume fractions ranged from 0% to 4% for Re number in the range of 200 to 1000. The effects of particle type, volume fraction, particle diameter, Reynolds number and different base fluids on the Nu number and friction factor were analyzed. The findings indicated that SiO_2 -water nanofluid had the highest Nu number and the Nu number increased with increasing the particle volume fraction and Reynolds number.

In this study, the heat transfer performance and friction factor in an elliptic channel with uniform heat flux by using different types of nanofluids, different nanoparticle volume fractions, different Re numbers and different aspect ratios are analyzed. Differently from previous study [21], in present study the effects on convective heat transfer and friction factor for each aspect ratio of different Re numbers and nanofluids are investigated.

II. NUMERICAL STUDY

The geometry of elliptic channel used in this study is illustrated in Fig.1. The geometry is accepted minor axis of elliptic channel as b , major axis of elliptic channel as a . The length (L) and hydraulic diameter (D_h) of the elliptic channel are 1000 mm and 12 mm, respectively. The problem is considered three dimensional.

Fig.1. The geometry of the elliptic channel used in this study

A. Governing Equations

It can be assumed that the flow is fully developed, laminar, incompressible, three-dimensional and steady. Additionally, nanofluid is considered as a Newtonian fluid. The single phase flow is assumed. The mixture of water and nanoparticles is homogenous and enters the channel at the same flow and thermal conditions. Gravity and radiation heat transfer are negligible. Therefore the governing equations based on these assumptions are as follows: continuity, momentum and energy equations ($i, j \in \{1, 2, 3\}$):

$$\frac{\partial}{\partial x_i} (\rho u_i) = 0 \quad (1)$$

$$\frac{\partial}{\partial x_i} (\rho u_i u_j) = -\frac{\partial p}{\partial x_j} + \frac{\partial}{\partial x_i} \left(\mu \left(\frac{\partial u_j}{\partial x_i} \right) \right) \quad (2)$$

$$\frac{\partial}{\partial x_i} (\rho C_p u_i T) = \frac{\partial}{\partial x_i} \left(k \left(\frac{\partial T_i}{\partial x_i} \right) \right) \quad (3)$$

B. Numerical Solution and Grid Independence

For the solutions of present problem are used the CFD code Fluent 6.3 [22]. A finite volume method is applied for discretizing the governing equations and they are solved by using the SIMPLE algorithm. The convergence criterion for energy equation is determined to 10^{-8} , for each variable is determined to 10^{-6} . The different cell numbers are applied to the geometry and simulated by calculating the Nusselt number at $Re=700$. The number of cells varied as 845000, 1528000, 1864000 and 1528000 cell and it shown no much difference in the values of Nusselt number. Thus, the cell number of 1528000 is chosen in present study to grid independent solution. In Table 1. is given the numerical solution parameters.

TABLE II. THE NUMERICAL SOLUTION PARAMETERS

Nanofluid	Volume fraction: (ϕ %)	Reynolds Number: Re	Aspect Ratio: (b/a) AR
Al_2O_3 - water	1, 3, 5	100, 400, 700	0.25, 0.5, 0.75, 1
CuO -water	1, 3, 5	100, 400, 700	0.25, 0.5, 0.75, 1
TiO_2 -water	1, 3, 5	100, 400, 700	0.25, 0.5, 0.75, 1
SiO_2 -water	1, 3, 5	100, 400, 700	0.25, 0.5, 0.75, 1

The fluid enters to channel with uniform temperature $T_o=300K$. At the inlet of channel is given uniform "velocity inlet" boundary condition. The flow at the outlet of channel is accepted fully developed and is performed "outflow" boundary condition. The constant heat flux condition is applied for all walls of elliptic channel. The channel walls are kept at a uniform heat flux (q'') of $2000 W/m^2$. At the channel walls are used the usual no-slip boundary conditions. For these boundary conditions, Nusselt number and friction factor are calculated.

C. Physical Properties of the Nanofluids

In order to obtain reliable numerical results, the most proper correlations must choose available in the literature. These properties include thermal conductivity, viscosity, density and heat capacitance depending on what form the governing equations are written. By assuming the nanoparticles are well dispersed within the base fluid, the effective thermo-physical properties of the nanofluids can be evaluated using some classical appropriate formulas. The following equations are used in this study.

$$\rho_{nf} = (1-\phi)\rho_{bf} + \phi\rho_{pt} \quad (4)$$

$$C_{nf} = (1-\phi)C_{bf} + \phi C_{pt} \quad (5)$$

$$k_{nf} = \frac{k_{np} + 2k_{bf} - 2\phi(k_{bf} - 2k_{np})}{k_{np} + 2k_{bf} + 2\phi(k_{bf} - 2k_{np})} \quad (6)$$

$$\mu_{nf} = \mu_{bf}(1 + 1.25\phi) \quad (7)$$

Where the subscript pt and bf is indicates the nanoparticle and base fluids, respectively. In this study, the single phase fluid model is considered. Different equations applied in literature studies are tested especially to calculate thermal conductivity, viscosity and heat capacitance values from thermo-physical properties of the nanofluids. It was observed that there was not so much changed values of this thermo-physical properties. Further details about the thermo-physical properties of nanofluids are available in literature [12, 23-28].

III. RESULTS AND DISCUSSIONS

The this study is validated by comparing the results obtained for different aspect ratios with uniform heat flux in an elliptic channel with the numerical results of Shariat *et al.* [14]. In Fig. 2 is indicated accordance between the calculated Nusselt numbers.

Fig. 2. Validation of present study with Ref. [14].

In present study, laminar forced convection of Al_2O_3 , CuO , TiO_2 and SiO_2 nanofluids with base fluid water in an elliptic channel under steady flow conditions is examined numerically. Nanoparticle type, nanoparticle volume fraction ($1 \leq \phi \leq 5$), aspect ratio of channel elliptic ($0.25 \leq AR \leq 1$) and the Reynolds number are changed. The Re number is considered as 100, 400 and 700.

The local and average Nu number is calculated from Eq. (8) and Eq. (9), respectively;

$$Nu_z = \frac{q'' D_h}{k(\bar{T}_{w,z} - \bar{T}_{b,z})} \quad (8)$$

$$Nu = \frac{1}{L} \int_0^L Nu_z dz \quad (9)$$

where, k is thermal conductivity of the nanofluid, D_h is hydraulic diameter, T_w is wall temperature of channel and T_b is bulk temperature of nanofluid. The effectiveness of the heat transfer is obtained by the heat transfer performance η , which is defined by Eq. (10).

$$\eta = \frac{Nu_n}{Nu_w} \quad (10)$$

Where Nu_n is Nu number calculated for each of nanofluids, Nu_w is Nu number calculated for base fluid (pure water).

Fig.3 The heat transfer performance varying with Re number and nanoparticle type (a: $AR=0.25$, b: $AR=0.5$, c: $AR=0.75$, d: $AR=1$)

In Fig. 3, heat transfer performance versus Re number with varying nanoparticle type is presented for four different aspect ratio (AR) at fixed concentration ratio ($\phi=5\%$). It is observed that the heat transfer performance increases as Re number increases at $AR=0.25$, 0.75 and 1 for each of nanoparticle type, A peak occurs at a specific value of Re number for each of nanoparticle type at $AR=0.5$ and the maximum heat transfer enhancement is take place at $Re=400$. The heat transfer performance (η) decreases with increasing the Re number after

a specific value. At $AR=1$, the same heat transfer performance is obtained for other tested nanofluids at all Re number excluding SiO_2 -water nanofluid. The results revealed that SiO_2 -water nanofluid has the highest the heat transfer enhancement at $Re=700$, at $\phi=5\%$ for all aspect ratio compared with other nanofluids in the elliptic channel.

The results reveal that the heat transfer is significantly affected by nanofluid type and Reynolds number. There is an enhancement in heat transfer for all of tested nanofluids compared with only base fluid flow. Although there have been satisfactory results for heat transfer enhancement, the effects of shear stress (pressure drop) are an important subject in channel flow. The nanoparticle type and particle concentration contributes to a significant increase in the shear stress because of the interaction and collision among particles, fluid and the flow passage surfaces. The nanoparticles increases the viscosity of the suspension. This is due to the nanofluids have a higher viscosity value in comparison with base fluids. For the evaluation of pressure drop in present elliptic channel, the friction factor is defined as $\Delta f = f_n / f_w$. Where f_n is skin friction of nanofluid and the f_w is skin friction of pure water.

In Fig. 4, the friction factor versus Re number with varying nanoparticle type and aspect ratios is indicated for nanoparticle volume concentration of 5% . It is observed that the friction factor increases as Re number increases at $AR=0.25$, 0.75 and 1 for each of nanoparticle type. A peak occurs at a specific value of Re number for each of nanoparticle type at $AR=0.5$ and the maximum friction factor is take place at $Re=400$. The friction factor (Δf) decreases, with increasing the Re number after a specific value. Also, the friction factor increases as aspect ratio decreases at for each of nanoparticle type. The results revealed that SiO_2 -water nanofluid has the highest the friciton factor at $Re=700$, $AR=0.25$, for $\phi=5\%$ compared with other nanofluids in the elliptic channel.

Fig.4 The friction factor varying with Re number and nanoparticle type ($AR=0.25$, b: $AR=0.5$, c: $AR=0.75$, d: $AR=1$)

SiO_2 -water nanofluid has the highest the heat transfer enhancement and friction factor compared with other nanofluids. Because SiO_2 has the lowest thermal conductivity among other nanofluids (but higher than base fluid) and has the highest average velocity due to its lowest density compared with the other nanofluids.

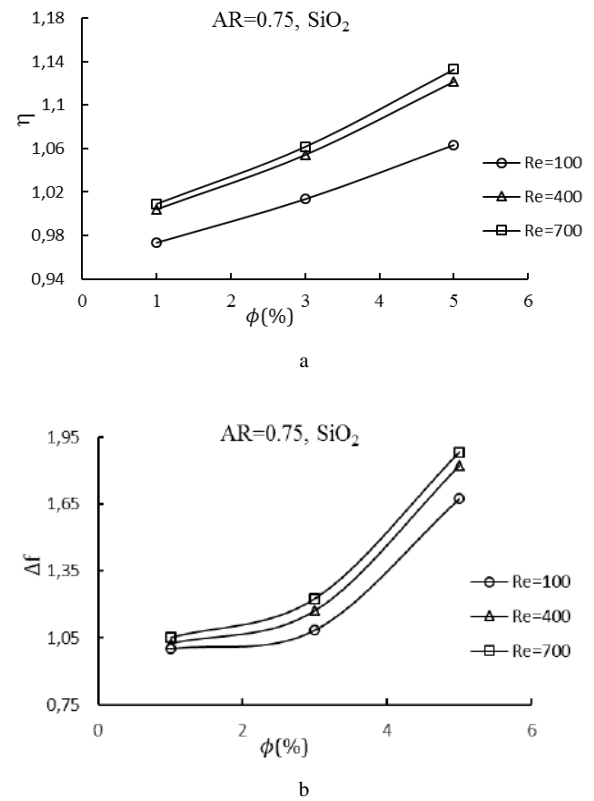

Fig.5 The heat transfer performance (a) and friction factor (b) varying with Re number and particle volume fractions of SiO_2 -water nanofluid at $AR=0.75$.

In Fig. 5a, the heat transfer performance and in Fig.5b, friction factor versus nanoparticle volume fracture with varying Re numbers are shown for SiO_2 - water nanofluid at $AR=0.75$. It is observed that the heat transfer performance and friction factor increased as Re number and nanoparticle volume fraction increases for SiO_2 - water nanofluid at $AR=0.75$.

IV. CONCLUSION

In this study, the heat transfer performance and friction factor of nanofluids in an elliptical channel have been studied numerically in the three-dimensional with uniform heat flux, steady under laminar flow conditions. The effects of aspect ratio, Re number and nanoparticle volume fraction using four different nanofluids of Al_2O_3 , CuO , TiO_2 and SiO_2 as base fluid water are analyzed. The numerical results indicated that the heat transfer performance increases significantly with increase in nanoparticle volume fraction and Re number but the other hand friction factor increases. The highest heat transfer performance and friction factor are obtained at SiO_2 -water nanofluid compared with other nanofluids. The heat transfer performance and friction factor are affected from varying aspect ratio. An elliptical channel having aspect ratio of 0.75 can be used to obtain maximum heat transfer enhancement and minimum friction factor.

Abstract— In this study it is investigated to find the ways to meet the electric demand (2966 kWh/day) of Inonu University with off-grid and on-grid optimum wind turbine and photovoltaic panel and to generate cost-effective electric energy. Homer software was used for simulations and four different energy system scenarios were carried out. Equipment consisting of energy system are wind turbine, PV panel, battery and converter. In the study annual energy production, annual energy consumption, costs of energy, total net cost of the systems designed were analyzed. It was seen that the costs of energy of off-grid wind and PV energy systems exceeded grid power price and total net costs were quite high according to the simulations results. The cost of energy of on-grid wind energy system was lower than grid power price and cost values of this system were negative sign meaning that incomes were more than expenses. It was also seen that cost values increased when wind turbine number and photovoltaic panel capacity decreased and battery number and converter capacity increased.

Keywords—Solar energy; wind energy; homer software; energy simulation; cost analysis

I. INTRODUCTION

Nowadays, energy has been considerably affecting people's life, health and welfare and hence the economic independence of the countries and their welfares. At present the world's energy demand is essentially and largely met by the fossil fuel which causes critical environmental pollution concerns [1]. Utilization of fossil fuels for energy systems causes many problems including air pollution and global warming. Moreover, this trend has been reinforced since the oil crises in 1970s [2, 3]. These problems can be overcome by using renewable energy sources like solar, wind, and biomass. These energy sources also exist relatively in a broad range contrary to conventional fuels limited in comparison with renewable energy sources. In literature there are many studies about renewable energy and cost analysis by using Homer program. Some examples are presented below.

Prasetyaningsari and his colleagues designed a solar-powered ventilation system for a fish pond in Sleman regency

via HOMER program. They modeled a system and endeavoured to obtain daily 2 kWh load with hybrid energy system. They also indicated that the optimal system which could be implemented according to the optimization result had consisted of 1 kW PV panel, 8 batteries with 200 Ah and 0.2 kW inverter. Initial investment cost and cost of energy of hybrid energy system were calculated respectively 4960 \$ and 0.769 \$ [4]. Shaahid and his colleagues analyzed wind speed and solar radiation data of Rafha, KSA, and assessed the technical and economic potential of hybrid wind-PV-diesel power systems to meet the load requirements of a typical remote village Rawdhat Bin Hab-bas (RBH) with annual electrical energy demand of 15,943 MWh, using HOMER software [5].

II. HOMER SOFTWARE AND ELECTRIC LOAD

A. What is Homer?

HOMER (Hybrid Optimization Model for Electric Renewable), is computer software developed by U.S. National Renewable Energy Laboratory to compare all technologies helping energy generation in a wide range and back up for micro energy system designs. The micro power optimization model, simplifies the task of evaluating designs of both off-grid and grid-connected power systems for a variety of applications. The large number of technology options and the variation in technology costs and availability of energy resources make these decisions difficult. HOMER's optimization and sensitivity analysis algorithms make it easier to evaluate the many possible system configurations. The users can design many energy systems with photovoltaic panels, wind turbines, boilers, hydro, electrolyzers, flywheels, batteries, invertors via Homer program by adding thermal load or electrical load. There can be seen Homer methodology in fig. 1.

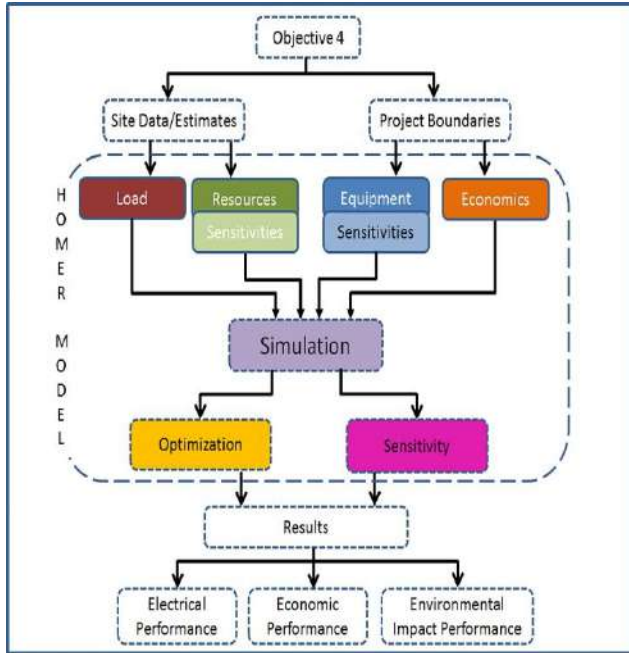

Figure 1. Schematics of HOMER Methodology [6]

B. Electric Load

The monthly electricity consumption amount of Inonu University is 890000 kWh. Electric load which will be supplied is %10. It corresponds to monthly 89000 kWh. Load data was transferred to program as daily 2966 kWh. Day to day and step to step randomness variable are respectively %10 and %15. The daily load profile was given in fig. 2.

Figure 2. The daily load profile

III. ENERGY RESOURCES

A. Solar Energy Resource

Malatya has quite high solar energy potential. But Inonu University average solar energy level is low. This value extracted from Homer database is approximately 4.83

kWh/m²/day. Malatya global solar radiation and average solar radiation data for Inonu University can be seen respectively in fig. 3 and in table 1.

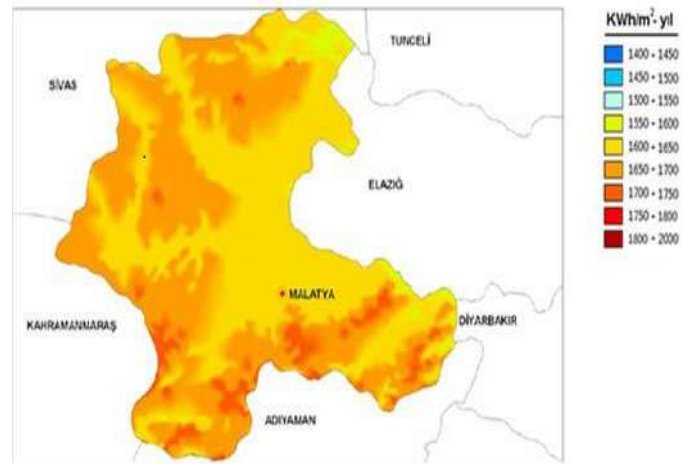

Figure 3. Malatya global solar radiation [7]

TABLE 1. Inonu University average solar radiation data

Months	Clearness Index	Daily Radiation (kWh/m ² /day)
January	0,455	2,060
February	0,490	2,907
March	0,545	4,302
April	0,542	5,307
May	0,580	6,433
June	0,665	7,706
July	0,701	7,899
August	0,701	7,115
September	0,712	5,980
October	0,594	3,796
November	0,530	2,534
December	0,461	1,887

B. Wind Energy and Temperature Resources

Wind energy is a necessary energy resource to specify wind speeds affecting wind turbines all the year round. Inonu University average wind speed extracted from Homer database like solar energy resource is 3.89 m/s. Altitude above sea level is 998 m in program. Anemometer height was chosen 50 m. Weibull K factor, autocorrelation factors, diurnal pattern strength, hour of peak wind speed were used respectively as 1.8, 0.86, 0.2, 15 h. Average wind speed data and temperature values for Inonu University can be seen in table 2. Temperature values of region were taken from Malatya regional directorate of

meteorology. Annual average temperature was specified as 15.93 °C.

TABLE 2. Inonu University average wind speed and temperature

Months	Average Wind Speed (m/s)	Temperature Values (°C)
January	4,070	4,1
February	4,110	4,9
March	3,620	10,4
April	3,550	15,4
May	3,460	19,6
June	3,740	23,9
July	4,220	30,3
August	4,320	30,8
September	4,180	22,7
October	3,620	15,3
November	3,790	7,3
December	3,960	6,4

IV. USED EQUIPMENT

A. Photovoltaic Panel

The PV window allows you to enter the cost, performance characteristics and orientation of an array of photovoltaic (PV) panels as well as choose the sizes you want HOMER to consider as it searches for the optimal system. Both flat panel and concentrating PV technologies can be represented by the PV component. Photovoltaic cells are semiconducting materials used to turn into electricity the sunbeams. Many solar cells generate DC power generally. In this study, the output current was taken DC and powersolar 250 Wp photovoltaic module consisting of monocrystalline silicium technology was used. In table 3, technical specifications of photovoltaic module were given. In the study temperature influence on photovoltaic panels was taken into account. In equation (1) the output power of photovoltaic array was given.

Table 3. Powersolar 250 Wp technical specifications [8]

Rated power	250 W
Open circuit voltage (V_{oc})	59,8 V
Rated power voltage (V_{pm})	48,6 V
Short-circuit current (I_{sc})	5,38 A
Maximum electric current (I_{pm})	5,15 A
Module efficiency	14,7 %
Nominal cell operating temp.	46 °C
Power temperature coefficient	-0,45%/°C
Capital cost	6.500 \$/kW
Replacement cost	6.500 \$/kW
Operating and maintenance cost	65 \$/year
Lifetime	25 year
Lowest and highest kW capacity	100 - 5000

$$P_{PV} = f_{PV} Y_{PV} \left(\frac{I_T}{I_S} \right) [1 + \alpha_P (T_c - T_{c,STC})] \quad (1)$$

where Y_{PV} is the rated capacity of the PV array, meaning its power output under standard test condition (STC); f_{PV} is the PV derating factor; I_T is the solar radiation incident on the PV array; I_S is the incident radiation at STC; α_P is the temperature coefficient of power; T_c is the PV cell temperature and $T_{c,STC}$ is the PV cell temperature under STC.

B. Wind Turbine

The wind turbine window allows you to choose the type of wind turbine you want to model, specify its costs, and tell HOMER how many to consider as it searches for the optimal system. A specified power curve that is a graphic belonging to the output power involving the wind speed in hub height is based and wind turbines are created in Homer. Homer assumes that this power curve is performed in standard air density (1,225 kg/m³) including standard temperature and pressure conditions. In this study E33 wind turbine model pertaining Enercon firm was used. Wind speeds and output powers were taken from firm catalog and power curve was constituted. In table 4, technical specifications of E33 wind turbine were given.

Table 4. E33 wind turbine technical specifications [9]

Rated power	330 kW
Rotor diameter	33,4 m
Hub height	50 m
Number of blades	3
Blade sweep area	876 m ²
Cut-in speed	3 m/s
Cut-out speed	25 m/s
Rotational speed	Variable 18-45 d/d
Capital cost	3.500 \$/number
Replacement cost	2.800 \$/number
Operating and maintenance cost	95 \$/year
Lifetime	25 year
Lowest and highest wind turbine number	1 - 15

C. Battery

Batteries store electric generated and back up the system when necessary. Homer assumes that battery properties are stable throughout batteries lifetime and don't be affected from external effects. In this study Surrette 6CS25P batteries which have 1186 Ah capacity with 6 V were used. One battery capital cost, replacement cost and operating and maintenance cost are respectively 1100 \$, 1000 \$, 10 \$/year [10]. While battery number data for off-grid systems were entered 0, 640, 1280, 2560, 5120, 10240 in search space, data for on-grid systems were entered 0, 80, 160, 320, 640, 1280, 2560 and 5120.

D. Converter

While an inverter converts DC electricity to AC electricity, a rectifier converts AC electricity to DC electricity. These two parameters are examined under converter section in Homer

software. Converter capital cost, replacement cost and operating and maintenance cost are respectively 900 \$/kW, 900 \$/kW, 0 \$/year [10]. While converter capacity for off-grid systems were entered 0 kW and 6000 kW, capacity for on-grid systems were entered 0 kW and 5000 kW.

turbine number, photovoltaic panel capacity, battery number and converter size as a result of simulations. Grid power price and grid sellback price were taken into account respectively 0.17 \$/kWh and 0.089 \$/kWh [11]. Costs of energy were evaluated in comparison with these prices.

a. Wind Energy System

In this scenario the electric load of Inonu University was obtained from off-grid wind energy system and system model was given in fig. 4. The system was consisted of wind turbine, battery and converter.

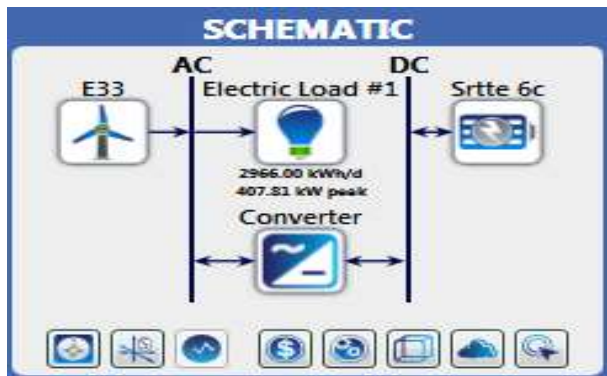

Figure 4. Off-grid wind energy system

Optimum wind energy system consisted of 15 wind turbines, 5120 batteries and 400 kW converters. Total net cost (NPC) and cost of energy (COE) were respectively 11.014.623 \$ and 0.913 \$/kWh according to simulation results. While electric consumption value was 1.082.593 kWh/year, electric generate value was 3.623.266 kWh/year. So, excess electricity meaning surplus electric energy was %63.3. When 7 wind turbines, 20480 batteries and 2000 kW converters were used instead of optimum system, electric generate value was 1.690.859 kWh/year. Therefore, much more batteries stored more energy and excess electricity was %17.3. But, when battery number and converter capacity increase, the costs augment depending parameters.

b. Photovoltaic Energy System

In this scenario the electric load of Inonu University was obtained from off-grid photovoltaic energy system and system model was given in fig. 5. The system was consisted of photovoltaic panel, battery and converter.

V. SCENARIO RESULTS

A. Off-grid Scenarios

In these scenarios two energy systems (wind and photovoltaic) were analyzed. Energy systems were investigated according to the optimum total net cost, cost of energy, wind

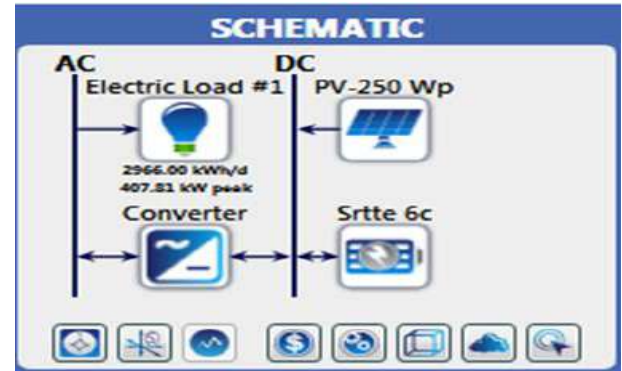

Figure 5. Off-grid photovoltaic energy system

Optimum photovoltaic energy system consisted of 1446 kW photovoltaic panel, 5120 batteries and 400 kW converters. Total net cost (NPC) and cost of energy (COE) were respectively 24.719.907 \$ and 2.05 \$/kWh according to simulation results. While electric consumption value was 1.082.593 kWh/year, electric generate value was 2.196.378 kWh/year. So, excess electricity meaning surplus electric energy was %38.9. When 945 kW photovoltaic panel, 20480 batteries and 400 kW converters were used instead of optimum system, electric generate value was 1.465.308 kWh/year. Therefore, much more batteries stored more energy and excess electricity was %12.8. But, likewise wind energy system when battery number and converter capacity increase, the costs augment depending parameters.

B. On-grid Scenarios

In these scenarios two energy systems (wind and photovoltaic) were analyzed. Energy systems were investigated according to the optimum total net cost, cost of energy, wind turbine number, photovoltaic panel capacity, battery number and converter size as a result of simulations. Grid power price and grid sellback price were taken into account respectively 0.17 \$/kWh and 0.089 \$/kWh [11]. Costs of energy were evaluated in comparison with these prices. While grid sale capacity was entered to the program as 10.000 kW, annual purchase capacity was entered as 0 kW and 1000 kW.

a. Wind Energy System

In this scenario the electric load of Inonu University was obtained from on-grid wind energy system and system model was given in fig. 6. The system was consisted of wind turbine, grid, battery and converter.

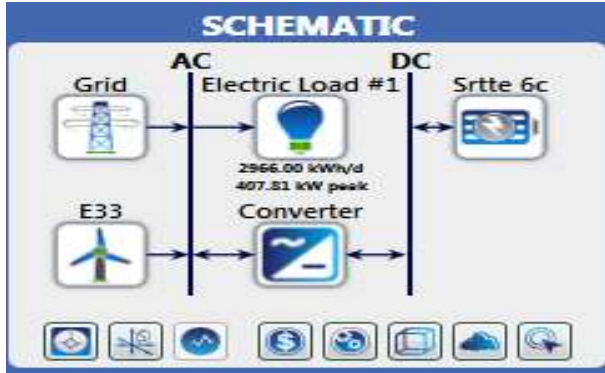

Figure 6. On-grid wind energy system

Optimum wind energy system consisted of 15 wind turbines and 1000 kW electric grid. Total net cost (NPC) and cost of energy (COE) were respectively -2.192.215 \$ and -0.0478\$/kWh according to simulation results. Negative sign means that revenues are more than expenses. While electric consumption value was 1.082.593 kWh/year, electric generate value was 3.721.256 kWh/year and electric grid sale was 3.034.149 kWh/year. When battery and converter were added to the system, cost values increased.

b. Photovoltaic Energy System

In this scenario the electric load of Inönü University was obtained from on-grid photovoltaic energy system and system model was given in fig. 7. The system was consisted of photovoltaic panel, grid, battery and converter.

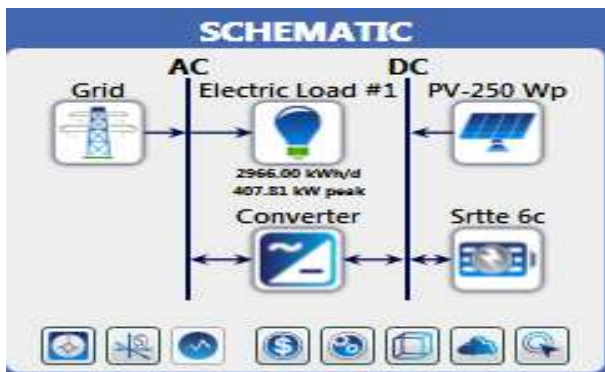

Figure 7. On-grid photovoltaic energy system

Optimum photovoltaic energy system consisted of 3500 kW photovoltaic panel, 1000 kW electric grid, 320 batteries and 3000 kW converters. Total net cost (NPC) and cost of energy (COE) were respectively 25.998.800 \$ and 0.437 \$/kWh according to simulation results. While electric consumption value was 1.082.593 kWh/year, electric generate value was 5.316.885 kWh/year and electric grid sale was 4.253.506 kWh/year. When lower PV capacity is used

for systems, grid sales will decrease and at the same time cost values will diminish, too.

VI. CONCLUSIONS

In this study, Inönü University which is located in Eastern Anatolia region electrical energy demand was supplied with off-grid and on-grid wind and photovoltaic energy systems via Homer software and optimum cost analysis were carried out. According to the simulations, results are listed as follows;

- The optimum energy system for off-grid systems is wind energy (0.913 \$/kWh). But this value is quite higher than grid power price (0.17 \$/kWh).
- Higher battery number and converter capacity and lower wind turbine number and photovoltaic capacity change the costs and enhance for off-grid systems.
- Excess electricity meaning surplus energy occurs for off-grid systems, because more wind turbines or photovoltaic panels produce redundant energy. So much more batteries are necessary to store this energy and to decrease excess electricity.
- The costs of photovoltaic energy system are very high because, photovoltaic panels used in Homer software are expensive in comparison with wind turbines.
- Off-grid energy systems are not suggested for this study.
- The optimum energy system for on-grid systems is wind energy (-0.0478 \$/kWh). Cost of energy has negative value as all revenues are more than expenses. Surplus energy are sold to the grid in this system.
- On-grid energy systems can be suggested to the users according to the study.

Wind speed and solar radiation of selected district are generally low. Equipment installation like wind turbine and PV panel will increase in this case. If wind speed and solar radiation of selected district are high and equipment costs become cheaper in time, renewable energy usage can be more productive.

ACKNOWLEDGMENT

We owe special thanks to Inönü University Scientific Research Projects Coordination Unit for their financial support about Homer software.

Abstract—Plate-screw fixation is frequently used in treatment of tibia diaphysis fractures. However, design of implants depends on biomechanical behaviors of bone-implant structures, whether they are used locked or unlocked plate-screw systems. In this study, mechanical effects of locked and unlocked plate-screw fixation methods, which are used in treatment of tibial diaphysal fractures. In addition, changes on callus structure, which depend on plate material for first week, were examined by using finite element methods. For this purpose, 3D fractured tibia models with a callus structure consisting of 90 ° fracture angle were established and plate-screw fixations were performed. Obtained models were analyzed by using ANSYS 15.0 software under axial force. When plate material was changed from Ti6Al4V to 316L material, stresses and displacements occurred in the models decreased. As a result of analyzes; it has been determined that locked plate systems provide higher stabilization than unlocked plate systems in terms of stresses and displacements occurring in bone-implant structures.

VII. INTRODUCTION

Bones that are located in limbs are more fragile than other parts of body related to either external forces such as strikes, sprains, falls, accidents or other factors such as ageing and osteoporosis. In order to fix these fractures, several methods are used in medicine. While some of them use nonsurgical treatment as is cast, others uses surgical treatments such as intramedullary necrosis or plate fixations. As a result of developing new techniques and materials, plate fixation become more convenient for these kinds of bone cracks [18].

Quality and time consumption of bone recovery highly depends on variety of materials and plate types. Two main plate types, which are unlocked and locked plate systems, are commonly used in treatments. Unlocked plates contain screws to keep together plate and bone with using traditional non-threaded screw head. This screw type tends to higher pressure on plate and lead to irrevocable damage on bone tissue

especially on osteoporotic bones. Conversely, locked plates are provided directly with screws by plate contact. Locked plates therefore expedite the healing process by contributing to callus formation and provide more flexible structure than unlocked plate systems. Despite all, there is no certain result for superiority of one system. Researches show that although locked plate systems are more reliable than unlocked alternatives, different opinions are still being proposed regarding using of locked and unlocked plate systems. In addition to these, latest studies on using locked, and hybrid plate systems have been proposed by [3, 6-12, 15-17].

In this study, effects of locked and unlocked plate fixation methods on bone-implant structures were investigated. For this purpose, a bone-plate-screw three-dimensional model (3D) was created taking into account of 90° fracture angle and callus structure (0-1 Week). Created models were analyzed with ANSYS 15.0 software under axial load conditions. As a result of analyzes, both mechanical effects of bone-implant structures and callus formation in the healing process have been investigated.

VIII. MATERIAL AND METHOD

In this study, methods of treatment were theoretically examined by using locked and unlocked plates. Biomechanical studies on the tibial bone have been examined and Kim et al.'s plate-screw-bone-callus 3D model has been selected as main model [12]. In modeling, the bone structure was separated as a cortical-trabecular bone and then callus, which formed during the healing process, was placed in the middle part of the obtained models to simulate fractured bone structure. The callus models were designed and modeled with 90 ° fracture angles. After this step, the bone structures were fixed with 6 screws and plates from the middle part (Fig. 1).

Modeling and assembling operations were performed using SolidWorks 2017 software. The models have been transferred to ANSYS Workbench 15.0 software for analysis. At this stage, locked and unlocked models were made of mesh. As a result, the models with 90 ° crack angle was

divided into 176254 elements. Table 1 shows the material properties of bone, implants and callus structures formed at different stages of healing process from obtained finite element models.

Fig. 5. Plate-screw-bone-callus 3D model

TABLE III. MATERIAL PROPERTIES [9]

Materials	Modulus of Elasticity (MPa)	Poisson Ratio
Ti-6Al-4V	113800	0,340
316L Stainless Steel	191000	0,3
Cortical Bone	17000	0,3
Trabecular Bone	1,061	0,225
Callus 0-1 Weeks	0,02	0,3

Axial loads acting on the tibia bone were taken into account as a boundary condition in analyzes [9]. At this point, distal part of the obtained 3D model was fixed in each direction and a compressive force of 600 N was applied from the proximal part (Fig.2).

Fig. 6. Axial load and boundary condition acting on the tibia bone

Finally, different contact types have been defined in order to define unlocked and locked plate systems. In unlocked plates, contact type is defined to allow screw-plate contact but also allows the axial and rotational movement of the screws. In locked plates, contact type is defined not to allow movement between the plate and the threads. Plates used in the study are numbered with material and type of plate system. Also, the model used in the study is shown as meshed at Fig. 3.

TABLE IV. NUMBERING OF THE PLATES USED IN THE STUDY

Plate No	Material and type of plate
1	Ti6Al4V- Locked
2	Ti6Al4V- Unlocked
3	316L- Locked
4	316L- Unlocked

Fig. 7. Mesh structure of the model used in the study

IX. RESULT AND DISCUSSION

A. Stresses in bone-implant structures

Bone-callus-implant models were analysis and divided into 3 groups depending upon stresses and deformations related to these. First, stresses in the plate, then stresses on the cortical bone, and finally, the amount of deformation in the callus structure. Stresses occurring in the bone and plate play an important role in the bone healing process. It is recommended in the literature that the elasticity modulus of the plate materials should be closer to the bone. The reason for this is to prevent the bone from becoming lazy during the healing process. However, when the first week of bone fractures is considered, it is desired that forces should be undertaken by cortical bone and plates. Because of this reason, stress occurring in the cortical bone and plates become more important [13]. Mean von Mises stresses obtained from the 1 mm and 2 mm gap sizes of the Ti6Al4V and 316L unlocked and locked plate models used at 90° fracture angles are given in Fig 4.

(a)

(b)

Fig. 8. Stresses on the plates (a), Stresses on the cortical bone (b)

As seen in the graphs, the stress on the locked plates are lower than in the unlocked equivalents. This is valid for both plates which are made from Ti6Al4V and 316L materials. It is caused by connection between the plate and the screw. In contrast to unlocked plates, locked plates exhibits more rigidity because plate and screw have threaded joint. Due to this reason, load applied to plate is guided to center of plate by means of screws. While cross sectional area increase, behavior of plates display more rigidity.

On unlocked plates, because of the flat contact between the plate and the screw, the applied load concentrates on the contact areas of the plate and the screws. This causes high stress at the screw countersinks and also yield larger stresses on the plates. In addition, 316L plates are exposed to higher stresses than Ti6Al4V plates. This has led to different behaviors depending on the modulus of elasticity of the material due to analyzes are made in the elastic zone. Due to the high modulus of elasticity of 316L material compared to Ti6Al4V, it absorbs more energy under constant load and exhibits less deformation. When the stress in the cortical bone were examined, there was a decrease in the fixation with locked plates in comparison with unlocked plates. Furthermore, analyzes using 316L exhibited lower stress results than Ti6Al4V. As can be seen in the figures above, while locked Ti6Al4V was caused as 44.67 MPa stress, 316L was resulted as 32.57 MPa in the bone. This is about 23% decrease, which is considered to be a high value for the stresses in the bones. The reason for this is that 316L plates have more elasticity due to the modulus of elasticity and prevents stress on the bones.

In our study, fractured regions were examined at two different distances. From results, 2 mm gap size between plate and bone caused more stresses than 1 mm gap size alternatives. The reason for this is that the load applied in the case of axial loading is distributed to the bones and plates through screws. As the distance between the bones increases, more torque is applied to the region between the bones from the other screws on the side where the load is applied and this is increased stresses on the plates. The loads carried by the plates caused less stress on the bones with less load on the bones. Due to this reason, lower stresses in bones and higher stresses in plates occurred in 1mm gap sizes than 2mm gap size. Stresses occurring in 1 mm and 2 mm gap sizes, in plates and cortical bones are shown in Fig. 5.

Fig. 9. Stresses in plates in 1 mm gap size (a), cortical bones in 1 mm gap size (b) plates in 2 mm gap size (c), and 2 mm gap size in cortical bones (d)

B. Directional Deformations in Callus Structure

Deformations on the callus structures under axial load in Y direction for different fixation types are given in Fig. 6. From these values, it is seen that the displacements in locked plates are lower for both 1 mm and 2 mm gap sizes compared to unlocked plates. While displacement of the callus structure for Ti6Al4V with 1 mm gap size is 0.38 mm, it reaches 0.39 mm for unlocked equivalent. In addition to this, displacements of the callus structures exhibited different values for the plates for two different materials. The displacement of Ti6Al4V locked plate is 0.38 mm while that of 316L locked plate is reduced to 0.25 mm. These values indicate that the difference between two different materials is about 50%, which is a significant value for first week of callus constructions. Displacement of Ti6Al4V unlocked plate was 0.39 mm when the 316L unlocked plate was 0.31 mm. Since the first week of the healing period for callus structure is taken into account in our study, it is not desirable that callus structures are over deformed. Because of this reason, locked plates give better results.

Fig. 10. Deformations in callus structures

The most important phase in the treatment of bone fractures is to remove stress shielding effect [4]. After fixation, implant undertake load from bone and load is bypassed from callus structure. This called as stress shielding effect [1, 4, 14, 19]. In order to prevent long healing times, this effect must be kept at a minimum level. However, in the first stages of the healing process, contrary to this situation, it is desired that the bone-implant structure is sufficiently stable [4, 5, 8, 13, 19]. For this reason, analyzes were carried out taking into consideration of mechanical properties of callus structures for first stage of healing process.

Results that shows callus motions are shown in Fig. 7. When Fig. 7 is examined, it appears that using of locked plate system reduces callus motility during the healing process. In addition, callus motility value is reduced in plates made from 316L material. From literature studies, it has been concluded that fixation system must provide a higher stabilization at the early stages of healing process.

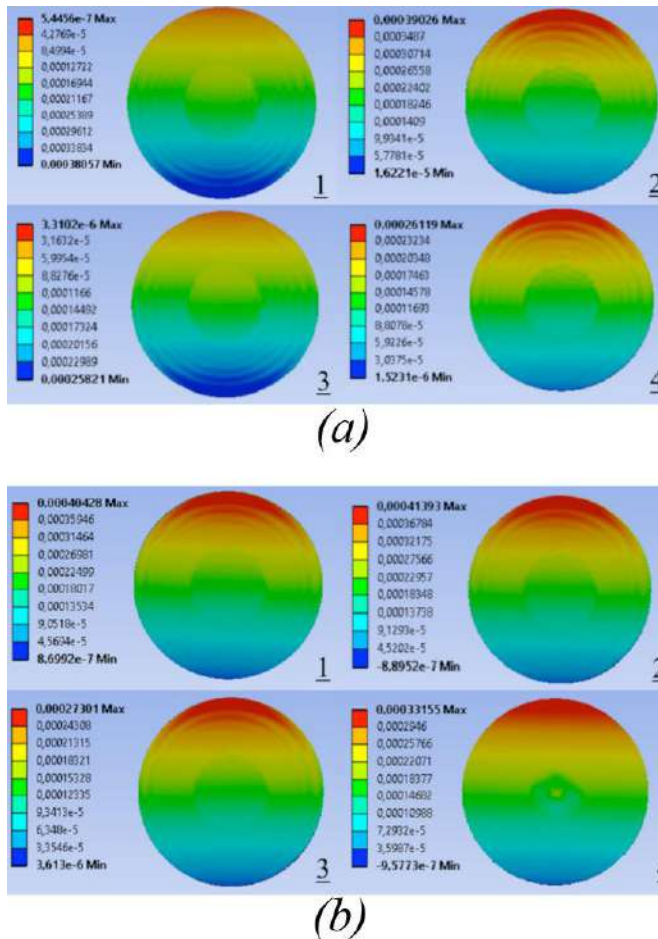

Fig. 11. 1 mm gap size (a) 2 mm gap size (b) Y-direction displacements in callus structures

Considering first stages of treatment of tibial fractures, it is seen that locked plate-screw systems are more convenient than unlocked plate-screw systems in terms of mobility. In addition to this, considering the amount of deformation of callus, 316L material can be selected as plate material.

X. CONCLUSION

In this study, in which locked and unlocked plate fixation methods were theoretically investigated, it was concluded that average plate stress in the bone-callus-implant models with 90° fracture angle for Ti6Al4V material was higher than 316L material. However, it has been observed that using of locked plates considerably reduces the stresses in the bone. When the individual pieces (Bone-callus-plate) are examined, the stresses are obtained from the locked plate made from the 316L material. When stresses on the plate are inspected, the lowest stress value is obtained from the fixation with the locked plate that is made from Ti6Al4V material. According to the amount of callus deformation in the Y direction, the lowest value was obtained from locked plate fixation system that is made of 316L material with a gap size of 1 mm.

Locked plate-screw systems have proven to be a more suitable method for the treatment of tibial fractures than unlocked plate-screw systems in that they provide higher stabilization at the beginning of the recovery process and higher mobility at later stages of the healing process.

Abstract: At the present time, significant improvements have been made in the iron-steel industry and investments in technology have become important. Hoisting and handling appliances are typical devices in order to transport the iron-steel products, especially steel plates and round bars. It is for sure that hoisting and handling appliances have to be used while manipulating the iron-steel products due to their heavy weights.

In this study, it has been mentioned about an innovative approach for preventing coil edge deformation problem arising from the poor viewpoint of the crane operator while manipulating the single jaw vertical coil tong which is used for the lifting of steel plate coils vertically. For this reason, the inner jaw of the vertical coil tong was provided to enter into the coil inner diameter properly by the crane operator by means of making good viewpoint with the camera system for helping to the crane operator.

In conclusion; the problem causing the loss of material was reduced to a minimum level in general and therefore a reasonable benefit was provided by means of the innovative system developed for the single jaw vertical coil tong.

Abstract— Cross-sectional area of air exiting of fans used in air handling units (AHU) is smaller than cross-sectional area of chambers which are located next to the fan such as heating/cooling coils, silencer (muffler), filter or heat recovery elements. To make the air handling unit work efficiently, it is required that the air is blown through fan diffuses with as low as possible pressure loss and homogeneous velocity distribution. Empty chambers with perforated diffuser is used to diffuse air from small cross-sectional area to large cross sectional area. In this concept, diffusion of air and pressure loss through the empty chamber with perforated diffuser are modelled and analyzed numerically. Using Taguchi Method, the effect of five parameters with different levels on the pressure drop is determined. These parameters are namely porosity, angle, diffuser thickness, diffuser distance and hole geometry.

Keywords — AHU; Diffuser; Pressure Drop; Taguchi Method; Air Flow

XI. INTRODUCTION

Average air velocities at discharge section of suction and/or supply fan is in the order of 8-15 m/s and velocity distribution of turbulent flow is much different from that of the fully-developed flow [1]. Exiting air from fans contacts with the certain surface sections of the heating/cooling coils, silencer (muffler), filter or heat recovery elements inside the chamber which are located after the fan if there is not any sufficient chamber length. The efficient chamber length which is approximately 3.5-3.7 times of fan impeller diameter or a shorter chamber including a perforated diffuser must be provided for effective air diffusing to the surfaces inside the chamber after the fan. Therefore, the chambers with perforated diffuser having the length of approximately 0.8-1.5 times of fan impeller diameter which are facilitated the air diffusion are used to efficiently working the chambers such as heating/cooling coils, silencer, mixing and filter or heat recovery element located after the fan exit [2]. Using a chamber with perforated diffuser in air handling

unit (AHU), to increase working efficiency of these chambers following the fan chamber by creating an uniform air flow from fan to following chambers such as heating/cooling coils, silencer, filter or heat recovery element and therefore decreasing of total internal pressure losses for central station AHU are possible [3, 4]. Decreasing of internal pressure losses in AHU and diffusing homogenously to chambers after fan is very important with respect to energy efficiency.

According to marketing investigation carried out among AHU manufacturers, it is determined that they cannot sufficiently ensure flow performance as expected due to the fact that there is not sufficient data on flow structure in chamber with perforated diffuser. According to literature review, it was seen that only one preview CFD (computational fluid dynamics) study for a chamber with truncated pyramid diffuser in was carried out and velocities at chamber exit was investigated [3, 4]. Any scientific study related with flow structure in a chamber having perforated diffuser geometry of V-profile shaped, which is often used in central station AHU applications because it has a simple geometric structure and manufacturing simplicity, has not found. Energy efficiency in AHUs is very important and it is seen that the ratio of electric energy operation costs of fans in their life cycle cost is at the order of 40-50 % approximately [5]. Therefore, even small reduction in internal pressure losses in AHUs is very important.

XII. MATERIAL AND METHOD

Numerical analyses were performed by ANSYS-Fluent 14.5 software. Five variable parameters were considered in numerical analysis. The effect of these parameters on pressure loss in the chamber was investigated. To reduce the numerical simulation number, Taguchi Method was used.

A. Geometry

Solid model of the AHU chamber is illustrated Fig. 1. Perforated diffuser is located in this chamber.

Fig. 12. Solid model of AHU chamber

Top view of the chamber with perforated diffuser with some geometrical details is shown in Fig. 2. The cross-sectional dimensions of the chamber of 730 mm x 550 mm with 450 mm in length and cross-sectional dimensions of air inlet section of 230 mm x 230 mm are considered for the numerical analysis. Diffuser distance in the chamber from the air inlet section is shown with L_0 ;

Fig. 13. Geometrical details of the chamber with perforated diffuser

B. Parameters

In this study, five parameters was determined as porosity, angle, thickness, diffuser distance (L_0), hole geometry. Porosity characterizes the void spaces on the diffuser plate surface. Angle is defined as the angle between V – profile diffuser side plates. Thickness is the perforated diffuser plate thickness. Diffuser distance is defined as length from the fan exit to diffuser inside the chamber. And hole geometry is shape of hole on perforated diffuser. Parameters and their levels are given in Table 1.

TABLE V. PARAMETERS AND LEVELS

Parameters	Units	Level 1	Level 2	Level 3
1 Porosity (ϵ)	-	0.4	0.5	-
2 Angle (α)	°	60	90	120
3 Thickness (t)	mm	2	3	5
4 Diffuser Distance (L_0)	mm	50	75	100
5 Hole Geometry	-	Square	Circle	Hexagonal

C. Numerical Model

The numerical calculations were performed by using ANSYS Fluent 14.5 based on finite volume method. The fluid and the solid were described as air and aluminum, respectively. The boundary conditions were defined as following; for the air inlet surface having sizes of 230 mm x 230 mm as “velocity-inlet”, for the back surface of the chamber having sizes of 730 mm x 550 mm as “pressure-outlet” and for other surfaces as “wall”. Static pressure values of pressure-outlet were assumed as 400 Pa and wall roughness value as 0.0032 mm. Depending on geometrical details, About 10^6 tetrahedral cells are generated finely mesh. Three dimensional steady-state flow is assumed and standard k- ϵ turbulence model is chosen as turbulence model. Generated solid model with different viewpoints is given Fig. 3.

Fig. 14. Solid model for numerical analysis

Mesh form of half symmetric model what generated for numerical analysis is shown in Fig. 4. Symmetric model is considered for reducing computational time.

Fig. 15. Mesh form of the numeric model

D. Taguchi Method

Taguchi has developed this statistical method to investigate the effects of different parameters to the process that they are in. The number of tests that will be formed by the combination of different parameters and levels is quite high. Taguchi Method reduces these test numbers drastically. The main trust of Taguchi's techniques is the use of parameter design, which is an engineering method for product or process design that focuses on determining the parameter settings producing the best levels of quality characteristic with minimum variation [6]. With this method proposed by Taguchi, orthogonal arrays are used to define the effects of parameters and each level of parameters that are determined for a process. [7]. L18 orthogonal array is chosen from the orthogonal array option table given in Table II for eight parameters defined in this study.

TABLE VI. SELECTING OF ORTHOGONAL ARRAYS

		Number of Parameters								
		2	3	4	5	6	7	8	9	10
Number of Levels	2	L4	L4	L8	L8	L8	L8	L12	L12	L12
	3	L9	L9	L9	L18	L18	L18	L18	L27	L27
	4	L16	L16	L16	L16	L32	L32	L32	L32	L32
	5	L25	L25	L25	L25	L25	L50	L50	L50	L50

L18 orthogonal array is given in Table III together with the number of tests to be done and levels of parameters that will be used in the model to be analyzed for each test.

TABLE VII. L18 ORTHOGONAL ARRAY

Number of Analyses	Porosity	Angle	Thickness	Diffuser Distance	Hole Geometry
1	1	1	1	1	1
2	1	1	2	2	2
3	1	1	3	3	3
4	1	2	1	1	2
5	1	2	2	2	3
6	1	2	3	3	1
7	1	3	1	2	1
8	1	3	2	3	2
9	1	3	3	1	3
10	2	1	1	3	3
11	2	1	2	1	1
12	2	1	3	2	2
13	2	2	1	2	3
14	2	2	2	3	1
15	2	2	3	1	2
16	2	3	1	3	2
17	2	3	2	1	3
18	2	3	3	2	1

XIII. NUMERICAL ANALYSIS

Pressure loss that is calculated in each one of 18 models determined by Taguchi Method in results of analyses from ANSYS 14.5 program is given in Table IV.

TABLE VIII. PRESSURE DROP OF EACH ANALYSIS

Number of Analysis	Pressure Drop (Pa)
1	44.78
2	52.45
3	62.26
4	60.68
5	39.43
6	64.25
7	76.70
8	41.83
9	48.53
10	42.07
11	54.14
12	66.79
13	49.34
14	81.63

15	39.58
16	58.84
17	61.07
18	42.10

According to variable parameters given in Table III, total 18 model analysis were done numerically. Each of parameters which effects on pressure drop was observed. Statistics of parameters performance graphic is given in Fig. 5. It is seen that, diffuser distance from the variable parameters has a significant effect on pressure drop.

Fig. 16. Statistic of parameters performance

Optimum levels of the variable parameters were determined by Taguchi Method. It is seen that ideal design array caused by minimum pressure loss is in the form of 2-1-1-3-1. These array means that, porosity, angle, thickness, diffuser distance and hole geometry levels are respectively 0.5, 60°, 2 mm, 100 mm and square. When a model is generated with this ideal design array, optimum (lowest) pressure loss is calculated as 38.16 Pa.

Fig. 17. Contours of total pressure in air inlet

Contours of total pressure distribution which is obtained for optimum model analysis is shown in Fig.6. Also velocity streamlines of optimum model analysis is demonstrated in Fig. 7.

Fig. 18. Velocity streamline for optimum analysis

XIV.CONCLUSION

The following main findings from the numerical results can be given as:

- Pressure loss decreases as diffuser distance and porosity increase.
- Pressure loss increases as angle and thickness increase.
- Square hole geometry causes low pressure loss as regards other geometry types.

- To obtain minimum pressure loss, it is seen that optimum porosity value is 0.50.

Abstract— In this study, the thermal aging effect on the failure loads of V-notched composite plates were investigated with static tensile tests. The notched and un-notched composite plates were exposed to temperature with changed time. In addition to, the thermally aged composite plates results were compared with un-aged composite plates results. Two different study was realized. In the first study the temperature was changed as 80, 120 and 160 °C and the time was constant as 4 hours. In the second study, the time was changed as 2, 4 and 6 hours and the temperature was constant as 80 °C. The notch width (a) was changed as 5, 10 and 15 mm and notch depth was constant as 10 mm. The results were showed that the time and temperature increasing were lead to decrease of failure loads of composite plates as 19.9% and 25.4%, respectively.

Keywords— Thermo-aging, V notch, Composite plates, Failure analysis. *Introduction*

XV. INTRODUCTION

First, The fiber reinforced composite materials are a combination of continued fibers and resin matrix. Especially, the thermoset based composite plates, which are manufactured glass fiber and epoxy resin, are showed a linear elastic behavior. Because of this behavior, failure to these materials occurs suddenly. When the external objects impact to these materials or due to some structural requirements in the manufacturing process can cause small micro cracks and then the notches can appear with the growth of these cracks on the composite plates. In the traditional materials, the notches generally lead to local stress concentration at the tip of notch. Generally, the failure starts at this location. However, this is a different meaning for composite materials. The fiber orientation angle of composite materials can occur different stress concentration behavior. Thus, the failure propagates with fiber orientation angle of composite plates.

The notch effect on the composite materials were investigated lots of studies [1-5]. Khashaba et al. investigated bending behaviors of notched and un-notched glass fiber/epoxy composite plates with experimental study [1]. Fiber volume fraction effect on the tensile behavior of notched unidirectional

carbon fiber/epoxy composite plates were researched by Tomita et al [2]. They observed that, the failure propagated to the direction of fiber-reinforced angle. Bouiadjra et al. analyzed stress intensity factor at the crack tip with finite element method [3]. They determined that, the crack propagation resistance decreased with increasing fiber direction angle. Kannan et al. and Çelik et al. researched failure behaviors of central circular cut-out composite plates by using finite element method and static tensile test, respectively [4,5].

The temperature can change material properties and generally, increasing of temperature decreases mechanical properties of materials. The composite materials have lower thermal expansion coefficient; this situation prevents the increased temperature from being easily removed from the composite material.

Belaid et al. researched the thermo-aging effect on the mechanical properties of glass fiber/polyester composite plates [6]. The composite plates were kept at 80 oC constant temperature during 30, 60, 90 and 120 days. Ray investigated that the temperature and humidity effect on the interfacial shear strength of glass fiber/epoxy and carbon/epoxy composite plates [7]. The interfacial shear strength of composite materials was determined by short beam shear test methods. They observed that the interfacial shear strength decreased with increasing temperature and absorbed moisture [7]. Allock et al. researched the mechanical properties of composite plates which exposed to temperature [8]. The composite plates exposed to temperature interval (from -40 ° C to 140 ° C) and the dynamic and static tensile tests were realized. Péreza et al. investigated the short-term temperature effect on the mechanical properties of composite plates with experimentally [9]. Mouzakis et al. analyzed mechanical properties of composite materials which exposed to temperature, moisture and UV radiation [10]. In this study, the mechanical properties were determined with static tensile test and three-point bending test [10]. Turan researched the buckling behavior of thermo-aged woven glass fiber/epoxy composite plates [11].

The major aim of this study was investigated failure behavior of V-notched composite plates, which were exposed temperature at different times. The thermal aging effect were analyzed with two studies. In the first, the V-notched composite plates were exposed to 80, 120 and 160 °C temperature with constant time at 4 hours and the second, the V-notched composite plates were exposed to 2, 4 and 6 hours with constant temperature at 80 °C. In addition, obtained results were compared to un-aged specimens. The results were presented as tables and graphs.

XVI. EXPERIMENTAL STUDY

In the experimental study, the eight layered woven glass/epoxy matrix composite plates were used as materials. The composite plates were provide from *Izoreel Composite Production Company*. The V notched were opened to the half-length of composite plates with using milling cutter. The dimension of problem was presented in Figure 1.

FIGURE 1. THE GEOMETRY OF PROBLEM.

FIGURE 2. EXPERIMENTAL SET-UP AND LOAD-EXTENSION GRAPH (FOR A= 5MM, TEMPERATURE 80°C AND WAITING TIME 6 HOUR).

III. RESULTS AND DISCUSSIONS

The results of experiments were evaluated at two stages. First of these; the time was changed as 2, 4 and 6 hours for constant temperature at 80 °C. The second of these, the temperature was changed as 80, 120 and 160 °C for constant time at 4 hours. In addition, these results were compared with un-aged specimens, which were stayed in room temperature conditions.

The notch width (a) was changed as 5, 10 and 15 mm and notch height (h) was constant at 10 mm. The prepared samples were kept in the electric oven at the prescribed temperatures and times. The variations of time, temperature and notch geometry were given in Table 1.

TABLE IX. THE VARIATIONS OF TIME, TEMPERATURE AND NOTCH GEOMETRY.

Notch width (a) mm	Time (Hour)	Temperature (°C)
5	0, 2, 4 ,6	25, 80, 120, 160
10	4	25, 80, 120, 160
15	4	25, 80, 120, 160

All of tests were repeated three times for reliability of failure loads. The failure loads were obtained from arithmetic average of maximum load for these tests. As a result of thermal aging process, the samples were waited in room temperature and then statically tensile tests were conducted. The tensile tests were realized in 100 kN capacity Instron BS8801 tensile testing machine with 1 mm/min tensile speed. The loads were applied to the samples until the ultimate failure was observed. The load and extension values, which were obtained from tensile testing machine, were recorded into the computer. At the end of experiments, the plotted graphs were obtained from these records. The experimental set-up and typical load-extension behavior of notched specimens were presented in Figure 2.

III.A. THE TIME CHANGING EFFECT ON THE FAILURE LOADS

The time changing effect on the failure loads were studied as 2, 4 and 6 hours for constant temperature at 80 °C. The failure loads of aged specimens were compared with un-aged specimens. The average maximum loads of composites were presented in figure 3.

FIGURE 3. THE AGING TIME EFFECT ON THE FAILURE LOADS FOR 80 °C CONSTANT TEMPERATURE VALUE.

It can be seen from Figure 3, the failure loads were decreased with increasing aging-time. The maximum failure load was obtained for a=5 mm and un-aged specimen (stayed in room temperature) as 18087.69 N. The minimum failure load was obtained for a=15 mm and aged specimen in 6 hours at 80°C temperature as 12969.65 N. When the aged specimen's results are compared with un-aged specimen's results, it is observed that the decreasing rates of failure loads vary in a certain interval as 7.7% - 19.9% . The all decreasing rates obtained from tensile test are presented in Table 2. It was observed from Table 2, aging time is an effective parameter on failure load for glass fiber reinforced composites. On the other hand, it can be said that notch width is not important for maximum damage behavior as far as thermal aging.

TABLE II. THE VARIATIONS OF TIME, TEMPERATURE AND NOTCH GEOMETRY.

Time	2 hour	4 hour	6 hour
a=5 mm	7.7	17.4	19.9
a=10 mm	10.8	18.8	19.6
a=15 mm	11.2	16.9	18.4

III.B. THE TEMPERATURE CHANGING EFFECT ON THE FAILURE LOADS

The temperature changing effect on the failure loads were studied as 80, 120 and 160 °C for constant time at 4 hours. The failure loads were presented in figure 4.

FIGURE 4. THE AGING TEMPERATURE EFFECT ON THE FAILURE LOADS FOR 4 HOURS CONSTANT AGING TIME.

The increasing of temperature leads to decrease both a=5 mm notched and un-notched specimen's failure loads as seen in

Figure 4. The maximum failure load was obtained for un-aged and un-notched specimen as 42118.43 N. The minimum failure

load was obtained as 13482.55 N for notched and aged specimen in 160 °C. The failure loads of thermo-aged specimens were compared to un-aged specimens.

The calculated decreasing rates were presented in Table 3.

TABLE III. DECREASING RATES (%) OF THE FAILURE LOADS FOR TIME CHANGING IN AGING PROCESS AT 4 HOURS.

Temperature	80 °C	120 °C	160 °C
Notched (a=5 mm)	17.4	24.7	25.4
Un-Notched	6.8	9.6	12.9

It can be said that, the V notch were decreased the failure loads of composite plates in figure 4. The failure loads of notched and aged specimens were compared with un-notched and un-aged

specimens. The failure loads of notched composite plates (a=5mm) for 0, 80, 120 and 160 °C were decreased as 57.1%, 62.4%, 64.2% and 63.2% rates, respectively.

III.C. THE FAILURE STARTING AND PROPAGATING IN V-NOTCHED SPECIMENS

In the experimental study, the failure starting and propagating were observed, additionally. The failure mechanisms are showed in Figure 5. Stress concentrations at the tip of notch occur because of the notches. This situation leads to failure starting at this location. When the ultimate failure is realized, it is expected that the composite plate can cracked and breaking occurred. But, in the experimental analysis, it was observed that the matrix failure (epoxy resin) was obtained and fibers fractured. The failure started and propagated along the fiber direction.

FIGURE 4. THE FAILURE STARTING AND PROPAGATING IN V NOTCHED COMPOSITE PLATES. (TEMPERATURE 120 °C, TIME 4 HOURS, A= 5 MM).

IV. CONCLUSIONS

In this study, the thermo-aging effect on the V-notched glass/epoxy laminated composite plates was investigated experimentally and some of aspects are concluded as follows:

- The failure loads were decreased with opened notch as 57.1%-64.2% rates according to the un-notched composite plates. It is expected situation for failure analysis.
- The increasing of temperature was decreased the failure load for un-notched composite plates as 6.8%-12.9% rates.
- The increasing of temperature was decreased the failure loads of V notched composite plates ($a=5\text{mm}$) as 17.4%-25.4% rates. So, it can be said that variation of temperature is more important parameter on maximum failure load for notched composites
- The increasing of exposure time was decreased the failure loads of V notched composite plates 7.7% - 19.9% rates.
- Variation rates of maximum failure loads remains constant ($\sim 18\%$) for 4 and 6 hours for all notch width. It is seen from results that high curing time does not change variation rates.
- Generally, obtained results shows that thermal aging effect on maximum failure load is independent from notch length and thermal aging is more important effect that reduces the strength for composite materials. Designers of laminated composite plates should choose material and product composites considering this effect in the manufacturing stages.

Abstract—In this study, magneto-hydrodynamic mixed convection of alumina-water nanofluid over a backward-facing step was numerically investigated for various electrical conductivity models. The bottom and top wall of the channel are heated and cooled isothermally while other walls assumed to be adiabatic. Finite element method was used to solve the governing equations. Effects of Hartmann numbers, inclination angles of magnetic field and solid volume fraction of nanoparticles are numerically investigated for three different electrical conductivity models. It was observed that the convective heat transfer characteristics are affected by the variation of these parameters and there exists discrepancy between different electrical conductivity models.

Keywords—nanofluids, electrical conductivity, backward-facing step, mixed convection

XVII. INTRODUCTION

Flow separation and reattachment is of importance in many engineering applications such as flow around buildings, MEMs, airfoils and many others. This phenomenon occurs also for flow over backward/forward facing step geometry [1–11]. The mixed convection studies deals with the complicated interaction between the forced and natural convection effects. Various geometrical configurations and boundary conditions for the mixed convection case has been studied extensively. To increase the convective heat transfer coefficients, convective heat transfer fluids are replaced by nanofluids. Nanofluids are known as new type of heat transfer fluids which consist of nanometer sized particles (nanoparticles sizes 1-100 nm) suspended in the base fluids. They were proved to perform better for heat transfer applications as compared to base fluids. The size, shape and type of nano-particles are effective for the heat transfer enhancement of the base fluid [12, 13]. The influence of magnetic field on electrical conductivity and heat transfer with nanofluids is important for the engineering applications such as coolers of nuclear reactors, purification of molten metals and many other systems. Nanoparticles could be added to the base fluid to affect the thermal conductivity of the

base fluid. In the literature, there are various electrical conductivity models for the nanofluids. In this study, we numerically examined the MHD mixed convection of nanofluid over a backward-facing step for various electrical conductivity models. Effects of various pertinent parameters such as Hartmann number, magnetic inclination angle, solid particle volume fraction on the flow and heat transfer characteristics over a backward-facing step geometry where flow separation and reattachment occurs were analyzed for different electrical conductivity models.

XVIII. MATHEMATICAL FORMULATION

A schematic description of the geometry is shown in Fig 1. The backward step size is H and the height of channel is $3H$. At the inlet of the channel velocity is imposed as parabolic and the temperature is uniform. The channel has a length of $40H$. The walls of the channel are assumed to be adiabatic, except the bottom wall downstream of the channel and the top wall. The working fluid is alumina-water nanofluid under the influence of an oriented magnetic field. The thermophysical properties of the fluid are assumed to be constant. The flow is assumed to be laminar and 2D. Table 1 presents the thermophysical properties of water and alumina nanoparticles at reference temperature.

Fig.1. Schematic diagram of the physical model with boundary conditions

TABLE 1: THERMOPHYSICAL PROPERTIES

Property	Water	Al ₂ O ₃
$\rho(\text{kg/m}^3)$	997.1	3970
$C_p(\text{J/kgK})$	4179	765

K (W/mK)	0.6	25
B (1/K)	2.1×10^{-4}	0.85×10^{-5}

Conservation equation of mass, momentum and energy in a 2D Cartesian coordinate system can be written in dimensional form.

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (1)$$

$$\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = -\frac{1}{\rho_{nf}} \frac{\partial p}{\partial x} - v_{nf} \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) + \frac{\sigma_{nf} B_0^2}{\rho_{nf}} (\sin(\gamma) \cos(\gamma) - \sin^2(\gamma)) \quad (2)$$

$$\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = -\frac{1}{\rho_{nf}} \frac{\partial p}{\partial x} - v_{nf} \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) + \beta_{nf} g (T - T_c) + \frac{\sigma_{nf} B_0^2}{\rho_{nf}} (\sin(\gamma) \cos(\gamma) - \sin^2(\gamma)) \quad (3)$$

$$\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha_{nf} \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) \quad (4)$$

Following parameters can be used to non-dimensionalize the governing equations:

$$X = \frac{x}{H}, Y = \frac{y}{H}, U = \frac{u}{u_0}, V = \frac{v}{u_0}, P = \frac{p}{\rho_f u_0^2}, \theta = \frac{T - T_c}{T_h - T_c}, Gr = \frac{g \beta_f (T_h - T_c) H^3}{\nu_f^2}, Pr = \frac{\nu_f}{\alpha_f}, Ra = Gr Pr \quad (5)$$

$$Ha = B_0 H \sqrt{\frac{\sigma_f}{\mu_f}}, Re = \frac{u_0 H}{\nu_f}, Ri = \frac{Gr}{Re^2}$$

A. Nanofluid effective thermo-physical properties

The effective thermophysical properties of nanofluids are defined by using the following formulas:

$$\rho_{nf} = (1 - \phi) \rho_{bf} + \phi \quad (6)$$

$$(\rho c_p)_{nf} = (1 - \phi) (\rho c_p)_{bf} + \phi (\rho c_p)_p \quad (7)$$

Thermal expansion coefficient of the nanofluid is;

$$(\rho \beta)_{nf} = (1 - \phi) (\rho \beta)_{nf} + \phi (\rho \beta)_p \quad (8)$$

The effective thermal conductivity of the nanofluid includes the effect of Brownian motion. Effects of particle size, particle volume fraction and temperature are taken into account :

$$k_{nf} = k_{st} + k_{Brownian} \quad (9)$$

where k_{st} is the static thermal conductivity.

$$k_{st} = k_f \left[\frac{(k_p + 2k_f) - 2\phi(k_f + k_p)}{(k_p + 2k_f) + \phi(k_f + k_p)} \right] \quad (10)$$

The interaction between the nanoparticles and the effect of temperature are;

$$k_{Brownian} = 5 \times 10^4 \phi \rho_f c_{p,f} \sqrt{\frac{k_b T}{\rho_p d_p}} f(T, \phi, d_p) \quad (11)$$

$$\mu_{nf} = \mu_{st} + \mu_{Brownian} = \mu_f (1 - \phi)^{-0.25} + \frac{k_{Brownian}}{k_f} \times \frac{\mu_f}{Pr_f} \quad (12)$$

B. Electrical conductivity models for alumina-water nanofluid

In this study, three different electrical conductivity models for alumina-water nanofluids were considered. The first model was Maxwell's model which was developed for calculating the electrical conductivity for random suspension of spherical particles. For Maxwell model (M1 model), electrical conductivity of nanofluid is written as [14]:

$$\sigma_{nf} = \sigma_f \left(1 + \frac{3(f-1)\phi}{(f+2) - (f-1)\phi} \right) \quad (13)$$

The second model (M2) is an experimental study for alumina-water nanofluid effective electrical conductivity was obtained by Ganguly et al. [15]

$$\sigma_{nf} = \sigma_f (3679.049\phi - 1.085779T - 42.6384) \quad (14)$$

The electrical conductivity of the nanofluid enhances linearly with volume fraction and temperature.

The third model (M3) used in the study was the experimental correlation from Minea and Luciu [16]:

$$\begin{aligned} \sigma_{nf} = & 176.69 + 588.41(\phi \times 100) - 13.64T - 86.31(\phi \times 100)^2 + \\ & 0.36T^2 + 1.07(\phi \times 100)T + 11.06(\phi \times 100)^3 - 0.03T^3 + 0.18T^2 - \\ & 1.01T(\phi \times 100)^2 \end{aligned} \quad (15)$$

XIX. SOLUTION METHODOLOGY

To solve the governing equations, Galerkin weighted residual finite element method was used. In this method, computational domain was divided into non-overlapping regions and the field variables are approximated by using the Lagrange polynomials of different orders. The convergence of the solution is assumed when the relative error is less than 10^{-6} . The grid independence of the solution is assured and the code is validated by using various sources in the open literature (results are not shown here).

Local Nusselt number is calculated by using the following given equation:

$$Nu_x = -\frac{k_{nf}}{k_f} \left(\frac{\partial \theta}{\partial n} \right)_{wall} \quad (16)$$

Average Nusselt number is calculated along the hot wall of the bottom wall downstream of the step by using:

$$Nu_m = \frac{1}{L} \int_0^L Nu_x dx \quad (17)$$

where L denotes the length of the bottom wall downstream of the step.

IV. RESULTS AND DISCUSSION

Numerical study of nanofluid flow over a backward facing step for the mixed convection under the effect of oriented magnetic field for various electrical conductivity models is performed. It is expected that the variations of the flow conditions and by change of the thermo-physical properties, the transfer and fluid flow characteristics are changed. It is also expected different electrical conductivity models results in variations of heat transfer rates.

In the simulation, Richardson number was fixed to 0.5. In this regime, both forced and natural convective effects are important. Effects of Hartmann number on the streamline and isotherm distributions are demonstrated in Figure 2 for Maxwell model (M1 model). Flow separates at the edge and a recirculation region is formed behind the step. As the value of Hartmann number increases, the length of the separation reduces and it is restricted to a small zone near the step. Steep thermal gradients are seen near the reattachment point and it is getting denser for higher Hartmann values. Table 2 presents the results of average Nusselt number for various Hartmann number and electrical conductivity models. For higher values of Hartmann number, average Nusselt number becomes higher for model 1, but for M2 and M3 model, at the highest value of Hartmann number its value becomes lower which is due to the different electrical conductivity of the models. The sensitivity of M2 and M3 models for changes in Nusselt number with respect to a change in Hartmann number is higher as compared to M1 model.

Effects of varying magnetic inclination angle on the streamline and isotherm distributions are demonstrated Figure 3. There are some small variations in the flow and isotherm structures behind the step. Table 3 presents the results of average Nusselt numbers for different inclination angles and different electrical conductivity models. Average heat transfer rate enhances with magnetic inclination angle which is due to the effect of Lorentz forces caused by magnetic field in the x and y momentum. There are variations in different models (M1, M2 and M3) and the rate of change is lower for Maxwell model (M1) as compared to other models.

Adding nanoparticles to the water results in thermal conductivity enhancement. In this study, alumina solid particle volume fraction up to 0.03 was used. As it is seen in Table 4, the average heat transfer rate increases with nanoparticle addition for all considered models. Average heat transfer enhancement is lowest for M1 model while it is highest for M2 model. For M1 model only 4.36% heat transfer enhancement was obtained while 8.04% was achieved for M2 model at the highest volume fraction as compared to solid volume fraction of 1%.

TABLE II.AVERAGE NUSSELT NUMBER FOR VARIOUS HARTMANN NUMBERS AND ELECTRICAL CONDUCTIVITY MODELS (M1,M2,M3)

Hartman Number	Averaged Nusselt Number		
	Model 1	Model2	Model3
0	7.365	7.365	7.365
20	7.784	8.045	7.719
40	8.080	7.594	6.216

Abstract—In this study, mixed convection of alumina-water nanofluid over a backward-facing step was numerically studied. The bottom wall of the channel is kept at constant hot temperature while the top wall is at isothermal cold temperature. The governing equations were solved with Galerkin residual finite element method. Effects of various parameters such as Richardson number (between 0.01 and 20) and solid volume fraction of nanoparticles (between 0 and 0.04) on the convective heat transfer characteristics are numerically studied. Average Nusselt numbers increases with increasing solid volume fraction of nanoparticle and decreases with Richardson number. The rate of the enhancement is about 8.5% at the highest volume fraction.

Keywords- backward-facing step, nanofluids, fem

I. INTRODUCTION

There are many various engineering applications such as flow around buildings, electronic devices, combustors, airfoils and collectors of power systems where flow separation and reattachment occurs as in flow over backward/forward facing step geometry [1–11]. The complex interaction between the natural and forced convection is very complicated in practical engineering systems and various studies have been performed for different geometries and boundary conditions. In convective heat transfer, nanofluids offer a great advantage to enhance the heat transfer coefficients [12, 13]. Nanofluids are known as new generation heat transfer fluids which consist of nanometer sized particles (nanoparticles sizes 1-100 nm) suspended in the base fluids. Nanofluids have been proved that they are better heat transfer fluids than base fluids. The size, shape and type of metallic or non-metallic nano-sized particles are effective for the heat transfer enhancement of the base fluid.

In this study, we study the mixed convective heat transfer for a backward facing step geometry with nanofluids. The aim was to numerically analyze the effects of various pertinent parameters such as solid particle volume fraction on the flow and heat transfer characteristics over a backward-facing step geometry where flow separation and reattachment occurs.

II. MATHEMATICAL FORMALISM

Fig 1 depicts a schematic description of the physical problem for a channel with a backward facing step. The backward step size is H and the height of channel is $3H$. At the inlet of the channel velocity defined as parabolic and the temperature ($T=T_c$) is uniform. The downstream length of the channel beginning from the step to the outlet is $40H$. The bottom wall downstream of the channel is maintained at ($T = T_h$). The channel is filled with alumina-water nanofluid for different solid particle volume fraction. The flow is assumed to be laminar and 2D. Thermophysical properties of water and alumina is given in Table 1.

Fig.1. Schematic diagram of the physical model with boundary conditions

TABLE 1: THERMOPHYSICAL PROPERTIES

Property	Water	Alumina
$\rho(\text{kg/m}^3)$	997.1	3970
$C_p(\text{J/kgK})$	4179	765
$K(\text{W/mK})$	0.6	25
$\beta(1/\text{K})$	2.1×10^{-4}	0.85×10^{-5}

Conservation equations of mass, momentum and energy in a two dimensional Cartesian coordinate system can be written in dimensional form as follows:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (1)$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = -\frac{1}{\rho_{nf}} \frac{\partial p}{\partial x} + \nu_{nf} \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) \quad (2)$$

$$u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} = -\frac{1}{\rho_{nf}} \frac{\partial p}{\partial y} + \nu_{nf} \left(\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} \right) + \beta_{nf} g (T - T_c) \quad (3)$$

$$\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha_{nf} \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) \quad (4)$$

Non-dimensional form of the above equations can be obtained by using the following parameters:

$$X = \frac{x}{H}, Y = \frac{y}{H}, U = \frac{u}{u_0}, V = \frac{v}{u_0}, P = \frac{p}{\rho_f u_0^2}$$

$$\theta = \frac{T - T_c}{T_h - T_c}, Gr = \frac{g \beta_f (T_h - T_c) H^3}{\nu_f^2}, Pr = \frac{\nu_f}{\alpha_f}, Ra = Gr Pr$$

$$Re = \frac{u_0 H}{\nu_f}, Ri = \frac{Gr}{Re^2} \quad (5)$$

A. Nanofluid effective thermo-physical properties

The effective thermo-physical properties of nanofluids are defined by using the following formulas:

$$\rho_{nf} = (1 - \phi) \rho_{bf} + \phi \rho_p \quad (6)$$

$$(\rho c_p)_{nf} = (1 - \phi) (\rho c_p)_{bf} + \phi (\rho c_p)_p \quad (7)$$

Thermal expansion coefficient of the nanofluid is;

$$(\rho \beta)_{nf} = (1 - \phi) (\rho \beta)_{nf} + \phi (\rho \beta)_p \quad (8)$$

The subscript 'bf' denotes the base fluid, 'nf' is nanofluid, 'p' is the solid particle. The effective thermal conductivity of the nanofluid includes the effect of Brownian motion. Effects of particle size, particle volume fraction and temperature are taken into account :

$$k_{nf} = k_s + k_{Brownian} \quad (9)$$

where k_s is the static thermal conductivity,

$$k_{st} = k_f \left[\frac{(k_p + 2k_f) - 2\phi(k_f + k_p)}{(k_p + 2k_f) + \phi(k_f + k_p)} \right] \quad (10)$$

The interaction between the nanoparticles and the effect of temperature are;

$$k_{Brownian} = 5 \times 10^4 \phi \rho_f c_{p,f} \sqrt{\frac{k_b T}{\rho_p d_p}} f'(T, \phi, d_p) \quad (11)$$

$$\mu_{nf} = \mu_{st} + \mu_{Brownian} = \mu_f (1 - \phi)^{-0.25} + \frac{k_{Brownian}}{k_f} \times \frac{\mu_f}{Pr_f} \quad (12)$$

III. SOLUTION METHODOLOGY

Galerkin weighted residual finite element method was used to solve the governing equations. The computational domain was divided into non-overlapping regions and the field variables are approximated by using the Lagrange polynomials of different orders. The convergence of the solution is assumed when the relative error is less than 10^{-6} . The grid independence of the solution is assured and the code is validated by using various sources in the open literature (results are not shown here).

Local Nusselt number is calculated by using the following given equation:

$$Nu_x = - \frac{k_{nf}}{k_f} \left(\frac{\partial \theta}{\partial n} \right)_{wall} \quad (13)$$

Average Nusselt number is calculated along the hot wall of the bottom wall downstream of the step by using:

$$Nu_m = \frac{1}{L} \int_0^L Nu_x dx \quad (14)$$

IV. RESULTS AND DISCUSSION

In this study, a numerical study of nanofluid flow over a backward facing step for the mixed convection is presented. It is expected that the variations of the flow conditions and by change of the thermo-physical properties, the transfer and fluid flow characteristics are changed.

Effects of Richardson number on the streamline and isotherm distributions are demonstrated in Figure 2. Richardson number is the ratio of the natural convection to the forced convection. Ri number was varied by changing the Reynolds number while keeping the Grashof number fixed. Therefore, an increment in the Ri number results in reducing the incoming velocity. The length of the recirculation zone behind the step reduces in size for higher Ri values which is due to the reduction of the x-velocity component and the effects of natural convection becomes important. Steep thermal gradients are seen near the reattachment point. Variations of the local and average heat transfer rates are given in Figure 3 and Figure 4. The location where the highest heat transfer rates are seen becomes closer to the step for higher values of Ri number. Average Nusselt number decreases with Ri number. Average heat transfer rate is reduced by about 56.13% at the highest value of Ri when compared to value for Ri=0.01.

Adding nanoparticles to the water results in thermal conductivity enhancement. In this study, solid particle volume fraction up to 0.04 was used. As it is seen in Figure 5, local Nusselt number increases for higher particle volume fraction. The rate of the enhancement is higher for the location away from the step after the maximum in the local Nusselt number is seen. Average Nusselt number increases linearly with solid particle volume fraction (Figure 6). Average heat transfer rate increases by about 8.5% at the highest volume fraction as compared to the base fluid.

Abstract— Electricity generation from renewable energy sources has a significant presence in Turkey's energy mix in recent years. In 2016, wind energy has 21.2% share among the new installed renewable power sources in Turkey. Wind energy accepted as one of the clean energy sources, but during manufacturing, construction, utilization and decommissioning stages wind turbine power plants have some adverse effects on environment. In this study carbon footprint and energy payback time of a 2 megawatt wind turbine, which is assumed to be installed on Develi/Kayseri, are calculated by using life cycle assessment approach. Life cycle assessment methodology is used to determine the environmental impacts of a system or product by compiling inputs and outputs from raw material extraction to recycling. Firstly, measured annual hourly wind velocities are processed to determine the wind potential of Develi and by using the power curve of selected wind turbine annual electricity production is predicted. In life cycle assessment stage, selected wind turbine's material and energy inputs are collected from manufacturers, literature, field research and assumptions. Functional unit is selected as 1kWh electricity production and lifetime of wind turbine is selected as 20 years. Collected data are entered the GaBi life cycle assessment software to obtain life cycle model and to determine the system descriptions. Results showed that carbon footprint of selected wind turbine is calculated as 3.93E-2 kg- CO₂/kWh and energy payback time of selected wind turbine is calculated as 37 months.

Keywords— carbon footprint; energy payback time; life cycle assessment; renewable energy, wind turbine.

I. INTRODUCTION

Renewable and non-renewable energy sources can be used to produce useful energy such as heat or electricity. Renewable energy sources (wind, hydropower, geothermal, biomass, solar energy) can replenish themselves in a short span of time. Non-renewable energy sources (coal, oil, natural gas, nuclear) can take to form thousands of years and they use up much faster than they are produced [1]. At present, besides the energy production affairs both from renewables and non-renewables, some environmental effects became current issues. Energy conversion from wind power into electricity is one of the cleanest and most

sustainable ways to produce electricity. Wind is caused by variable heating and cooling of the earth's surface. Windmills were using for water pumping and wheat processing in ancient times, but since twentieth century they have been using to generate electricity. Nowadays, wind energy is the fastest growing source of electricity together with hydro. Wind energy is accepted as emission-free source of energy. But they have some harmful effects on the environment. Today, to determine the environmental effects of electricity generation from wind power during the lifetime such as carbon footprint, life cycle assessment methodology is used. The aim of this study, to determine the carbon footprint of a 2 megawatt capacity wind turbine which is assumed to be installed on Develi. Moreover, energy payback time of selected wind turbine is calculated [2-4].

II. WIND ENERGY POTENTIAL OF DEVELI

Generated energy from a wind turbine is based on the wind potential of operation area and characteristics of selected wind turbine in general. Before installing of a wind turbine on a region, wind characteristics of selected area must be estimated. In this work, wind potential of Develi is analyzed. Develi is located at 38°23' latitude (N) and 35°29' longitude (E) with 1330 m altitude. Firstly, annual hourly wind speed and wind direction data, which were observed by Turkish State Meteorological Service at 10 m altitude, is processed on computer, so methodical wind data are obtained. Wind is exposed to some obstacles and surface roughness on the surface of the earth. So, wind velocity changes with height. Therefore, wind speed at 100 m altitude must be calculated. To calculate the wind speed at 100 m height, log law which is given in the following equation is used [5-7].

$$v = v_0 \left(\frac{\ln z/z_s}{\ln z_0/z_s} \right) \quad (1)$$

where, v is the wind velocity at the altitude of z , z_0 is wind speed at the height of z_0 and z_s is selected as 0.15 which is surface the roughness factor and depends on region. By using (1) annual wind speed data at 100 m height are calculated. Results show that mean and maximum wind speeds are 4.32 and 26.84 m/s, respectively. Annual mean wind speed data are given in “Fig. 1”. The graph shows that monthly mean wind speeds reach to the highest levels in April, March and June.

In this study, 2050 kW rated power capacity Enercon E82 brand wind turbine is selected for calculations with 2 m/s cut-in speed, 25 m/s cut-out speed, 100 m hub height and 82 m rotor diameter. To obtain the generated power at 100 m height from the selected wind turbine, power curve is used. “Fig. 2” shows the output power of selected wind turbine that varies with the wind speed. The graph shows that turbine starts to generate power the wind speed of 2 m/s and this point is called cut-in speed. The generated power reaches the maximum at the 13 m/s and this point is called rated output speed.

Moreover, to obtain the power for a given wind speed, 6th degree polynomial equation is derived by using curve fitting method applying on power curve. By substituting the annual hourly wind speed data into the 6th degree polynomial equation hourly generated power ($P_i(v)$) for a given speed is calculated. Annual total amount of generated power (E_p) is calculated by summing the hourly generated powers and defined in the following equation:

$$E_p = \sum_{t=1}^n P_i(v) t \quad (2)$$

where t is defined as one hour period and n is defined as the total number of hours. In this work n is selected as 8760, which is the total number of hours in a year.

Fig. 1. Monthly wind speed of Develi

Fig 2. Power curve of 2 megawatt wind turbine

III. LIFE CYCLE ASSESSMENT OF A 2 MEGAWATT WIND TURBINE

Life cycle assessment is defined as the methodology to evaluate the environmental impacts related to raw material extraction, production, assembly, use, dismantling and recycling stages of a system or product. Life cycle assessment consists of 4 stages and each stage interact with each other [8-9].

In goal and scope definition stage, purpose of the work, functional unit, system boundary, assumptions and target groups must be defined clearly. In this study, functional unit, which is used to compare the results, is selected as 1 kWh electricity generation by 2 megawatt wind turbine, system boundary consists of raw material extraction throughout dismantling and recycling, target groups defined as private sector, universities, ministries, decision makers and local governments. The lifetime of the wind turbine is selected as 20 years. GaBi life cycle assessment software tool is used for evaluations [10]. During inventory analysis stage, material and energy inputs must be gathered in accordance with system boundary to calculate the environmental impacts by using GaBi software. For this study, input data are gathered from wind turbine manufacturers, literature and active wind power plants. Selected wind turbine is assumed to be consist of foundation, nacelle, rotor, tower and other components [11-13]. Material input mass percentages are given in “Fig. 3”. The graph shows that foundation of wind turbine shares the maximum amount of material input by mass.

Fig. 3. Material mass inputs by turbine component

Fig. 4. Embodied energy by turbine component

Impact categories must be selected at impact assessment phase. For this study carbon footprint (kg CO₂-equivalent) is selected as impact category and CML2001 is selected as impact assessment method for calculations. Interpretation stage is the last stage of a life cycle assessment work and results are evaluated at this stage.

IV. RESULTS

Embodied energy (E_{Embodied}) is defined as consumed energy by a wind turbine's whole life cycle and calculated as $4.04\text{E}+6$. Also, energy payback time (E_{PT}) of selected wind turbine is defined as the consumed energy over produced energy (E_{Produced}) in a year and given in the following equation:

$$E_{\text{PT}} = \frac{E_{\text{Embodied}}}{E_{\text{Produced}}} \quad (3)$$

Embodied energies consumed by turbine components are given in the "Fig. 4" and the graph shows that foundation, nacelle and tower consume more energy during the whole life cycle of selected wind turbine.

Carbon footprint of 2 megawatt wind turbine is calculated by compiling the collected material and energy data into GaBi software. Results show that carbon foot print of selected wind turbine is $1.01\text{E}+6$ kg CO₂-mass. Effects of wind turbine components on carbon footprint are given in "Fig. 5". According to the graph amount of contribution on carbon footprint is higher for foundation with the 37 percentage.

By applying the (2), the total amount of energy E_p is calculated as $1.28\text{E}+6$ kWh. Life time of the wind turbine is selected as 20 years so the total amount of energy generated is calculated as $2.56\text{E}+7$ kWh. Carbon footprint of the selected turbine per kWh defined as the ratio of carbon footprint to the total amount of energy generated over 20 years and calculated as $3.93\text{E}-2$ kg-CO₂/kWh. By using (2) and (3) energy payback time is calculated as 37 months.

Fig. 5. Carbon footprint by turbine component

V. CONCLUSION

2 megawatt wind turbine assumed to be installed on Develi is selected to evaluate the carbon footprint per kWh and energy payback time. For this purpose, wind energy potential of Develi is analyzed and by using annual hourly actual wind speed data electricity production of selected wind turbine are calculated. Moreover, life cycle analyses of selected wind turbine are carried out by using GaBi software, functional unit is selected 1kWh electricity production and life time is assumed to be 20 years.

Main carbon footprint contribution of turbine components is caused by foundation and nacelle with 37% and 26%, respectively. Embodied energy of turbine components mainly originates from the foundation and nacelle with 28% and 27%, respectively. New developments on manufacturing processes of turbine components or material selection processes of wind

turbine components such as carbon fiber usage can reduce the contributions on carbon footprint and embodied energy in order to maintain the sustainability.

Energy payback time is crucial parameter for energy production facilities. It depends mainly on material used and manufacturing techniques also wind power characteristics of the turbine installed site. In this study, it is calculated as 37 months. Energy payback times of some other energy production techniques are specified as 49 months, 8 to 36 months and 10 to 40 months for solar photovoltaic power plants, wind turbines and geothermal power plants, respectively [14, 15].

Results of this study can be used by environment concerning institution, decision makers or investors who intend to install wind power plant in Develi.

Abstract— in the present paper, a numerical investigation is carried out using Ansys APDL for the active vibration reduction of smart composite plate. The structure composed of composite plate with three piezoelectric actuators bounded on their upper surface. PID algorithm code is developed and integrated in Ansys to provide damping to the smart composite plate.

Keywords—composite; vibraion; PID controller

Introduction (Heading 1)

Active vibration reducing techniques turn out to be a reality in wide range of applications. Motivated by the piezoelectricity phenomena, the active vibration technique require, bonding piezoelectric patches in a conventional structures to make a kind of smart structure which have the ability of self-control. Recently large numbers of research papers were focused on the mathematical modeling of smart structures using finite element method. [1] developed a finite element model based on third order laminate theory for the active vibration control of composite beams with distributed piezoelectric sensors and actuators. [2] developed a finite element formulation for modeling and analysis of isotropic as well as orthotropic composite beams with distributed piezoelectric actuators subjected to both mechanical and electrical loads. [3] suggested a finite element method (FEM) of to study the active vibration control smart FGM beam based on higher-order shear deformation theory. Piezoelectric sensors and actuators distribution on the structure disturb the control performance, hence many researchers were interested by the search of the most appropriate location that lead to cost and weight reduction. [4] presented an approach based on the Rayleigh–Ritz (RR) assumed mode shape method to predict the behavior of a thin plate with piezoelectric patches bonded to its surface. [5] proposed optimization technique of the placement and size and the feedback control gains of the control system for vibration damping of beam structures. [6] studied the optimization of the size and location of piezoelectric actuators/sensors, and the controller parameters of composite beam by using the particle swarm optimization algorithm. Moreover, extra research papers are used commercially software such Ansys has the ability to model piezoelectric materials and perform the investigation of

the active vibration control. [7] proposed a performance criterion for the optimization of piezoelectric patch actuator locations on flexible plate structures using Ansys and genetic algorithm. [8] dealt with the active control of a smart laminate composite structure (SLCS) by using type of controllers direct velocity feedback (DVF) and displacement feedback (DF) controls with constant gain are used. [9] proposed prototype developed in Ansys for the active vibration control of lightly damped cantilever aluminum using a linear quadratic controller (LQ). [10] coupled Ansys and Matlab to study the active vibration control of a cantilever beam by means piezoelectric patch and PID controller.. In the present work, numerical study of active vibration control of composite plate using PID control algorithm is carried out. The structure was accomplished in the commercial finite element software Ansys, and then a PID control law is designed and integrated in Ansys to perform closed loop simulations.

VI. MODELING OF SMART COMPOSITE PLATE

A. Modal analysis

Consider a smart composite plate bonded by three piezoelectric actuators. It must be noted that the location of the piezoelectric actuator is determined based on [7], [11].. The host plate is made of four graphite–epoxy (carbon-fiber reinforced) layers. Each layer is of thickness 3/4 mm, while the orientations is take as (0 45 -45 90), the piezoelectric actuator is made of PZT5A fiber composite. The material properties of the considered structure are given in table 1. The simulation process has been carried out using Ansys and it's depicted in the flowchart given in Fig. 1.

In the present section, the proposed model is subjected to a modal analysis .The Block Lanczos method is used for performing modal analysis in ANSYS to find the frequencies and mode shape of the composite plate with piezoelectric actuator. First four frequencies are given in Table 2. Fig. 2 presents the first four mode shape

The model has been loaded with a nominal force of -2 N with an impulse lasting 0.01 s modeling the effect of deflection of the plate away from the equilibrium position and letting it go without any further force interactions. The displacement of the composite plate with and without PID controller is presented in Fig. 3. It can be noticed that the PID controller is successfully reduced the vibrations. The figure showed that the vibrations attenuated quickly in terms of amplitude and time. The input control voltage for each actuator is presented in Fig. 4.

Fig. 3. Tip deflection of the composite plate with and without PID controller.

Fig 4. Applied voltage on the three actuators.

CONCLUSION

In this study, we present an approach to Integrate PID control algorithm into the finite element commercial software Ansys to investigate the active vibration control of composite plate with surface bounded piezoelectric actuators. The benefit behind this technique is it does not require any mathematical model. Some macros that are combined with finite element solutions are developed to design a proper controller. Assumptions assigned in a simulation should be tested with analytical solutions and experiments. The results prove that the technique is efficient for the study of active vibration control and it motivated us to use it in more complex structures.

Abstract—Sunlight is converted into electrical energy by the help of photovoltaic (PV) panels obtained by semiconductor materials. However, the power values obtained from the PV panels varies continuously due to low efficiency of the panels and the atmospheric conditions changing throughout the day. This is the main drawback of the PV energy systems. Therefore, the output power obtained from PV panels must be at maximum level all the time. However, PV panels, which are subject to partial shadowing due to various reasons such as clouds, buildings, trees, are getting weaker and many maximum power points appear in the system. In this study, the mathematical model of the PV panel in the 100 Watt power plant was developed and the partial shading condition of one of the six series PV panels was examined with the solar array simulator (SAS). It has been observed that different maximum power points occur by obtaining current-voltage (I-V) and power-voltage (P-V) curves according to different shading ratios. The most appropriate maximum power point (MPP) for the system is determined by the conducted analyses.

Keywords—*partial shading; maximum power point; PV panel; solar array simulator*

VII. INTRODUCTION

After the introduction of the mechanized industry emerged from Industrial Revolution, fossil-based resources such as coal and oil have begun to be used as energy sources. Although oil-derived resources are mostly used today, the search for energy sources that can be an alternative to these sources has also been continuing rapidly as a result of the fact that the gases resulting when the fossil fuels burn pollute the environment and these fuels will run out in the future. As a result, renewable energy sources such as wind, solar, geothermal and biomass have gained a great importance. The use of wind and solar energy, especially in the production of electricity has been more prominent among the other renewable energy sources. With the incentives and investments made in this area, it has become able to compete with other energy sources [1-3].

Among the existing alternative energy sources, PV energy is one of the most important renewable energy sources. The most important advantages of these energy sources are that the PV energy is clean and simple to install, not needing too much maintenance and providing power to megawatts. Moreover, the

PV energy has gained an increasing demand since it has been widely used in many areas such as water pumps, solar home systems, and remote buildings from the grid. However, the low efficiency of the PV panels, the variation of the atmospheric conditions during the day, and therefore the continuous change of the power values obtained from the PV panels occur the most important disadvantages of the PV energy systems. Therefore, in recent years, the recent studies have aimed at maximizing the energy level of the PV energy [4-7]. However, partial shadowing occurs when any part of the PV panel is shaded for various reasons such as clouds, buildings, chimneys and trees. This significantly affects the output power of the PV panel and therefore many MPPs occur. Particularly serial PV panels are very influenced by this situation. When one of the serial PV panels is subjected to partial shadowing in order to increase the voltage, the output power of the system decreases considerably. Moreover, hot spots are formed in the cells exposed to the shadow effect, which causes damage to the cells and causes power losses. Bypass diodes are connected parallel to the PV panels to eliminate these adverse effects [8-11].

In this study, Perlite brand PLM-100P/12 100 Watt polycrystalline structured PV panels are used and the mathematical model was formed in Matlab program by using the catalogue data of the panel. Six PV panels were connected to the system in serial and the power of the system was increased to 600W. The current and voltage information of the PV panels modeled in the Matlab program is loaded on the Chroma 62150H-600S brand SAS. The partial shadows of the PV panels with SAS and bypass diodes are examined at different ratios and the P-V curves of the panels are analyzed.

VIII. MATHEMATICAL ANALYSIS

A. The Analysis of the Photovoltaic Cell

In order to determine the values such as current, voltage and power obtained from the PV panels, it is necessary to determine the equivalent circuit model of the PV cell. The solar cell is produced by p-n semiconducting materials. Therefore, it is symbolized by a diode which is one of the basic elements electronics and a current source connected parallel to it. PV cell losses are represented by parallel-series resistance. The equivalent circuit model of the PV cell is shown in Fig. 1.

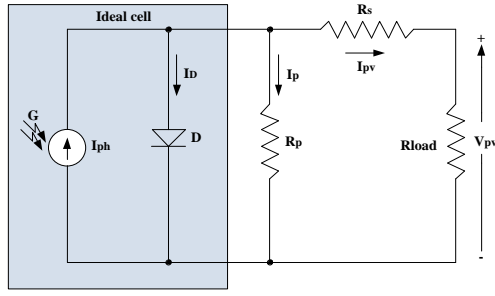

Fig. 4. Equivalent circuit model of PV cell.

Equation (1) obtained according to the circuit model in Fig. 1 [12].

$$I_{pv} = I_{ph} - \left[e^{\left(\frac{q(V_{pv} + I_{pv} \cdot R_s)}{A \cdot k \cdot T_c} \right)} - 1 \right] - \frac{V_{pv} + I_{pv} \cdot R_s}{R_p} \quad (1)$$

Where;

I_{ph} : Photovoltaic current of the PV cell

q : Electric charge (1.602×10^{-19} C)

A : Quality factor of diode

k : Boltzman constant ($1.3806505 \times 10^{-23}$ J/K)

T_c : PV cell temperature (in Kelvin)

The power-current (P-I), power-voltage (P-V), and current-voltage (I-V) characteristics for six series-connected PV panels are analyzed at 25 °C temperature and solar radiation changes under 250, 500, 750 and 1000 W/m² using the mathematical equivalent circuit model.

(b)

(c)

Fig. 5. The (a) P-I, (b) P-V and (c) I-V characteristics of panel.

B. Analysis of the Shaded PV Panel

In Fig. 3, six serial PV panels and a partially shaded panel are given.

Fig. 6. Series connected PV panels and partial shaded condition.

The short circuit current ($I_{sc}=0$) of the panel is zero in case of partial shading. In this case, the current passing through the circuit passes through the parallel resistance in the cells. The voltage of the shaded panel decreases since the value of the parallel resistor value is higher than the series resistance. This reduces the total voltage and power of the series connected PV panels. If the voltage of the PV panel is V_{pvn} while all the cells of the panel with the cell number n are under the sunlight, and the voltage of the single PV cell is V_{pvs} , then the voltage of the shaded panel is calculated as in Equation (2).

$$V_{pvs} = V_{pvn} - (R_p + R_s) \cdot I_{pv} - \frac{V_{pvn}}{n} \quad (2)$$

Shaded cells are also damaged by heat. To overcome these drawbacks, active bypass diodes are used in the event of shading. Bypass diodes are connected in parallel to the panel to allow current to flow through the diode and prevent damage to the panel [13].

IX. SAS RESULTS

In Fig. 4, six series-connected PV panels are shown in the simulator with I-V and P-V variations under 1000 W/m^2 of solar irradiance. The red dot of the simulator shows 600 W which is the maximum power rating of the panels.

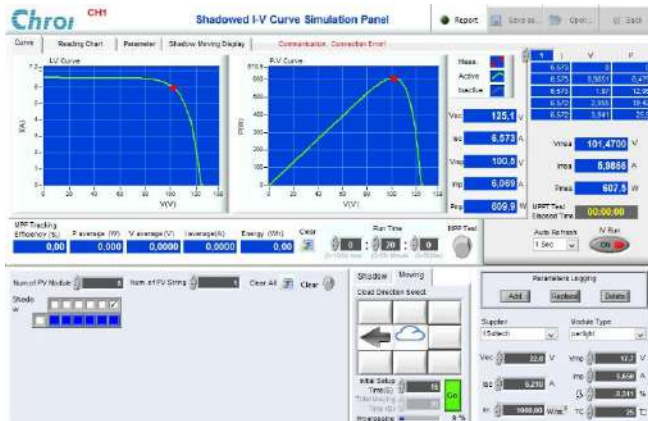

Fig. 7. I-V and P-V changes of the panels under 1000 W/m^2 solar irradiance.

When a panel is subjected to partial shadowing (shadow irradiation 400 W/m^2), the I-V and P-V characteristics shown in Fig. 5 are obtained.

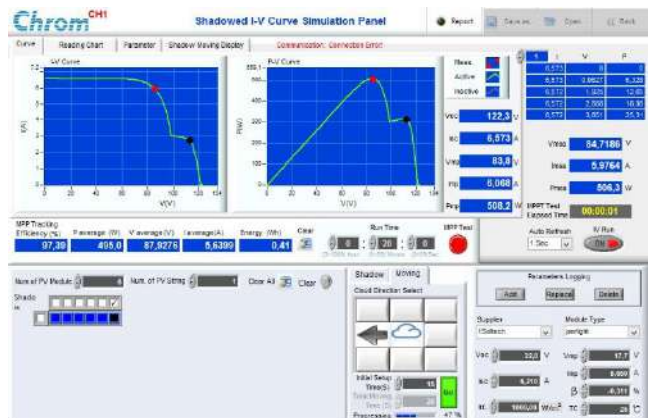

Fig. 8. I-V and P-V changes of one of the panels under 400 W/m^2 shadow irradiance.

When I-V and P-V characteristics shown in Fig. 5 are examined, it is seen that the total power is decreased to 500 W the same time, there are two maximum points due to partial shadowing. The dot in red is the global MPP, and the black dot is the local MPP. Fig. 6 shows the power, voltage, and current variations of the system subjected to the partial shadowing in the global MPP mode.

(a)

(b)

Fig. 9. (a) Power and (b) voltage-current changes of the system subjected to the partial shadowing operating at global MPP.

When the system is operating under the local MPP, the power decreases to approximately 300 W . In this case, the power of the system decreases even further. Fig. 7 shows the I-V and P-V variations obtained when one of the panels has a shadow irradiance of 600 W/m^2 .

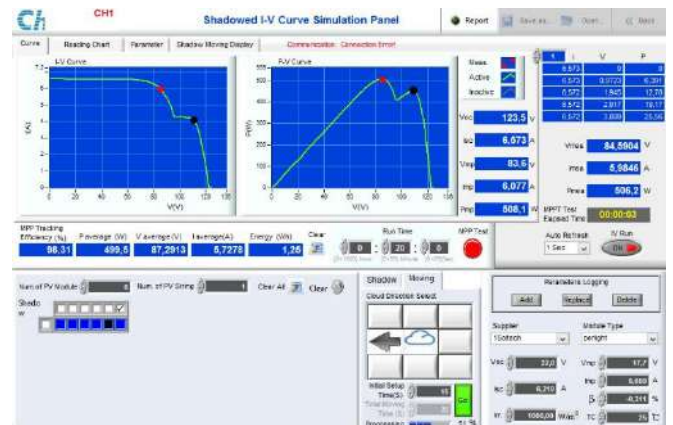

Fig. 10. I-V and P-V changes of one of the panels under 600 W/m^2 shadow irradiance.

When Fig. 7 is examined, it is seen that the global MPP value is 500 W and the local MPP value is about 450 W . In this case it can be said that when the value of the shadow irradiance increases, the local MPP value increases.

X. RESULTS AND DISCUSSION

It is seen that when one of the bypass diode series connected PV panels is subjected to partial shading for any reason, there are two maximum points in the system. One of them is the global and the other is local MPP. According to the simulator analyses, global MPP value is seen to be greater than the local MPP

value. Therefore, more power will be obtained when the PV systems subjected to partial shadowing operates in the global MPP. Therefore, it will be more convenient for the systems especially using the maximum power point tracking (MPPT) algorithm to operate in the global MPP rather than in the local MPP. Thus, more power will be obtained and utilized effectively in PV systems.

Abstract—The thermohydraulic behavior of equilateral triangular wire coil insert in a square duct is investigated by using ANSYS FLUENT v17. The results of Nusselt number and friction are compared with smooth pipe. Three different pitches ($P=54, 72$, and 90 mm) were examined in the range of Reynolds numbers between 4504 and 18415 . The Renormalized Group (RNG) $k-\epsilon$ turbulence model is used to evaluate the fluid domain. The testing fluid is selected as air and its thermal properties are considered temperature dependent in order to obtain actual fluid properties through the fluid domain. The results showed that Nusselt number increases with increasing Reynolds number and with decreasing the pitch ratio. The friction decreases with increasing Reynolds number and with increasing the pitch ratio. Nusselt number and friction factor raised around 37 to 93% and 82 to 266% . The Nusselt number of 54 mm pitch is higher than 72 and 90 mm around 4.5 and 6.9% , respectively. The friction of 54 mm pitch greater than 72 and 90 mm around 22 and 48% , respectively. The heat transfer performance of 90 mm pitch is around 30% compared with smooth pipe.

Keywords—heat transfer enhancement; wire coil; ANSYS

XI. INTRODUCTION

Heat exchanger uses in industry to cool or heat a system. In the past century, many studies have been done to enhance heat transfer in heat exchanger systems. Passive heat transfer technique is one of the popular examples of heat enhancement techniques. The passive techniques are required no external power for the system. In passive techniques, inserts are generally used to enhance heat transfer. The heat-transfer enhancements of these inserts are related with interconnection between their geometrical parameters and fluid domain. The wire coils are one of the popular ways for this purpose.

Gunes et al. [1] investigated the equilateral cross sectional wire coil inserted in a pipe. In this study, wire coils were separated from the wall to prevent the contamination formation. The effects of three different pitch ratios ($p/D=1, 2$, and 3) and the length side of triangle wire thickness to diameter ratios ($a/D, 0.0714$ and 0.0892) were investigated in the range of Reynolds number between 3500 and 27000 . Uniform heat-flux boundary

condition at the wall was applied. Results showed that the insert with high a/D and lower p/D had the best in the thermal performance factor which is around 36.5% compared with smooth pipe.

Garcia et al. [2] investigated the heat transfer and friction factor characteristics for laminar, transition, and turbulent regimes in circular tubes with helical wire coils having six different characteristic dimensions. The water and water-propylene glycol mixtures were used as the working fluids. The range of the pitch ratio was between 1.17 and 2.68 and the range of wire thickness to the diameter ratio (e/D) was between 0.07 and 0.10 . Results showed that when Reynold numbers smaller than 500 (in the pure laminar regime) wire coil effect on heat transfer enhancement was found very low, however, when the Reynolds number range was between 500 and 3000 (in transition region), there was considerable variation in heat transfer enhancement. In this region, the enhancement was strongly bounded on Prandtl number. Over 3000 Reynolds, Prandtl effect on the enhancement was observed as a negligible. Transition region was found the most effective region for the heat-transfer enhancement. For wire inserts with lower pitch ratio, heat transfer enhancement reached 200% in transition region. In another work of Garcia et al. [3], wire coil inserts having pitch ratios of $1.25, 1.72$ and 3.37 in a horizontal pipe were investigated. Reynolds number range was between 10 and 2500 and Prandtl range was between 200 and 700 . Wire coil effect on heat transfer enhancement was found negligible when Reynolds number was smaller than 200 , however, the results showed that the best performance was in the Reynolds number region between 200 and 1000 . Heat transfer coefficient of a pipe with wire coil was up to eight times more effective than the smooth pipe at $Re=1000$.

Promvonge [4] experimentally investigated heat transfer augmentation by using square cross sectional wire coil turbulators in a pipe. The effects of two different pitch ratios (0.315 and 0.421) were applied in the range of Reynolds numbers between 5000 and 25000 . The working fluid was air. Results showed that wire coil had a good performance in the

Reynold number range between 5000 and 9000. Square wire coil showed better performance than a circular wire coil about 10 % at low Reynolds number.

Shoji et al. [5] investigated the effect of the ratio of the wire coil length in a pipe. Pitch ratio was equal to 10 and wire diameter was 1.5 mm. The full length of wire coil turbulators showed better heat transfer enhancement than others.

Akhavan-Behabadi et al. [6] studied the inserted wire coil in a double pipe heat exchanger. The pitch of wire coil was in the range of 12 to 69 mm, and the two thickness of the wire coils were 2 and 3.5 mm. Results showed that 3.2 fold enhancement in Nusselt number was observed for the wire coil of 3.5 mm thickness.

Eiamsa-ard et al. [7] investigated the effect of tandem wire coil insert in a square duct with under uniform heat flux conditions in the range of Reynolds numbers between 4000 and 25000. Results showed that full-length wire coil turbulators had better heat transfer enhancement than tandem short length one.

Wang and Sunden [8] compared the heat-transfer enhancement and friction factor penalty of the twisted tape and wire coil in laminar and turbulent regimes. Results showed that wire coil and twisted tape were more effective in case of the laminar region. A twisted tape insertion was found better than a wire coil at both regions when the friction factor was neglected.

Xing et al. [9] experimentally investigated the effect of rotating double wire coil turbulators with a thickness of 4 mm in a pipe on heat transfer performance in the turbulent regime. The length of wire coils was 1520 mm in a pipe with a length of 1975 mm. Pitch ratio was equal to 2.654. The results indicated that the 1.3 fold enhancement in the heat transfer the 5 fold penalty compared with those in the plain tube was observed.

Gunes et al. [10] experimentally investigated the heat transfer characteristic of equilateral triangle cross sectioned wire coil. The pipe test length of the study was 3.1 m and each length of equilateral triangle was 6 mm. Three pitch ratios (1, 2, and 3) were applied on the wire coil. The inner diameter of the pipe was 56 mm. The Reynolds number range between 4105 and 26400. In this numerical study, Gunes et al. [10] study was used for validation. Pitch ratio 3 or 168 mm pitch was selected for this purpose.

In this study, the thermohydraulic behavior of equilateral triangular wire coil with 54, 72 and 90 mm inserts separated from the square duct wall is examined by using ANSYS FLUENT v17.

XII. NOMENCLATURE

- A: area (m²)
- C_p: fluid specific heat (J.kg⁻¹. °C⁻¹)
- d: diameter of pipe (m)
- D_h: hydraulic diameter (m)
- f: friction factor
- h: heat transfer coefficient (W.m⁻².K⁻¹)
- k: fluid thermal conductivity (W.m⁻¹.K⁻¹)

- L: length of pipe (m)
- l: length of wire coil (m)
- \dot{m} : mass flow rate
- Nu: Nusselt number
- p: pitch (m)
- PEC: heat transfer enhancement efficiency, performance evaluation factor
- p/D: pitch ratio
- ΔP : pressure drop (Pa)
- Re: Reynolds number
- Pr: Prandtl number
- T_o: outside temperature (K)
- TT: twisted tape
- U_{mean}: mean velocity (m/s)
- Y: twist ratio
- WC: wire coil
- Greek Symbols*
- ρ : density
- μ : viscosity (kg/ms)
- Subscript*
- a: augmented
- b: bulk
- h: hydraulic diameter
- i: inlet
- o: smooth pipe
- w: wall

XIII. CFD MODELLING

A. Numerical Solution

The commercial CFD solver ANSYS FLUENT 17 is used to carry out the analysis, to solve the governing equations with a pressure-based solver. Semi-implicit pressure linked equation method (SIMPLE) algorithm for pressure velocity coupling and RNG k-ε for modeling turbulence are used. The convergence criterion of 10⁻⁶ for energy and of 10⁻⁴ for momentum, continuity, k, and ε is selected. The numerical modeling involves numerical solutions of the conservation equations for mass, momentum, and energy. These can be written as follows.

Mass conservation

$$\frac{\partial \rho}{\partial t} + \nabla(\rho \bar{u}) = 0 \quad (1)$$

Momentum conservation

$$\frac{\partial(\rho \bar{u})}{\partial t} + \nabla \cdot (\rho u \bar{u}) = \rho g - \nabla \cdot P + \nabla \cdot (\bar{\tau}) \quad (2)$$

where

$$\bar{\tau} = \mu \left((+\nabla \bar{u} + \nabla \bar{u}^T) - \frac{2}{3} \nabla \cdot \bar{u} I \right) \quad (3)$$

Energy conservation

$$\frac{\partial(\rho e)}{\partial t} + \nabla \cdot (\bar{u}(\rho e + P)) = \nabla \cdot (K_{\text{eff}} \nabla T + (\bar{\tau}_{\text{eff}} \cdot \bar{u})) \quad (4)$$

B. Geometry

The length of the square duct was 1.25 m and each side of duct was 18 mm. Equilateral triangular cross sectional wire coil (TWC) was assumed separately from the wall in a square duct. The each side of TWC was 2 mm. Figures 1 show geometry of TWC inserted in a square duct. Three different pitches (54, 72, and 90 mm) were examined.

Fig. 1. Triangular cross sectional wire coil

C. Mesh for Validation

Mesh was produced by using Ansys Meshing v17. Four different meshes were applied for the mesh independency. The number of mesh elements were 3535477, 8937123, and 13184499. The number of mesh elements was chosen 8937123, however after this point Nusselt number and friction deviation were lower than 1 percent. Figure 2 and 3 shows the longitudinal section mesh of triangular cross sectional wire coil, inlet and wall mesh of the wire coil insert.

Fig. 2. The longitudinal section mesh

Fig. 3. The inlet and wall mesh of the wire coil inserted pipe

D. Mesh for the Study

Table 1 shows the mesh independency of the triangular wire coil insert in square duct. 7648959, 7570517, and 6051072 mesh elements were used for triangular wire coil with 54, 72, and 90 mm respectively. Mesh independency procedure of TWC insert in square duct were applied the changing of Nusselt number and friction. When deviation is lower than 1%, mesh elements were chosen. The mesh quality of the three study for skewness and orthogonal quality were equal to 0.84 and 0.19, respectively. Figure 4 shows the inlet section mesh for TWC insertion in square duct.

Fig. 4. The inlet section of mesh for TWC insert in square duct

Table I. Mesh independency of the study

Mesh	Re	Nu	f
Mesh independency of TWC for P=54 mm			
4854852	4511,77	23,859	0,141
7648959	4506,51	24,059	0,14
11362117	4505,43	24,077	0,14
Mesh independency of TWC for P=72 mm			
4925983	8235,12	35,297	0,075
7570517	8240,4	34,911	0,074
11745660	8240,66	34,927	0,074
Mesh independency of TWC for P=90 mm			
3982837	9301,27	37,886	0,060
6051072	9304,53	37,523	0,061
8235559	9307,61	37,467	0,061

E. Boundary Condition

The working fluid of the present study was air. The boundary condition of the inlet section was 25°C. The study was carried out under uniform heat flux condition. Reynolds number was in the range of 4504 to 18415.

XIV. DATA REDUCTION

In the present study, Reynolds number (Re), friction (f), and convective heat transfer coefficient (h), Nusselt number (Nu) were calculated by using equation 1, 2, 3, and 4, respectively. Blasius equation (5) for turbulence regime was used for smooth pipe friction calculation.

$$Re = \frac{\rho \cdot U_{mean} \cdot D_{hydraulic}}{\mu} \quad (1)$$

$$f = \frac{2 \cdot \Delta P \cdot D}{\rho \cdot U_{mean}^2 L} \quad (2)$$

$$h = \frac{m \cdot C_p (T_o - T_i)}{A (T_w - T_b)} \quad (3)$$

$$Nu = \frac{h \cdot D_{hydraulic}}{k} \quad (4)$$

$$f = \frac{0.316}{Re^{0.25}} \quad (5)$$

Heat transfer enhancement efficiency or Performance evaluation factor (PEC) show the efficiency of the study. PEC is calculated by equation 6. Nu_a and Nu_0 express the Nusselt number of wire coil insert and smooth pipe, respectively. f_a and f_0 express the friction of wire coil insert and smooth pipe, respectively.

$$PEC = \frac{Nu_a}{Nu_0} \left(\frac{f_a}{f_0} \right)^{1/3} \quad (6)$$

Nusselt number of smooth pipe was calculated by using Glienski equation (7). This equation can be written such as

$$Nu = \frac{\left(\frac{f}{8} \right) (Re - 1000) Pr}{1 + 12.7 \left(\frac{f}{8} \right)^{1/2} (Pr^{2/3} - 1)} \quad (7)$$

XV. RESULTS AND DISCUSSION

A. Numerical Results of Validation

The experimental study of Gunes et al. [10] was used for validation. Figure 5 shows the numerical and experimental results of Nusselt number versus Reynolds number and Figure 6 shows the numerical and experimental results of friction versus

Reynolds number. The Nusselt number was calculated by using equation (4) and friction calculated by using equation (2). Validation results show that Nusselt number deviation band is between 2.43 to 9.56 % and friction deviation band is between 1.87 to 15.59 %. In the experimental study of Gunes et al. [10], teflon rings were used to wire coil separate from the wall and so the deviation of friction may be affected by teflon rings.

Fig. 5. Nusselt number results of numerical and Gunes et al. [10] studies versus Reynolds number

Fig.6. The friction results of numerical and Gunes et al. [10] studies versus Reynolds number

B. Numerical results for TWC insert in square duct

In the present study, TWC was fitted into a square duct. Three types of pitch were used. These pitches were equal to 54 mm, 72 mm, and 90 mm. Wire coil is assumed separated from the duct wall (s=2 mm). The Reynolds number range of was between 4831 and 18578. Figures 7 and 8 shows the Nusselt number and friction versus Reynolds number for different pitches.

Fig. 7. Results of Nusselt number versus Reynolds number for TWC inserts

Fig. 8. Results of friction versus Reynolds number for TWC inserts

As understanding from Figure 7, Nusselt number increased with decreasing pitch and increasing Reynolds number. At lower Reynolds number, the Nusselt number of 54 mm pitch is higher than 72 mm and 90 mm approximately 4.5 and 6.9 %, respectively. At higher Reynolds number, Nusselt number of 54 mm pitch is higher than 72 mm and 90 mm approximately 1.56 and 1.75 %, respectively. The Nusselt number of smooth pipe was calculated by using Glienski equation (7). Results showed that Nusselt number increased with increasing Reynolds number

for smooth pipe. However, the Nusselt number of wire coil insert for any pitch is higher than smooth pipe.

As understanding from Figure 8, friction decreased with increasing pitch and Reynolds number. At lower Reynolds number, the friction of 54 mm pitch is higher than 72 mm and 90 mm approximately 21 and 45 %, respectively. At higher Reynolds number, friction of 54 mm pitch is higher than 72 mm and 90 mm approximately 22 and 48 %, respectively. The friction of the smooth pipe was calculated from Blasius equation (5). The friction of the smooth pipe was lower than all pitches in the range of Reynolds number. The negative effect was observed on friction. However, the friction of TWC insertion for any pitch was higher than smooth pipe in the range of Reynolds number. Results showed that the Nusselt number and friction increased with decreasing pitch such as in literature.

Figure 9 shows the PEC versus Reynolds number. PEC was calculated by using equation (6). Results showed that heat transfer enhancement was achieved around 30.46% for 90 mm pitch.

Fig. 9. Results of PEC versus Reynolds number

As understanding from Figure 9, PEC increased with decreasing Reynolds number and increasing pitch. The maximum point of PEC (1.3) was obtained at Reynold number around 4500. The lowest PEC (1.01) was obtained at Reynold number around 18415.

XVI. CONCLUSION

In the present study, triangular wire coils with varying pitches inserted in square duct were investigated. The aim of the study was to numerically understand the effects of wire coil inserts on heat transfer enhancement. Wire coil produces the secondary flow and it effects the retention time of the fluid. Secondary flow effect on convective heat transfer and Nusselt number increases with wire coil insertion. The negative effect of wire coil insert was observed pressure drop. However, the friction of TWC insertion for any pitch was higher than smooth pipe in the range of Reynolds number. The result of study was compared

with smooth pipe. The Nusselt number increased with increasing Reynolds number. The higher Nusselt number was obtained at lower pitches. The friction raised up with decreasing pitch and Reynolds number. The highest PEC was obtained at lower Reynolds numbers and higher pitch ratios.

Abstract—Present study is focused on numerical investigation of heat enhancement and fluid flow from a heated surface by using nanofluids with three impinging jets. Effects of volume fraction, different heat flux and different types of nanofluids (NiO-water, CuO-water, Cu-water) on heat transfer and fluid flow were studied numerically. NiO-water nanofluid was used as a coolant. Three impinging jets were used to cool the surface. Low Re k- ϵ turbulent model of PHONEICS CFD code was used for numerical analysis. It is obtained that increasing volume fraction from 1% to 4% causes an increase of 8.6% on average Nusselt number. Increasing surface heat flux can not cause any significant increase on local Nusselt number. Using Cu-Water nanofluid can cause an increase of 4.4% on local Nusselt number according to the water.

Keywords—Heat transfer; Nanofluids; Volume fraction; Impinging jets

I. INTRODUCTION

A nanofluid is defined as a suspension of solid particles which have 1-100 nm size in a base fluid. In heat transfer applications using nanofluid, the particles suspended in the base fluid, expand thermal capacity of the fluid. Interactions and collisions between particles cause to increase in turbulence and turbulence intensity of the transition surface. Turbulence intensity and large surface area enables more heat transfer. Nanoparticles carry 20% of their atoms at the surface that makes them ready to heat transfer. Another advantage of using nanofluids is the particle agitation cause micro-convection in the fluid due to its very small size and therefore increases the heat transfer. For this reasons nanofluids can be applied to many heat transfer applications, in particular heat transfer from surfaces with high heat flux, as well as industry, medicine and space research. One of the optimum heat management techniques that provide high cooling efficiency in the industry is the jet impinging technique. The jet impinging technique is used to intensify heating, cooling or drying processes on a surface. The factor that makes the jet impinging technique attractive is that a high heat transfer is can be achieved on a narrow surface. In this method solid surfaces are cooled by means of fluid jets. Thus, at

a very high rate heat transfer can be acquired with a minimum flow rate. The jet impinging is used to obtain a high local heat transfer coefficient between the fluid and the surface, resulting in considerable increases in heat transfer as well as energy savings.

Many studies on nanofluids or impinging jets can be found in the literature. Teamah et al. [1] investigated heat transfer and flow structure formed by Al_2O_3 nanofluid to flat plate by experimentally and numerically with various Re number ($\text{Re}=3000-32000$) and different volume fraction of nanofluids ($\phi=0-10\%$). As the nanoparticles in the base fluid increases, the heat transfer from the surface increases and heat transfer coefficient can be enhanced by 62% according to the water is used base fluid only. They observed that heat transfer can be increased of 8.9% by using CuO-water with respect to Al_2O_3 -water. Manca et al. [2] surveyed the effect of impinging jets on heat transfer from a flat plate with a constant heat flux when pure water and Al_2O_3 -water nanofluids were used as a working fluid. Jet Reynolds number ($\text{Re}=100-400$) and dimensionless channel height ($H/W=4-10$) are the parameters used in operation. It has been stated that as the Reynolds number and the concentration of the particles in the fluid increases, the local heat transfer coefficient and the Nusselt number increase. The highest increase (36%) in the average heat transfer coefficient was obtained when $H/W=10$ and the nanoparticle volume ratios are $\phi=5\%$. Sun et al. [3] researched the effect of a single impinging jet using CuO-water nanofluids as working fluid on heat transfer. It has been determined that when the nanofluid is used, important advance can be achieved in heat transfer with respect to the use of water only, no significant change in pressure drop, a higher heat transfer coefficient is obtained when a circular nozzle is used, and a higher heat transfer coefficient is obtained when the jet angle is 90° . Çakır M.T. [4] experimentally evaluated the thermal performance of the system by using a nanofluid with 2% Al_2O_3 nanoparticles as a working fluid in a thermosyphon type heat pipe. As a result, the thermal resistance was significantly reduced however the thermal performance was not fully stabilized. Chien et al. [5] experimentally investigate the application of nanofluid in the flat plate heat pipe. It was obtained that the use of nanofluid achieves 40% reduction in thermal resistance compared to pure water utilization. Kang et al. [6] operated a nanofluid formed with silver nanoparticles and pure water. It was determined that when 10 nm and 35 nm sized particles used, thermal resistance diminished by 50% and 80% compared to pure water respectively. Xuan Y., Li Q., [7] studied the effect of Cu-water nanofluid, prepared at varied volume ratios, on heat transfer for different volume ratios, particle sizes, particle shapes and nanoparticle properties. As a result, it has

been found that an increase of 2.5% to 7.5% in the volume fraction causes 1.24 to 1.78 proportional increases in the coefficient of thermal conductivity of nanofluids. Shang et al [8] studied the heat transfer characteristics of a closed-loop vibrating heat pipe system with Cu-water nanofluid. When nanofluid was used heat transfer capacity of the system increases by 83% compared with pure water. Umar et al. [9] investigated the heat transfer from constant heat flux surface in laminar flow condition using varied ratios of Cu-Water nanofluid. As a result, it was found that as the particle volume ratio increased and the Reynolds number increased, the heat transfer coefficient increases, the highest increase in heat transfer coefficient (61%) occurred at a particle volume ratio of 4% and Reynolds number $Re = 605$. Qu et al. [10] investigated the thermal performance of a closed-loop vibrating heat pipe utilizing Al_2O_3 -water as a nanofluid. As a result, they found that the thermal resistance of the system decreased by 32.5% in proportion to pure water. Naphon et al. [11] investigated the heat transfer between the nanofluids (titanium-ethanol) and the closed two-phase thermosyphon. It was found that achieving a 10.6% improvement in evaporation heat transfer coefficient in the case of using nanofluid compared to only ethanol. Kilic et al. [12] surveyed the cooling of a flat plate with the support of the impinging fluid air jet for different Reynolds numbers and dimensionless channel heights. The mean Nusselt number was found to increase by 49.5% in $Re = 4000-10000$ and 17.9% in $H/Dh = 4-10$. Lin Z.H. Et al. [13] experimentally investigated heat transfer in confined fluid jets. The effects of Reynolds number and jet-target plate spacing on heat transfer were studied in this study. As a result of local and average Nusselt numbers at the stagnation point, it has been found that effect of the change in jet-target plate distance is not very important on the heat transfer, but the increase in Reynolds number increases heat transfer. Two experimental correlations were determined for mean Nu number and Nu number at the stagnation point in the range of $190 \leq Re \leq 1537$ and $1 \leq H/W \leq 8$. Nada S.A. [14] experimentally investigated the jet flow from the slits in different geometries to the cylinder surface. Two different jet / cylinder configurations have been tried. In the first application jet flow was applied so that the slit length was equal to the cylinder length. In the second application jet flow was applied to the cylinder from three separate slots so that the slit length would be equal to the cylinder diameter. Reynolds number range was taken between 1000 and 10000. The ratio of the slit width (w) to the cylinder diameter (d) is between 0.125 and 0.5. The effect of these widths on the local Nusselt number has been investigated as the width of the slit (w), the distance from the cylinder (z) ratio between 1 and 12. As a result, cooling of the cylinder with multiple slits provides more efficient cooling than cooling with a single slit. In both cases the Nusselt number increases as the Re number increases. Again, in both cases, the average Nusselt number is the maximum at $4 < z/w < 6$. Khudheyer S. M. [15] studied heat transfer numerically in different jet widths, different jet counts, different fin counts and different Reynolds number flows. In this study, surface was heated and tried to cool with channel flow and jet flow. It was

observed that the vortex formation region and local Nusselt number is greatly influenced by jet and flap width, jet spacing, flap thickness and jet Reynolds number. In addition, it has been found that the variation of the position of the fins relative to the jet significantly influences the heat transfer. Choo K. and Kim S. [16] experimentally surveyed the effect of confined and unconfined impinging jet on heat transfer. Air and water used as a fluid. It has been found that confined jet flow performance is similar to unconfined jet flow at constant pump power. At the constant flow rate, the confined jet flow thermal performance was found to be 20% to 30% less than the unconfined jet flow thermal performance. McGuinn A. et al. [17] numerically and experimentally investigated the heat transfer of the flow from the nozzle with two separate output geometries (straight out and shaped). The jet flow is applied to a copper plate representing uniform temperature. The variation of Nusselt number for different flow frequencies and different nozzle-plate distances was investigated. Frequency variation and surface distance hydraulic diameter ratio was investigated in the range of 40 Hz-160 Hz and (H/D) 1-6 respectively. As a result, it has been observed that the shaped nozzle provides more efficient heat transfer than straight nozzle. At the same time, it has been found that uniform flow from the shaped nozzle delays flow disturbances causing turbulent flow. Consequently, it was acquired that the heat transfer in the surface is not only depends on the turbulence formed but also depends on the flow geometry of the surface.

II. PRELIMINARY DEFINITIONS

The heat transfer from the surface will take place by convection, conduction and radiation.

$$Q_{convection} = Q_{total} - Q_{conduction} - Q_{radiation} \quad (1)$$

The total amount of heat to be given to the plate is;

$$Q_{total} = \frac{V^2}{R} \quad (2)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where V is the voltage value of the power unit and R is the resistance of the heater. Here, the heat generated by the heater placed under the copper plate will be transmitted to the upper surface of the plate through the copper plate thickness by conduction, and as a result, the plate surface will be cooled by using nanofluid with impinging jet. Heat transfer by conduction along the plate;

$$Q_{conduction} = \frac{-k_c \cdot A_c \cdot (T_{bottom} - T_{upper})}{L_c} \quad (3)$$

$$\alpha + \beta = \chi. \quad (1)$$

here, k_c is the heat transfer coefficient of the copper plate, A_c is the copper plate surface area, and L_c is the copper plate thickness.

Thermal losses due to radiation;

$$Q_{radiation} = \varepsilon \cdot \sigma \cdot A \cdot F \cdot (T_s^4 - T_{bulk}^4) \quad (4)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where ε is the copper plate emissivity, σ is the Stefan-Boltzmann constant, A is the radiation surface area, T_s is the surface temperature, and T_{bulk} is the mean fluid temperature.

$$T_{bulk} = \frac{T_{in} + T_{out}}{2} \quad (5)$$

It is assumed that heat transfer with radiation is negligible in this study because surface temperature is under 573.15°K.

Heat transfer from surface with convection;

$$Q_{convection} = h \cdot A \cdot \Delta T \quad (6)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where h is the heat transfer coefficient, A is the convection surface area, ΔT ($\Delta T = T_s - T_{bulk}$) is the difference between the measured surface temperature and the fluid mean temperature.

Nusselt number (Nu) is a dimensionless parameter indicating the ratio of heat transfer with conduction to heat transfer with convection.

$$Nu = \frac{(Q_{convection} \cdot D_h)}{(T_s - T_{jet}) \cdot k_{nf}} \quad (7)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where T_s is the measured surface temperature, D_h is the hydraulic diameter, and k_{nf} is the coefficient of thermal conductivity of the nanofluid. Reynolds number (Re) is used to determine for forced convection whether the flow is laminar or turbulent. Reynolds number based on turbulent flow;

$$Re = \frac{(\rho_{nf} \cdot V_{jet} \cdot D_h)}{(\mu_{nf})} \quad (8)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where ρ_{nf} is the nanofluid density, V_{jet} is the jet velocity, and μ_{nf} is the nanofluid dynamic viscosity. The density of nanofluids is;

$$\rho_{nf} = (1 - \varphi) \cdot \rho_{bf} + \varphi \cdot \rho_p \quad (9)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where ρ_{bf} is the base fluid (water) density, φ is the volumetric ratio of the nanofluid, and ρ_p is the density of the solid particles in the nanofluid. The volumetric ratio of nanoparticles is;

$$\varphi = \frac{1}{(1/\omega) \cdot (\rho_p - \rho_{bf})} \quad (10)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where ω is the density difference between the fluid and the main fluid (water). The nanofluid specific heat is calculated from;

$$C_{p_{nf}} = \frac{\varphi \cdot (\rho \cdot C_p)_p + (1 - \varphi) \cdot (\rho \cdot C_p)_f}{(\rho_{nf})} \quad (11)$$

Where $C_{p(p)}$ is specific heat of particle, $C_{p(f)}$ is specific heat of base fluid. The effective thermal conductivity of nanofluid is calculated according to Massimo [18];

$$\frac{k_{eff}}{k_f} = 1 + 4.4 Re^{0.4} Pr^{0.66} \left(\frac{T}{T_{fr}} \right)^{10} \left(\frac{k_p}{k_f} \right)^{0.03} \varphi^{0.66} \quad (12)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where Re is the nanoparticle Reynolds number, Pr is the Prandtl number of the base liquid. k_p is the nanoparticle thermal conductivity, φ is the volume fraction of the suspended nanoparticles, T is the nanofluid temperature (°K), T_{fr} is the freezing point of the base liquid. The effective dynamic viscosity of nanofluids;

$$\mu_{nf} = \mu_{bf} (1 + 2.5 \varphi + 4.698 \varphi^2) \quad (13)$$

III. NUMERICAL MODEL

Low Re k-ε turbulence model of PHOENICS CFD code was used for this numerical analysis. CFD simulation domain is shown in Fig 1. Mesh structure is shown in Fig.2.

Fig. 1. CFD simulation domain

Fig. 2. Mesh structure

The continuity, Reynolds averaged momentum and time averaged energy equations governing 3-dimensional steady, flow of air with constant properties used for turbulent solutions can be written in the Cartesian coordinate system as follows:

Continuity equation:

$$\frac{\partial U_i}{\partial x_i} = 0 \quad (14)$$

Momentum equation:

$$\rho U_i \frac{\partial U_j}{\partial x_i} = -\frac{\partial P}{\partial x_j} + \frac{\partial}{\partial x_i} \left[\mu \left(\frac{\partial U_i}{\partial x_j} + \frac{\partial U_j}{\partial x_i} \right) - \rho \overline{u'_i u'_j} \right] \quad (15)$$

(11)

Energy equation:

$$\rho c_p U_i \frac{\partial T}{\partial x_i} = \frac{\partial}{\partial x_i} \left[k \frac{\partial T}{\partial x_i} - \rho c_p \overline{u'_i T'} \right] \quad (16)$$

All the boundary conditions used in the study are summarized in Table 1. It was used 96x15x34 (48960 elements) meshes for this application. Mesh structure was prepared according to flow conditions. In order to get more precise numerical results, we intensified mesh numbers in some region as jet inlet, surface of copper plate. Sweep number was studied between 400 and 2500 and cell number was also studied between 24 and 44. It is observed that numerical geometry was independent from sweep number and cell number when sweep number was 600 and cell number was 96x15x34.

IV. RESULTS AND DISCUSSIONS

In this section, numerical results were prepared for three parameters.

- Effect of NiO-water nanofluid with 25 nm sized particles for different volume fractions on heat transfer ($\phi=1\%$, 2% , 4% , 5%),
- Effect of different heat flux of copper plate with NiO-water nanofluid on heat transfer ($q''=111111W/m^2$, $148148W/m^2$, $185185W/m^2$, $222222W/m^2$).
- Effect of different type of nanofluids on heat transfer (CuO-water, Cu-Water, NiO-Water).

A. Effect of different volume fraction of NiO nanofluid

Fig 3 shows temperature of heated surface when cooled with different volume fractions ($\phi=1\%$, 2% , 4% , 5%) of NiO-water nanofluid;

Fig 3. Temperature distribution on surface

It can be seen that the surface temperature decreases on stagnation point of first impinging jet. There is a temperature

increase before the stagnation point of second jet. The reason of this is decreasing of the fluid velocity with effects of second jet. So location of stagnation point of second jet goes upward. When velocity of the fluid decreases, thermal boundary layer thickness increases again. In impact region of the second jet, boundary layer thickness is decreased and heat transfer increases. Effect of third jet reduced because of the channel flow of first and second jet. Jet effect and channel flow effect can also be seen at this region. Therefore, heat transfer rate has the highest level at this region.

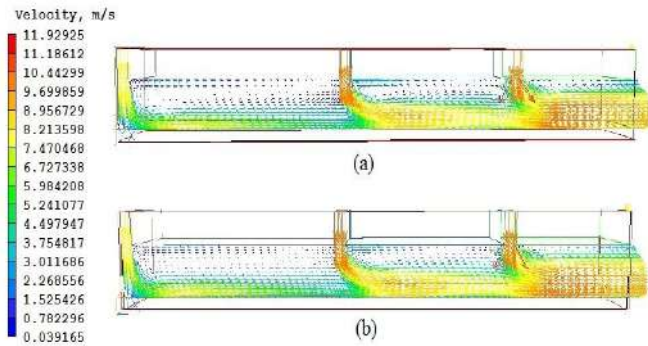

Fig 4. (a) Velocity vectors of 1% NiO-water nanofluid
(b) Velocity vectors of 4% NiO-water nanofluid

Fig 4 shows velocity vectors of NiO-water nanofluid for $\phi=1\%$ and 4% respectively.

Fig 5 shows the analysis of change in Nusselt number when different volume fractions of NiO used as a heat transfer fluid.

Fig 5. Local Nusselt numbers for different volume fractions

It can be seen that increasing volume fraction of NiO from $\phi=1\%$ to 4% causes an increase of 8.5% on average Nusselt number. But there is not a prominent difference on average Nusselt number between $\phi=4\%$ and $\phi=5\%$.

B. Effect of heat flux of copper plate on heat transfer

Fig 6 shows Nusselt number for NiO-water nanofluid for different heat flux ($q''=111111\text{ W/m}^2$, 148148 W/m^2 , 185185 W/m^2 , 222222 W/m^2).

Fig 6. Local Nusselt numbers of nanofluid for different heat fluxes

It was seen that increasing heat flux two times has not a considerable effect on local Nusselt number.

C. Effect of different type of nanofluids

Numerical analysis is conducted for different type of nanofluids (Cu-water, CuO-water and NiO-water) with 25 nm particle size and volume fraction 4%. Properties of nanofluids were calculated at 293K.

TABLE XI. THERMO-PHYSICAL PROPERTIES OF NANOFLUIDS AT 293K.

Nanofluid	ρ (kg/m ³)	C_p (J/kgK)	μ (Pa.s)	Kinematic	k (W/mK)	β (m ² /2)
CuO-water	1218,272	3403,881	0,001099764	9,02725E-07	0,662101313	0,0001597
NiO-water	1230,672	3389,813	0,001099764	8,93629E-07	0,663961878	0,0001592
Cu-water	1316,672	3148,451	0,001099764	8,35261E-07	0,66843348	0,0001612

Fig 7. Nusselt numbers for nanofluids

Fig 7 shows variation in Nusselt number for water, CuO-water, NiO-water and Cu-water. It was acquired that using Cu-water nanofluid causes an increase of 3.5%, 2.4%, 4.4% on average Nusselt number with respect to CuO-water, NiO-water and water. Fig 8 and Fig 9 shows surface temperature contours for water and Cu-water nanofluid. It can be seen that using Cu-water nanofluids shows better heat transfer performance.

Fig 8. Surface temperature contours for water

Fig 9. Surface temperature contours for Cu-water nanofluid

V. CONCLUSION

The main goal of the current study was to examine heat enhancement and fluid flow from a heated surface by using nanofluids and three impinging jets numerically. Effect of

volume fraction, different heat flux and different types of nanofluids (Water, NiO-water, CuO-water, Cu-water) were on heat transfer and fluid flow were studied numerically. According to our constraints the result of this study indicate that increasing volume fraction from $\phi=1\%$ to 4% causes an increase of 8.6% on average Nusselt number. But there is not a slight difference between $\phi=4\%$ and 5% . Increasing heat flux two times has not a significant effect on heat transfer. Using Cu-water nanofluid causes an increase of 3.5%, 2.8%, 4.5% on average Nusselt number with respect to CuO-water, NiO-water and water. Using Cu-water nanofluid shows better heat transfer performance. Research areas for future investigations can be investigation of effect of hybrid nanofluids on heat transfer.

Abstract—This work present, a study of the vibration behavior of clamped-clamped functionally graded beam (FGB). The aim of this paper is to investigate the influence of the skin of the sandwich beam on the natural frequencies of the system using Euler-Bernoulli classical theory (CLBT) taking into account that the material properties of the FGM layer in continually graded in the thickness direction with power law distribution.

Keywords—vibration; sandwich; FGM; beam; frequencies

Introduction

Functionally graded (FG) materials are a type of composite composed of two or more materials which are designed to have a spatial continuity of properties. These materials are used in many engineering candidates such as nuclear reactors and high-speed satellite industries.

FGM are produced by continuously changing of the volume fractions in the thickness direction to obtain a well-defined profile. Generally, these materials are made from a mixture of ceramic and metal or a combination of different materials [1].

The beam is considered as the structural element most responded, as an integral part in most of the construction works or machinery parts [2], which made necessary the study of their static / dynamic behavior. The beams are used as structural component in several construction applications and a large number of studies can be found in the literature about the transverse vibration of the uniform isotropic beams [3]. The importance of developing an analysis of the vibration behavior of the beams is related to the use of the beams as a basic element in achieving the structures, and to determine the effects of changes in boundary conditions, and changes of the material on the natural frequencies and natural modes of vibration.

FGM sandwich can mitigate a concentration of shear stress between the faces because of the gradual change in material properties at the interface -Coeur skins. The effects of FGM nucleus have been studied by Venkataraman and Sankar [4] and Anderson [5] on the shear stresses at the skin interface of a beam -Coeur sandwich FGM. Pan and Han [6] analyzed the static response of the rectangular plate made of several functionally graded layers, anisotropic, Shen [7] studied two types of laminated hybrid plates, one with FGM

core and piezoelectric skins ceramic and the other is with FGMs skins and piezoelectric ceramic core. In the present paper we investigate the influence of volume fraction index on the frequency response of a clamped-clamped FG sandwich beam.

I. MATHEMATIC MODELS

Considering a clamped - clamped sandwich FGM beam with uniform thickness composed of three heterogeneous layers relative to a Cartesian coordinate system (x,y,z). Upper and lower faces are located at $Z = \pm h/2$ and the sides of the beam are parallel to the x and y axes fig 1.

Fig. 11. FGM rectangular sandwich beam (c-c) in Cartesian coordinates

The FGM beam, is composed of three elastic layers, named; layer "1", layer "2" and layer "3" on the front ,lower and the top of the beam. The vertical coordinates of the lower face, the two interfaces, and the upper sides are denoted by $h_1 = -h/2$, h_2 , h_3 , and $h_4 = +h/2$, respectively. On the front, lower and the top of the beam. The vertical coordinates of the lower face, the two interfaces, and the upper sides are denoted by $h_1 = -h/2$, h_2 , h_3 , and $h_4 = +h/2$, respectively.

Fig. 12. Geometry of FGM rectangular sandwich beam in Cartesian coordinates.

The properties of the FGM vary continuously as a function of the volume fraction of the material in the direction of the thickness. A function of power law is commonly used to describe this variation in material properties. The sandwich structures FGMs is discussed as follows.

The volume fraction in the P-FGM is provided by a power law depending on the thickness:

$$V^{(1)} = 0 \quad z \in [h_1, h_2] \quad (1)$$

$$V^{(2)} = \left(\frac{z - h_2}{h_3 - h_2} \right)^p \quad z \in [h_2, h_3] \quad (2)$$

$$V^{(3)} = 1 \quad z \in [h_3, h_4] \quad (3)$$

Where $V(n)$ ($n=1,2,3,\dots$) denotes a function of the volume fraction of the layer n ; p is the index of the volume fraction ($0 \leq p \leq +\infty$), which indicates the physical change through thickness.

Fig. 13. Distribution of ceramic material through the beam depth according to the power-law form

Actual material properties such as Young's modulus E , and Poisson's ratio ν and bulk density ρ can be expressed by the law of mixtures [8] as:

$$P^{(n)}(z) = P_2 + (P_1 - P_2)V^{(n)} \quad (4)$$

Or $P^{(n)}$ is the actual physical ownership of FGM layer n . P_1 and P_2 are the physical properties of the upper and lower surfaces of the layer 3 and 1, respectively, in this study, it is assumed that the Poisson's ratio is constant [9]

II. RESULTS AND DISCUSSIONS

Considering Clamped-Clamped sandwich beam composed of two rigid homogeneous in its upper and lower surface and FGM in its heart, As the top facet is made of 100% ceramic Al_2O_3 (Alumina), while the lower facet is made of 100% metal Al (Aluminum). The material properties of the considered structure are given in table 1.

Table 1. Material properties

properties	Ceramic (Al_2O_3)	Aluminum (Al)
Poisson's ratio ν	0.33	0.33
Density ρ (Kg/m^3)	3800	2708
Young's Modulus (Gpa)	380	70

Table 2. The natural frequencies for Clamped-clamped (C-C) beam with the power low index

scheme	frequency		
	$P=0.1$	$P=1$	$P=10$
2-1-2	29.425	29.807	30.488
	81.112	82.164	84.043
	159.01	161.07	164.75
1-1-1	29.635	30.178	31.466
	81.707	83.160	86.739
	160.14	163.02	170.04
1-2-1	30.048	30.869	33.217
	82.828	85.093	91.564
	162.37	166.81	179.50
1-3-1	30.216	31.381	34.484
	83.291	86.504	95.059
	163.28	169.58	186.35
1-8-1	29.763	32.558	37.500
	82.042	89.750	103.37
	160.83	175.94	202.64
0-1-0	26.368	33.830	41.073
	72.684	93.254	113.22
	142.49	182.82	221.95

Fig. 14. Natural frequencies versus volume fraction index ($p=0.1, p=1, p=10$) for a clamped-clamped sandwich FGM beams

The tab.1 and Fig. 4 show that for the power law index $p=0.1$, the frequency is more important when the thickness of the FGM layer take 60% of the total thickness; and its less important when rapport between the FGM layer and the total thickness is 1; elsewhere for $p=1$ and $p=10$ the frequency response is maximum when $h_{fgm}=h$ and minimum when the $h_{fgm}=0.2h$.

Fig. 15. Natural frequencies of a clamped - clamped In sandwich beam compared to the natural frequencies of an aluminum for beam for $p=0.1$

Fig. 16. Natural frequencies of a clamped - clamped In sandwich beam compared to the natural frequencies of an alumina for beam for $p=0.1$

Fig.5 and Fig.6 show that the natural frequencies of a sandwich beam FGM are proportional to the natural frequency of the base materials (ceramics, metal). The plot of the beam with combination "0-1-0" has the smallest frequencies value while that corresponding to "1-3-1" has the largest value.

CONCLUSION

In this study, the free vibrations of sandwich beams FGM assuming that the material properties vary depending on the thickness with a power distribution (P-FGM) is examined. The main purpose of this work is to study the influence of the volume fractions of base materials on the frequencies and modes. The variation in the thickness of the FGM material on the natural frequencies is also studied for various boundary conditions. The results show that the frequencies are proportional to the FGM ratio and getting larger when the structure has a superior ceramic percentage.

Abstract— This work is a simulation study to determine the modes shapes and natural frequency in first plate then we do a harmonic vibration of an inflatable wing of drone (fixed wing UAV), to achieve this a wing constructed of an external restraint made of Kapton coated Kevlar fabric encasing a bladder is considered for internal pressures ranging from 3 to 15 psig. The simulation study was driven by Ansys APDL.

Keywords— Inflatable Wing, UAV drone, Natural Frequency, Internal Pressure, Harmonic Vibration.

I. INTRODUCTION

Inflatable wings provide a new solution to unmanned aerial vehicles requiring small cramped volumes, such as those used for military reconnaissance or extra-planetary exploration. There is desire to implement warping actuation forces to change the shape of the wing during flight to allow for greater control of the aircraft. In order to quickly and effectively analyze the effects of wing warping strategies on an inflatable wing. With the ever-expanding technology in the aviation (uav) industry. The inflatable wing, which is produced by using lightweight flexible composite materials made of Kapton coated Kevlar fabric [1], is a new modality of structure with advantages of lowcost, small volume, light weight, high reliability etc. Therefore, for variety of types of UAV, it has wide application and research prospects [2, 3]. The goal of this work is to calculate the natural frequency at different internal pressure then determinate the harmonic response of the wing by using Ansys code.

The paper is organized as follows: In Section 2, we describe the model of wing chosen for this study with principal dimensional and adaptive type of profile. In Section 3 and 4, we present the fundamentals simulation results. In Section 5 concludes the paper.

II. DESIGN OF THE INFLATABLE WING

In this work we choose a model of inflatable wing as clarifier in Fig.3. NACA 4318[4, 5] wing profile was selected as a target in this study.

Fig. 1. Geometry of inflatable wings, 36-inch semi-span [4].

III. FINITE ELEMENT ANALYSES

A. Description of Model

The finite element (FE) model of the wing was created using ANSYS FE software. The wing geometry was created in ProEngineer from wing dimensions provided by the manufacturer [1]. For simplicity of modeling [3], the wing tip was modeled as a flat vertical surface, rather than the tip seam seen in Fig.1. Once the geometry was created, the model was meshed with SHELL181 elements, which are 4-node shell elements with 6 DOF at each node. An element thickness of $3.302 \times 10^{-5} \text{ m}$ (0.013 inches) was used, corresponding to the thickness of the Kapton coated Kevlar material.

The model was containing 17,697 elements after meshing of wing and 16,911 nodes. The final model mesh is shown in Fig.2.

A linear orthotropic material model was used in the analysis, with material properties obtained from [1]. The Kapton coated Kevlar is presently under examination for use in construction of double-walled structures show Tab.1.

Fig.2. Finite element model of inflatable wing.

TABLE I STIFFNESS RESULTS FOR THE DIFFERENT MATERIALS FROM UNIAXIAL TESTING.

Material	Direction	Young's modulus	Uniaxial (MPa)	Estimated Biaxial (MPa)
PAIDAE	Warp	E_1	13375.83 ± 482.63	8273.71 ± 551.58
	Fill	E_2	13306.88 ± 689.47	8204.76 ± 482.63
IRVE	Warp	E_1	9307.92 ± 413.68	7101.6 ± 1103.16
	Fill	E_2	8411.6 ± 275.79	4757.38 ± 68.94

B. Results

The finite element solution process consisted of multiple steps. First, internal pressure loadings were applied to the "restraint" areas of the model show Fig.3, and the solution was computed using the standard linear sparse solver in ANSYS. Subsequently, a modal analysis was performed using the Block-Lanczos solver, including pre-stress effects from the pressure application solution.

Tab.2 and Fig.4 summarizes the mode shapes and frequencies obtained from the simpler modeling process in which the pressure solution was obtained using a linear solver in ANSYS. For this simpler solution process, results were obtained for all pressure cases considered, though results do not fully follow expected trends. Most notably, the wing stiffness should increase with pressure. In general, this is the case; however, the first bending mode of the 0.02 and 0.08 MPa (3 and 12 psi) cases proves higher than the 0.04, 0.06

and 0.1 MPa (6, 9 and 15 psi) cases show Fig.5. In fact for many of the linearly-solved pressure cases, there were many localized large deflections, which sometimes made identifying wing mode shapes difficult.

Fig 3. Internal pressure loadings

TABLE XII. FINITE ELEMENTS PREDICTIONS OF WING FREQUENCIES (Hz).

Mode	0.02 MPa	0.04 MPa	0.06 MPa	0.08 MPa	0.1 MPa
First bending mode	10.011	9.4984	8.7210	10.894	7.8075
First torsional mode	26.528	27.085	27.424	28.316	26.869
*Mode in chord direction (Figure 6)	33.789	33.837	33.852	33.642	33.623
Second bending mode	45.775	46.743	46.990	47.488	47.136
Second torsional mode	53.841	60.961	65.634	66.223	70.617

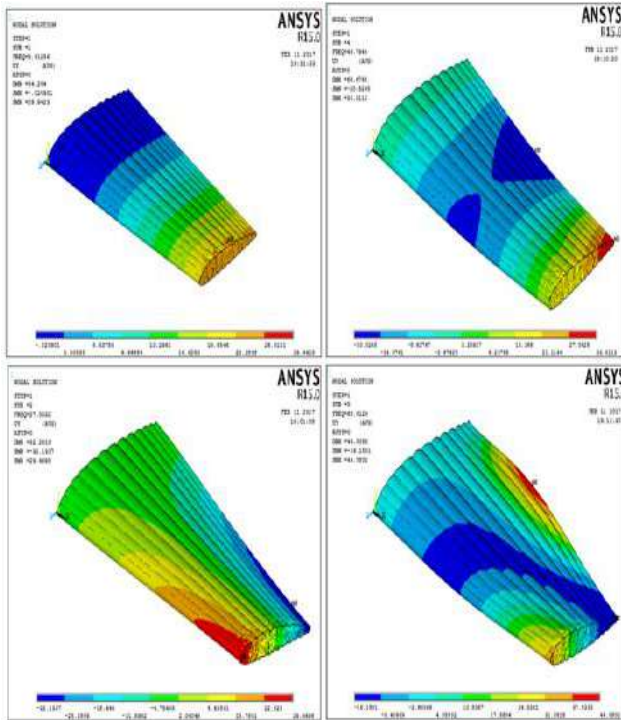

Fig. 4. First four mode shapes of inflatable wing

Fig.5. Natural frequency of bending and torsional for different internal pressure.

Fig.6. Mode in chord direction

IV.HARMONIC RESPONSE:

This study evaluates the response to aerodynamic forces [6], in the form of graphs illustrating the signal amplitude as a function of frequency according to the different internal pressure. We suppose that the vector of excitation forces of frequency response Fig.7.

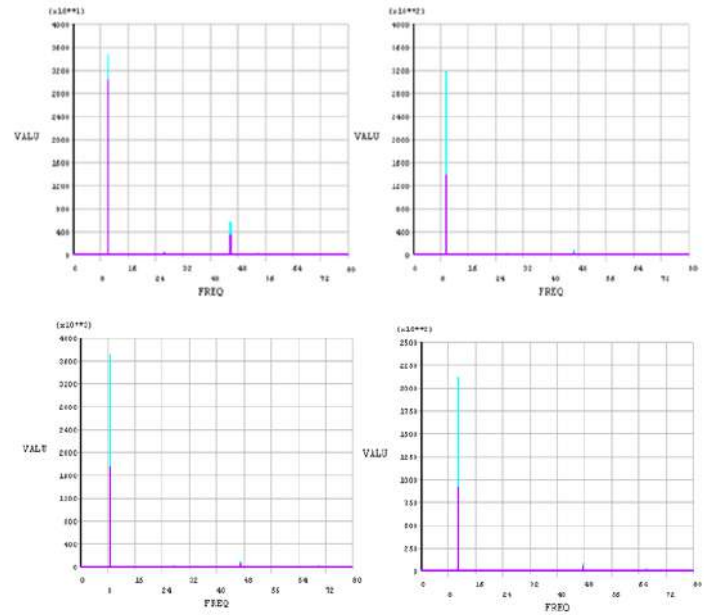

Fig. 7. Harmonic response for different internal pressure 0.02, 0.04, 0.06, and 0.08 MPa respectively X (cyan), Z (purple).

V.CONCLUSIONS

Modal parameter estimation was performed using finite elements method for determined frequency response functions, to determine resonant frequencies, damping, and mode shapes of the wing. We can conclude from these numerical modeling approaches that the dynamic behavior of the inflatable wing of different internal pressure, as frequencies of the internal pressure 0.02 and 0.08 MPa (3 and 12 psi) in this case proves higher than the 0.04, 0.06 and 0.1 MPa (6, 9 and 15 psi) for first bending mode. The visualization of modes shows that the end of the inflatable wing is the area most highly stressed whatever the lag, flapping or twisting. And finally for performance Flight must select tow internal pressure 0.02 and 0.08 MPa (3 and 12 psi) one for flexible wing and second for rigid wing respectively.

Abstract— The present work is a study of active vibration control of a smart beam. In this regard, piezoelectric patches are using as sensor and actuators. Based on Euler-Bernoulli theory a state space equation is adopt and extend to the case of cantilever beam, moreover, LQR and LQG controller are using. The analysis studies are carried out using Ansys and Matlab.

Keywords—component; formatting; style; styling; insert (key words)

III. INTRODUCTION

Unwanted vibrations can caused a catastrophic breakdown of structures, hence scientist worked toward to provide solutions to prevent this kind of failure. different technique are used to damped vibration we noted passive and active vibration control. Piezoelectric materials are kind of smart structure which have the ability to change behavior under extreme stress, this advantage make piezoelectric material as the most appropriate smart materials for the active and semi-active control of structures such as beams, plates. remarkable research paper dealt with the analytical and numerical analyses of smart structures employing distributed piezoelectric sensors and actuators. [1] developed a finite element model based on the classical laminated plate theory for the active vibration control of a composite plate containing distributed piezoelectric sensors and actuators. [2] developed a finite element model based on third order laminate theory for the active position and vibration control of composite beams with distributed piezoelectric sensors and actuators. [3] presented an analytical solution of composite beams with piezoelectric laminate. [4] developed a three-node beam finite element for the analysis of composite laminated beams with distributed piezoelectric sensor/actuators. in the present paper the active vibration control of isotropic beam is investigated. the Euler-Bernoulli theory is used to provide a state space equation to be able use the LQG and LQR controller. different simulation are presented.

I. EQUATION OF MOTION OF INTELLIGENT BEAM

Consider a beam bonded by with piezoelectric actuators on the top surface and sensors on the bottom surface Based on the Euler Bernoulli theory the beam motion equation can be expressed as

$$E_b I_b \frac{\partial^4 w}{\partial x^4} + \rho_b A_b \frac{\partial^2 w}{\partial t^2} - b \sum_{i=1}^m \frac{\partial^2 M_i^a}{\partial x^2} = 0 \quad (1)$$

Where w is the deflection of the beam are Young's modulus, inertia moment, density, width and cross-sectional area of the beam, respectively; $M_a(t)$ is the force moment induced by actuator i [4], which can be expressed as

$$M_a(t) = C_a V_a(x, t) \quad (2)$$

And

$$C_a = E_a d_{31} h_{an} \quad (3)$$

where d_{31} and E_a are the piezoelectric strain constant and Young's modulus of the actuators, respectively, $V_a(x, t)$ is the voltage applied to actuator i , and h_{an} denotes the distance measured from the neutral surface of the beam to the mid-plane of the actuator.

The voltage distribution of actuator i can be expressed as

$$V_a(x, t) = V_a(t) R(x) \quad (4)$$

in which R is the Heaviside step function that can be expressed as

$$R(x) = H(x - x_{a1}) - H(x - x_{a2}) \quad (5)$$

Where x_{a1} ; x_{a2} are the coordinates of the two ends of actuator i : The general solution of (1) can be expressed as the sum of the normal modes. Hence, the displacement distribution of the beam is represented by

$$w(x, t) = \sum_{i=1}^{\infty} Y_i(x) \phi_i(t) \quad (6)$$

Where $\phi_i(t)$ is the modal displacement vector, $Y_i(x)$ is the mode shape matrix. Substituting (2)– (4) into (1) using the orthogonality properties, taken the case of clamped and using the structural damping yield the following equation:

$$\ddot{\phi}_i(t) + 2\xi_i w_{in} \dot{\phi}_i(t) + w_{in}^2 \phi_i(t) = G_a [Y_i(x_{a2}) - Y_i(x_{a1})] V_a(t) \quad (7)$$

where w_{in} , ξ_i are the natural frequency, the damping ratio and $G_a = b E_a d_{31} h$

the piezoelectric sensors will produce electrical charge while the beam has some external stimulus, the output voltage of the i^{th} piezoelectric sensor can be gained as follows:

$$V^s(t) = \square \sum_{m=1}^{m=2} \sum_{n=1}^{n=2} [Y_i(x_{a2}) - Y_i(x_{a1})] q(t) \quad (8)$$

Where

$$\alpha = \frac{k_{31}^2 h + h_{an}}{g_{31} C_r}$$

In which, g_{31} , k_{31} , C_r are the voltage constant the electromechanical coupling factor, and the Piezoelectric capacitance.

II. LQR OPTIMAL CONTROL

The idea beyond the LQR is to minimize a cost function given as [1]:

$$J = \int_0^\infty (X^T Q X + U^T R U) dt = \min \quad (9)$$

Where the matrices Q and R are weighting matrices. It assumed that the desired state is $\mathbf{x} = \mathbf{0}$, but the initial condition is non-zero, so the matrix Q penalizes the state error in a mean-square sense. Similarly, the matrix R penalizes the control effort, i.e., limits the control signals magnitude.

Design the optimal feedback control force U by the application of classical LQR control method:

$$U = K * x(t) \quad (10)$$

The gain matrix $K = R^{-1} B^T P$ which minimizes J can be found by solving a matrix Riccati equation that given by:

$$PA + A^T P + Q - PBR^{-1}B^T P = 0 \quad (11)$$

III. LQG OPTIMAL CONTROL

In the previous equation it was assumed that all the states were completely observable and there could be directly related to the output and used by the control system. However, that is not always the case and a more realistic approach would consider that only the outputs can be known and measured, hence it will be necessary to estimate the states from a model of the system, usually that estimate is made by a state estimator or observer. Here we use Kalman-Bucy filter.

$$\begin{aligned} \dot{X}(t) &= AX(t) + BU(t) + B_w W(t) \\ Y(t) &= CX(t) + V(t) \end{aligned} \quad (12)$$

$W(t)$ and $V(t)$ are modeled as white noise, featuring Gaussian stochastic processes with zero mean. It is considered that $W(t)$ and $V(t)$ are not correlated. The output vector is the system states, and the output matrix is an identity matrix.

$$W(t) = E[W(t)W^T(t)] = R_f \quad (13)$$

$$V(t) = E[V(t)V^T(t)] = Q_f > 0 \quad (14)$$

E denotes the expectation operator The estimator states \hat{X} would thus be governed by the equation:

$$\dot{\hat{X}}(t) = AX(t) + BU(t) + K_e(t)[CX(t) + V(t) - C\hat{X}(t)] \quad (15)$$

$K_e(t)$ is known as Kalman-Bucy filter given by

$$K_e(t) = P_f C^T V^{-1} \quad (16)$$

IV. LQG OPTIMAL CONTROL

In this section. A clamed beam bonded by piezoelectric actuator on upper surfaces and sensor on the lower surface as shown in Fig.1. The principal material proprieties of the beam and the piezoelectric patches are listed in Tab.1.

Fig. 1 FEM model of intelligent plate

TABLE I. MATERIAL PROPRIETIES OF SMART BEAM

Proprieties	PZT-5	Aluminum
Elastic modulus E (N/m ²)	6.3 x 10 ¹⁰	70 x 10 ⁹
Poisson's ratio	0.35	0.3
Density ρ (kg/m ³)	7600	2702
Piezoelectric constant d ₃₁ (m/V)	-1.66 x 10 ⁻¹⁰	-
The electromechanical coupling factor k ₃₁	0.34	-
Voltage constant g ₃₁ (Vm/N)	-1.15 x 10 ⁻²	-
Capacitance C(F)	1.05 x 10 ⁻⁷	-

to validate the current method, the natural frequencies of the cantilever beam are compared with those obtained with Ansys and given in Tab.2 . the results are in good agreement and prove the accuracy of the present model. the corresponding mode shape are depicted in fig. 2.

Fig. 4 The output voltage corresponding to the sensor

Fig. 5 The input voltage corresponding to actuator

V. CONCLUSION

An extensive study of the active vibration control analysis of cantilever beam using bonded piezoelectric sensor and actuator is presented.

First, the Euler Bernoulli theory have been used to analyze the behavior of the beam ,then an optimal control strategies, linear quadratic regulator (LQR) and linear quadratic Gaussian (LQG) controllers were adopted. The obtained result shows that the stabilization time, around 5 seconds for LQR and 3 seconds for LQG controller and with a maximum voltage of 150 V for LQR and 120 V for LQR. It been clearly seen that LQG presents a better control in bandwidth with a lower control voltage.

Abstract— In this study, an air heated solar collector (AHSC) dryer was designed to determine the drying characteristics of the green pepper. In the experiments thinly sliced green pepper samples were used. Collector inlet and outlet air temperatures, drying chamber inlet and outlet air temperatures, ambient temperature, radiation, air velocity and drying rate were considered as parameters affecting the drying feature. The results obtained were presented as a function of drying time. Moisture content (MC), moisture ratio (MR) and drying rate (DR) values obtained from the experiments were modeled with 3-layer artificial neural network (ANN) using Logsig Activation function and Backpropagation learning function. Mean square error (MSE) was used to determine of the statistical validity of the developed model. As a result, drying behavior of green pepper was successfully predicted by ANN for existing drying conditions.

I. INTRODUCTION

Solar energy is a clean energy source that does not run out of reserves and does not pollute the environment. Because of its ability to easily convert to heat energy, this energy is widely used in the drying of agricultural products all over the world. The simplest benefit from drying out from solar energy is to spread outdoor agricultural products on the exhibition grounds. Outdoor drying is completed in a long time and the quality of the dried products obtained is low. For this reason, solar energy dryers are needed for quality and quick drying of commercial vegetables and fruits in our country [1].

Drying is the removal of water or other liquids from gases, liquids or solids. The most common use of drying is to evaporate water or volatile substances from solid materials by thermal methods. In drying applications, the heat required

to evaporate the moisture is transferred by convection from the solid surface contacting the article to be dried, radiation, or the substance to be dried by bringing the substance to be dried directly into contact with the hot gases [2].

Various studies have been carried out in the national and international literature in the field of solar energy supported food drying. Durmus and Kurtbas have been dried the apricots in the airy solar collector and vertically positioned tray dryer. They have experimentally examined drying performance. Experiments have shown that drying speed depends on dryer air speed and temperature, collector performance, dried product thickness, and contact surface area [3]. Chen et al. carried out experimental studies on the solar energy assisted food drying system, which was formed from the dryer compartment and the solar air heater. Lemon slices were chosen as an example and dried. It has been observed that the moisture content of the limon (wet) decreases by 75-85% by 7-8% and the heat efficiency of the dryer is 30.86% according to the measurements made during drying [4].

Today, many studies have been done about the modeling of solar energy assisted drying systems with ANN. Koni, Dincer and Turker have been investigated the identification and modeling of the drying process of bread yeast in a fluidized bed. The critical input parameters of this drying process have been determined. In the system identification, they were utilized by the artificial neural network because of the nonlinear nature of the system [5]. Sevik, Aktas and Ozdemir used mushroom dryer with solar energy collector and solar energy heat pump dryer. In the experiments, they dried mushroom at 45 ° C and 55 ° C drying air temperature and 0.9 m / s-1.2 m / s air speeds. The moisture content, removable moisture content and drying rate values obtained from the experiments are modeled by ANN using the Levenberg-Marquardt (LM) backpropagation learning algorithm and the Fermi transfer function [6]. Erenturk examined the drying kinetics of the carrot monolayer for different drying conditions and different sample thicknesses.

They obtained drying curves by using drying data. They have applied four different drying models in the literature to the system in order to express drying kinetics. They compared the models by finding r , r^2 , χ^2 , and SSR values. In addition, they have applied artificial neural network models to predict moisture content and comparisons with selected models [7].

In this study, green pappers was dried in AHSC. It is aimed to model *MC*, *MR* and *DR* with ANN by analyzing drying test results.

II. MATERIALS AND METHOD

A. Experimental Set-Up

Experimental set up mainly consists of an indirect forced convection solar dryer with a solar air collector (1400 mm x 800 mm), a circulation fan and a drying cabinet (Fig. 1). Solar air collector is constructed from stainless steel sheets (thickness, 0.5 mm), outer surface of which is painted with black collector paint. Solar air heater was covered with copper sheet (thickness, 0.4 mm), which was painted with black collector paint. A glass is used as a transparent cover for air heater to prevent top heat losses. Solar heater was oriented southwards under the collector angle of 23.7° (local latitude 38.4°). This angle was fixed by foots. Frame was made of stainless steel sheet.

Fig. 1. Experimental set-up

1-Solar collector; 2-Frame; 3-Foot; 4-Connection pipe; 5-Circulation fan; 6-Drying cabinet; 7-Channel selector; 8-Digital thermometer 9-Anemometer; 10- Pyrometer; 11- Digital solar integrator; 12- Hygrometer

Drying cabinet was constructed from wood as a rectangular tunnel (45 cm x 45 cm x 45 cm). Bottom side of the cabinet was a circular tube connected to the same diameter to connect the main collector tube. The connection to this tube was made with bendable spiral aluminium tube of the same diameter. Drying air was exited from circular pipe

at topside of the cabined. One end of the cabinet was manufactured in type of cover, which was used to load or unload the cabinet. One drying tray (40 cm x 40 cm) was placed inside the drying cabinet. A centrifugal fan (0.0833 m³s⁻¹, 0.25 kW, 220 V, 50 Hz, 1380 min⁻¹) connected to drying cabinet provides air (velocity, 0.4 ms⁻¹).

Fresh long green peppers (sweet) obtained from Elazig, were refrigerated. Generally, samples of uniform size were selected. Thickness of pepper was measured as 1.7 ± 0.2 with a micrometer. Solar drying experiments were carried out during the periods of June 2016 in Elazig, Turkey. Test started at 9:30 a.m. and continued till 17:30 p.m. Elazig is locate at $38^\circ 60'N$ and $39^\circ 28'E$ and above 950 m of sea level in the eastern part of Anatolia, Turkey.

In the experiments, weather temperature and relative humidity, inlet and outlet temperatures of air in the solar collector, the temperatures at the various points of drying cabinet, humidity, inlet and outlet temperatures of air in the cabinet, wind speeds, the amount of solar radiation, and mass loss of long green peppers were measured at 30 mins intervals. The flow charts of the thin layer forced drying processes are presented in Fig. 2.

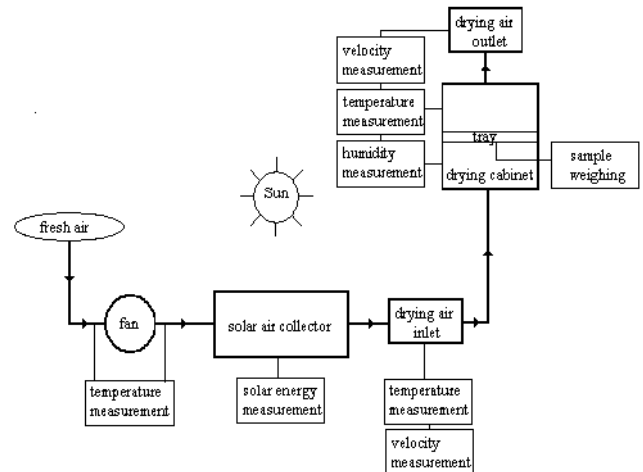

Fig. 2. Flow diagram of thin layer forced solar drying process

In the measurements of temperatures, J type iron-constantan thermocouples were used with a manually controlled 20-channel automatic digital thermometer (ELIMKO, 6400, Turkey), with reading accuracy of $\pm 0.1^\circ C$. A thermo hygrometer (EXTECH, 444731, China) was used to measure relative humidity just above long green peppers, with reading accuracy of $\pm \% 0.1$. The wind speed was measured by a 0-15 m/s range anemometer (LUTRON, AM-4201, Taiwan), with reading accuracy of ± 0.1 m/s. Moisture loss of long green peppers were recorded during drying for determination of drying curves by digital balance (BEL, Mark 3100, Italy) in the measurement range of 0-3100 g and an accuracy of ± 0.01 g. The solar radiation during the

operation period of drying system was measured with a Kipp and Zonen pyrometer in $\pm 0.1 \text{ Wm}^{-2}$ accuracy and its CC12 model digital solar integrator. The initial and final moisture content of long green peppers was determined at 80°C by a Mettler infrared moisture analyzer in $\pm 0.001 \text{ g}$ accuracy.

B. System Analysis

Some general equations used in the drying analysis of the system are given below. For the values of moisture content (MC_{KA}) according to dry basis in green pepper;

$$MC_{KA} = \frac{WW-DW}{DW} \quad (1)$$

for the values of moisture content (MC_{YA}) according to wet basis in green pepper;

$$MC_{KA} = \frac{WW-DW}{WW} \quad (2)$$

equations have been used. In Equations (1) and (2); WW is wet weight and DW is dry weight.

Adjustable moisture ratio (MR) values have been calculated using the following formula.

$$MR = \frac{M-M_e}{M_0-M_e} \quad (3)$$

Drying speed (DR) values have been calculated from the formula below.

$$DR = \frac{M_{t+dt}-M_t}{dt} \quad (4)$$

In Equations (3) and (4); M is moisture, M_e is equilibrium moisture, M_0 is first moisture, M_{t+dt} is moisture content at " $t + dt$ " and M_t is moisture content at " t ".

C. Artificial Neural Networks

Artificial neural networks has emerged as a result of artificial simulated efforts of the human brain's working system. Based on certain values, the ANN links the points in the input field to a particular function in the output field [8]. Artificial neural networks, pattern recognition, estimation, classification, etc. have wide application area. Artificial neural networks learn with examples similar to humans. For this reason, the data set is divided into two parts as training and test cluster [9].

In this study, Levenberg-Marquardt (LM) backpropagation learning algorithm, Logsig activation function and Backpropagation learning function were used in ANN for the moisture content (MC), separable moisture content (MR) and drying rate (DR) values obtained from experiments. Mean squared error (MSE) has been used to compare predicted values to actual values on model

evaluation. MSE values have been calculated using the following formula by ANN.

$$MSE = \frac{1}{n} \sum_{i=1}^n (DATA_{exp,i} - DATA_{ANN,i})^2 \quad (5)$$

In Equations (5); $DATA_{exp,i}$ is experimental data and $DATA_{ANN,i}$ is predicted data.

The time dependent MC , MR , and DR values of the experiments have been calculated from Equations (1), (3) and (4). Solar radiation values were measured with a digital solar integrator. As input data for the network; Time (t), drying air velocity (v), drying air temperature (T), drying air relative moisture (RM) and solar radiation (SR) values were used. As output data; MC , MR , and DR values were used. As a middle layer; Three hidden layers were created and the best solutions were tried to be obtained by changing the number of intermediate layers. The structure of the generated ANN model was given in Fig. 3.

Fig. 3. ANN structure

III. RESULTS AND DISCUSSION

A total of 128 data were used in ANN model. Of these data, 112 were used for training and 16 were used for testing. The ANN structure used for MC , MR , and DR is shown in Table I.

TABLE I. STRUCTURE OF ANN

Structure of ANN used for the estimation of MC, MR, and NR	
Number of Layers	3
Number of Neurons in Layers	6-6-3
Weight Ratings	Random
Activation Function	Logsig
Learning Function	Backpropagation
Learning Ratio	0,97
Mean- Squered Error	1e-06

The network learning process has been successfully completed. The performance of the ANN model developed for *MC*, *MR*, and *DR* is shown in Fig. 4. Since the difference between the predicted values and the experimental values is very small and negligible, it can be seen that there is a harmony between the values.

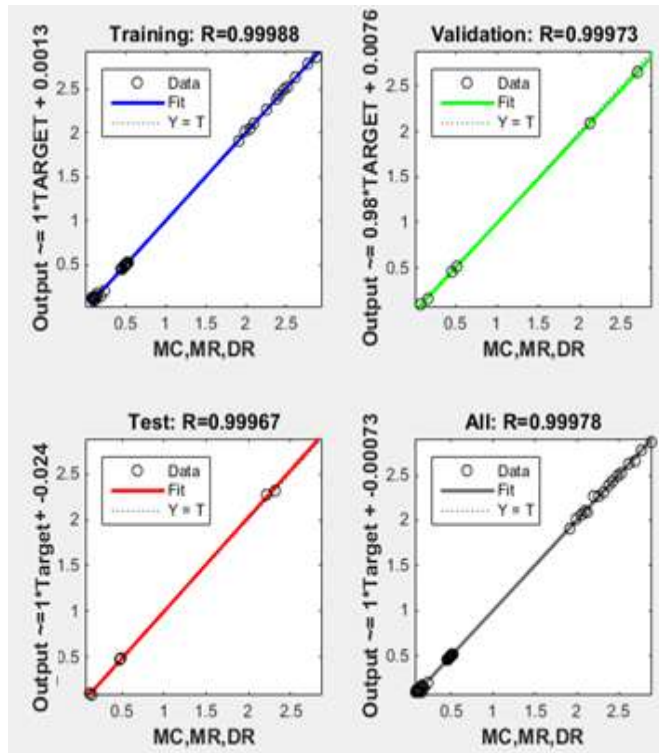

Fig. 4. Regression graph for MC, MR and DR

IV. CONCLUSIONS

In this study, green pepper was dried with AHSC drying system. *MC*, *MR* and *DR* parameters were experimentally calculated for different temperature and air velocity values at 30 minute intervals during green pepper drying. ANN was used for estimation of *MC*, *MR* and *DR* parameters. Estimated values with YSA and actual values obtained after the test are shown in Fig. 5-7. As a result, ANN estimation for *MC*, *MR* and *DR* parameters were successfully performed.

Abstract— In this study, a fixed air heated solar collector (AHSC) and solar tracking AHSC were used. Thermal performance of the collector with moving and fixed have been experimentally investigated. Collector inlet and collector outlet air temperatures, radiation, air outlet velocity, absorbent plate temperature, collector jacket outer surface temperature and transparent cover temperatures were measured. The thermal efficiencies of both collectors were calculated according to the measurements. With the obtained experimental data, the artificial neural network (ANN) module was created and the heat output from the collector and the air temperature were determined for different input parameters. Calculated thermal efficiencies were compared, and moving AHSC was found to work more efficiently. As a result, it was determined that ANN model successfully predicted thermal efficiency and collector output temperature of fixed and moving AHSC.

Keywords— *Solar Tracking System, Solar Collector, Thermal Efficiency*

I. INTRODUCTION

Today, energy demand is increasing due to factors such as population growth, rapid technological developments, economic growth and globalization. In order to be able to respond to increasing energy needs, mankind has begun to focus on alternative energy sources as well as existing energy sources [1].

AHSC is a low-cost simple device that does not have problems such as long life, light, corrosion. A conventional AHSC surrounds a well-insulated enclosure, a scraping plate placed inside the enclosure, and a transparent cover at the top. There is also a fan in the system, depending on whether the airflow is natural or forced. At AHSC the heat transfer coefficient between the damping plate and air is low. For this reason, these collectors can not work at the desired thermal efficiency values [2].

In the literature, solar tracking system studies have been carried out in order to benefit more effectively from solar energy. Iscan designed a solar tracking system circuit that can

follow the sun continuously in two directions throughout the day. He made a working analysis of the system during the day and prepared cost analysis for different powers to be designed [3]. Demirtas designed and manufactured a computer controlled two axis solar tracking system. The vertical and horizontal movement of the system is secured by step motor. It has been used a microcontroller controlled interface to record the obtained data in a computer environment and to control the system with a computer. With the solar tracking system, it produced an average of 16 volts in normal daylight [4]. Seme and Štumberger have developed a new estimation algorithm for solar angles using solar radiation and Differential Evolution on a biaxial solar tracking system [5]. Kırbaş et al. have provided effective use of solar energy in air heated solar collectors using solar tracking mechanism. In their work, two collectors, one fixed and one moving, measured to determine the difference between the output temperatures. In the morning and afternoon they determined that the outlet temperature of the moving type collector is 5-12 ° C higher than the fixed collector [6].

Today, many studies have been done about the modeling of solar energy assisted drying systems with ANN. Altıntaş at all have been examined the efficiency of the solar collector and the output temperature of the collector with with the flat absorber plate and the conical spring absorber plate. They have estimated the values they obtained with ANN and obtained 97% prediction success. [2]. Sevik, Aktas and Ozdemir used mushroom dryer with solar energy collector and solar energy heat pump dryer. In the experiments, they dried mushroom at 45 ° C and 55 ° C drying air temperature and 0.9 m/s -1.2 m/s air speeds. The moisture content, removable moisture content and drying rate values obtained from the experiments are modeled by ANN using the Levenberg-Marquardt (LM) backpropagation learning algorithm and the Fermi transfer function [7]. Erenturk examined the drying kinetics of the carrot monolayer for different drying conditions and different sample thicknesses. They obtained drying curves by using drying data. They have applied four different drying models in the literature to the

system in order to express drying kinetics. They compared the models by finding r , r^2 , χ^2 , and SSR values. In addition, they have applied artificial neural network models to predict moisture content and comparisons with selected models [8].

In this study, AHSC designed with solar tracking ability to increase thermal efficiency was made. The thermal efficiencies of the designed moving AHSC and fixed AHSC were found both experimentally and with the ANN model.

II. MATERIALS AND METHOD

The moving and fixed AHSC's are measuring 800mm x 1400mm and the absorber plates are made of sheet material painted black. One of the most important factors affecting AHSC's performance is the maximum benefit from sunlight. For this, the collector of the rays of the sun must come constantly at 90°. The moving AHSC is designed to track the sun in the east-west and north-south directions with a programmable logic controller (PLC) system for the sun's rays to reach the collar at right angles. Fixed AHSC is fixed to 42° for Elazığ province according to the azimuth angle. The experimental setup is shown in Fig.1.

Fig. 1. Experimental set-up

After the installation of the test apparatus, the system was operated under open air conditions and the necessary measurements were made. The measurement points in the experiment set are given in Fig.2. For this purpose, the temperature was measured from the inlet and outlet, absorber plate and under the cabinet of the collectors. Air speed measurement at the outlet of the collectors. The value of solar radiation is measured by a solar radiation meter. The data recording interval was set to thirty minutes.

Fig.2 Measuring Points

1. Global radiation value (I)
2. Collector inlet air temperature (T_i)
3. Exit speed of air from the collector (V)
4. Collector output air temperature (T_o)
5. Absorber plate surface temperature (T_p)

values were measured. Tests started at 9:00 a.m. and ended at 17:00 p.m.

A hotwire type anemometer with a sensitivity of $\pm 0,2$ m/s was used for air speed measurement. The air speed was measured by placing an anemometer on the exit air duct. In order to measure the output air temperature, two heat sensors were installed in the output channel and the average of the measurements was taken. The thermal sensors used are sensitive to ± 0.5 °C. A solar radiation meter was used to measure the global amount of radiation. In the experiments, air temperature, air velocity, surface temperature and solar radiation values were measured. With these measurements mass flow rate and thermal efficiency calculations were made.

III. HEAT EFFICIENCY ACCOUNT

The useful energy (Qu) in the solar-powered air collector depends on the inlet and outlet temperatures of the fluid passing through the collector were calculated by Equation (1).

$$Qu = \dot{m} \cdot Cp \cdot (To - Ti) \quad (1)$$

Here, \dot{m} is the mass flux (kg/s) of the air passing through the collector, Cp is the specific heat of the air (J/kgK), Ti and To are the collector inlet and outlet temperatures respectively ($^{\circ}C$).

The mass flux of the air passing through the collector was calculated by Equation (2).

$$\dot{m} = \rho \cdot V \cdot Ak \quad (2)$$

Here, ρ is the density of the air (kg/m³), V is the airflow rate (m/s), and Ak is the output cross-sectional area (m²) of the collector.

Utilizing the first law of thermodynamics, the thermal efficiency of the collector was calculated by Equation (3).

$$\eta = \frac{\dot{m} \cdot Cp \cdot (To - Ti)}{I \cdot AC} \quad (3)$$

Here, η is the heat efficiency, I is the solar radiation coming to the surface of the collector (W/m²), and AC is the surface area of the absorbing plate that is directly hit by solar radiation (m²).

IV. MODELING OF DATA WITH ARTIFICIAL NEURAL NETWORKS

Artificial neural networks, pattern recognition, estimation, classification, etc. have wide application area. Artificial neural networks learn with examples similar to humans. For this reason, the data set is divided into two parts as training and test cluster [10]. Artificial neural networks has emerged as a result of artificial simulated efforts of the human brain's working system. Based on certain values, the ANN links the points in the input field to a particular function in the output field [9].

In the system, artificial neural networks are modeled as five inputs and one output. The collector inlet temperature (Ti) of the air, the absorber surface temperature (Tp), the global radiation (I) value, the air outlet velocity (V) and the collector air outlet temperature (To) were taken as input data. The thermal efficiency (η) is used as the output data. The structure of the generated YSA model is given in Fig 3.

Fig.3 ANN model structure

MATLAB 2014b software was used in the modeling of artificial neural networks. The information cluster contains 192 input and output information. Of these, 168 were used in the training process. 24 were used in the test process. As a learning algorithm, Feed Forward Back Propagation algorithm was used. The ANN structure used for The thermal efficiency (η) is shown in Table I.

TABLE I Structure of ANN

Structure of ANN used for the estimation of The thermal efficiency (η)	
Number of Layers	3
Number of Neurons in Layers	6-6-1
Weight Ratings	Random
Activation Function	Logsig
Learning Function	Backpropagation
Learning Ratio	0,95
Mean- Squared Error	1e-06

The accuracy of the result obtained from the modeling of AHSC with ANN was determined using root mean square error (RMSE). For the training, the coefficient of multiple determinations (R^2) method was used.

$$R^2 = 1 - \left[\frac{\sum_{m=1}^n (\eta_{exp,i} - \eta_{ANN,i})^2}{\sum_{m=1}^n (\eta_{ANN,i})^2} \right] \quad (4)$$

$$RMSE = \sqrt{\frac{\sum_{m=1}^n (\eta_{ANN,i} - \eta_{exp,i})^2}{n}} \quad (5)$$

V. RESULTS AND DISCUSSION

In this study, the thermal performance of the moving AHSC with the fixed AHSC was estimated experimentally and the thermal efficiency was determined by the ANN.

Fig.4 shows the thermal efficiency and predicted thermal efficiency of the fixed AHSC.

Fig. 4. Thermal efficiency graph of fixed AHSC

Fig.5 shows the thermal efficiency and predicted thermal efficiency values of the moving AHSC.

Fig.5. Thermal efficiency graph of moving AHSC

VI. CONCLUSIONS

In this study, the thermal performance of fixed and moving AHSCs was experimentally tested. The heat dissipation of the collectors is calculated by the data obtained from the experiments. It has been seen that the moving AHSC has a higher thermal efficiency than the fixed AHSC.

Different parameters have been tried at training time to improve the predictive ability of Artificial Neural Networks. The structure of artificial neural networks giving the most favorable result was accepted as a training parameter. The predicted thermal efficiency and actually measured thermal efficiency curves of the ANN model generated are similar to each other. It has an accuracy rate of 0.95 according to the R^2 method. The heat efficiency of the moving AHSC has been achieved as a result of its successful prediction with 95% accuracy of ANN.

Abstract—The growing concern about energy consumption of heating and cooling of buildings has led to a demand for improved thermal performances of building materials. In this study, an experimental investigation is performed to predict the thermal insulation properties of wall and roof structures of which the mechanical properties are known, by using back-propagation artificial neural network (ANNs) method. The produced samples are cement based and have relatively high insulation properties for energy efficient buildings. In this regard, 102 new samples and their compositions are produced and their mechanical and thermal properties are tested in accordance with ASTM and EN standards. Then, comparisons have been made between the determined thermal conductivity of the newly produced structures, which are obtained from experimental method and ANN method that uses mechanical properties as input parameters. From the test results, since the percentage errors in the thermal conductivity values between experimental data and neural network prediction vary from -1.09% to 6.4%, It can be concluded that the prediction of the artificial neural network has proceed in the correct manner.

Keywords— Concrete, thermal conductivity, mechanical properties, back-propagation, energy efficient building

I. INTRODUCTION

Heating ventilating and air conditioning (HVAC) system has been the most important solution for the humanity who can live in spaces having comfort conditions along whole year. The main purpose of the HVAC system is to keep the changing temperature in the comfort zones by heating and cooling air within a space. For this reason, it is necessary to heat the living spaces in winter season by giving sufficient amount of moisture, and to cool the spaces in summer season. Building heating or cooling requirements for the winter and summer seasons constitutes loss or gain through windows, walls, roofs, infiltration and equipment's used. In many

buildings, walls and roofs are responsible for a major fraction of heat loss or gains for the heating or cooling loads due to their large surface area [1]. Since air conditioning systems consume large amount of electricity, especially in hot regions, it is critical to improve the thermal performance of these structures in terms of reducing the energy use. [2] In order to describe the thermal performance of the opaque envelope components, many studies have been conducted to identify the dynamic thermal characteristics of the components which indicate the magnitude of heat loss and gains through building structures under periodic boundary conditions and are influenced by the effective parameters, which can be categorized as environmental parameters (ambient air temperature, solar heat flux, ventilation etc.), design parameters (orientation, solar absorptivity, emissivity etc.) and thermophysical properties (thermal conductivity, specific heat, density, thickness etc.) [3]. Many investigations declared that those characteristics strongly depend on the thermal conductivity of the building's layer materials [4–11]. Besides, the thermal conductivity of a building wall or roof material are strongly affected by microstructure, mineralogical composition, proportion, supplementary materials, moisture content, and porosity, as shown in Fig. 1 [12]. Furthermore, these structures also need to have suitable mechanical properties because they must stand without being damaged from natural causes for many years. Therefore, if these structures having appropriate thermal and mechanical properties are selected, also accurate cooling load calculation is performed, and then suitable HVAC system components can be selected in terms of reducing the energy use. However, it is difficult to determine the ideal thermal conductivity properties of these structures by means of both energy and time efficiency due to the accuracy of test methods and high price of the devices. Hence, this situation leads scientists to search for new solutions. The mathematical models which are

used to describe experiences gathered from data of concrete mixes behaviors are most reliable and accurate as well as recommended methods [13]. These models based on experimental data are generally in regression forms, and called

Fig.1. Parameters affecting thermal conductivity of structures

“Free models”[14]. However, because of more assumptions and less accuracy in regression form, regression methods cannot be used when the problem contains many independent variables. Recently many new modeling methods such as artificial neural networks (ANN), expert systems as a free model can complex relation and approximate non-linear due to any parameters and trial and error process by learning real record relationship without any presumptions [15]. Artificial neural networks (ANN) are a family of massively parallel architectures that are producing meaningful solutions to the problems capable of learning and generalization of examples and experiences, even if the input data is incorrect or incomplete. ANN is a powerful tool to solve for some complex engineering problems. The basic strategy for developing a neural network-based model for material behavior is to train a neural network on the results of a series of experiments using that material. If the experimental result contains relevant information on the behavior of the material, the neural network training will contain sufficient information on the behavior of a material to qualify as a model material [16]. This learning of the neural network not only be able to reproduce the experimental results, but would be able to bring the results of other experiments by the generalization ability.

In the literature, the ANN has been used to predict the effect of material behavior, especially on mechanical properties. Marai M. Alshihri et al [15] are used the neural networks (NNs) to predict the compressive strength of light weight concrete (LWC) mixtures after 3, 7, 14, and 28 days of curing. It is concluded that the cascade correlation (CC) neural network model predicated slightly accurate results and learned very quickly as compared to the back propagation (BP)

procedure. Furthermore, Guang and Zong, [17] proposed a method to predict 28-day compressive strength of concrete using multilayer feed-forward neural networks. Dias, [18] presented an artificial neural network model for predicting the strength and slump of ready mixed concrete. Eldin and Senouci, [19] employed a neural network for measuring and predicting of the strength of rubberized concrete. Lai [20] predicted the mechanical properties of concrete by ANNs. Moreover, Gencel et al [21] predicted the thermal conductivity of concrete with vermiculite by using artificial neural networks approaches with 20 datasets. The root mean square error, the mean absolute error, and determination coefficient statistics are used as evaluation criteria of the models, and the experimental results are compared with these models.

Therefore, this research aimed to predict ideal thermal conductivity values of concrete wall or roof structures by using an ANN method so as to reduce the energy consumption of the buildings. The structures were prepared by changing the volume fraction of aggregate materials in the cementitious matrix, which were exposed to the same conditions. The test program was conducted mainly to investigate the effect of pumice (PA), rubber aggregates (RA) and expanded perlite (EPA) on the thermal property of samples by using thermal response method. The findings and results are presented in detail in the following sections.

II. EXPERIMENTAL PROCEDURE

A. Concrete Mixtures, Materials and Test Methods

Several materials were used to obtain different lightweight building elements. The materials were locally available ordinary Portland cement (PC) (CEM I 42.5R), silica fume (SF), fine aggregate, coarse aggregate, RA, PA, EPA and superplasticizer (SP). Concrete mixtures were designed with a constant water–cementitious material (w/c) ratio of 0.48 and total cement content of 350 kg/m³. Normal aggregates were replaced by PA, EPA and RA at different volume fractions vary between 10% and 50%. In total, 102 concrete samples were produced and their mechanical tests which are the compressive strength, bulk density, porosity are performed on air dry samples aged 28 days. The thermal conductivity test was performed on same state with the age of 35 days according to EN 12667. In this study, ISOMET 2104 device (Fig. 2) was used to measure thermal conductivity of concrete samples on the basis of TPS method and the values of the device ranges for the measured parameters are presented in Table 1. In the TPS technique, the source of heat is a hot disc made out of a bifilar spiral, which also serves as a sensor for temperature increase in the samples. In comparison with stationary or steady state methods, the advantage of transient methods is that some of them give a full set of thermophysical properties within a single rapid measurement. All test result measurement values presented in the tables are based on the average values \pm a tolerance limit (less than 4%) in order to cover the range of all properties as measured for different samples of the same category.

B. Construction of Neural Network Model and Parameters

Neural networks have been designed to counterpart the thinking, recognize and problem solving abilities of biological human brain. ANN is a computational model and useful when especially for extremely complex problems. ANN was used in this study to estimate of thermal insulation properties of lightweight building materials. Fig. 3 shows a basic neural model where consist of 4 inputs and a single output. The basic

Fig. 2. The thermal property measurement device used in this study.

structure of ANN is composed of input, hidden, and output layers. The neuron will combine weighted inputs with a threshold value and activation function.

Design procedure of ANN involves two main part: training and validation. In training process, the weights are modified until the model has learnt the problem. Further, in validation phase, the network is tested with new unknown parameters. The back-propagation technique is very common and powerful strategy for the nonlinear functions and thus has inspired many researchers apply ANN to various system.

There are a number of activation functions in use with NN such as step, sigmoid or hyperbolic tangent function. In training process, the error between network prediction and experimental result of concrete samples was calculated. The error was propagated backward through the neural network, and every neuron weights are updated. This was done to ensure that in the next round, the error would be reduced for the same inputs.

For construction of NN, Matlab - Neural Network Toolbox is used to design, train and simulate. In this article, the neural network is designed as three-layer network structure. Every layer in network has 3-5-4 neurons, respectively. Using this program, a neural network model was constructed, trained and tested using the available test data of 102 different concrete mix-designs gathered from experimental setup. The data used in neural network model are arranged in a format of four input parameters that cover the bulk density, porosity, compressive strength, and the percentage lightweight aggregate content (%).

TABLE I. VALUES OF DEVICE RANGE FOR MEASURING PARAMETERS

Measurement	Measurement range	Accuracy
Thermal conductivity coeff.	0.015–6 W/mK	5 % of reading + 0.001 W/mK
Operating temperature	From -20 – +70 °C	1°C

Fig. 3. Basic neural network model

III. RESULT AND DISCUSSION

The results of the experimental tests gathered from the mechanical and thermal properties of PC, NC, EPC and RC, and mixtures prepared, in contrast with the control mixture are shown in Table 2 below.

After experimental setup was performed, an artificial neural network (ANN) method, which is Levenberg-Marquart algorithm is selected for prediction of thermal conductivity of concretes of which the mechanical properties are known. In the training session, validation is stopped after 9 iterations at mean squared error value of 0.019. Fig. 4 presents mean squared error (MSE) performance. In this figure best validation performance occurred at iteration 3 and the neural network at this iteration is returned. After 3 iteration. test set and validation set error have similar properties and no over-fitting occurred.

A linear regression between the network output and the corresponding target is shown in Fig. 5. The output follows the targets well and the correlation coefficient R is 0.96845 for the total response that indicate good matching between the experimental and prediction data.

Table 3 shows a comparison between the predicted thermal conductivity of concrete against experimental data, which emphasizes that it is a good agreement between them. From the

TABLE II. MECHANICAL AND THERMAL PROPERTIES OF PRODUCED CONCRETE SAMPLES^a

Types of concrete	Compressive strength σ_c (MPa)	Bulk density ρ (kg/m ³)	Porosity ϕ (%)	Thermal conductivity λ (W/mK)

test results, it is an evident that the error percentage conductivity lies in the range from -1.09% to 6.4% between experimental data and neural network prediction. Therefore, it can be concluded that the prediction of the artificial neural network has proceed in the correct manner.

IV. CONCLUSION

In this study, an experimental investigation is performed to predict the thermal insulation properties of wall and roof

structures of which the mechanical properties are known, by using an artificial neural network (ANNs) method. Then, comparisons have been made between the determined thermal conductivity of the newly produced structures, which are obtained from experimental method and ANN method that uses mechanical properties as input parameters. Initially, the number of neurons in the hidden layer is optimized by trial and error method. Then the neural network 3-5-4 is trained using Levenberg-Marquardt (LM) training algorithm, the value of the mean squared error and the correlation coefficient R were found as 0.019 and 0.99939, respectively. From the test results,

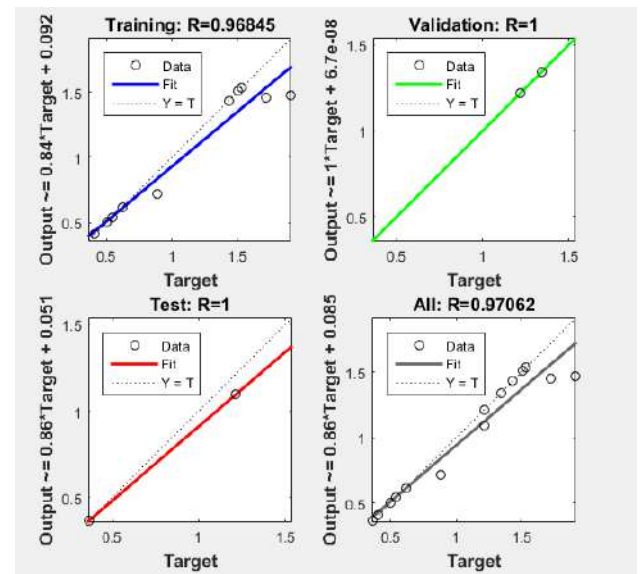

Fig.5-Regression plot for LM algorithm

Abstract—Present study is focused on numerical investigation of heat enhancement and fluid flow from a heated surface by using nanofluids and impinging jets. Effects of Reynolds number, different particle diameter and different types of nanofluids (Cu-water, Al_2O_3 -water, TiO_2 -water) on heat transfer and fluid flow were studied numerically. Al_2O_3 -water nanofluid was used as a base coolant. Three impinging jets were used to cool the surface. Low Re k- ϵ turbulent model of PHOENICS CFD code was used for numerical analysis. It is obtained that increasing jet velocities from the first phase to the third phase causes an increase of 51.4% on average Nusselt number (ANN) but increasing jet velocities from the third phase to the fourth phase causes a decrease of 5.6% on ANN. Decreasing particle diameter from $D_p=80\text{nm}$ to 10nm causes an increase of 12.8% on ANN. Using Cu-water nanofluid causes an increase of 9.3%, 8.4%, on ANN with respect to Al_2O_3 -water, TiO_2 -water.

Keywords—heat transfer; nanofluids; particle diameter; Impinging jets

V. INTRODUCTION

Suspension of solid particles which have 1-100 nm size in a base fluid called as nanofluid. Nanoparticles suspended in base fluid can expand thermal capacity of the fluid and also interactions and collisions between nanoparticles cause to increase in turbulence and turbulence intensity of the transition surface. Nanoparticles have 20% of their atoms on the particule surface, making them ready to heat transfer with high heat transfer coefficient. Nanoparticles provide another advantage which called as the particle mobility to nanofluids. Particle mobility causes micro-convection in the liquid due to its nano size and therefore increases heat transfer. Hence, they have a wide range of application in industry as microelectronics medicine and space research.

The jet cooling technique provides an important enhancement in heat transfer. Impinging jet technique can be used to boost up heating, cooling or drying processes on a selected surfaces. Impinging jets technic enhance heat transfer by increasing local heat transfer coefficient between the

impinging fluid and a selected surface. Combination of the liquid jet impingement and the nanofluid technologies provides advantages of both and consequently improves the heat transfer significantly. This improvement means compact size and low weight which reduces the cooling system capital cost.

Many studies on nanofluid or impinging jet, can be found in the literature. Teamah et al. [1] examined the heat transfer and flow structure for a flat plate by numerically and experimentally with different Reynolds numbers ($\text{Re} = 3000\text{--}32000$) and nanofluid volume ratios ($\phi = 0\text{--}10\%$) by using Al_2O_3 nanofluid. It has been observed that as volume fraction of nanoparticles in the fluid are increased, the heat transfer from the surface increases. Heat transfer coefficient can be increased by 62% when compared with the water. Sun et al. [2] searched the effect of a single jet using CuO nanofluid for heat transfer. It has been determined that when the nanofluid is used, a significant increase in heat transfer can be achieved compare with water. When a circular nozzle is used, a higher heat transfer coefficient is obtained compared to a square shaped nozzle, and the highest heat transfer is obtained when the jet angle is 90° . Çakır M.T. [3] experimentally examined the thermal performance of the thermosiphon-type heat pipe which is using nanofluid as a working fluid. The nanofluid contained 2% by volume Al_2O_3 . As a result, significant reduce on thermal resistance is obtained but a complete stabilization at thermal efficiency could not be provided. Manay et al. [4] have compiled recent studies which focusing on using of nanofluids in microchannels. As a result, nanofluids using in microchannels increases heat transfer, but the presence of nanoparticles causes an increase in pressure loss. Chien et al. [5] experimentally observed the application of nanofluid in the flat plate heat pipe. It was acquired that the use of nanofluid achieve 40% reduction in thermal resistance compared to pure water utilization. Kang et al. [6] determined that, when nanofluid which include 10 nm and 35 nm sized Ag nanoparticles is used, thermal resistance diminished by 50% and 80% compared to pure water respectively. Xuan and Li [7]. Prepared nanofluid that include Cu and they investigated heat transfer effect of nanoparticle volume fraction, heat

transfer effect of particle diameter and heat transfer effect of particle geometry. As a result; it has been found that an increase of from 2.5% to 7.5% in the volumetric range causes an increase in the coefficient of thermal conductivity of nanofluid from 1.24 to 1.78. Shang et al. [8] studied the heat transfer characteristics of a closed-loop vibrating heat pipe with Cu-water nanofluid. They obtained that compared with pure water, the heat transfer capacity of the system increased by 83% when nanofluid was used. Umar et al. [9] researched the heat transfer from constant heat flux surface in laminar flow regime for varied volume fraction and Reynolds number. They used Cu-water nanofluid in their analysis. As a result, They observed that as the particle volume ratio increases and the Reynolds number increases, the heat transfer coefficient increases, the highest increase in heat transfer coefficient (61%) occurs at a particle volume ratio of 4% and Reynolds number $Re = 605$. Qu et al. [10] Used Al_2O_3 -water as working nanofluid in their experiment to investigate the thermal performance of a closed-loop vibrating heat pipe. As a result, they observed that the thermal resistance of the system decreased by 32.5% compared to pure water. Naphon et al. [11] investigated the heat transfer between the nanofluids that they built using titanium-ethanol and the closed two-phase thermosiphon. An increase of 10.6% on heat transfer was obtained by using nanoparticles, compared to ethanol using. Kilic et al. [12] examined the cooling of a flat plate by using impinging fluid air jet. It was observed that the mean Nusselt number increases by 49.5% when Reynold numbers is between 4000 and 10000. Lin Z.H. et al. [13] investigated heat transfer in confined fluid jets systematically in their study experimentally. The effects of Reynolds number and jet-target plate spacing on heat transfer were analyzed in their study. They observed that the effect of the change in jet-target plate distance has not significant effect on heat transfer, but the increase in Reynolds number increases heat transfer. In the range of $190 \leq Re \leq 1537$ and $1 \leq H/W \leq 8$ two experimental correlations were determined for the Nusselt number at the starting point and mean Nusselt number.

VI. PRELIMINARY DEFINITIONS

The heat transfer from the surface will take place by convection, conduction and radiation.

$$Q_{convection} = Q_{total} - Q_{conduction} - Q_{radiation} \quad (1)$$

The total amount of heat to be given to the plate is;

$$Q_{total} = \frac{V^2}{R}$$

$$\alpha + \beta = \chi. \quad (1)$$

Where V is the voltage value of the power unit and R is the resistance of the heater. Here, the heat generated by the heater placed under the copper plate will be transmitted to the upper surface of the plate through the copper plate thickness by

conduction, and as a result, the plate surface will be cooled by using nanofluid with impinging jet. Heat transfer by conduction along the plate;

$$Q_{conduction} = \frac{-k_c \cdot A_c \cdot (T_{bottom} - T_{upper})}{L_c} \quad (3)$$

$$\alpha + \beta = \chi. \quad (1)$$

here, k_c is the heat transfer coefficient of the copper plate, A_c is the copper plate surface area, and L_c is the copper plate thickness.

Thermal losses due to radiation;

$$Q_{radiation} = \varepsilon \cdot \sigma \cdot A \cdot F \cdot (T_s^4 - T_{bulk}^4) \quad (4)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where ε is the copper plate emissivity, σ is the Stefan-Boltzmann constant, A is the radiation surface area, T_s is the surface temperature, and T_{bulk} is the mean fluid temperature.

$$T_{bulk} = \frac{T_{in} + T_{out}}{2} \quad (5)$$

It is assumed that heat transfer with radiation is negligible in this study because surface temperature is under $573.15^\circ K$.

Heat transfer from surface with convection;

$$Q_{convection} = h \cdot A \cdot \Delta T \quad (6)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where h is the heat transfer coefficient, A is the convection surface area, ΔT ($\Delta T = T_s - T_{bulk}$) is the difference between the measured surface temperature and the fluid mean temperature.

Nusselt number (Nu) is a dimensionless parameter indicating the ratio of heat transfer with conduction to heat transfer with convection.

$$Nu = \frac{(Q_{convection} \cdot D_h)}{(T_s - T_{jet}) \cdot k_{nf}} \quad (7)$$

$$\alpha + \beta = \chi. \quad (1)$$

Where T_s is the measured surface temperature, D_h is the hydraulic diameter, and k_{nf} is the coefficient of thermal conductivity of the nanofluid. Reynolds number (Re) is used

to determine for forced convection whether the flow is laminar or turbulent. Reynolds number based on turbulent flow;

$$Re = \frac{(\rho_{nf} \cdot V_{jet} \cdot D_h)}{(\mu_{nf})} \quad (8)$$

$$\chi \cdot \quad (1) \quad \alpha + \beta = \quad (1)$$

Where ρ_{nf} is the nanofluid density, V_{jet} is the jet velocity, and μ_{nf} is the nanofluid dynamic viscosity. The density of nanofluids is;

$$\rho_{nf} = (1 - \varphi) \cdot \rho_{bf} + \varphi \cdot \rho_p \quad (9)$$

$$\chi \cdot \quad (1) \quad \alpha + \beta = \quad (1)$$

Where ρ_{bf} is the base fluid (water) density, φ is the volumetric ratio of the nanofluid, and ρ_p is the density of the solid particles in the nanofluid. The volumetric ratio of nanoparticles is;

$$\varphi = \frac{1}{(1/\omega) \cdot (\rho_p - \rho_{bf})} \quad (10)$$

$$\chi \cdot \quad (1) \quad \alpha + \beta = \quad (1)$$

Where ω is the density difference between the fluid and the main fluid (water). The nanofluid specific heat is calculated from;

$$C_{p_{nf}} = \frac{\varphi \cdot (\rho \cdot C_p)_p + (1 - \varphi) \cdot (\rho \cdot C_p)_f}{(\rho_{nf})} \quad (11)$$

Where $C_{p(p)}$ is specific heat of particle, $C_{p(f)}$ is specific heat of base fluid. The effective thermal conductivity of nanofluid is calculated according to Massimo [14];

$$\frac{k_{eff}}{k_f} = 1 + 4.4 Re^{0.4} Pr^{0.66} \left(\frac{T}{T_{fr}} \right)^{10} \left(\frac{k_p}{k_f} \right)^{0.03} \varphi^{0.66} \quad (12)$$

$$\chi \cdot \quad (1) \quad \alpha + \beta = \quad (1)$$

Where Re is the nanoparticle Reynolds number, Pr is the Prandtl number of the base liquid. k_p is the nanoparticle thermal conductivity, φ is the volume fraction of the suspended nanoparticles, T is the nanofluid temperature ($^{\circ}K$),

T_{fr} is the freezing point of the base liquid. The effective dynamic viscosity of nanofluids;

$$\mu_{nf} = \mu_{bf} (1 + 2.5 \varphi + 4.698 \varphi^2) \quad (13)$$

$$\chi \cdot \quad (1) \quad \alpha + \beta = \quad (1)$$

VII. NUMERICAL MODEL

Low Re k- ϵ turbulence model of PHOENICS CFD code was used for this numerical analysis. CFD simulation domain is shown in Fig 1. Mesh structure is shown in Fig.2.

	$U(m/s)$	$V(m/s)$	$W(m/s)$	$T(^{\circ}K)$	k	ϵ
Nanofluid inlet jet 1	U=0	V=0	$W=W_{inlet}$	$T=T_{inlet}$	$(T_1 W_{jet})^2$	$(C_p C_p)^{3/4} \frac{k^{3/2}}{L}$

Fig 1. CFD simulation domain

Fig. 2. Mesh structure

The continuity, Reynolds averaged momentum and time averaged energy equations governing 3-dimensional steady, flow of air with constant properties used for turbulent solutions can be written in the Cartesian coordinate system as follows:

Continuity equation:

$$\frac{\partial U_i}{\partial x_i} = 0 \quad (14)$$

Momentum equation:

$$\rho U_i \frac{\partial U_j}{\partial x_i} = -\frac{\partial P}{\partial x_j} + \frac{\partial}{\partial x_i} \left[\mu \left(\frac{\partial U_i}{\partial x_j} + \frac{\partial U_j}{\partial x_i} \right) - \rho \overline{u'_i u'_j} \right] \quad (15)$$

(11)

Energy equation:

$$\rho c_p U_i \frac{\partial T}{\partial x_i} = \frac{\partial}{\partial x_i} \left[k \frac{\partial T}{\partial x_i} - \rho c_p \overline{u'_i T'} \right] \quad (16)$$

All the boundary conditions used in the study are summarized in Table 1. It was used 96x15x34 (48960 elements) meshes for this application. Mesh structure was prepared according to flow conditions. In order to get more precise numerical results we intensified mesh numbers in some region as jet inlet, surface of copper plate. Sweep number was studied between 400 and 2500 and cell number was also studied between 24 and 44. It is observed that numerical geometry was independent from sweep number and cell number when sweep number was 600 and cell number was 96x15x34.

BOUNDARY CONDITIONS

VIII. RESULTS AND DISCUSSIONS

In this section, numerical results were prepared for three parameters.

- Effects of different water flow regime for $R_n/R_1=1-1.33-1.67$ to $1-1.17-1.33$
- Effects of Al_2O_3 -water nanofluid with 25 nm sized particles for different particle diameter on heat transfer ($D_p=10, D_p=25, D_p=40, D_p=80$).
- Effects of different nanofluids on heat transfer (Cu-Water, TiO_2 -Water, Al_2O_3 -Water).

A. Effects of variant Reynolds number

Numerical analysis were conducted for different water flow regime for $R_n/R_1=1-1.33-1.67$ to $1-1.17-1.33$ when particle diameter was $25\mu m$ and inlet temperature $T_{inlet}=20^\circ C$.

REYNOLDS NUMBERS

	$W_1(m/sn)$	$W_2(m/sn)$	$W_3(m/sn)$	$Re_1(jet-1)$	$Re_2(jet-2)$	$Re_3(jet-3)$	Re_1/Re_1	Re_2/Re_1	Re_3/Re_1
1.phase	6	8	10	21440,42	28587,23	35734,03	1	1,33	1,67
2.phase	8	10	12	28587,23	35734,03	42880,84	1	1,25	1,5
3.phase	10	12	14	35734,03	42880,84	50027,65	1	1,2	1,4
4.phase	12	14	16	42880,84	50027,65	57174,46	1	1,17	1,33

Velocity vectors and Temperature contours for different Reynolds rates are shown in Fig 3 and Fig 4.

Fig 4. Temperature counters for (a) $R_n/R_1=1-1.33-1.67$ (b) $R_n/R_1=1-1.2-1.4$

It can be seen that increasing jet velocities from the first phase to the third phase local surface temperature decreases and local Nusselt number increases. But increasing jet velocities to the fourth phase causes an increase on surface temperature. The reason of this vortexes, which occurs at the bottom of the close side enlarge while velocity on the first jet is increasing. And these vortexes reduce impinging effects and causes an increase on surface temperature. These effects continue at impinging region of second jet but effects of channel flow increases at this region. At the impinging region of the third

jet there is not a significant difference between third and fourth phase because channel flow effects reduces impinging effects at this region by increasing velocities from third to fourth phase. So increasing jet velocities from the first phase to the third phase causes an increase of 51.4% on average Nusselt number but increasing jet velocities from the third phase to the fourth phase causes a decrease of 5.6% on average Nusselt number because of the effects of vortexes and the best velocity profile is the third phase. Local Nusselt number for different jet velocities are shown in Fig 5.

Fig 5. Local Nusselt number for different jet velocities

B. Effects of different nanoparticle diameters

Effect of different particle diameter (10 nm, 25 nm, 40 nm, 80 nm) was analyzed numerically. It was observed that decreasing particle diameter from 80nm to 10nm causes a decrease on a surface temperature. Temperature contours on heated surface and variation of surface temperature for different particle diameter are shown in Fig 6. and Fig 7.

Fig 6. Temperature counters on surface for (a)Dp=10nm and (b)Dp=80nm

Fig 7. Temperature distribution on surface for different nanoparticles

Average surface temperature increases 1°C between Dp=10nm and 80nm. ANN increases of 10.9% between Dp=10nm and 25nm. But there is not any significant difference on ANN between Dp=25nm and Dp=80nm. So total decrease on average Nusselt number between Dp=10nm and Dp=80nm occurs 12.8%. Variation of local Nusselt number for different particle diameter is shown in Fig 8.

Fig 8.
Local

Nusselt number for different particle diameters

C. Effects of different type of nanofluids

Numerical analysis is conducted for different type of nanofluids (Cu-water, TiO₂-water and Al₂O₃-water) with 25 nm particle size and volume fraction 4%. Calculated properties of nanofluids are shown in Table 2.

THERMO-PHYSICAL PROPERTIES OF NANOFLUIDS AT 293K.

Nanofluid	Density ρ (kg/m ³)	Specific Heat C_p (J/kgK)	Dynamic Viscosity μ (Pa.s)	Kinematic Viscosity ν (m ² /s)	Thermal Conductivity λ (W/mK)	Thermal Expansion Coefficient β (m ² /2)
Al ₂ O ₃ -water	1113,472	3706,840499	0,001099764	0,000000988	0,6635	0,000160745

TiO-water	1128,272	3655,247586	0,001099764	0,000000975	0,6615	0,000160405
Cu-water	1316,672	3148,451174	0,001099764	0,000000835	0,6684	0,000161244

Temperature difference on surface of heated place is shown

Nomenclature	
C_p	Specific Heat (J/kgK)
ρ	Density (kg/m ³)
ϕ	Nanoparticle volume fraction
μ	Dynamic viscosity (Pa.s)
bf	Base fluid
nf	Nanofluid
p	Particle
Pr	Prandtl Number, $Pr = \frac{C_p \cdot \mu}{k}$
Re	Reynolds number $Re = \frac{(\rho_{nf} \cdot V_{jet} \cdot D_h)}{(\mu_{nf})}$
Nu_x	Local Nusselt number $Nu_x = \frac{(Q_{convection} \cdot D_h)}{(T_s - T_{jet}) \cdot k_{nf}}$
k_{eff}	Effective Thermal Conductivity (W/mK)

in Fig. 9. TiO-water, Al₂O₃-water and Cu-water. It was obtained that using Cu-water causes a decrease of 1°C on average temperature with respect to Al₂O₃ approximately. The maximum temperature difference on local surface temperature between Cu-water and Al₂O₃ is 1.5°C.

Fig. 9. Temperature distribution on surface for different nanofluids

It was acquired that using Cu-water nanofluid causes an increase of 9.3%, 8.4% on ANN with respect to Al₂O₃-water and TiO-water. It can be seen that using Cu-water nanofluids shows better heat transfer performance. Variation of local Nusselt number for different nanofluids is shown in Fig 10.

Fig 10. Local Nusselt number for different particle diameters

IX. CONCLUSION

Present study is focused on numerical investigation of heat enhancement and fluid flow from a heated surface by using nanofluids and impinging jets. Effects of different Reynolds numbers, particle diameter and different types of nanofluids (Cu-water, TiO-water, Al₂O₃-water) on heat transfer and fluid flow were studied numerically. According to our constraints it is obtained that increasing jet velocities from the first phase to the third phase causes an increase of 51.4% on ANN but increasing jet velocities from the third phase to the fourth phase causes a decrease of 5.6% on ANN. Decreasing volume fraction from Dp=80nm to 10nm causes an increase of 12.8% on ANN. But there is not any significant difference on average Nusselt number between Dp=25nm and Dp=80nm. Using Cu-water nanofluid causes an increase of 9.3%, 8.4%, on average Nusselt number with respect to Al₂O₃-water, TiO-water. Velocity of the third phase, Dp=10 nm and using Cu-water nanofluids shows better heat transfer performance. Research areas for future investigations can be investigation of effect of hybrid nanofluids with different base fluids on heat transfer.

Abstract—Surface coating of orthopaedic implants are applied for reduce insert wear and also prevent metal leaching to body fluid which causes allergic diseases. CoCrMo alloys are widely used as femoral component in total knee arthroplasty. In this study, we investigated effect of coating on CoCrMo femoral component articulated insert in terms of wear by finite element modeling. In the analysis, UHMWPE insert was used as insert material and three different femoral materials were used as uncoated CoCrMo alloy, TiN coated CoCrMo alloy and seven layered coated CoCrMo alloy. CAD modeling of insert-femoral component was obtained by using a special 3D scanning system. Assembly of models was performed by using SolidWorks. Assembled model imported to ANSYS16 software and FEM analysis were performed. It is seen that; coating of femoral component has reduced shear stress and deformation of insert.

Keywords—TKA; implants; coating; multilayer; biomaterial, wear

I. INTRODUCTION

Implants used in total knee arthroplasty have a great importance for human health. Thanks to advanced materials and engineering technologies and also advanced surgical techniques, comfortability and lifespan of implants have enhanced. Nevertheless, when the young patients who has knee implants considered, enhancing lifespan of knee implants still an essential research area for researchers.

Wear and metal ionization as a result of corrosion are the main issues of TKA implants [1,2,3]. Materials which are used in knee arthroplasty must have not only biocompatibility but also high corrosion and wear strength [4, 5, 6, 7]. CoCrMo alloys are used widely in femoral component of TKA thanks to good mechanical properties they possess as high elasticity modulus, high tensile strength, high corrosion and wear strength

[8,9]. But on the other hand metal ionization in body fluid causes diseases and also decreases the lifespan of implant as a result of early wear [10]. Therefore early reconstructive surgery are needed [1]. In order to avoid this; biomaterials used in orthopedic implants are coated to prevent metal ionization into human body fluid which causes allergic diseases and also to reduce wear rate of insert [1,11,12].

Application of coating implant surfaces are usually performed as thin ceramic films [13, 14, 15]. Ceramic materials are being preferred in orthopaedia because of their properties as biocompatibility, strength, hardness, wear and corrosion resistance [16]. Ceramics which are widely used in surface coating of implants are alumina (Al_2O_3), zirconia (ZrO_2), zirconia toughened alumina, alumina toughened zirconia, Silicon-nitride (Si_3N_4), TiN, ZrN and hydroxyapatite [17]. Application of ceramic coatings on implant surfaces are usually performed by physical vapour deposition (PVD) or chemical vapour deposition (CVD) processes [18].

There had been a lot of researches about surface coating of implants in the past. Mc Entire et al. have been a comprehensive literature review on ceramics used in orthopaedia and ceramic coatings of orthopaedic materials [17].

Qingliang Wang et al. applied CrN coating on CoCrMo substrate material which is used as implant material. They obtained enhanced hardness on coated surfaces and reduced wear rate of tibial component [19].

B. Alemón et al. have investigated corrosion behavior and metal leaching of CoCrMo substrate that multilayer coated with TiAlVCN/CNx, in simulated body fluid [9]. They observed significant reduces in wear rates and friction coefficients results of tribocorrosion tests. They achieved that multilayer coating has prevent the metal leaching significantly.

C. Balagna et al. coated CoCrMo substrate with Ta because of its properties like biocompatibility, low metal ionisation and high corrosion resistance. They applied three different coating system on substrate material. One coating was with Ta which possesses low carbon content, other coating was with Ta possesses high C content and the last one was metallic Ta. As result of their study they observed that multilayer coating with low C content Ta have high strength values thanks to its multilayered structure [20].

R. Hubler et al. have studied thin surface coating of 316L stainless steel femoral implant with Ti/TiN and Cr/V. Regarding to stoichiometric, microstructure, hardness, wear and corrosion resistance tests they obtained result that TiN coating can be used as protective coating compared to other coatings [13].

Lukasz Łapaja et al. have investigated mechanical properties of 11 retrieved TiN coated femoral heads from patients. According to the results they obtained, coated femoral heads had low wear rate compared to uncoated femoral heads [21].

Peiyun Yi et al. performed multilayered coating of TiAlN on Ti6Al4V alloy via closed field unbalanced magnetron sputter ion plating process. They concluded that multilayer coating has high adhesion strength to substrate material [22].

Sung-Hsiu Huang et al. have performed a study which investigates the mechanical and tribologic properties of multilayer CrN/ZrN coatings which are formed via cathodic arc deposition process. They observed that hardness and tribologic features were significantly affected from bilayer period [23].

Yin-Yu Chang and Chen-Jui Wu have investigated mechanical properties and impact strength of multilayer TiAlN/ZrN coatings. As result of their studies, they obtained that, multilayered coating had higher hardness than one layer ZrN and TiAlN. Furthermore, according to impact strength test results, multilayer coating had the higher impact strength [24].

Mohd. Zakuan Bin Abdullah et al. have performed a study that investigates of metal ionisation from stainless steel substrate material to multilayer ceramic coating. They applied coating on stainless steel substrate material as one layer of Cr, as two layered Cr/CrN, as three layered Cr/CrN/CrCN, five layered Cr/CrN/CrCN/CrN/ZrN and seven layered Cr/CrN/CrCN/CrN/CrCN/CrN/ZrN by PVD process. They obtained as a result of seven days metal release test; except Cr coated material, from uncoated substrate to multilayer coating ion concentration were decreased [25].

With this study, wear analysis of seven layer coated (Zr/CrN/CrCN/CrN/CrCN/CrN/ZrN) [26], one layer TiN coated [26,27] and uncoated CoCrMo [28] femoral components which articulate with UHMWPE insert, has modeled with ANSYS. This study aims to estimate wear behaviour of insert with articulating uncoated femur, seven layered coated femur and TiN coated femur.

II. MATERIALS AND METHOD

A. Materials

Three different femoral components were used for performing analysis. TiN coated, seven layered coated and

TABLE XIII. LAYER SEQUENCE AND THICKNESS OF COATING

Layers	Coating Material	Thickness of Coating (μm)
7th Layer	ZrN	2,5
6th Layer	CrN	0,5
5th Layer	CrCN	0,5
4th Layer	CrN	0,5
3rd Layer	CrCN	0,5
2nd Layer	CrN	0,5
1st Layer	Zr	0,1

TABLE XIV. PROPERTIES OF MATERIALS USED FOR ANALYSIS [29,30]

Material	Young Modulus (GPa)	Poisson's Ratio
CoCrMo	230	0.3
UHMWPE	69	0.29
ZrN	510	0.25
CrN	290	0.22
Zr	88	0.34
CrCN	320	0.25
TiN	590	0,25

uncoated CoCrMo alloy were used as femoral component during analysis. Table 1. shows the materials, their thickness and layer sequence of multilayered coated femoral component. Thickness of TiN coating was set to 5,1 μm . UHMWPE was used for all analysis as insert material. Properties of materials which were used in analysis are given in Table 2.

B. Method

Femur (Size 5, Otimed) and insert components were scanned separately by a 3D Scanner (David-SLS3) system and images were obtained by using its own software. Image of scanning system was given in Fig. 1. Assembly of obtained CAD models were carried out on Solidworks 2016 and imported to Structural Interface of ANSYS software. ANSYS image of modelling was given in Fig. 2. During analyzing material properties were set as given in Table 2. Axial force value was set to 800 N according to ISO14243-1 while performing analysis for three different femoral-insert components.

Fig. 17. Image of scanning system

Fig. 18. ANSYS image of assembled model

III. RESULTS AND DISCUSSIONS

A. Contact Pressure

Image of contact pressure analyze of uncoated femur-insert component is given in Fig. 3. Maximum contact pressure was obtained 37,953 MPa for insert that articulate uncoated femur. Fig. 4. shows the contact pressure analysis of TiN coated femur-insert model. Contact pressure value for insert articulated TiN coated femur, was calculated 39,84 MPa. For seven layered coated femoral-insert component this value was 40,451 MPa as can be seen in Fig. 5. According to the results it is thought that coating of CoCrMo alloy femoral head which have same size, will increase the contact pressure between femur-insert interface and therefore wear depth of insert will increase. However, according to the Archard's Wear Law calculation, wear depth calculations showed that obtained increased contact pressure values didn't make big differences in spanlife of insert. Furthermore, it is thought that, forming metal debris will be prevent by reduced metal ionisation from femur to insert thanks to ceramic coating [13].

Fig. 19. Pressure Analyze of Insert articulated with uncoated femur

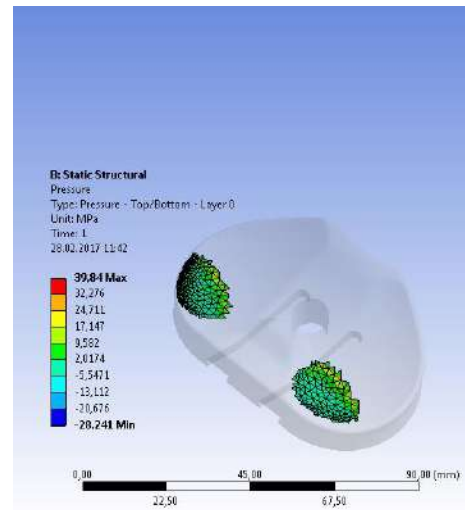

Fig. 20. Pressure Analyze of Insert articulated with TiN coated femur

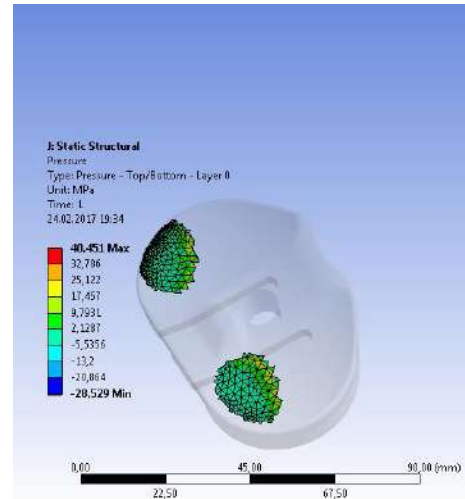

Fig. 21. Pressure Analyze of Insert articulated with seven layered coated femur

B. Von Mises Stress Analysis

Fig. 6. shows the Von Mises Stress Analysis of the models. Maximum equivalent stress for uncoated femur-insert model was obtained 32,246 MPa. While for TiN coated femur-insert

component this value was obtained 32,404 MPa, for seven layered coated femur-insert model it was 31,362 MPa. Von Mises stress analysis shows that coating of femur has decreased the maximum equivalent stress on the insert.

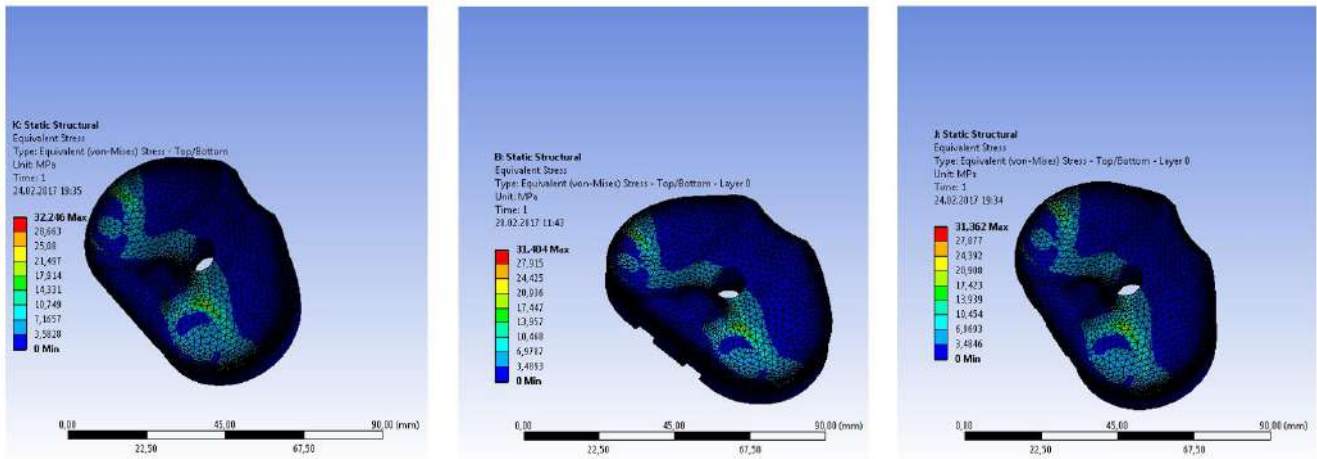

Fig. 22. Von Mises Analysis of a) insert-uncoated femur model b) insert-TiN coated femur c) insert-multilayered coated femur

C. Shear Stress Analysis

Image of shear stress analyze of insert articulated with uncoated femur model is given in Figure 7. Maximum shear stress was measured 10,203 MPa. For TiN coated femur-insert model this value was obtained 9,5513 Mpa. Figure 8. shows the shear stress analyze of insert-TiN coated femur model. As a result of shear stress analyze of insert articulated with seven layered coated femur component, maximum shear stress value was obtained 9,5726 MPa as can be seen in Figure 9. According to the results of shear stress analysis it can be say that coating has a favorable effect on shear stress which occurs on insert.

Fig. 23. Shear stress analyze of insert-uncoated femur model

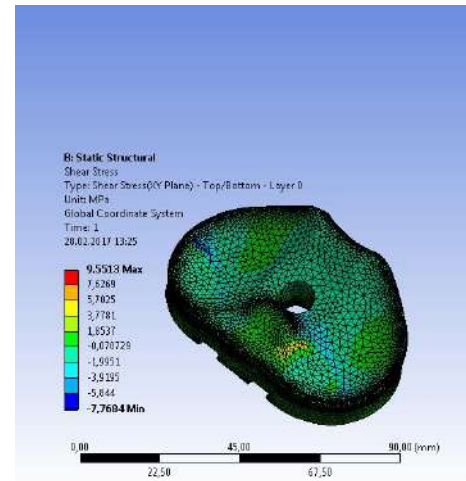

Fig. 24. Shear Stress Analyze of insert-TiN coated femur model

Fig. 25. Shear Stress Analyze of insert-multilayered coated femur model

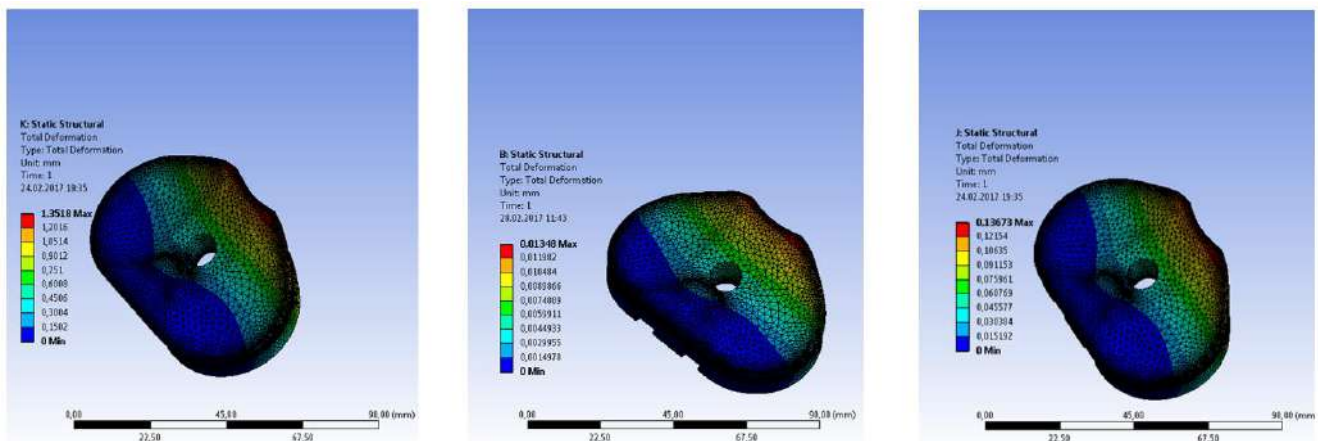

Fig. 26. Deformation analyze of a) insert-uncoated femur model b) insert TiN coated femur c) insert-multilayered coated femur

Fig.10. shows the deformation analysis of all models. Maximum deformation value for uncoated femur-insert model was obtained 1,3518 mm. TiN coated femur-insert model has 0,01348 mm maximum deformation value and multilayered coated femur-insert model has 0,13673 mm maximum deformation. According to these results it can be said that coating has a favorable effect on insert deformation.

IV. CONCLUSIONS

In this study, static analysis of three different femur component articulated with UHMWPE insert performed successfully. It is seen that, coating of femur has increased contact pressure on insert, however when reduced metal ionization considered it was thought that this increase couldn't cause early wear of insert. According to the results of shear stress and deformation analysis, it is thought that, coating of CoCrMo femoral component can be reduce wear rate of UHMWPE.

Abstract- Multilayer beams are widely used in robotic area due to some advantages. To create a special motion in fixed spaces, multilayers are essential for both designers and engineers. This motion can be used for moving a system or another purposes. Nowadays, the soft grip is a new term for robotic and mechanical engineering fields. It uses the same theory of multilayer beams to create a displacement. Unlike conventional multilayers beams, it uses soft material such as silicon, rubber or fabric because of some advantages. In this study, a pneumatic soft gripper have been designed and analysed with engineering softwares. Also a design of experiment (DOE) have been performed to see effect of each factor such as air pressure, material property, geometrical variables etc. Results and graphs of study have been shared at the final stage. According the results of DOE, designers can optimise their systems.

Keywords— Soft grip, Multilayer beam, DOE

I. INTRODUCTION

The development of new types of robots, and materials offers new opportunities for cross-functional researches. This paper focus on a new methodology based on multilayer beam theory. Due to some advantages of bending, science and engineering world have created a new definition, the soft robotic.

With the absence of wheels, electric motors and rigid skeletons, the motions of soft robots are usually inspired from the soft organisms [23]. For the easy fabrication, actuation and control of soft robots, only simple motions of natural species have been used in soft robots, such as caterpillar inspired locomotion [8,9], multi-gait quadruped [10,11], bristle-crawler [12], worm inspired locomotion [13–14], snake inspired locomotion [15], jellyfish inspired swimming [16], etc.

II. THEORY OF MULTILAYER MOTION

A. Relationship Between Multilayer Beams & Soft Robots

Soft robotics is a sub-field of robotics that deals with non rigid robots constructed with soft and deformable materials like silicone, plastic, fabric, rubber, or compliant mechanical parts like springs. Soft robots can actively interact with the environment and can undergo “large” deformations relying on inherent or structural compliance due to their softness and other morphological features.

The multilayer beam bending theory can be explained as follow. A simple cantilever beam can be bend by a concentrated nodal force, pressure or heat. The main question is that can we use this bending for different purposes. This question have been created the soft robotic area.

If we have a beam which has different layers and different stiffness sections, with internal forces like pressure it can be bended. So, this reaction gives a new name the beam. Shown as in figure 2.1 a multilayer beam can work as a robotic gripper to carry objects.

Fig. 2. 1 Two layer beam with one air chamber soft gripper [25]

Fig.2.2. Embedded electrical wire can create adequate heat to bend the beam because of thermal expansion [22].

As in practical applications the bending deformation of the beam may be actuated by other methods (e.g. shape memory polymers [4], electroactive polymers [5], dielectric elastomers [6] and pneumatic pressurization [7]),

Shown as in figure 2.3 a muscular thin films also shares the bending theory like multilayer beams. A physical action will create a different reaction in layers not only because of their material properties but also their geometry. For example, if we heat up a multi-layer beam shown as figure 2.2 or like a MTF which is shown in figure 2.3, different axial displacement going to be occurred. Thus, the overall beam going to have a circular shape. Other sources can be used as action like air. In next sections, the effect of pressured air will be discussed widely.

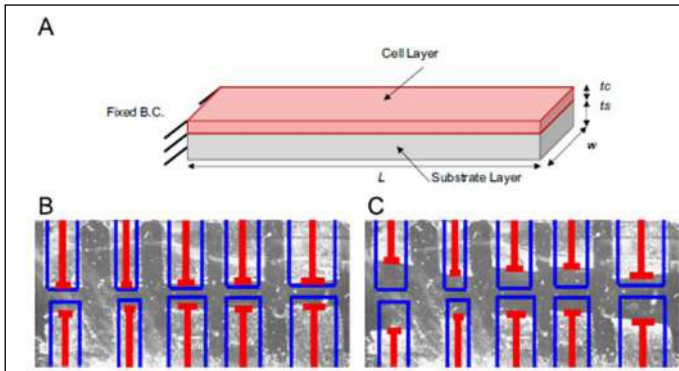

Fig. 2.3. (A) Schema of the MTF cantilevers. A biocompatible cantilever is supported by a fixed boundary condition (B.C.) and a thin cell layer is seeded on the surface. Contraction in the cell layer causes the substrate layer of the MTF to bend upwards. (B) Experimental image of 'Heart-on-a-chip' muscular thin films in their minimum contracted state (diastole). (C) Experimental image of 'Heart-on-a-chip' muscular thin films in their maximum contracted state (systole). In Band C solid blue outlines indicate the original shape of the PDMS film while capped red bars indicate the projection of the thin film during contraction. (For interpretation of the references to color in this figure caption, the reader is referred to the web version of this paper [22].)

B. Pneumatic Pressurization

To bend the system for using bending theory of multilayer beam, pressured air is one of the best method. An inlet line

which comes into between two layer is a force source. High pressure going to push walls from inside to outside to as a reaction. This creates the displacement. The example of pressured air effect can be seen in figure 2.1.

Fig. 2.4 a) A close-up photograph showing a textured surface which has been modified independently of the PneuNets. A set of ridges formed in Ecoflex provided better traction than a flat surface (this texture is more compliant than a solid surface because half of the volume has effectively been removed, and each ridge is pliable and deforms easily). b) A photograph demonstrating an actuated leg on the gripper; the individual chambers that make up the network are visible. The minimum radius of curvature achieved in this design is less than 5 mm [24].

According to design, soft parts can react the pressured air differently. In Figure 2.4 the design shows rotational reaction but there is also creative design which can extent axially. For example, Pneumatically-driven McKibben-type actuators are among the most highly developed soft actuators, and have existed for more than fifty years; they consist of a bladder covered in a shell of braided, strong, inextensible fibers [17].

Another design can provide a crawling motion to system. If the pressure of air changes alternately maximum to zero the beam can move like caterpillar shown as figure 2.5.

As you see, the

Fig. 2.5 Bilayer beam with different frictional coefficients at the two ends of the contact surface. The cross sections of each layer are rectangular with the same thickness and different heights of h_1 and h_2 [23].

III. SOFT GRIPPER DESIGN

In our modern industry, there are many different robotic parts or systems try to grip object without any damage but the hardness of surfaces of many system causes fundamental material problem. Conventional robotic systems use the rigid material to grip objects. This may create surface cracks or other type damages.

The use of compliant materials allows grippers to manipulate objects such as fruit[20] with varied geometry[21]. The egg example can be seen in figure 3.1. The gripper holds the it gently.

Fig. 3. 1 An egg translated by a soft gripper without any damage in four step.

Figure 3.2 illustrates the 3D model the soft gripper which analyzed in paper. In the egg example the soft gripper has 6 beam. It is clear to say that increasing of beam number going to decrease the contact stress which will be occurred between egg and soft material. In our study, there is only one beam has been designed and analyzed. The results can be optimize or assumed for multi-beam grippers.

CAD data of our soft gripper can be seen in figure 3.2 Cross section of solid model serves some technical trick. Every air chamber connect each other by small links. In next figure (fig. 3.3) these links are occurred.

Fig. 3.2 Solid model of Gripper

There are many various factors which plays an important role on soft gripper design. In our study, we have focused on some variables like air pressure, material stiffness, geometrical variables.

Fig 3. 3 Cross Section of Solid Model. Little tubes let air goes to another chamber. This causes the equal pressure distribution

A. Materials of Soft Robotic Parts

Soft robots are usually fabricated predominantly in elastomeric polymers without hard skeleton. Through appropriate design a simple elastomeric structure can provide a multifunction such as joint [1], bearing [2] and actuation[3], without the complexity of a multicomponent mechanical structure in hard machines.

Silicone rubber is an elastomer (rubber-like material) composed of silicone—itsself a polymer—containing silicon together with carbon, hydrogen, and oxygen. Silicone rubbers are widely used in industry, and there are multiple formulations. Silicone rubbers are often one- or two-part polymers, and may contain fillers to improve properties or reduce cost. Silicone rubber is generally non-reactive, stable, and resistant to extreme environments and temperatures from -55°C to $+300^{\circ}\text{C}$ while still maintaining its useful properties.

B. Geometry Of Gripper

The shape of gripper must designates the purpose of system. There are many different systems in soft robotic area.

According to demands , a system can show a axial or rotational displacement. For example , if someone wants to simulate muscular behaviors, the axial extension type actuators should be used as mentioned previous sections.

Fig. 3. 4 Three Dimension Analysis Result of Gripper. Touch condition areas can be seen clearly.

In our study , we try to reach and hold an object. Thus, the gripper must show axial and rotational movement at the same time. Thanks to its unique shape this aim can be achieved by our design.

Fig. 3. 5 Two dimension model of gripper

The system work as follows, the air chambers, around top of layer , filled by a pressured air. This force initially extents the gripper axially and rotationally. But the majority of the first stage of movement is extending axially. In first stage, there is only minor rotational displacement . At the same time the walls of chambers close each other as extent from inside to outside due to the pressure. When a chamber wall touch to another, because of frictionless contacts walls slip on each other. This creates a huge rotational torque which can be used to wrap objects.

As you can see ,the design of gripper is the main factor of a gripping strategy which has an important role on behavior of system.

C. Geometry Of Target Object

The target object means that the object which is held by soft gripper in our study. Target objects may have various shapes such as cylindrical, cubic , prismatic etc. One of the advantages of the soft gripper is that they can handle very big range on shapes. Even a cactus can be held by well designed a soft gripper without any damage.

Our analysis have been performed to grip a cylindrical target object with different radius and different center of gravity centers.

IV. ABAQUS CAE

A. Stages of CAE Analysis

Like many other commercial computer added engineering soft wares, Abaqus also needs to be given some specific inputs from user to calculate the finite element method demands such as stress , displacements etc.

Before we start the calculation, we need to set up a few steps as follows.

1) *Create or Import Parts* : There is a embedded CAD module in Abaqus which can be used create 2D,3D or Wire elements. Or import menu can be used import a part which created by another CAD softwares.To decrease work load and use time efficiently, we use the simplified 2D part.

2) *Define Materials* : Two material properties have been created .One of these is hyperelastic material which makes up the gripper. The Neo Hookean method has been chosen for hyperelastic material.Another one is elastic material for target object.

3) *Create Sections* : Both gripper and object section have been created as solid homogenous.

4) *Create Steps* : General ,Static step has been created.

5) *Create Assembly* : Two parts have been imported and arranged in assembly space.

6) *Define Intersections* : There are two intersection in model. One is between gripper and object. Another one is self-intersection which is necessary to see touch condition of walls of air chambers.

7) *Define Boundary Conditions* : One side of gripper has been fixed. For this, encastre boundary condition has been applied.To simulate air the pressure has been applied inside of chamber walls.

8) *Meshing Parts* : To get maximum resolution minimum mesh size has been created

9) *Create A Job* : Jobs allow that a model can be used for different analysis such as static, thermal or explicit. Thus , in abaqus every model requires a job which will has the results according the analysis type

10) *Results* : After completed job running the program creates a output file which can be monitored in visualization menu.

V. DESIGN OF EXPERIMENT ANALYSIS

A. Definiton Of DOE

DOE (design of experiments) helps researchers to investigate the effects of input variables (factors) on an output variable (response) at the same time. These experiments consist of a series of runs, or tests, in which purposeful changes are made to the input variables. Data are collected at each run. You use DOE to identify the process conditions and product components that affect quality, and then determine the factor settings that optimize results.

B. Create Factors

Reaction forces are one of responses of the system. To investigate which factors affect reaction forces, we should investigate main variables. According to a study content, number of factors can be changed. As factors increase, the total time and number of experiments going to rise.

In our study four different factors have been chosen. These are System Pressure (P) , Material Stiffness(K) , Radius of Target Object (R) and Position of Target Object (PTO).

Another criterion of doe method is factor level. It means that variance of factor internally. For example, if the pressure has two different options such as low or high, it means that this factor has two levels. Each factor of study has two levels.

For two levels factor , count of total experiments calculated shown as follows in equation 1. The n means number of factor and two indicates level of factors. In our study, there are four different factors. Thus, we have to run sixteen different cae analysis according to DOE method.

$$\text{Total Experiment Number} = 2^n \quad (1)$$

VI. RESULTS

A. CAE Results

CAE analysis results are shown as below:

Different results have been displayed in various monitoring type . Next graphs going to mention some important output of the analysis and system.

Major output of the system is reaction forces which will be occurred between the target object and soft gripper.

The first image (Figure 6.1) shows the beginning of the analysis. As you can see , there is no any touch condition between the gripper and target object.

Fig. 6. 1 Meshed Gripper and Target Object

Second image (Figure 6.2) illustrates the stress level which occurred at the end of holding process. High stress areas have occurred mostly at chamber walls. Because of thickness this is not unexpected situation.

Fig. 6. 2 Stress Areas

The biggest reaction forces have been observed at fixing area of soft gripper. Shown as Figure 6.3 , the reaction forces change at the Y direction.

Fig. 6. 3 Changing of Reaction Force Vectors. Maximum reaction force occurred at the bottom

Displacement plot (Figure 6.4) show the total translation magnitude. The gripping process have been completed at this step. More pressure will create self-interaction problems at gripper. So , maximum pressure have been chosen properly and limited.

The aim is achieved. A target object can be wrap by soft gripper which uses pressured air.

Fig.6. 4 Displacement plot

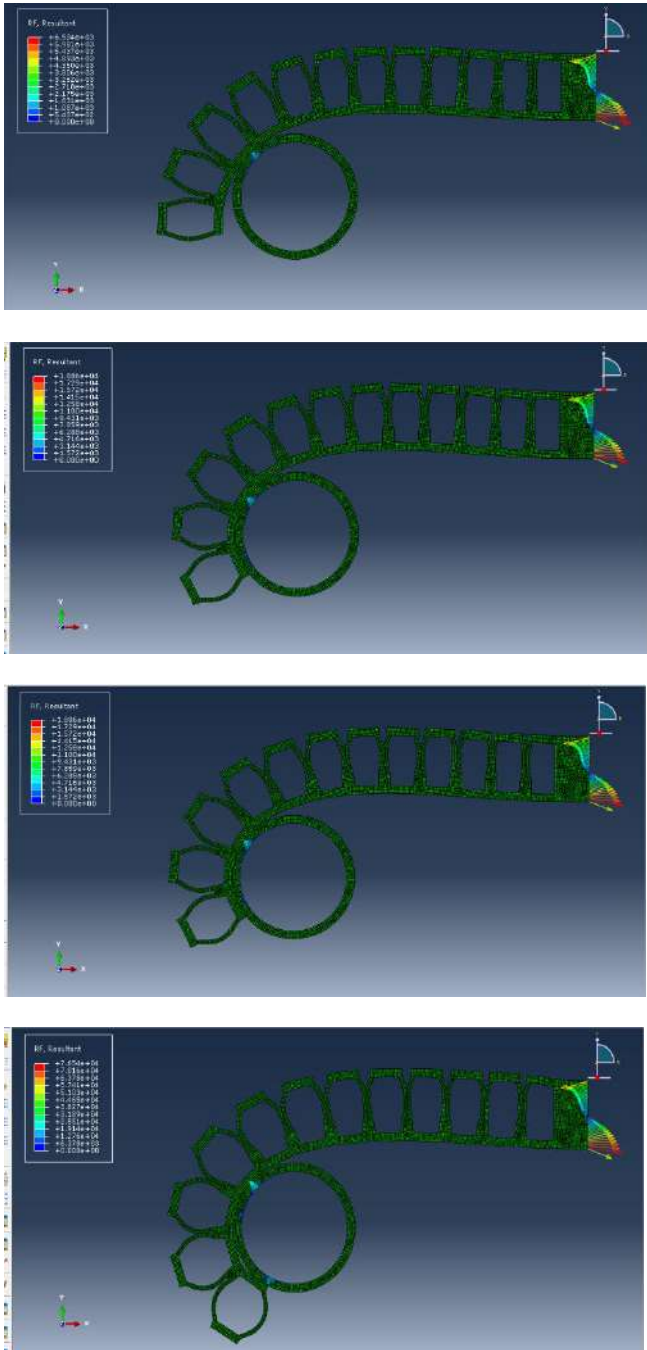

Fig 6.5 : Two different scenarios have been compared to see effect of factors. First scenario, small target radius and big x coordinate of target object gravity center. Second scenario, big target radius and small x coordinate of target object gravity center.

B. DOE Results

Result of CAE analysis have been illustrate in pareto chart , cube plot and main effect plot for reaction forces as shown below.

According to DOE results , it is clear to say that the system pressure has an important role on reaction forces. Second factor is radius of target object. The reaction forces go up while radius is increasing. But the material stiffness of gripper and position of target object show negative behavior. When material stiffness increased , reaction forces decreased.

Fig 6. 6 : Result of DOE analysis

VII. CONCLUSION

As a conclusion, the study has reflected the fundamental design rules of a soft grip design. The design basically use the multilayer beam technic but with some modifications. Bended beam has wrapped and held an object as expected and shown as in figures.

CAE and DOE analysis clearly show that there are different factors which play an important role on designing a soft gripper.

For reaction forces, the most important factor is the air pressure according to the results.

As mentioned in the first stages of study, to get maximum mechanical efficiency, factors of soft gripper should be chosen properly. So, the designers and researchers can use this study and its results as a reference.

Abstract— The comparison of heat transfer performances of circular and square cross-sectioned helicoidal heat exchangers (HCHEs) for a boiling operation is the subject of this study. An experimental analysis was firstly carried out for the estimation of the heat transfer properties of the circular HCHE. The circular HCHE was modeled numerically using CFD (Computational Fluid Dynamics) tool and its results were validated with the experiments. The testing fluid was selected as thermal oil and the effect of the actual fluid properties instead of constant property approach was established. The flow was considered fully developed turbulent with low Reynolds number based on the fluid inlet temperature ranging from 150–110°C. For the CFD analysis, Ansys Fluent was used with the $k-\omega$ turbulence model closure to evaluate the fluid domain. The results indicated that the square cross-sectioned heat exchanger enhances the heat transfer up to 1.6% relative to the circular one under the given conditions.

Keywords— circular helical coil; square helical coil; heat exchanger; boiling; CFD

I. INTRODUCTION

Curved or helicoidal pipes are widely used in various engineering applications such as power generation, nuclear industry, process plants, heat recovery systems, refrigeration, food industry, etc. [1]. In food industry, the helicoidal pipes are used as a part of heat exchanger which provides to heat foods. Cooking is a type of process applied in these systems which involve boiling realizing at the solid-liquid interface. The energy demand for this process is generally provided by electrical or thermal power. For large applications, thermal energy is used in usual. The thermal energy transfer to the liquid is realized by a heat exchanger which facilitates the exchange of heat between the two fluids separated by a solid wall while keeping them from

mixing with each other. Heat is first transferred from the hot fluid to the wall by convection, through the wall by conduction, and from the wall to the cold fluid again by convection. This is the basic heat transfer mechanism of boiling process to be used for cooking facility.

Heat transfer and flow through a curved tube is comprehensively reviewed by [2–4]. The characteristics of flow, pressure drop and heat transfer have been investigated by many researchers. In most of these studies, constant wall temperature or constant heat flux boundary conditions were applied to evaluate heat transfer coefficient. The constant wall temperature is more suitable for phase changing process in heat exchangers. On the other hand, the constant wall heat flux case is used for heat transfer studies of nuclear fuel elements and electrically heated tubes.

Heat transfer in helical coils has been experimentally investigated by [5] both for laminar and turbulent flow regimes for flow of water under constant wall flux. The curvature ratios of the coils were 0.0096 and 0.0588. The range of Reynolds number (Re) studied was 6000–65,500. Rogers and Mayhew [6] studied heat transfer to fluid flowing inside a helical pipe heated by steam for a range of Re from 10,000 to 100,000. Curvature ratios of the coils used in studies were 0.0926, 0.075 and 0.05. Mori and Nakayama [7,8] investigated forced convective heat transfer in turbulent regime for constant wall temperature and wall heat flux boundary conditions. It was considered two configurations of helical coils with curvature ratio of 0.0535 and 0.025. The effect of torsion on the flow in a helical tube of circular cross-section was experimentally investigated by Yamamoto et al. [9] for a range of Re about 500 to 20,000. Jayakumar et al. [1] analyzed helically coiled heat exchanger considering conjugate heat transfer (fluid-to-fluid) and

Financially supported by the Scientific Research Project Division of GAUN under the contract of MF.11.13.

temperature dependent properties of heat transport media. An experimental study was performed for the estimation of the heat transfer characteristics and compared with the CFD (Computational Fluid Dynamics) results. Jayakumar et al. [10] investigated also the variation of local Nusselt number (Nu) along the length and circumference at the wall of a helical pipe. The effects of pitch circle diameter, tube pitch and pipe diameter on heat transfer were studied. Yilmaz et al. [11] made a thermal model for wheat cooking pot using analytic method and compared the results with the experimental data. Yilmaz and Göksu [12] studied also the numerical heat transfer behavior of the helicoidal heat exchanger (HCHE) used in the cooking pot.

The numerical heat transfer characteristics of circular and square cross-sectioned HCHEs for cooking operation were investigated in this study. An experimental methodology was carried out for the validation of the heat transfer characteristics of the circular HCHE. Obtained satisfactory results were proceeded for comparing the heat transfer performances of both heat exchangers using CFD tool.

II. METHODS

A. Experimental Analysis

An experimental setup was installed for comparing both the results obtained from the numerical and experimental analyses. The setup basically consisted of a temperature controlled electric heater, a cooking pot containing a circular cross-sectioned HCHE (see Table I for the properties), a thermal expansion tank, gear pump and measuring instruments. The heat transfer fluid (HTF) used in the loop was selected as Renolin therm 320. The HTF was circulated by a frequency-controlled gear pump which was used to adjust the flow rate. The effective power capacity of the electric heater was 6000 W which was controlled by a PID controller.

TABLE I. SPECIFICATIONS OF THE CIRCULAR HCHE

Pipe material	304L SS
Inner pipe diameter	0.0157 m
Outer pipe diameter	0.0213 m
Coil pitch	0.085 m
Coil radius	0.175 m
Outer surface area	0.288 m ²

The temperature measurements in the experimental setup were performed by the resistance temperature detectors (Pt100, Class A) connected with two leads. The flowmeter was selected as coriolis type to measure the mass flow rate of the HTF circulating within the loop. During the experimental tests, data on temperature and flow were gathered by the DAQ (Data Acquisition) devices. For this task, highly-accurate voltage and temperature processing DAQ devices were selected and connected to the computer and managed by an interface software program (TracerDAQ Pro) to process data logging. The temperature dependent error of the temperature detectors are designated by the relation $\pm(0.15 + 0.002T)^{\circ}\text{C}$ and calibrated according to the standard of IEC751:1983. The

flowmeter has an accuracy of $\pm 0.1\%$ with a repeatability of less than 0.05%. The temperature processing DAQ contributes additional error except the error of the sensor itself with a typical error of $\pm 0.12^{\circ}\text{C}$ for sensor temperature (between 0°C and 200°C).

B. Numerical Analysis

Figure 1 illustrates the schematic of the circular cross-sectioned HCHE used for the cooking operation, and the square cross-sectioned HCHE for the performance comparison. For performance comparison, only the cross-section of the square HCHE is changed as to be peripherally equal to that of the circular one while keeping all remaining parameters identical.

a) Circular

b) Square

Fig. 1. Geometry of the circular cross-sectioned HCHE

For the numerical simulations, Ansys Fluent v17 software package was used to solve the governing equations (the conservation equations for mass, momentum, and energy) together with the boundary conditions applied. It is considered the flow inside the coil to be steady-state and fully developed turbulent. These considerations are reasonable since the experimental data were taken under steady conditions and the flow is fully developed due to negligible entrance effect compared to the coil length. The boundary conditions used include

- No-slip and no-penetration conditions exist on the coil wall.
- Constant temperature and velocity inlet conditions are used in the tube's inlet.

- The turbulence intensity is assumed to be around 5% at the inlet.

The computational domain was discretized using tetrahedron elements with structured elements in the wall normal directions. The coupling of pressure and velocity was made with the SIMPLE algorithm. Second-order upwind schemes were employed for integrating the governing equations together with the boundary conditions over the computational domain. The y^+ value of about 1 was ensured for all simulations to obtain the high resolution of gradients in the near wall regions. The solution convergence was satisfied when the scaled residuals of continuity, momentum, turbulence kinetic energy, turbulent dissipation rate and energy ceased after about 800 successive iterations. The values of the scaled residuals were in the order of less than 10^{-4} for the continuity equation, less than 10^{-5} for velocity, turbulent kinetic energy and turbulent dissipation rate and less than 10^{-7} for energy. The thermophysical properties of the HTF as a function of temperature were derived from the manufacturer's supplied data as below.

$$\rho = 1058.108 - 0.651T \quad (1)$$

$$c_p = 692.370 + 4.289T \quad (2)$$

$$k = 0.154 - 7.176E-5T \quad (3)$$

$$\mu = 0.334 - 2.153E-3T + 4.667E-6T^2 - 3.392E-9T^3 \quad (4)$$

Here ρ , c_p and k are valid at the temperature range $273 \text{ K} \leq T < 373 \text{ K}$, μ is valid for $373 \text{ K} \leq T < 473 \text{ K}$. Mesh dependency studies were applied for each run considered in the study. The solution was considered grid independent when the maximum changes in the outlet temperature were less than 1% as the mesh element size was changed. The number of mesh elements with 3685776, 7100622 and 11217391 was applied for the circular cross-sectioned HCHE, respectively. Then 7100622 mesh elements were used in the analyses after mesh refinement. For the square cross-sectioned HCHE, 1336620, 6216296 and 8571340 mesh numbers were applied and 6216296 mesh elements were used after refinement. The mesh structures of the computational domains are illustrated in Figure 2.

a) Circular

b) Square
Fig. 2. Sample mesh for the geometries

III. RESULTS AND DISCUSSION

Table II shows the dataset of boundary conditions resulting from the experimental study of the circular cross-sectioned HCHE and the predicted parameters from the analytical approach given in [12]. These boundary conditions also applied to the square HCHE to analyze the performance variation.

TABLE II. Boundary Conditions

Data set	Flowrate kg/s	Inlet temp. °C	Boiling temp. °C	Surface temp. °C	Convection coeff. W/m ² °C
1	0.0847	150.01	100.02	105.40	2371
2	0.0917	145.03	100.15	105.40	2265
3	0.1000	140.04	100.20	105.31	2152
4	0.1111	135.00	100.03	104.67	1765
5	0.1379	130.06	100.02	104.95	1996
6	0.1380	122.61	100.06	104.47	1597
7	0.1393	115.35	99.90	103.72	1188
8	0.1440	110.00	100.00	103.15	813

Figure 3 shows the results obtained from the experimental and numerical analyses. As it is seen, the results are pretty well suited with each other for the estimation of the outlet temperature. The maximum experimental error is expected to be 0.53°C in temperature measurements due to the accuracy of the temperature detectors. The maximum deviation of the numerical approach from the experimental results is obtained 1.12%.

Fig. 3. Comparison of experimental and numerical results

Figure 4 shows the numerical results of both HCHEs obtained under the same conditions. It is clearly seen that the square HCHE enhances the heat transfer at relatively higher inlet temperatures. As the inlet temperature decreases, the outlet temperatures of both HCHEs come close each other due to reduced differential temperature but the square HCHE still shows better performance. Enhancing the heat transfer provides to minimize the size of the HCHE to accomplish the same task with the circular HCHE. This is important for the cooking pot having limited size but needs increased capacity.

Fig. 4. Effects of cross-section on heat transfer enhancement

Fig. 5 Temperature contours at the outlet (as Kelvin)

Temperature distributions at the outlet of the HCHEs are shown in Figure 5 for the data set 1. The flow pattern is quite different relative to a straight pipe since the most prominent characteristic of flow in helicoidal pipes is the secondary flow induced by centrifugal force which causes the fluid particles

inner side of the coil to move faster than the outer and thus provides benefit to enhance the heat transfer rate [12].

IV. CONCLUSION

In this study, two different cross-sectioned HCHEs exposed to boiling process were analyzed numerically. Firstly, the circular cross-sectioned HCHE was modeled in Ansys Fluent and the results were validated with the experimental results. The experimental setup was established to measure the primary parameters of the flow in fluid side. The CFD predictions match pretty well with the experimental results with a deviation lower than 1.12% thus this harmony will provide to make various parametric under different conditions. Subsequently, the square cross-sectioned HCHE was modeled to compare its thermal performance to the circular one. The results indicated that the square cross-sectioned heat exchanger enhances the heat transfer up to 1.6% relative to the circular one under the given conditions.

Abstract— In this study, flow and heat transfer were investigated by inserting a square fin into a channel at 5, 10, 15 m/s and 573 K air temperature. A thermoelectric module was placed on the bottom surface of the fin structures. The other surface of the thermoelectric is set to be at 22 °C. The results include parameters such as temperature, Nusselt, Reynolds, current, heat flow for channel flow and thermoelectric using flow and thermal - electric parameters. Numerical results show that the heat transfer coefficient of the square wing is 625 W/m²K and the temperature varies between 476 and 526 K. The results of the temperature, heat flow, current and heat of the thermoelectric placed under the wing structures were found to be 249.09 °C, 9.1852 W/mm², 103.15 mA and 155.58 W, respectively.

Keywords: Channel flow, fin, thermoelectric.

I. INTRODUCTION

In engineering applications, channel flow is frequently encountered. It is used in many places where there are fluid movements such as cooling of electronic devices, heat exchangers, heating and cooling of buildings. Improvement of heat transfer in the duct flow in engineering is a frequently encountered problem that needs to be continuously improved. Especially cooling of electronic devices and turbine blades is important for their performance. One of the methods intensively used to increase heat transfer in today's technology is extended heat transfer surfaces. Finned surfaces, by increasing the surface area and increase the turbulence of the flow of convective heat and mass transfer. The application area of finned surfaces is very diverse. Thermoelectric generators are also used in applications such as heating or cooling various small volumes. Thermoelectric is a fast and quiet machine, one surface is hot and the other surface is cold.

In general, a thermoelectric generator (TEG) consists of a number of semiconductor pairs that are connected electrically in a series and thermally in parallel, and each pair includes a p-type and an n-type element. Although in theory, a single piece of semiconductor material could work, a series connection is used to meet the high voltage potential

requirements. P-type and n-type elements are alternated to assure that the carriers transport in the same direction. [1]

When the literature is surveyed Tsai et al. [2], analyzes were performed on 4 different Reynolds numbers (10000, 20000, 30000 and 40000), 3 different fin sizes (30, 45, 75 mm) and 7 different angle values (45, 60, 75, 90, 105, 120, 135). For the short wing height (30 mm), it was emphasized that increasing the bending angle increased the thermal resistance, the Reynolds number increased from 100 to 100, from 45 to 135, the thermal resistance was changed by 10%, the thermal resistance and the pressure decreased. Karabulut et al. [3], two different types of wing were investigated numerically to increase the heat transfer of the heat exchangers. ANSYS Fluent 3D Navier-Stokes was steady state solution. As a result, for the Re 400, the hot and cold air velocities were set at 0.69 and 1.338 m/s for inlet temperatures of 300 K and 600 K, respectively. Jonsson and Moshfesh [4], have experimentally studied in a channel tunnel, in which the heat sink has 7 different fins (plate, strip and pin fin). They have designed and tested a total of 42 different heat sinks, with a height of 10, 15, 20 for each fin, with a width of 52.8. In the study, they obtained empirical correlations on how heat and hydraulic performances of heat receivers are affected. Re 2000 to 16500, while the fin height / channel height (H / CH) was 1, 0.67, 0.33. Yang et al. studied the effect of heat transfer performance on pin fin heat sinks density in twelve inline and staggered, such as circular, elliptic and square cross-section. Compared to the heat transfer coefficients of the pin fin heat sinks, they found that staggered arrangement were better, while elliptical pin fin had lower pressures [5]. Erturun et al. investigated the power generation performance of the thermoelectric device and the possible effect of the thermomechanical on the different thermoelectric leg geometry. They performed finite element analysis in ANSYS for thermoelectric models with various leg geometries (rectangular prism, trapezoidal prism, cylindrical and octagonal prism) and gradients at different temperatures (100 and 300 °C). For each model, they investigated temperature distribution, power outputs, thermal stresses. As TEG material,

they used bismuth tellurium, bismite tellurium / cobalt lead. The maximum stresses for rectangular and cylindrical legs of 100 °C were 49.9 MPa and 43.3 MPa and 94.2 and 85.7 MPa for the temperature gradient of 300 °C, respectively [6]. In their study of Erturun and Mossi [7], thermomechanical size investigated the effects of different leg structure and power production performance of thermoelectric devices. They have made 4 designs with their original, rotated and coaxial-legs configurations. As a result, in the concentric structure, the maximum temperature decreases by 10% and the conversion efficiency increases by 7%. In the case of rotating, the thermal resistance and the transport efficiency are the smallest between 1.2% and 0.3%, respectively. Rabari et al. in their work, they modeled a two-dimensional TEG system using nanostructured thermoelectric semiconductor material. The p – type nano structured bismuth antimony tellurium (BiSbTe), n – type contains bismuth tellurium (Bi₂Te₃) added 0.1% by volume of silicon carbide [8].

In this study, flow and heat transfer were investigated by inserting a square fin into a channel at 5, 10, 15 m/s and 573 K air temperature. A thermoelectric module was placed on the bottom

surface of the fin structures. Numerical calculations have been investigated in ANSYS 15 with Fluent and Thermal electric module.

II. MATHEMATICAL MODEL AND NUMERICAL METHOD

The schematic diagram of the geometry and the computational domain is shown in Fig. 1. The turbulent three dimensional Navier–Stokes and energy equations are solved numerically (using finite-difference scheme) combined with the continuity equation to simulate the thermal and turbulent flow fields. An eddy viscosity model is used to account for the effects of turbulence. The flow is assumed to be steady, incompressible, and three-dimensional. The buoyancy and radiation heat transfer effects are neglect. In addition, the thermo physical properties of the fluid are assumed to be constant. The three-dimensional governing equations of mass, momentum, turbulent kinetic energy, turbulent energy dissipation rate, and energy in the steady turbulent main flow using the standard k–ε model are as follows [9]:

Continuity equation

$$\frac{\partial \rho u_i}{\partial x_i} = 0 \quad (2.1)$$

Momentum equation

$$\rho u_j \frac{\partial u_i}{\partial x_j} = -\frac{\partial P}{\partial x_i} + \frac{\partial}{\partial x_j} \left[\mu_t \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) \right] \quad (2.2)$$

Energy equation

$$\rho u_j \frac{\partial T}{\partial x_j} = \frac{\partial}{\partial x_j} \left[\left(\frac{\mu_L}{\sigma_L} + \frac{\mu_t}{\sigma_t} \right) \frac{\partial T}{\partial x_j} \right] \quad (2.3)$$

Transport equation for k

$$\rho u_j \frac{\partial k}{\partial x_j} = \frac{\partial}{\partial x_j} \left(\frac{\mu_t}{\sigma_k} \frac{\partial k}{\partial x_j} \right) + \mu_t \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) \frac{\partial u_i}{\partial x_j} - \rho \epsilon \quad (2.4)$$

Transport equation for ε

$$\rho u_j \frac{\partial \epsilon}{\partial x_j} = \frac{\partial}{\partial x_j} \left(\frac{\mu_t}{\sigma_\epsilon} \frac{\partial \epsilon}{\partial x_j} \right) + c_1 \mu_t \frac{\epsilon}{k} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) \frac{\partial u_i}{\partial x_j} - c_2 \rho \frac{\epsilon^2}{k} \quad (2.5)$$

The empirical constants appear in the above equations are given by the following values [9]:

$$c_1 = 1.44, c_2 = 1.92, c_\mu = 0.09, \sigma_k = 1, \sigma_\epsilon = 1.3, \sigma_t = 0.7$$

Some assumptions in the model solution are;
The flow is solved in three dimensions and turbulence. Newtonian flow, accepted. In the Y-axis direction, the gravitational force -9.81 is used. Steady state of the solution was made. The k-ε turbulence model was made realizable.

III. RESULT AND DISCUSSION

A. Validation and verification

A reference study was taken into account in order to test the accuracy of the results obtained in the

numerical study. In comparison to the study, the emphasis is on the accuracy of the path. The obtained solutions were compared with the results in the reference study. In the first comparison, the comparison between the thermal resistance and the Reynolds number of the square fin in the channel is shown in Fig. 1. Another comparison shows the temperature change of the internal structure of the thermo electrical element shown in Fig. 2. As a result of these comparisons, results that are compatible with the reference works have been obtained. So the result is that the numerical method used is correct.

Fig. 1. Literature comparison with current study for channel flow

Fig. 2. Literature comparison of the thermoelectric structure with the current study.

B. Module geometries and material properties

The square fin is made of copper material in 40x40x12 mm dimensions and the fin structures are 2x2 mm wide. It is approximately 210 mm from the edge, as it would be in the middle of the channel. It

is shown in Fig. 3 and 4. The geometry is designed with a copper plate with dimensions of 50x50x500 mm and a thickness of 2 mm.

Fig. 3. Geometric features of model

Fig. 4. Schematic representation of the fin and thermoelectrics

Fig. 5. Mesh structure of model.

Once the geometry and mesh structure has been constructed, it is necessary to enter the boundary conditions required for FLUENT and to describe the fluid properties (Fig. 5 and 6). In this study, the air

to be sent into the channel was considered to have a temperature of 573 K. Channels and fins were made of copper.

Fig. 6. Thermoelectric mesh structure.

C. Performance comparison of square fin

In this study, air at a temperature of 573 K was sent to a channel at 5, 10 and 15 m/s at different speeds. The square fin structure placed in the channel was modeled and numerically investigated. The temperature distribution for three different velocities of the square fin is shown Fig. 7. The fluid at 573 K temperature sent into the channel decreases with

decreasing speed. The temperature values of the fin are decreasing from the upper parts of the fluid contacting the lower surface. As can be seen, it has a speed of 5 m/s with a minimum temperature of 472 K. As a result, the heat transfer increases as the speed increases.

a)

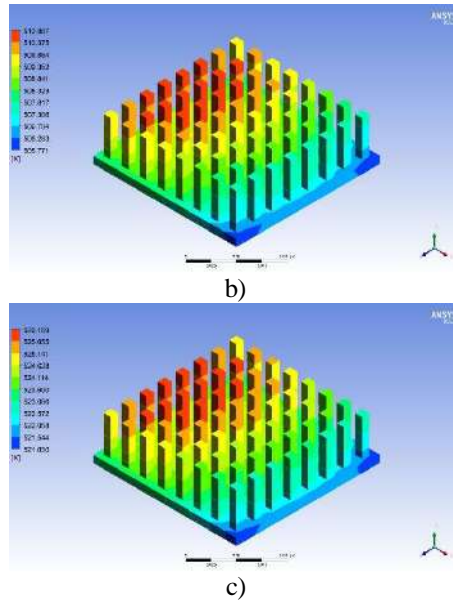

Fig. 7. Temperature distribution for square fin a) $V = 5$ m/s b) $V = 10$ m/s c) $V = 15$ m/s

For a square fin, the temperature variation along the channel, depending on the Reynolds number, is given in Fig. 8. Initially, the temperature of the air at 573 K is reduced to a certain length depending on the number of Reynolds. The temperature is stable between 100 - 200 mm. The cause is the uniformity of the temperature because the flow does not encounter any obstacles until it reaches the region in the channel. A certain temperature rise and drop is found in the fluid channel after it has hit the fin,

which is placed in the channel. After passing the fin, the temperature was held steady, depending on the Reynolds number. Depending on the initial temperature, the curve with the lowest temperature loss $Re = 5247.1$, the highest temperature loss is $Re = 15741.3$. The surprise of the fins is that the greatest increase in temperature is in the square fin. The change in Nusselt number along the canal of Reynolds number for the square fin is given in Fig. 9.

Fig. 8. Variation of temperature across the canal for different Reynolds numbers

Fig. 9. For different Reynolds numbers, change the local Nusselt numbers along the channel

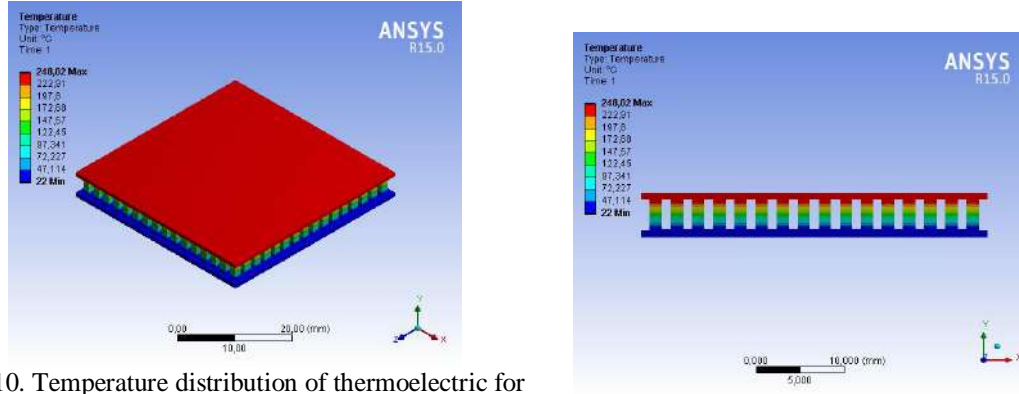

Fig. 10. Temperature distribution of thermoelectric for square fin

Fig. 11. Current distribution of thermoelectric for square fin

The numerical results of the thermo electrical for square fin in ANSYS thermal - electricity are shown in Table 1. The result for thermoelectricity placed under square fin founded $Re = 15741.3$. Fig. 10 and 11 show the temperature and current distribution for the square fin. The results are presented as a table.

Table 1. Numerical results of thermoelectricity for square and staggered square fin

	Temperature (°C)	Heat Flux (W/mm ²)	Current (mA)	Heat (W)
Square fin (5 m/s)	199.3	7.1718	79.375	121.46
Square fin (10 m/s)	232.76	8.5248	95.35	144.39
Square fin (15 m/s)	248.02	9.1422	102.64	154.85

IV. CONCLUSIONS

Numerical results show that the heat transfer coefficient of the square wing is $625 \text{ W/m}^2\text{K}$ and the temperature varies between 476 and 526 K. The best heat transfer was achieved with 15 m/s, 10 m/s and 5 m/s, respectively. For different speeds for the square fin, the temperature values varied between 476.934 and 526.169 K. When the speeds are compared, the best heat transfer is achieved with 15 m/s, 10 m/s and 5 m/s, respectively. The results of thermoelectric temperature, heat flow, current and heat were found to be 249.09 °C, 9.1852 W/mm², 103.15 mA and 155.58 W respectively.

Abstract—In this study, a novel approach to signal processing namely Hilbert-Huang Transform (HHD) and its application on High Voltage Direct Current (HVDC) are discussed. The virtual ground-phase faults obtained in Matlab environment and fault current and voltage values of each signal recorded simultaneously while the simulation is running. Then, HHD is used to extract feasible features from the instantaneous frequency and magnitude values of each Instant Mode Function (IMF) on Empirical Mode Decomposition (EMD) and Hilbert Spectral Analysis (HSA). Finally, Extreme Learning Machine (ELM) is determined to estimate the fault locations and the performance of the hybrid approach are discussed. Also, It can be seen from results and HHD analysis, this new approach can properly expose the nonlinear and non-stationary elements unlike the traditional methods are inadequate.

Keywords—Hilbert-Huang transform; High Voltage Direct Current transmission; Extreme Learning Machine; fault estimation; empirical mode decomposition.

I. INTRODUCTION

HVDC transmission systems are preferred mostly on the connection of offshore renewable energy sources to the mainland, bulk power transmission through long distance, interconnection systems with different frequencies, power flow, and voltage control of different AC transmission systems, etc. When considering AC transmission, especially bulk power over long distance, HVDC transmission has less overall cost and losses. Also, the major concerns associated with interconnection of two system, like security, reliability, frequency control and so on are no longer become any problem in HVDC systems. Different topologies, multi-terminal applications, fast tripping and robust switching elements of voltage source converters (VSC) increase the application of HVDC systems. Due to its fast controllability, dc transmission has a full control action, and ability to enhance dynamic and transient stability related with ac network and can limit fault current in the dc lines [1]. There are also some obstacles to be overcome in the application of HVDC technology. Some of them are high cost of conversion equipment and converter station [2] the requirement of reactive power supply in converter stations, the complexity of control

action [3]. The widespread of different high voltage and high power switching elements like GTO and IGBT and different Pulse Width Modulation (PWM) techniques accelerated the practical usage of VSC based HVDC systems [4], [5]. Those self-commutating switches can be turned on-off at will. This feature regulates the voltage/current in a VSC properly and controls the power factor as well. Additionally, power reversal in a VSC can be made with both current and voltage at the dc side [6].

HVDC control strategies are mainly focused on protection of the converter stations and protection of the dc transmission line [7]. In this study, we will focus only the dc transmission lines fault techniques and introduce new protection strategies for this purpose. In HVDC systems, the most commonly used fault detection and protection algorithms are differential protection [8], traveling wave protection [9], [10], over current and under voltage derivatives protection [11], impedance measurement, wavelet transform (WT) [12] and short-time Fourier transform (STFT) based signal processing methods and the artificial intelligence applications that have recently attracted attention [13]. Considering protection scheme for point to point HVDC systems, classical main protection and backup protection algorithms do not perform well to detect high impedance faults. In different versions of traveling wave protection and derivative protection, this undesirable situation can be eliminated by using two terminal measurements and fast communication channels. A detailed information of classic HVDC system protections can be found in [14]. Another protection algorithms that mentioned before can be thought as the analysis of high-frequency components or the sampling of fundamental and transient components of fault signals. When a fault occurs on dc line or converter station, non-stationary current and voltage fluctuations continuous until the high-frequency components are damped. By taking advantages of this phenomenon and using different filtering techniques can successfully be exposed the hidden and valuable information in fault signals. In literature surveys, mostly preferred and proposed method be Discrete Wavelet Transform (DWT) and the hybrid approach with traveling wave dispersion to find modulus maximas of traveling voltage and current waves. Also, calculation of signal's energy [15] and

entropy values [16], wavelet coefficients of forward and reverse voltage waves [17], transient current characteristic [18], the measurements of dc line terminals [19], can be thought the different implementation of the wavelet transform. Unlike these, different signal processing methods such as mathematical morphology [20], [21], Stockwell transform (S-transform) [22], [23], HHT [24], [25] are some examples of this area. In this study, as before mentioned, we will mainly focus on HHT and a new machine learning method to locate phase-ground faults in dc line.

II. HILBERT-HUANG TRANSFORM

Data analysis is an essential process in observing the behavior of transient events on power systems and transmission lines. Until now, traditionally the data analysis methods are either Fourier-based or wavelet based for the linear and nonstationary phenomenon are designed. However, considering nonlinear and nonstationary processes, there are very limited options in data analysis methods. At this point, other than the periodicity, constant width Fourier window or wavelet family, the nonlinear and nonstationary processes need different approaches. HHT method proposed by Huang in [26] is an adaptive and time domain based preprocessing tool which consists of two parts as EMD and HSA. The detailed information will mention the following sections.

A. Empirical Mode Decomposition

EMD is an adaptive, direct and intuitive method which is a necessary step to reduce any data set into a collection of IMF. It can be considered as the simple oscillatory modes of significantly different frequencies, one superimposed on the other. At the end of the process, similar to wavelet decomposition levels, each IMF represents not only different frequency levels but also simple oscillatory modes. In HHT method, each IMF must satisfy two conditions. First of all, an IMF must have the same number of extrema, minima, and zero crossings or differ from at most by one. Secondly, at any point, the mean value of the function must be zero. When these conditions are ensured, one can decompose into components any signal through a sifting procedure [27], [28].

For any data set, the local extrema points are identified using a cubic spline envelope. The upper and lower envelopes should encompass all data. When $x(t)$ represents the original signal and its mean values designated as m_1 , the difference between original signal values and mean values is the first proto-IMF component and can be represented as h_1 . This definition is given as in (1).

$$h_1 = x(t) - m_1 \quad (1)$$

Normally, it is expected that h_1 satisfy the definition of IMF but changing a local zero from rectangular coordinate system to curvilinear one may cause new extrema, so the sifting process must be repeated to eliminate background waves and to make the wave profiles more symmetrical. In the each iteration step, the existing proto-IMF h_1 treated as the original signal and in the next iteration process continuous as in (2).

$$h_{11} = h_1 - m_{11} \quad (2)$$

After k times of iterations, expected conditions are satisfied, h_{1k} becomes the first IMF c_1 moreover, mathematically expressed in (3).

$$\begin{aligned} h_{1k} &= h_{1(k-1)} - m_{1k} \\ c_{1k} &= h_{1k} \end{aligned} \quad (3)$$

The first IMF contains high-frequency components and corresponds the detail coefficients in wavelet transform. Obtaining another frequency band components from the original signal, IMF is extracted from the signal and a residue term obtained. The first residue term r_1 moreover, all subsequent terms r_j are shown in (4) and (5), respectively [26], [28].

$$r_1 = x(t) - c_1 \quad (4)$$

$$\begin{aligned} r_2 &= r_1 - c_2 \\ &\vdots \\ r_n &= r_{n-1} - c_n \end{aligned} \quad (5)$$

The decomposition process of the original signal continuous until the residue term becomes a constant or a monotonic function, in other words, a trend. Also, the original signal can be reconstructed by summing up all IMF components and residue term. This expression is given in (6).

$$x(t) = \sum_{j=1}^n c_j + r_n \quad (6)$$

While the sifting process continues for many iterations and makes the amplitude variations of the new constructed waves, some undesirable situations occur on physical properties of the components. Eliminating these side effects and make HHT more compact to implement in different applications, Huang and colleagues proposed two separate stoppage criterions. The first proposed method is similar to Cauchy convergence test but slightly different from the original one. This stoppage criterion mathematical expression is given in (7) [28].

$$SD_k = \frac{\sum_{t=0}^T |h_{k-1}(t) - h_k(t)|^2}{\sum_{t=0}^T h_{k-1}^2(t)} \quad (7)$$

In equation (7), SD_k represents the stoppage criterion and the sifting process repeats if the squared difference of two successive sifting is smaller than the previous determined value. The another stoppage criterion depends on the experiences from the extensive tests and determined between 3 and 8.

B. Hilbert Spectral Analysis

Hilbert spectrum represents the decomposed data in the time-frequency-energy domain and assigns the energy levels of different components correctly. When applying a Hilbert transform to the each IMF components, the instantaneous frequency, and magnitude values are obtained. In contrast to Fourier transform, this IMF functions represents a time-varying function of amplitude and frequency. This time-frequency representation of magnitude is called as a Hilbert spectrum. For any function $x(t)$ of L^p class, its Hilbert transform is given in (8) [29].

$$y(t) = \frac{1}{\pi} P \int_{-\infty}^{+\infty} \frac{x(\tau)}{t-\tau} d\tau \quad (8)$$

Where P represents the Cauchy principal value, τ is the sifting value in time domain and $y(t)$ is Hilbert transform of

$x(t)$. The instantaneous frequency and amplitude values of Hilbert transform of $y(t)$ can be derived from its analytic function as in (9) and (10) respectively.

$$z(t) = x(t) + iy(t) = a(t)e^{i\theta(t)} \quad (9)$$

$$\omega(t) = \frac{d\theta}{dt}, \quad a(t) = \sqrt{x^2 + y^2} \quad (10)$$

Here ω represents instantaneous frequency and a represents the magnitude. When we have both frequency and magnitude values, we can also obtain the energy values in terms of square of the magnitude in time-frequency domain. In HSA, an alternative spectrum expression of the entire data set so called marginal spectrum can measure of the total energy contribution of each IMF. The marginal spectrum is given in (11)

$$h(\omega) = \int_0^T H(\omega, t) dt \quad (11)$$

where $[0, T]$ is the preprocessing domain of IMFs samples is defined temporally.

III. THE SIMULATION STUDY AND FEATURE EXTRACTION BY HHT

The simulation of a monopolar HVDC system is utilized for creating the phase-ground fault data sets. In the simulation, DC line is 300 km length and both rectifier and inverter station uses 12 pulse converter and control systems for inverter and rectifier made up 'Discrete HVDC Controller Block' in Simpowersystems library, in Matlab. The control action of inverter and rectifier uses several parameters like alpha (α) and gamma (γ) control. The alpha (α) value is the firing delay angle ordered by the regulator. Gamma parameter observes the extinction angle for each 6 pulse thyristor bridge. There are also another control system which is called 'Master Control' and generates the current references for both converters and initiates the starting and stopping of the DC power transmission.

At both sides of rectifier and inverter, there are two breakers, 0.5 H reactors, and AC filters. The DC line is a 1000 MW (500 kV, 2 kA) interconnections of two different grid. Rectifier side has a 500 kA, 5000 MVA 60 Hz AC network and inverter side has a 345 kV, 10000 MVA, 50 Hz AC network. The DC transmission line properties are given in Table I.

TABLE I. PROPERTIES OF DC TRANSMISSION LINE IN THE SIMULATION

Transmission Line	Properties
Length	300 km
Class	Distributed parameter
Circuit Structure	Serial RLC
Connection Style	single phase-ground
Smoothing Reactors	0.5 H (2 units)
Primary voltage	0.90 (rectifier side) 0.96 (inverter side)
Sampling Time (s)	50×10^{-6} s
DC line voltage (kV)	500 kV
DC line current (kA)	2 kA
Fault resistance R_d	R_{on} (1 ohm)

Grid frequency	50 / 60 Hz
Multiplication factor	1:100
Per km;	
Resistance	0.015 ohm/km
Inductance	$0.792 \cdot 10^{-3}$ H/km
Capacitance	$14.4 \cdot 10^{-9}$ F/km

A. Steady State and Faulted Conditions of Simulation Study

DC currents (I_dR ve I_dI) and DC voltages (V_dLR ve V_dLI) defined in control blocks are scaled to p.u (1 p.u. current=2 kA, 1 p.u. voltage=500 kV). In steady state condition, the current value of the rectifier (I_{dref}) moreover, the voltage value of the inverter (V_{dref}) pursue a predefined reference value in the system. They set at 0.1 and 0.05 pu, respectively. The current and voltage values of steady-state and faulted state are demonstrated in Fig.1 and Fig.2 respectively.

Fig. 1. Steady state conditions of DC line (a) current (b) voltage values, rectifier side

Fig. 2. Phase-ground fault on the 150.km of DC line, (a) fault current, (b) fault voltage, rectifier side

The sample of phase-ground fault occurs at ($t=0.7$ s) and continuous until ($t=0.8$ s). At the beginning of fault application,

current increases to approximately 2.2 pu and DC voltage falls to zero at the rectifier. The Voltage-Dependent Order Limiter (VDOL) and DC protection detect this voltage drop. While current continues to circulate and the voltage falls into negative

region, the protection algorithm is on mode and firing angle is forced to 166 degrees. Then, rectifier operates in inverter mode until the recovery of DC voltage and current is done. The screenshot of the simulation is demonstrated in Fig 3.

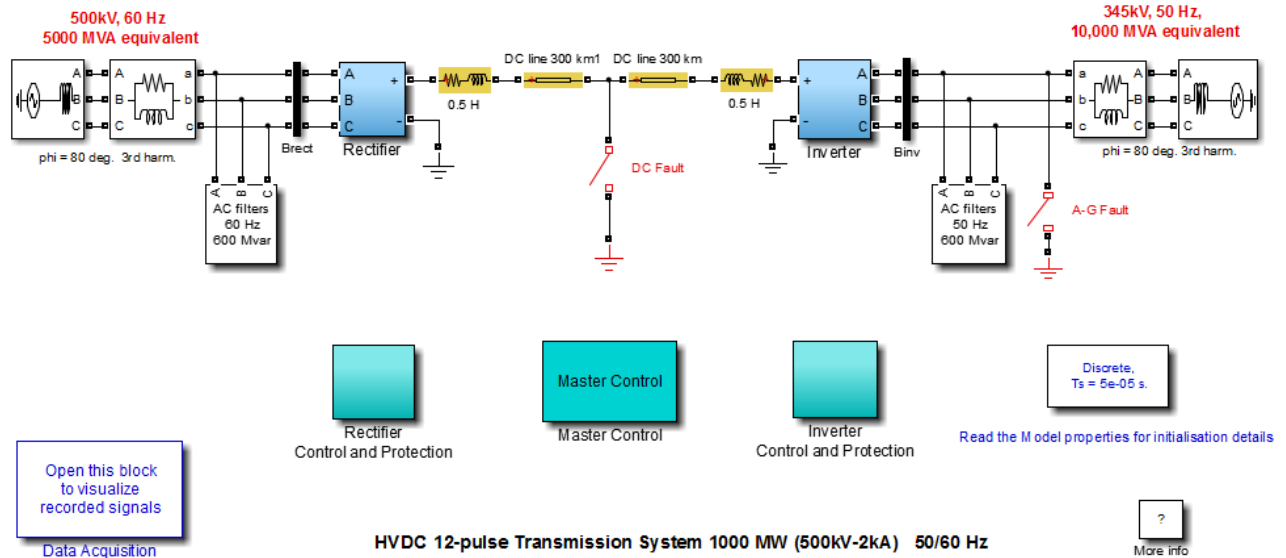

Fig. 3. 12 pulses monopolar HVDC system and equipment in the simulation study

In this study, the fault current and voltage signals recorded between 15.km and 285.km of DC line. Fault resistance and fault duration are kept constant for each km and appeared between [0.7-0.8] seconds after the simulation start.

B. Feature Extraction by Using HHT

After the recording of the fault signals, HHT is applied to extract instantaneous frequency and magnitude values. Unlike from DWT; it examines the whole data set on the time domain, because of analyzing the IMFs on time domain. In order to obtain each of IMF; the iteration step is adjusted as 10 and it is automatically completed the analysis in the case of the signal became a trend or monotonic function. The sampling period of the HHT is set to 5×10^{-5} s similar to the simulation study. The total duration of the HHT signal analysis is 1.6 seconds.

The numbers of IMF obtained from the HHT are not the same for each fault current and voltage signal. Therefore, while signals are decomposed up to 12 level, the number of IMF to be used during the fault estimation stage has been determined to be the first 3 IMFs that cover all signal data set.

The HHT method, as detailed in Section II, allows being obtained EMDs if certain conditions are met. These are in general; The IMF's average must be zero, the maximum, minimum and zero crossings must be equal or differ from at most by one. These necessary conditions that allows the EMD process can lead some problems as no maximum or

minimum point can exist at the beginning and end of the signal. This undesirable condition, also known as the end effect, causes distortions in waveforms at the beginning and end points of the IMF. Different approaches such as characteristic wave extension, mirroring, data duplication and similarity research are used to eliminate this problem [30].

The first three level of IMF obtained from the fault current, and voltage signals of DC line at 15.km is shown in Fig. 4.

Fig. 4. The first 3 IMF of DC fault signal (a) current (b) voltage at 15.km,rectifier side

The Hilbert energy spectrum obtained from EMD for current and voltage of DC line is shown Fig 5.

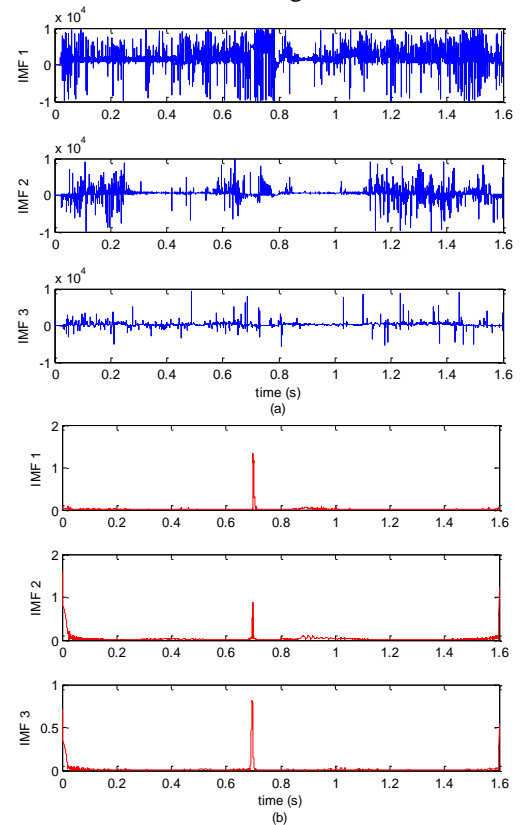

Fig. 5. Hilbert energy spectrum of DC fault signal (a) current (b) voltage

Finally, at the feature extraction process for representing fault signals properly, the average of instantaneous frequency and magnitude and standard deviation of instantaneous frequency and magnitude values have been calculated. This procedure is implemented to the first 3 IMF of both each fault current and voltage signal. So, the feature vector has 24 properties which include both current and voltage values. The property distribution of the first 3 IMFs is mentioned in Table II.

TABLE II. PROPERTY DISTRIBUTION OF THE FIRST 3 IMFS OF FAULT CURRENTS AND VOLTAGES

Parameters	IMF-1	IMF-2	IMF-3
The Average of instantaneous frequency	Feature_1	Feature_2	Feature_3
The Average of instantaneous magnitude	Feature_4	Feature_5	Feature_6
The standard deviation of instantaneous frequency	Feature_7	Feature_8	Feature_9
The standard deviation of instantaneous magnitude	Feature_10	Feature_11	Feature_12

The instantaneous frequency and magnitude values of the first 3 IMF for current and voltage at 15.km of DC line is shown in Fig 6.

Fig. 6. Instantaneous frequency and magnitude values of voltage (a,b) and current (c,d) signals respectively

IV. PERFORMANCE EVALUATION OF ELM AND FAULT ESTIMATION PROCESS

ELM is a single layer feed forward neural network (SNLF) and proposed firstly by Huang in [31] to overcome some problems such as slow training performances of gradient based algorithms, improper learning steps or easily converge to local minima. Also, the idea of choosing input weights and biases randomly if the activation function is infinitely differentiable, the output of a neuron can be determined numerically. By this approach, a remarkable computational burden can be abolished and still have able to obtain expectable results.

Considering a data set which contains N different sample (x_i, y_i) ; $x_i = [x_{i1}, x_{i2}, x_{i3}, \dots, x_{in}]^T \in \mathbb{R}^n$ moreover, corresponding outputs are $y_i = [y_{i1}, y_{i2}, y_{i3}, \dots, y_{im}]^T \in \mathbb{R}^m$, \tilde{N} represents hidden layer and $g(x)$ activation function, SLFN's can mathematically model as in (12) [32].

$$\sum_{i=1}^{\tilde{N}} \beta_i g_i(x_j) = \sum_{i=1}^{\tilde{N}} \beta_i (w_i x_j + b_i) = o_j \quad j = 1, 2, \dots, N, \quad (12)$$

Where $w_i = [w_{i1}, w_{i2}, w_{i3}, \dots, w_{in}]^T$ is the randomly chosen weight vectors connecting i th hidden layer and input layer, $\beta_i = [\beta_{i1}, \beta_{i2}, \beta_{i3}, \dots, \beta_{im}]^T$ is the weight vectors connecting i th hidden layer and output layer. Also, b_i represents the threshold value of the i th hidden layer.

In the ELM method, mathematical representation of the network in a different manner can be thought as a multiplication of data matrices ($H\beta = T$) [33]. Considering that the output matrix of the hidden layer of the SLFN is H , the weight vector is β and the T matrix expresses the real outputs vectors and can mathematically expressed as shown in (13).

$$H(w_1, \dots, w_{\tilde{N}}, b_1, \dots, b_{\tilde{N}}, x_1, \dots, x_N) = \begin{bmatrix} g(w_1 x_1 + b_1) & \dots & g(w_{\tilde{N}} x_1 + b_{\tilde{N}}) \\ \vdots & \dots & \vdots \\ g(w_1 x_N + b_1) & \dots & g(w_{\tilde{N}} x_N + b_{\tilde{N}}) \end{bmatrix}_{N \times \tilde{N}} \quad (13)$$

$$\beta = \begin{bmatrix} \beta_1^T \\ \vdots \\ \beta_{\tilde{N}}^T \end{bmatrix}_{\tilde{N} \times m} \quad T = \begin{bmatrix} t_1^T \\ \vdots \\ t_N^T \end{bmatrix}_{N \times m}$$

This matrix computation is only possible if the ($H\beta = T$) is a square matrix. However, in most cases, the input vectors are higher than the hidden layer nodes. In ELM method, this equation rearranged by using Moore-Penrose inverse matrix as $\hat{\beta}$. This inverse matrix enables to solve nonsquare matrixes and invertible. The equation of Moore-Penrose transform is given in (14).

$$\hat{\beta} = H^+ T \quad (14)$$

The equation of $\hat{\beta} = H^+ T$ is also one of the least squares solutions of generalized ($H\beta = T$) linear system. The lowest training error can be achieved with this particular solution. The minimum training error criterion is also mathematically expressed in (15).

$$\|H\hat{\beta} - T\| = \|HH^+ T - T\| = \min_{\beta} \|H\beta - T\| \quad (15)$$

In this study, to improve the generalization ability of the standard ELM in which uses a constant such as C is preferred. This approach also is known generalized ELM (RELM) and can improve the performance of ELM. The main difference of ELM and RELM is that training error is reduced simultaneously and the output weights with the regulation parameter is a norm. The mathematical representation of RELM and its Lagrange equivalent is shown in (16) [34].

$$\min_{\beta} C \|e\|_2^2 + \|\beta\|_2^2 \quad (16)$$

$$L(\beta, e, \lambda) = C \|e\|_2^2 + \|\beta\|_2^2 + \lambda^T (y - H\beta - e)$$

where $e = [e_1, e_2, \dots, e_N]^T$ is the training error and λ is the Lagrange multiplier. In RELM, the regulation parameter is set to 1×10^{-6} . The size of the training matrix is $[24 \times 163]$, and the size of the testing and validation matrix is $[24 \times 54]$. The number of hidden layer neuron is defined as ($n=900$). The estimated fault locations and regression value is shown in Fig 7 and Fig 8, respectively.

Fig. 7. The estimated fault locations and actual fault locations

Fig. 8. Regression value of testing process of RELM

In this study, the root mean square error (rmse) calculated as (rmse=6.4858), and total regression value is calculated as (R=0.9987)

CONCLUSION

In this study, a novel signal processing and machine learning method are discussed. The ELM-HHT hybrid protection algorithm as seen from regression value and estimation process can be used for DC phase-ground faults. Also, HHT analysis gives us more information about signal and does not need an extra preprocessing stage.

In the future applications, HHT analysis can be implemented on bipolar and multi-terminal HVDC systems and the performance of proposed algorithm can be investigated by using benchmark tests.

The Reinforcing Effect Of Nylon 6,6 Nanofibrous Mats On Gfrp Modified With Nanoparticles Subjected To Low Velocity Impact

Vildan ÖZKAN¹, Murat YILDIZ¹, Ahmet YAPICI¹

¹*Mechanical Engineering Department, Iskenderun Technical University, 31200, Hatay.*

This work investigates the low velocity impact resistance of GFR-epoxy laminates interleaved with electrospun nylon 6,6 nano-fibres. The main goal is to investigate the interaction between the nanofibrous mats interleaved into a laminate and their influence on the property of the whole body and in particular their reinforcing effect. Different nanomodified configurations are suggested and tested together with virgin specimens. The multi-walled carbon nanotubes (MWCNTs) and graphene were used as nanoparticles. The prepared solution for electrospinning process contains 16 wt% nylon 6,6. The solvent mixture of formic acid/dichloromethane (2:1 wt/wt ratio) was trusted as an efficient solvent for nylon 6,6 materials. The nylon 6,6 nanofiber layers were studied by SEM. The nanofiber mats were placed between the woven glass fiber materials. Special molds were designed to produce composite materials. The results of the low velocity impact tests show that the interaction between the resin and the nano-fibre is the key feature of the reinforcement mechanism. The relation between the nanofiber layer numbers and the damping ratio was obtained.

Abstract— This study is about analyzing the wind characteristics using Weibull distribution. Weibull is generally used to analysis wind speed data sets in statistical analysis. For this purpose, building-mounted wind measurement masts were established on suitable place in Muğla Sıtkı Koçman University Central Campus in Kötekli. Mean wind speeds were measured hourly at 15 m height. Annual of hourly measured wind data between from July 2015 to June 2016 was analyzed in this study. Weibull parameters were calculated by statistical analysis. Subsequently, considered wind speed distributions were evaluated with The Coefficient of Determinations (R^2) and Root Mean Square Error (RMSE) analysis for determination of Weibull distributions.

Keywords— Wind Speed; Wind Characteristic; Weibull Distribution; Muğla

V. INTRODUCTION

Renewable energy sources are an environmental type of energy compared to fossil fuels that pollute the atmosphere. Wind energy is one of the fastest growing energy sources in the world and in our country among renewable energy sources. At the present time, a lot of studies on the assessment of wind characteristics were investigated.

Ucar and Balo [1] evaluated wind characteristics using the wind speed data collected of the six meteorological stations in Turkey during the period 2000-2006. This study pointed out that the mean annual value of Weibull shape parameter k is between 1.71 and 1.96 while the annual value of scale parameter c is between 6.81 and 9.71 m/s. Yaniktepe et al. [2] investigated the wind energy potential that is a result of the distribution of wind speeds in Osmaniye, which is located east of the Mediterranean Sea in Turkey. Wind data, consisting of wind speed, direction

and flow time at a height of 10 m, were collected by the Turkish State Meteorological service for a period of 44 months, from January 2008 to August 2011. To determine the Weibull parameters, they used a graphical method.

Ozgener [3] determined the wind energy potential of the Celal Bayar University Muradiye Campus. In this study the wind speeds were obtained between 2006 and 2007 using an experimental system. Ozgener predicted that the installation of wind energy system would not be economical due to its low capacity factor of 14.1%. Ozerdem and Turkeli [4] presented the wind characteristics such as wind speed, turbulence intensity and wind direction for Izmir Institute of Technology campus. They concluded that the campus region had a high wind potential to utilize wind turbine systems. Furthermore, they selected the most suitable wind turbines as 600 kW and 1500 kW.

VI. MATERIAL AND METHOD

Information of wind speed distribution is very significant factor for evaluating the wind potential of windy regions [5,6]. In this study, wind characteristics of Muğla Sıtkı Koçman University Central Campus in Muğla were investigated by using Weibull distribution. For this purpose, building-mounted wind measurement masts were established on suitable place in Muğla Sıtkı Koçman University Central Campus in Kötekli. Hourly mean wind speeds were measured at 15 m height. Annual of hourly measured wind data between from July 2015 to June 2016 was analyzed.

A. Site description and Wind data measurement mast

Muğla Sıtkı Koçman University Central Campus is positioned a country known as Menteşe of Muğla province.

Muğla province is located in the south –western Anatolia region. Locations and coordinates of measurement mast in campus are displayed in Fig.1 and Table 1, respectively.

Fig. 1. The location of the wind measurement masts in Campus [7]

Table 1. Geographical coordinates of station used in the study

Station	Latitude	Longitude	Elevation
Campus	37°09'43.1"N	28°22'09.6"E	723 m

The wind speed was measured at 15 meters high by building-mounted wind measurement mast. Measurement mast has direction sensor, anemometer, temperature and pressure sensors. Measured data is transferred to a data collector.

B. Weibull Distribution Method

The wind speed probability density function can be calculated as [8]:

$$f(v) = \frac{k}{c} \times \left(\frac{v}{c}\right)^{k-1} \exp\left(-\left(\frac{v}{c}\right)^k\right), (k > 0, v > 0, c > 1) \quad (1)$$

Where $f(v)$ is the probability of observing wind speed v , c is the Weibull scale parameter and k is the dimensionless Weibull shape parameter. The Weibull parameters k and c , characterize the wind potential of region under study. Mainly, the scale parameter, c , shows how 'windy' a wind location under consideration is, whereas the shape parameter, k , shows how peaked the wind distribution is (i.e if the wind speeds tend to be very close to a certain value, the distribution will have a high k value and is very peaked) [9].

In this study, the shape parameter and the scale parameter are calculated by using statistical analysis.

C. Error Analysis

The errors expressed in terms of the Root Mean Squared Error (RMSE) and coefficients of goodness of fit (R^2) are determined between the observed and calculated wind speed frequencies by using statistical analysis [10]. The Root Mean Squared Error is calculated by:

$$RMSE = \left[\frac{1}{N} \sum_{i=1}^N (y_i - x_i)^2 \right]^{0.5} \quad (2)$$

The coefficients of goodness of fit are calculated by:

$$R^2 = 1 - \frac{\sum_{i=1}^N (y_i - x_i)^2}{\sum_{i=1}^N (y_i - \bar{y})^2} \quad (3)$$

VII. RESULTS AND DISCUSSIONS

The mean monthly values of wind speed variations at a height of 15 m are presented in Fig 2. It indicates that the highest monthly mean wind speed is determined as 2,03 m/s in March 2016 while the lowest mean wind speed 0,87 m/s in December 2015.

Fig. 2. The mean monthly values of wind speed variations at a height of 15 m

The Weibull parameters calculated for the months measured between July 2015 and June 2016 using the wind data of the wind measurement station are given in Table 2. Accordingly, to this table, Weibull shape parameter k varies between 1.15 and 1.53, while scale parameter c varies between 0.92 and 2.23 m/s

Table 2. Monthly variations of Weibull parameters

	k (shape)	c (scale)
July	1,45	1,86
August	1,48	1,83
September	1,32	1,75
October	1,31	1,42
November	1,21	1,38
December	1,15	0,92
January	1,39	1,83
February	1,30	1,93
March	1,49	2,23
April	1,27	1,94

May	1,50	2,14
June	1,53	2,18

Table 3. Coefficients of determination and root mean square errors (m/s)

	RMSE)	R ² (%)
July	0,0280706	94,7
August	0,0298098	95,9
September	0,0444510	91,9
October	0,035164	96,2
November	0,0316470	97,1
December	0,0412024	97,2
January	0,0554300	86,7
February	0,0397272	91,9
March	0,0449434	87,5
April	0,0456820	89,4
May	0,0386144	91,1
June	0,0357993	92,1
Annual	0,0311973	94,8

It is seen from Table 3 the highest value of RMSE was 0.0554300 m / s, while the lowest value of R² was 86.7%. In addition, annual of RMSE was calculated as 0.0311973 and R² was calculated as 94.8%. When these factors are evaluated, it is expected that the value of R² should be close to 1 when the RMSE value is required to be close to zero in terms of the accuracy of the analyzes. When the chart is examined, it is seen that logical results are obtained. Correlations between observed, Weibull wind speed frequencies in annual are illustrated in Fig. 3.

Fig.3. Correlations between observed, Weibull wind speed frequencies in annual

VIII. CONCLUSION

When the error analysis is evaluated, it is seen that the Weibull distribution is highly compatible with the observed wind speeds. Due to the variability of the wind speed, the wind potential may vary from year to year. For this reason, wind measurements should be taken for more than 1 year in order to obtain good results. This study can also be applied to different areas of the campus area to determine the wind map of the campus area.

Abstract—Flow separation and reattachment regions significantly affect the heat transfer inside the ducts. Heat transfer is enhanced by using obstacles such as fins, turbulators to provide flow separation in this perspective. The aforementioned method is based on production of secondary flow or fluctuations due to the obstacles and utilized for heat exchangers, solar collectors, cooling parts of appliances etc. In the present study, turbulent flow and heat transfer characteristics is determined in the existence of fins placed between the parallel plates. Symmetrical fins are mounted periodically on the internal walls of the parallel plates. Constant wall temperature is taken as boundary condition to the plates and the fins. At the inlet of the system, the velocity of water is 0.15 m/s. The comparison of finned and unfinned horizontal parallel plates is done in terms of turbulent convective heat transfer at $Re = 6000$. In the numerical study, standard $k-\omega$ turbulence model has been used. As a result of the study, the enhancement in heat transfer due to flow separation has been provided by fins on the internal sides of the parallel plates.

Keywords— CFD; fin; heat transfer; parallel plate; turbulent flow

I. INTRODUCTION

Heat transfer is enhanced by using different techniques. One of these methods is placing of obstacles on the internal sides of the channel. Fundamentally, this method is based on flow separation and reattachment regions which significantly affect the heat transfer inside the devices. Baffles, fins and turbulators have been utilized to provide flow separation which provides the increment of heat transfer. Secondary flow or fluctuations based procedure is preferred for heat exchangers, solar collectors, cooling parts of appliances. In the literature, similar studies for convection heat transfer with fluid flow have been encountered. Kakac (1968) has numerically solved the forced convection heat transfer for air flowing between two parallel plates at $Re = 9370$ and $Re = 17100$. The changes of air velocity and effective diffusion through the cross-section of the channel were considered. Local Nusselt numbers have been obtained via the results of transient runs by assuming that air has fully developed turbulent velocity profile [1]. Kelkar and Patankar (1987) have analyzed the laminar flow and heat transfer in finned passages at $Re = 100$ and $Re = 500$. The fins have been kept at a constant temperature and arranged on parallel plates with staggered distribution. The fins were used for the flow deflection and this

causes the increment of the heat transfer considerably. Heat transfer was increased for fluids with the increment of Prandtl numbers as a result. However, it was found that shorter fins decreased the heat transfer in terms of lower Prandtl numbers [2]. Bejan and Scihubba (1992) have scrutinized the forced convection for the cooling process of parallel plates. The optimum distance between the plates has been determined by considering board length, fluid properties and pressure difference in terms of laminar flow regime in this study. Moreover, maximum total heat transfer has also been given with the dependence on pressure difference, stack thickness and temperature difference [3]. Abe et al. (1994) have recommended a turbulence model to handle the turbulent flows with separation of fluid and heat transfer, which has been developed from low-Reynolds-number $k-\epsilon$ turbulence model. The present model was successful for capturing the separation and reattachment regions of flow in the wake of backward-facing step. The heat transfer coefficient had the maximum value at the reattachment point and eddy viscosity was important for the determination of thermal field in the vicinity of that point [4]. Ooi et al. (2002) have calculated the flow and heat transfer characteristics of blocks periodically placed on the channel wall by conducting Reynolds-averaged simulations. Two and three dimensional v^2-f , Spalart-Allmaras and two-layer $k-\epsilon$ turbulence models were used, but the closest results to the experiments have been obtained with v^2-f model [5]. Bazdidi-Tehrani and Naderi-Abadi (2004) have numerically investigated the laminar fluid flow and heat transfer in the entrance zone of the horizontal channel. Various blockage ratios for $h/H = 0.1, 0.2$ and 0.3 have been considered in case of constant temperature for both sides of the channel at $100 \leq Re \leq 500$. It is declared that local Nusselt numbers increased in the reattachment points owing to separated flow from the ribs. Recirculation zones between the ribs reduced the local Nusselt number so ribs underwhelmed [6]. Korichi and Oufer (2007) have numerically examined heat transfer in rectangular channel including heated obstacles on the internal walls. Two-dimensional and transient analyses for air have been conducted at $Re = 50, 500$ and 1000 corresponding the values of laminar flow regime. As a result, flow characteristics and Nusselt numbers have been determined [7]. Oztog et al. (2009) have considered three blocks with constant surface temperature inside the horizontal channel for the control of fluid flow and heat transfer. In the numerical study, a triangular bar has been

evaluated at two different positions and compared to the case without the bar. As a conclusion, heat transfer has been enhanced by using the bar and the optimum position for the bar has been recommended [8]. Silin et al. (2012) have used the parallel-plate channel with uniformly cooled in the experimental system in which water flowing inside it. The effects of inlet temperature and wall heat flux on the study have been taken into account in the range of $5000 \leq Re \leq 10000$ [9]. Altac and Ugurlubilek (2016) have simulated the unsteady natural convection heat transfer of two- and three-dimensional rectangular enclosures with different slenderness ratios. Various turbulence models have been utilized and compared about aforementioned cases in the range of $10^8 \leq Ra \leq 10^{13}$. As a result of the study, Nusselt numbers have been attained in that range of Rayleigh numbers [10]. Ayli et al. (2016) have studied on steady forced convection regimes of square cross-sectional channel in the range of $1.7 \times 10^8 \leq Re \leq 2.47 \times 10^8$. Rectangular fins have been mounted on the bottom wall and various aspect ratios have been tested both experimentally and numerically and the results have been given as empirical correlation for Nusselt number [11].

In the present study, turbulent flow and heat transfer characteristics have been determined in the existence of obstacles placed between the two-dimensional parallel plates. Symmetrical obstacles have been periodically mounted on the internal walls of the parallel plates. Here, comparison of finned and unfinned horizontal parallel plates has been done in terms of turbulent convective heat transfer at $Re = 6000$.

II. MATERIAL AND METHOD

Transient convection heat transfer with turbulent flow between horizontally placed two parallel plates has been numerically examined by using standard k- ω turbulence model at $Re = 6000$. Reynolds number has been given as $Re = (U_\infty D_H)/\nu$, based on the hydraulic diameter which is $D_H = 2H$. H is the distance between the plates, ν is the kinematic viscosity and U_∞ is the free-stream velocity value.

Fig. 27. Schematic of the horizontal parallel plates.

Fig. 1 shows the two-dimensional system with finned plates including all boundary conditions used in the numerical study. Unfinned plates have been considered without the fins on the inside walls. The length of the plate, L , is taken as 1 m and its thickness is taken as zero. The distance between the plates is

expressed as $H = 0.02\text{ m}$. Parallel plates are assumed to be at constant wall temperature of $T_{top} = T_{bottom} = 400\text{ K}$ while water at $T_{water} = 300\text{ K}$ enters to the system with $U_\infty = 0.15\text{ m/s}$. The height of the fin is given by $h = 0.005\text{ m}$ which is equal to its width as $w = 0.0025\text{ m}$. Fin spacing is defined as $S = 0.02\text{ m}$. Moreover, uniform wall temperature of $T = 400\text{ K}$ for the fins has been taken into consideration in case of the finned plates.

Mesh independence analysis has been done for various mesh sizes with respect to dimensionless number which is Nusselt number calculated as $Nu = (h D_H)/k$. At $Re = 6000$, five different numbers of elements have been tested. One of them done via standard k- ω turbulence model has been given as an example in Table 1.

TABLE XV. MESH INDEPENDENCE ANALYSIS AT $Re = 6000$

Number of elements	Mean Nusselt number (Nu)
189885	55.98
322567	54.99
581342	54.86
898803	53.88
1070791	54.12

Nusselt numbers change with the grid sizes. Grid system has been determined with respect to Nusselt number which is given in (1) and (2) as in the empirical correlation expressed by Shah and Bhatti (1987) [12]:

$$Nu_\infty = \frac{(f_m/2)(Re - 1000)Pr}{1 + 12.7(f_m/2)^{1/2}(Pr^{2/3} - 1)} \quad (1)$$

$$f_m = A + \frac{B}{Re^{1/m}} \quad (2)$$

Here, $A = 1.28 \times 10^{-3}$, $B = 0.1143$ and $m = 3.2154$ are the values in (2) which is valid in the range of $4000 \leq Re \leq 10^7$. Prandtl number has been obtained as $Pr = 5.83$ for water [13]. Empirical correlation of Nusselt number has been calculated in respect to empirical correlation in (1) correspondingly applicable for $2300 \leq Re \leq 5 \times 10^6$ and $Pr > 0.5$, respectively. The value for Nusselt number has been evaluated as $Nu_\infty = 44.84$ by using the correlation in (1). For lower grid sizes of flow domain, Nu values are higher and then decrease with increasing numbers of elements. However, the percentage difference is about 0.02% when the number of grid elements ascends from 898803 to 1070791 . Therefore, numerical analyses have been conducted for 898803 grid elements used in the flow domain owing to fewer requirements of computer capacity and computational time.

The governing equations for an incompressible flow form of the continuity equation and the Reynolds-Averaged Navier-Stokes are specified below in the following equations in (3) and (4) [14].

$$\frac{\partial \bar{u}_i}{\partial x_i} = 0 \quad (3)$$

$$\frac{\partial \bar{u}_i}{\partial t} + \frac{\partial \bar{u}_i \bar{u}_j}{\partial x_j} = \frac{1}{\rho} \frac{\partial \bar{p}}{\partial x_i} - \frac{\partial \tau_{ij}}{\partial x_j} + \nu \frac{\partial^2 \bar{u}_i}{\partial x_i \partial x_j} \quad (4)$$

where u_i and u_j are the filtered velocity components along the Cartesian coordinates of x_i and x_j , p is the pressure, ρ is the fluid density and ν is the kinematic viscosity of the fluid [14].

The standard $k-\omega$ model is an empirical model based on model transport equations for the turbulence kinetic energy, k , and the specific dissipation rate, ω , which can also be thought as the ratio of k . As the $k-\omega$ model has been modified over the years, production terms have been added to both the k and ω equations, which have improved the accuracy of the model for predicting free shear flows [14].

$$\frac{\partial}{\partial t}(\rho k) + \frac{\partial}{\partial x_j}(\rho k u_j) = \frac{\partial}{\partial x_j} \left[\left(\mu + \frac{\mu_t}{\sigma_k} \right) \frac{\partial k}{\partial x_j} \right] + G_k - Y_k + S_k \quad (5)$$

$$\frac{\partial}{\partial t}(\rho \omega) + \frac{\partial}{\partial x_j}(\rho \omega u_j) = \frac{\partial}{\partial x_j} \left[\left(\mu + \frac{\mu_t}{\sigma_\omega} \right) \frac{\partial \omega}{\partial x_j} \right] + G_\omega - Y_\omega + S_\omega \quad (6)$$

In these equations (5) and (6), G_k represents the generation of turbulence kinetic energy due to mean velocity gradients. G_ω represents the generation of ω . Γ_k and Γ_ω represent the effective diffusivity of k and ω , respectively. Y_k and Y_ω represent the dissipation of k and ω due to turbulence. All of the above terms are calculated as described below. S_k and S_ω are user-defined source terms [14].

Energy equation is expressed as given in (7) as follows [14]:

$$\frac{\partial}{\partial t}(\rho E) + \nabla \cdot (\bar{\mathbf{v}}(\rho E + p)) = \nabla \cdot \left(k_{eff} \nabla T - \sum_j h_j \bar{\mathbf{J}}_j + \left(\bar{\boldsymbol{\tau}}_{eff} \cdot \bar{\mathbf{v}} \right) \right) + S_h \quad (7)$$

where k_{eff} is the effective conductivity ($k + k_t$, where k_t is the turbulent thermal conductivity, defined according to the turbulence model being used), and $\bar{\mathbf{J}}_j$ is the diffusion flux of species. Energy transfer, E , is due to conduction, species diffusion, and viscous dissipation, respectively. S_h includes the heat of chemical reaction, and any other volumetric heat sources defined.

III. RESULTS AND DISCUSSION

Heat transfer between horizontal parallel plates for turbulent flow has been investigated by using standard $k-\omega$ turbulence model. The results of unfinned plates have also been given for comparison. Fig. 2 indicates the time-averaged results of streamwise velocity components $\langle u \rangle$, cross-stream velocity components $\langle v \rangle$, distributions of temperature $\langle T \rangle$ and pressure $\langle P \rangle$ at the inlet and outlet regions of unfinned and finned plates at $Re = 6000$. Moreover, the aforementioned characteristics have been given in Fig. 3 for the finned region to compare with unfinned one. The dimensions of all images have been normalized with the height between the plates as $L' = L/H$ and $H' = H/H$. The maximum and minimum values are indicated as a legend bar for the contours in each figure and divided with 15 levels.

Time-averaged streamwise velocity components have been given in the range of $-0.01 \text{ m/s} \leq \langle u \rangle \leq 0.15 \text{ m/s}$ for the inlet and the outlet regions of the unfinned and the finned plates in Fig. 2. At the inlet of parallel plates for both the finned and unfinned channel flow, the velocity values are almost identical and the value of inlet velocity is more common.

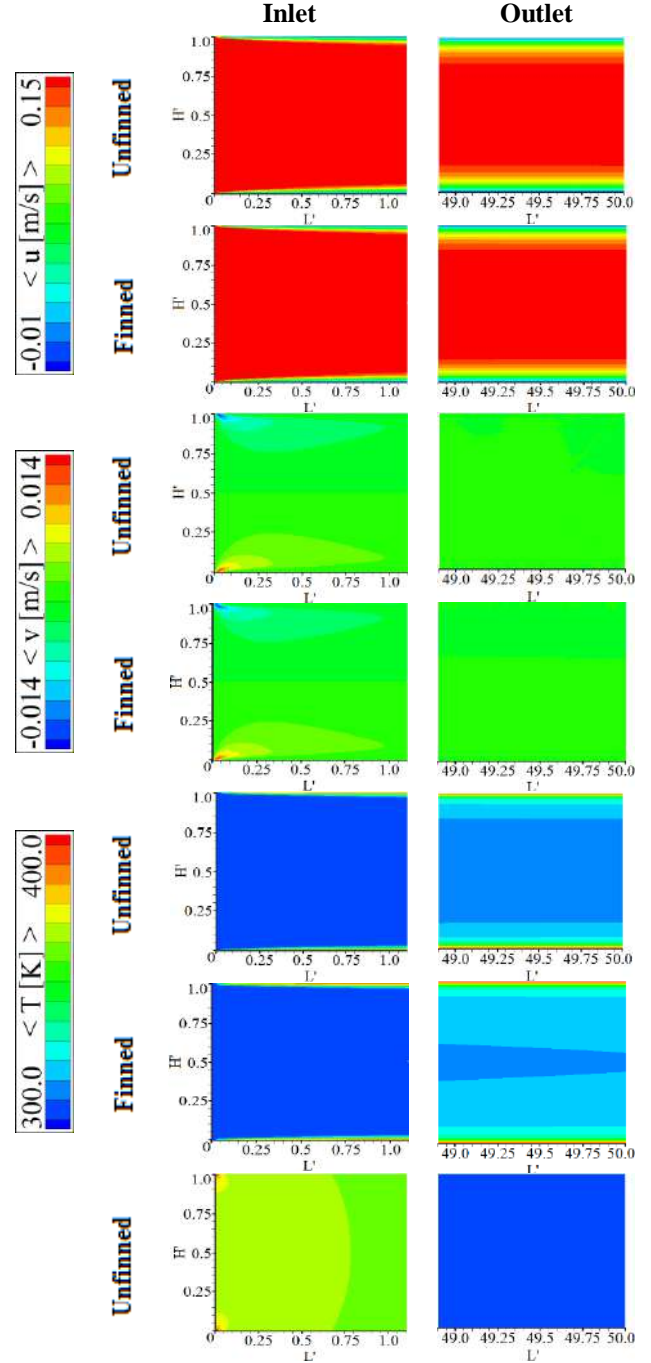

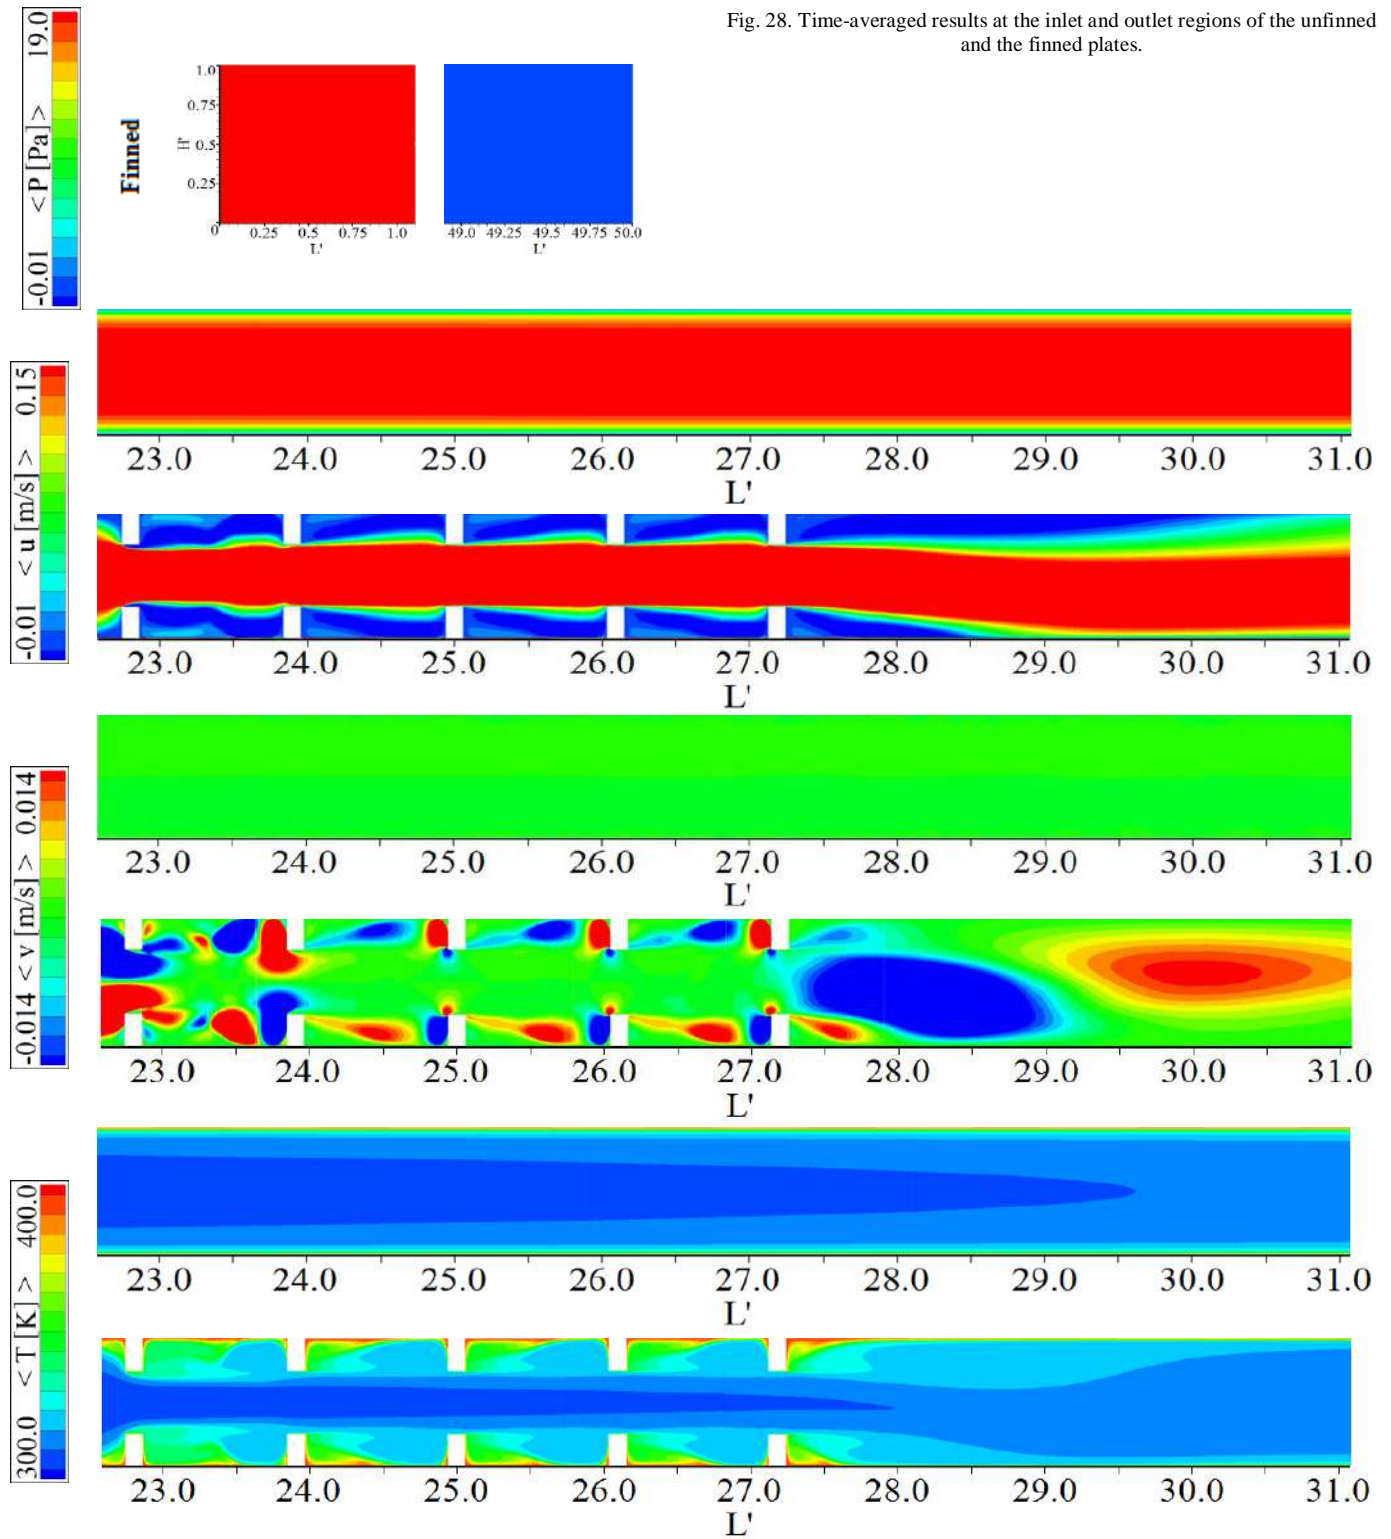

Fig. 28. Time-averaged results at the inlet and outlet regions of the unfinned and the finned plates.

Fig. 29. Comparison of the unfinned and the finned regions in terms of time-averaged results.

The formation of hydrodynamic boundary layer can be seen from the starting point of the plates for both channel types. At the right hand side of the time-averaged streamwise velocity figures, the velocity profile at the exit of the channel is given. It can be seen from the figure that, the distance after the last fin for the finned channel is sufficient for the development of the velocity profile since the hydrodynamic boundary layer of the finned channel gets the same value of unfinned plates. Moreover, streamwise velocity components at the outlet of the parallel plates indicated same characteristics since flow recovery completed long before the outlet region for both unfinned and finned plates. The unfinned and the finned plates have also been investigated for time-averaged cross-stream velocity components for $-0.014 \text{ m/s} \leq \langle v \rangle \leq 0.014 \text{ m/s}$. After the first contact between the fluid and the plates, the symmetrical clusters of cross-stream velocity components have been observed at the inlet. While positive values of cross-stream velocity components are on the bottom side, negative ones are seen on the opposite side. The symmetrical clusters are only effective in the beginning section as $0 \leq L' \leq 1.0$ for both cases. Temperature distributions are shown with $300.0 \text{ K} \leq \langle T \rangle \leq 400.0 \text{ K}$ in terms of the inlet and the outlet regions of the unfinned and the finned plates. At the inlet, the temperature of the fluid is more efficient and its effect lost through the plates as a result of convection heat transfer. At the exit region of the finned plates, the temperature of the fluid is significantly higher than the unfinned ones because of the enhancement effect on heat transfer via the fins. The fins cause the increment of heat transfer surface area between the wall and the fluid; also the fins cause distortion of flow patterns. Secondary flows caused by flow separation increase the temperature of fluid at the exit of the plates. Pressure distributions have been ranged as $-0.01 \text{ Pa} \leq \langle P \rangle \leq 19.0 \text{ Pa}$. For the unfinned plates, mean pressure value is seen at the inlet while maximum pressure value is observed in case of the finned ones with respect to the legend. However, pressure distributions are nearly same for the outlet region. The pressure drop is higher for the finned plates according to the whole pressure loss.

Time-averaged results have been compared for the investigation of the finned region in Fig. 3. At the top of first figure, the streamwise velocity contours $\langle u \rangle$ are given for both the finned and the unfinned plates. As can be seen from the figure, the flow is separated from the first fin at the top and the

bottom surfaces symmetrically and the mean flow is increased owing to the decreasing cross-sectional area. Two circulation zones are occurred between the first and the second fins but only one circulation zone can be seen between the other fins. And also symmetrical circulation zones can be observed at the top side of the plate. The main difference that distorts the symmetry can be seen at the bottom layer after the last fin as the flow reattachment. At the second figure, the cross-stream velocity values $\langle v \rangle$ can be seen. This figure also shows a symmetrical contour of velocity according to the duct axis. The effect of first fin on the fluid flow is much more as can be seen from this figure. After passing through the first fin, the flow recovers at the downstream fins. After the last fin, the flow reattachment region can also be seen with in accordance with the first figure. In the third figure, the temperature distribution is shown. From the whole of the figure, the mean temperature is considerably higher than the unfinned plate for the investigated region. The increment of the heat transfer surface area and secondary flows due to the flow distortion causes the increment of the fluid temperature. Again a symmetric figure is occurred according to the duct axis until the reattachment region after the last fin. In according to the first and the second velocity figures, there is circulation behind the fins; which is coherent with the temperature distribution. The temperature contours between the fins show that the fresh-fluid can enter the cavities much more after the second fin. The point of the flow reattachment after the last fin is coherent with velocity figures. At the exit of temperature profile, the figure gets the values of the unfinned duct since the length after the last fin is adequate for the redevelopment of the thermal boundary layer. The last image of Fig. 3 is related with the pressure distributions along the plate. The difference between the unfinned and the finned plates is significant. As can be seen from the figure, pressure drops suddenly after the first fins and keep its trend until the outlet. In the design of heat transfer equipment, two points should be examined more deeply. First one is the increment of the heat transfer while the second one is the pressure drop.

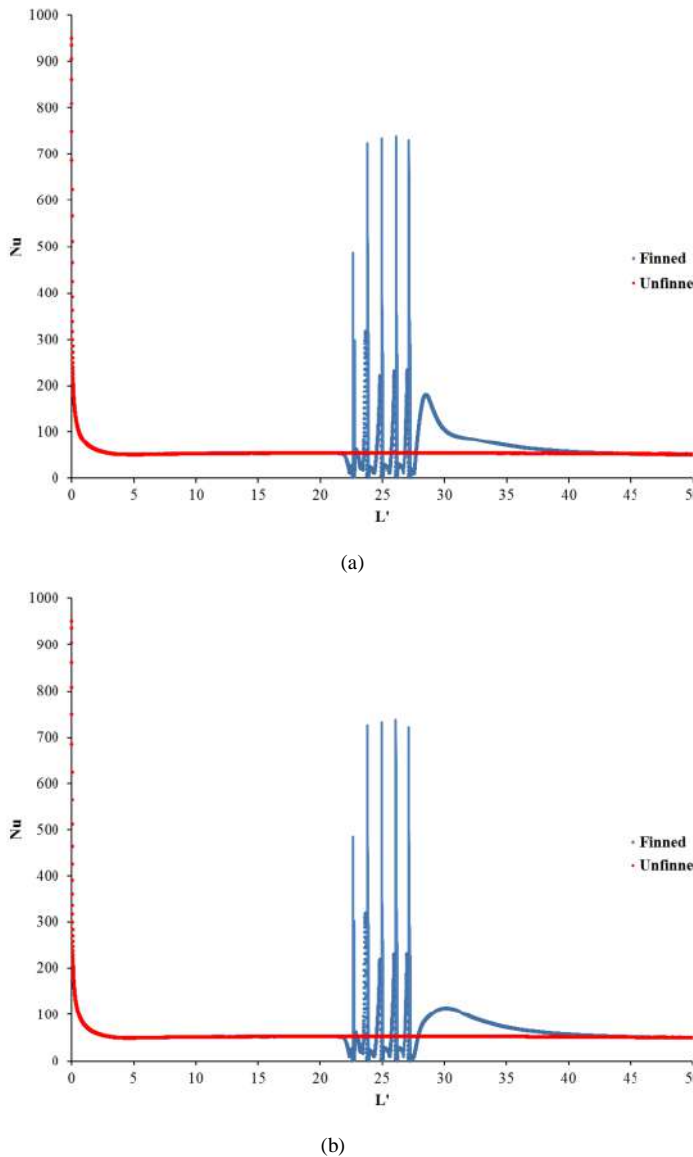

Fig. 30. Comparison of local Nusselt numbers for (a) the bottom plate and (b) the top plate of the unfinned and the finned plates

Fig. 4 indicates the distribution of the local Nusselt numbers at the bottom and the top plates compared with the unfinned ones. As can be seen from both figures, Nusselt numbers values are greater at the second fin compared to the first one on both sides and gradually increase through the fourth one. The value of local Nusselt number is higher after the fifth fin at the bottom plate than the top plate. This result is parallel to the results of Fig. 3. The red line given in Fig. 4 is the local Nusselt number values of the unfinned plates. Nusselt number values are significantly higher than the unfinned plates. After the fifth fin, the flow redevelops and gets the values of the unfinned plates. The local Nusselt number value gets its maximum value at the flow reattachment region for both bottom and top plates. The reattachment point is at about $L' = 28.0$ for the bottom plate and $L' = 30.0$ for the top plate and flow recovery regions are

proportional to these values at both plates. The Nusselt number values gradually decrease before the first fin and get the maximum value at the top of the fin. In the cavities, Nusselt number decreases to the minimum value and increases through the next fin. Nusselt number values draw similar curves after the second one. The circulation in the cavities causes in accordance with the results of Fig. 3.

IV. CONCLUSIONS

The heat transfer and the fluid flow between the horizontal parallel plates for turbulent flow has been investigated by using standard $k-\omega$ turbulence model in terms of the unfinned and the finned plates. The results obtained from the solutions can be outlined as follows:

- 1) The fins placed between the parallel plates affect the heat transfer and fluid flow characteristics significantly when compared to the unfinned plates.
- 2) The fins cause the increment of the velocity and also secondary flow between them.
- 3) The mean temperature of the flow increases significantly compared to the unfinned plates.
- 4) The pressure loss due to the fins has to be considered in the design of heat transfer equipment.
- 5) The turbulent model which is chosen for this problem is adequate to solve this kind of problem.
- 6) The heat transfer values are affected by using fins.

The Effects of the Ratio of Tool Rotational Speed to The Welding Speed on the Welding Performance for Dissimilar Aluminum Alloys

Şefika KASMAN

Department of Mechanical Engineering

Dokuz Eylül University

Izmir, Turkey

sefika.kasman@deu.edu.tr

Abstract— This study investigates the weldability of EN AW 5083 and EN AW 2024 by friction stir welding. The EN AW 5083 is used in transport applications, including marine and automotive. It is well known that the welding of EN AW 5083 aluminum alloy by the fusion welding techniques is good, but, includes many defects and cause to the loss of some elements. Due to these problems, the strength of the joints decreases when compared to the base material. The other material EN AW 2024 is difficult to weld by the fusion welding technique and mostly used in many aerospace structural applications. Dissimilar welding of EN AW 5083 and EN AW 2024 alloys is difficult by fusion welding techniques. In order to obtain defect free joint weld, the joining of the mentioned materials was performed by friction stir welding which is one of the solid state welding techniques. The ratio of the tool rotational speed to the welding speed was associated with the tool pin shape. All of weld experiments were exposed to the mechanical and microstructural investigations. The results showed that the ratio of the tool rotational speed to the welding speed has an impact on the strength of the weld joint. The tool rotational speed also has an impact on the joint strength irrespective of welding speed. A decrease in tool rotational speed resulted in increased strength of the weld joint.

Keywords—Friction stir welding, tensile properties, dissimilar welding

I. INTRODUCTION

Dissimilar welding of EN AW 5083 and EN AW 2024 alloys is difficult by fusion welding techniques due to the difficulty of the selection of the appropriate filler material and process parameters considering the metals to be welded. In some cases, the solid state welding techniques are considered to be the best alternative. The friction stir welding (FSW) is one of the solid state welding techniques and takes below the melting temperature of subjected material. The FS welding is performed by a tool which consisting of a shoulder and shaped pin. The rotational tool pin and by the effect of heat generated from friction between tool and materials plasticizes materials and with the advance movement of the tool, the

materials on butted surface of the plates are mixed and the joining is finished [1]. The literature related to the dissimilar FS welding of EN AW 5083 and EN AW 2024 alloys is limited. Sundaram et al. [2] have studied weldability of AA2024-T6 and AA5083-H321 by dissimilar friction stir welding. They used five different pin profiles, tool rotational speeds, welding speed and axial forces to determine appropriate welding condition. From the statistical analyze results; they reached a FS welding condition with higher tensile strength and elongation. Apart these, some of researcher studied on AA2XXX and AA5XXX alloys. The Mastanaiah et al. [3] have investigated dissimilar friction stir welds of aluminum alloys AA5083 and AA2219 to attain defect free joints by selecting process parameters. The statistical methods, analysis of variance and response surface methodology were used. Dilip et al. [4] have carried out the dissimilar FSW application to the AA2219 and AA5083. As the process response, weld microstructures, hardness and tensile properties were investigated. Koilraj et al. [5] have performed statistical analyses for dissimilar FSW of AA5083 and AA2219 to predict optimal process parameters (tool rotational speed, welding speed, pin profile and, ratio between tool shoulder diameter and pin diameter. From the literature reviews, it is reached an important knowledge, the pin shape; tool rotational speed and partly welding speed are the most critical factors on the joint performance.

Friction stir welding (FSW) is one of the solid state welding techniques [6] and uses a cylindrical tool consisting of a shoulder and a shaped pin [7]. Both of tool shoulder and pin is responsible from the stirring action and generating heat. The heat for welding is generated from the friction between tool and materials to be welded [7]. Apart this, the tool rotational speed and welding speed determines the heat input per unit area. Higher rotational speed or lower welding speed generates higher heat. Therefore, the tool rotational, welding speed and tool properties are the main factor to achieve defect

free or sound weld joint. A weld joint produced by FSW technique is consisting of three zones for each side of the tool pin. These are nugget zone or stirring zone (NZ), thermo-mechanically affected zone (TMAZ) and heat affected zone (HAZ), respectively. The NZ is highly affected both stirring actions of tool shoulder and pin. By the effect of heat input and stirring action of a pin, the materials to be welded are plastically deformed and then are exposed to dynamically recrystallization, subsequently. Resulting of dynamically recrystallization, the grains at the nugget zone become smaller and equiaxed compared with the other zones [8]. The NZ is affected from the tool rotational speed, welding speed and pin shape. The other zone is TMAZ and this zone is affected by heat and deformation. The difference from the NZ is that the heat is not big enough to complete recrystallization mechanism. The HAZ is affected by heat and the plastic deformation is not issue.

In this study, the main aim is to investigate the effect of the ratio of tool rotational speed to the welding speed (v ratio) on the microstructural alteration and tensile properties. Two different aluminum alloys EN AW 5083 and EN AW 2024 were used and welds were performed according to an experimental layout consisting of two tool pin shapes and v ratios. The relation between the plates material and process conditions were also analyzed.

II. MATERIALS AND METHODS

The materials used for the welding experiments were EN AW 5083-H111 and EN AW 2024-T351 and their chemical compositions and mechanical properties were given in Table 1 and Table 2. For the welding, the EN AW 2024-T351 was placed at the advancing side and the EN AW 5083-H111 was placed at the retracting side of pin. Two types of tools were used for welding applications. The helically threaded pins which were in straight and tapered form are one of the parameters. The tools used in the FSW welding were shown in Fig. 1. The other parameters were tool rotational speed and welding speed. The welding process parameters and their values were listed in Table 3. According to the experimental layout, six different experiments shown in Table 3 were performed. The tool tilt angle was fixed at 2° to the normal of the plate and the tool rotation direction was fixed at the clockwise. A sample for welding experiments was shown in Fig. 2.

III. RESULTS AND DISCUSSION

The main question of this study is the ratio of tool rotational speed to the welding speed (v ratio) has how much effect on the mechanical properties and microstructural alterations. For this purpose, a small experimental group (layout) was conducted and the FS welding experiments were performed according to this layout. Each welding was characterized by the tensile test results and microstructure. The results were evaluated and discussed as below.

A. Mechanical Properties

The mechanical properties were investigated by the ultimate tensile strength (UTS) and percentage of elongation

(ϵ). The results were taken from the tensile tests and listed in Table 4. According to the results for CH shaped pin profile, both of UTS and ϵ increased with the increase of v ratio. The changing in UTS and ϵ is 20% and 68%, respectively. As for the SH shaped pin profile, similar trend shown in the CH shaped pin profile was observed. The changing in between both UTS and ϵ is 14% and 60%, respectively. As clearly seen from the results, the effect of the CH shaped pin profile on tensile properties is higher those of SH shaped pin profile. The literature review showed that the increase in v ratio causes to increase in heat input per unit area. This means that the dynamically recrystallization process after deformation of materials at the nugget zone is realized by the effect of increased heat input. The selection of appropriate pin profile, tool rotational and welding speed is the critical issues because of its effects on the tensile properties. Any defect causes a decrease in ultimate tensile strength and elongation. For the present study, all the FSW joints as shown in Fig. 3 consist defects and therefore, the UTS and ϵ was decreased. The weld joint efficiencies were determined by comparing of UTS for each joint and base material. The results were given in Table 4. As clearly seen that the weld joint efficiency for Exp. 2, Exp. 5 and Exp. 6 is higher compared with the others considering the UTS of EN AW 5083. However, the results compared with the EN AW 2024, the efficiency changes in between 58% to 72%. The reason is the UTS value of base material (EN AW 2024).

In order to compare the v ratios shown in Table 4, an experiment for each tool pin profile was done. In this experiment, the v ratio was kept at 5 by the combination at the TRS of 630 rpm and WS of 125 mm/min. The most important conclusion is that, even if the v ratio is kept at a constant value; the influential mechanism on the UTS and ϵ is the tool rotational speed.

TABLE IV. FSW EXPERIMENTAL LAYOUT (L_9 ORTHOGONAL ARRAY) WITH PERFORMANCE CHARACTERISTICS (UTS, ϵ %)

Fig. 3. The cross-section of each joint

B. Microstructural investigations

The macrostructural investigations were done on the entire cross-section of weld joint in order to detect defects and the nugget zone profile. The investigations were presented with the welding condition in the Fig. 3. The most common and existing defects for the weld joints fabricated with FSW are tunnel, voids, cavity, pinhole and wormhole. As mentioned before that the FSW process is performed at the solid phase, therefore the joints do not comprise any defects occurred during the solidification of the materials. The defects shown in fusion welding of dissimilar materials are the mismatch between filler material and welding materials, solidification behavior of materials. As for FSW, the tunnel, void and cavity like defects occurs by the effect of insufficient heat input and lack of material flow. The reason formation of pin hole and wormhole defects is the amount of heat input. The common reason of the defects shown in the FS welded joints is the generated heat. High and low heat input lead to the formation of defects. The generated heat during the FSW process is given in the Eq. 1 [9,10]. Inferences can be made from this equation is that, provided that the tool features keep at constant, the heat input is affected from both tool rotational speed and welding speed. As it can be seen from the Eq. (1), the tool rotational speed and the welding speed are the main factors for determining heat input per unit area. The heat input decreases with increasing in tool movement speed or welding speed.

$$Q = \frac{\alpha \cdot q}{W} = \frac{4}{3} \pi^2 \frac{\alpha \mu P \cdot TRS \cdot R^3}{WS} = \beta \cdot \frac{TRS}{WS} \quad (1)$$

where Q is the heat input per unit length, α is the heat input efficiency, and WS is the welding speed, TRS is the tool rotational speed. For a welding condition, α , μ , P , R and β are the constant values.

A weld joint fabricated by FSW consist of three distinct zones, nugget zone (NZ), thermo-mechanically affected zone (TMAZ) and heat affected zone (HAZ). Materials at the nugget zone are exposed to severe plastic deformation and higher heat input. These two dominant factors cause to recrystallization of materials and finally, the grain size in the NZ become small compared to the grain size in the TMAZ

and HAZ. For an example, a cross-section of weld joint comprising three zones is shown in Fig. 4. The figure is taken from the experiment 6. It is clearly detected that the grain size, the grain orientation and the shape of zones is different from each other. Besides, the grain sizes in a NZ vary depending on the heat input and heat dissipation. Fig. 5 shows the grain sizes in the nugget zones. The intensity of material flow and pin stirring at the tip of pin is higher those of the mid and top of the pin. By the effect of higher stirring and material flow causes decrease in the grain size at the weld joint root. A main point detected in the nugget zone is that the shape of nugget zone is highly affected by the tool rotational speed and welding speed. The tool rotational speed is responsible for the stirring action and the deformation of the grains. An increase in the tool rotational speed is caused to increase in heat input and deformation. It is known that for FS welding of dissimilar materials, the NZ comprises two different materials and the volume of these materials changes depending on the pin shape and the placement of materials. The illustrations in the Fig. 3 explain this approach. Studies performed at the low magnification showed that there are many small and big black lines on microstructure of the weld nugget zone. The mentioned lines can be clearly seen in Fig. 5. In order to detect and understand these lines, the microstructures of Exp. 3 and 5 at higher magnification were given in Fig. 6. The figures show that the small second phase particles are sorted in a zigzag line or small segment. These lines are the defect and called as the small segment [11]. According to the Khodir et al. [11] these defects affect the tensile properties of joints.

IV. CONCLUSION

The dissimilar welding of EN AW2024 and EN AW 5083 was performed by using friction stir welding by employing two different the ratio of tool rotational speed to the welding speed (v ratio) and pin shapes in order to determine the effect of both v ratio and pin shape on the tensile properties. The findings from the FSW experiments were presented as below:

- An increase in v ratio causes to increase in both ultimate tensile strength and percentage of elongation.
- At a constant v ratio (5), the ultimate tensile strength and percentage of elongation increased with increased in tool rotational speed irrespective of v ratio.
- Of the two tool pin shapes used in FSW experiments, conical threaded pin produced higher strength weld joints compared to the other pin shape.

- Of the six weld joints, the weld joint fabricated with the 1000 rpm and 100 mm/min has the highest strength, the measured value is 348.01 MPa.
- All the joins contain many clustered cavity defects.

Abstract— In this study, the friction stir welding were performed to investigate the effect of the constant ratio of welding speed to tool rotation speed ratio (WS/TRS) on the weld joint microstructure, hardness and ultimate tensile strength of AA7075 aluminum alloy plates. The welding experiments were carried out using two type pin shape which one is threaded and the other is pentagonal. The joints fabricated by threaded pin were sound and exhibited higher ultimate tensile strength (within the range of 69% - 72%) compared with the base metal. Relatively higher ultimate tensile strengths (UTS) were obtained at the 63/630 ratio for both pin shape and among four weld conditions, the highest strength was obtained at the 63/630 ratio with the pentagonal shaped pin. It is thought that the reason of increase in the strength is the increase in heat input owing to the larger frictional area and excessive deformed grains at the larger area. Shear fracture was investigated for all weld joints and showed that it is located outside the weld area. The fracture surface of the weld joints is almost similar to the base material and characterized by almost uniform small dimples.

Keywords— pin shape, friction stir welding, aluminum alloy

I. INTRODUCTION

Aluminum alloy is the most important material for many industries where weight, thermal and electrical conductivity, resistance to corrosion and energy saving are critical issues. In particular, the automotive, air craft and shipbuilding industries, along with the construction of storage tanks use aluminum alloys in sheet form to produce body parts. The welding is the main process for these industries, and it requires specialized techniques. Depending on the aluminum grade, for some cases and processes, aluminum is either easy or difficult to weld. As is known, the conventional fusion welding (CFW) processes, which is tungsten inert gas (TIG), metal inert gas (MIG) and plasma keyhole arc welding, are performed with inert gas shielding, use filler metal, and require care and skill. Under certain improper conditions, the CFW operation causes many defects in the fusion zone, such

as cracks, porosities, voids and segregations [1-3]. However, solid phase welding techniques are completely different processes, in which, the use of above mentioned instruments for carrying out the welding are not the case [2,3].

Friction stir welding (FSW) is one of the solid – state welding techniques, and it occurs without any melting. The method uses a cylindrical tool which is composed of a shoulder and a geometrically shaped pin. During the FSW operation, three important case occurs; first case is the rotating tool is plunged into the abutted plates, second case is generation of frictional heat is generated and third case is to transfer of generated heat towards to the weld line [4,5]. The most important feature of FSW when compared to CFWs[1] is the metallurgical advantages: very small distortion due to relatively lower heat, finer grain structure and a narrow heat affected zone. Apart from this, the above mentioned defects and the mismatch of filler metal in dissimilar metal welding are not the case in FSW process. A joint fabricated with FSW is divided into three distinct zones; the nugget zone (NZ), the thermo-mechanically affected zone (TMAZ), and the heat affected zone (HAZ) [6]. AA 7XXX series aluminum alloys are mostly used in the automotive and aircraft industries and the alloys in this series are composed from Al-Zn-Mg-Cu which are characterized by its high strength[7-9] and heat treatable and provide good stress-corrosion cracking resistances in sheet products. Despite these advantageous, it is difficult to join this alloy using CFW techniques [9] due to poor solidification microstructure, porosity and the dendritic structure formed in the fusion zone[10-12]. FSW, being a solid phase process, the loss of strength is not the case. Considering this aspect, the FSW technique is the best candidate for joining of difficult to weld alloys.

In many studies related to the joining of AA7075 sheets using the FSW technique, the investigations has concentrated on the effect of pin shape and welding parameters on the mechanical and microstructural properties. In the present study, two types of pin shape (threaded and pentagonal) and a constant welding speed to tool rotational speed (WS/TRS)

ratio (0.1) are associated with the mechanical and microstructural properties. Therefore, the effects of relatively lower or higher tool rotation and lower or higher welding speed on the mechanical and microstructural properties of the joints are investigated.

II. EXPERIMENTAL STUDIES

The FSW butt welds were made on 5mm thick, 100mm wide and 150mm long rolled aluminum alloy grade 7075. The chemical and mechanical properties of AA 7075 are given in Table 1. In order to provide a good overlap between the abutted surfaces, the plate edges were machined. Before welding, each plate was placed on a backing plate and clamped with studs and bolts, as seen in Fig. 1. Welding was performed on the rolled direction of the plates using two different pin, shaped threaded and pentagonal. The nominal diameter of the tool shoulder was 18mm, and the pin lengths were 4.90mm. The tool and pin profiles are shown in Fig. 2, and Table 2 also shows the tool configurations used in the experimental studies. Additionally, all of the FSW experiments were performed at 2° of tilt angle between the tool and the plates. As shown in Table 3, three parameters; pin shape, tool rotational speed (TRS) and welding speed (WS) at different values were selected to perform the welding of AA7075 plates.

The strength of each joint was analyzed with a tensile test. Therefore, tensile samples were cut from the transverse cross section of the weld joint. The dimensions of the tensile samples were taken using the ASTM E8M. The tests were performed at room temperature and at a 2mm/min crosshead speed in a hydraulic tensile machine. For each condition, at least three tests were done, and the average of these was used for the final result for both ultimate tensile strength (UTS) and percentage of elongation (PE). Results of the tests were compared with the base material. The fractured surfaces were characterized using scanning electron microscopy (SEM). The precipitated phase in the fusion zone was determined through energy dispersive spectrometer (EDS) analyses.

The microstructural analyses of joints were performed with the aim of observing the microstructural change as a function of the selected process conditions. With this approach, each cross-sectioned joint was ground and polished. Following these processes, the surfaces were etched with Keller's reagent. A Vicker's microhardness test was employed to determine the hardness distribution on the cross-section of each joint line. The measurements were started at the centerline of the joint and continued throughout the base materials to each side with a spacing of 1mm and applied with a load of 100gr for 10 seconds. In total, fourteen measurements were performed on each side of the joint.

III. RESULTS AND DISCUSSION

The preliminary studies indicated that the pin shape, tool rotational speed and welding speed are the most influential

parameters on the mechanical properties and microstructures of the weld joints fabricated with friction stir

A. Macrostructure of Welded Joints

The macrostructure of weld joints, consisting of three distinct zones, HAZ, TMAZ and NZ of each side, is shown in Fig. 3. From the cross-section view of the weld joints, it can clearly be detected that the joints display different images. While the joints in Fig. 3a and 3b are fabricated with the threaded pin, the joints in Fig. 3c and 3d are fabricated with the pentagonal pin. As can be seen in the weld joints, for a constant $WS/TRS(0.1)$ ratio that is obtained at the 40/400 and 63/630, the major conclusion that can be drawn from the macrostructures in Fig. 3a - d is that there is no major changes in macrostructural form with the using of constant WS/TRS ratio. If you need to compare, the NZ form and sizes, and the width of the TMAZ are quite different from each other. When considered in this context, it can be drawn following conclusion from the macro-structure of the weld joints: for the 63/630 of WS/TRS of each group (b and d), the width of the TMAZ is larger than that fabricated by 40/400 of WS/TRS (a and c). Moreover, the weld joints fabricated by the pentagonal pin exhibit a larger NZ size and TMAZ size than those using the threaded pin. Additionally, the shape of the NZ is closer to a basin shape. As is known, the rotation of the tool between two adjacent plates creates turbulence, and the grains around the turbulence are thrown away from the tool. The intensity of this turbulence is determined by the tool rotational speed; the higher the rotational speed, the more intense the turbulence becomes [13]. For the present experimental conditions, *Exp. b* and *d* fabricated at the highest tool rotational speed, and a careful examination of the related macrostructure in Fig.3 shows that the effect of the vortex around the NZ covers a larger area than other conditions (*Exp. a* and *c*). In addition, it can be concluded from the macrostructure that the turbulence intensity is higher in weld joints fabricated by the threaded pin than fabricated by the pentagonal pin. It is considered that there is a relationship between the TMAZ width and turbulence intensity. The shape of the NZ and the width of area in that the grain distributed creates difference in both UTS and PE. Additionally, the generated frictional heat that occurs at interface between tool and plates is the effective factor on the wideness of NZ and TMAZ. It can be drawn second conclusion is that the pentagonal pin is generate more frictional heat per unit joint length than threaded pin due to larger frictional surface. This result overlaps with the NZ profile shown in Fig 3a-c and Fig 3 - d. The common effect of the larger frictional surface and the higher tool rotational speed generates higher heat and causes more deformed grains at the TMAZ due to softened material.

The typical grain structure of base metal is shown in Fig. 4. This grain structure was changed to fine and equiaxed grain structures at the NZ. The reason of this changing is high temperature generated by frictional heat and severe plastic deformation fabricated by tool rotation and movement. These

two factors causes to occurring of dynamic recrystallization and responsible for the grain size. Figure 5 shows microstructures and grain structure of weld nugget zone in the joint fabricated by constant WS/TRS ratio. From the measuring of grain size on microstructure of NZ showed that the grain size at WS/TRS of 63/630 is lower than the WS/TRS of 40/400 for two type pin. The average grain size for NZ was reported at Table 4.

Figure 6 shows microstructures taken from three different region of a weld fabricated with the threaded pin at 63/630 of WS/TRS . The microstructure in Figs. 6a, 6b and 6c was taken from beneath of the shoulder, the middle of the nugget zone, and at the root of the weld joint, respectively. The coarse and elongated grains of base metal transformed into a relatively smaller grains at the beneath of the tool shoulder, middle and root of weld joint. The measurement results were showed that the average grain size at the root of all joint is smaller than compared with the other two regions. The average grain size on the beneath of the tool shoulder is larger than that the root of all joint apart from joint 63/630 of WS/TRS fabricated with the threaded pin. However, the difference is small enough to be neglected. Also, there is a transition area that occurred by the influence of stirring intensity and the amount of generated heat. On the other hand, the defects on the joints are investigated. Microstructural examinations in the Fig. 7 were showed that there are small tunnel like defects in the joint fabricated with pentagonal pin at the condition of 40/400 and 63/630 of WS/TRS . It is thought that the defects were occurred by the effect of higher turbulence, insufficient stirring of the plasticized material and generated fractional heat. The other joints are without defects and sound.

B. Tensile properties of joints

The results of tensile properties of the joints as a function of pin profile and constant *WS/TRS* ratio composed from different *WS* and *TRS* values for each weld joint were illustrated in Figures 8 and 9. The average UTS results show a noticeable difference for the constant *WS/TRS* ratio range from 40/400 to 63/630. It can be seen from Fig. 8 that the UTS value of each weld joints fabricated at 63/630 of *WS/TRS* ratio are higher than the weld joints fabricated at the 40/400 of *WS/TRS* ratio for two type pin. All results were compared with the base metal strength and showed that the tensile properties of each joint are lower than the base material [15]. The joint efficiency are calculated based on the UTS and reported at Table 4. It was found that the joint efficiency varies between 69% and 75%. The higher joint efficiency was achieved at the weld joint fabricated with the pentagonal pin at the 63/630 of *WS/TRS* ratio. From the results shown in Table 4 can be drawn an obvious conclusion is that the joint strength of 63/630 of *WS/TRS* ratio for each group of weld is closer to the base metal than joint strength of 40/400 of *WS/TRS*. It is considered that the higher UTS can be associated with the intensity of tool rotation and wider *TMAZ* and *NZ*. Furthermore, irrespective of *WS/TRS* ratio, the pentagonal pin generates higher temperature due to the wider frictional surface area. This helps to reduce the stress in the grains around the pin. Hence, the highest UTS are achieved at the joints fabricated with the 63/630 of *WS/TRS*. In all joints, the poor joint was achieved in the first condition of the threaded pin, and its UTS and PE values are 398MPa and 4.22%. Compared to the highest and lowest UTS among the four welding condition, there is a difference of almost 7.65%. However, the difference in the PE is very small and can be considered negligible (as in Fig. 9). The yield strengths (YS) also support this result. The highest YS (335MPa) are obtained for the joint fabricated with the second condition (63/630 of *WS/TRS*) of the pentagonal pin. From Figures 7-9, it can be seen that although the joint fabricated with pentagonal pin at the condition of 63/630 of *WS/TRS* has higher UTS value, it has small defects that cause to decrease in PE value. The similar result was also shown in the joint of 40/400 of *WS/TRS* fabricated with pentagonal pin. It can also be seen from Table 4, the variation in PE is very

small and so that, the joint fabricated with threaded pin at the weld condition of 63/630 of *WS/TRS* as optimal weld condition. This result was also supported by the micrographs.

TABLE IV. WELDING RESPONSES

Group no	Exp. no	Results			
		UTS (MPa)	PE (%)	Joint efficiency (%)	Average grain size (μm)
Group 1	a	398.18	4.22	69	4.55
	b	416	4.62	72	3.57
Group 2	c	405.16	4.45	70	3.68
	d	431.38	4.23	75	3.01

C. Hardness

Hardness measurements were performed on the cross-section of the weld joints and in the middle of the thickness. Results are illustrated in Figure 9. The hardness of AA 7075 – T651 alloy is 175 HV_{0.1}. The highest hardness at the NZ is 166HV_{0.1}, which was measured in the second condition (63/630 of *WS/TRS*) of the pentagonal pin. Minimum hardness was achieved at the HAZ on both sides of all joints and the hardness increases towards to the NZ. The tendency in hardness shows similarity for all joints. In a general approach, a difference can be seen at the hardness of between TMAZ and NZ, but it cannot be said that the tool pin shape and the constant *WS/TRS* creates significant changes in the hardness of the NZ. When the hardness of both the NZ and BM are compared, it can be seen that the hardness of the NZ is lower than the hardness of BM. According to Bahemmat et al. [8], the lower hardness at the NZ compared with the BM is attributed to precipitate dissolution and coarsening. The lowest hardness (103HV_{0.1}) is observed at the HAZ for each joint case. In the HAZ of precipitate hardened aluminum alloy like AA 7075, the hardness shows lowest value when compared the other region [14]. From the HAZ region, there is a steep climb in the hardness towards to the NZ. Comparing the hardness of the HAZ and TMAZ showed that the plastic deformation that is realized on the TMAZ causes the hardness to show an increase. It can be concluded that a considerable difference in the hardness of NZ is achieved irrespective of pin shape and *WS/TRS* ratio. This can be explained by the fact that there is a grain transformation on the NZ owing to the plastic deformation and dynamic recrystallization.

Fig. 8. Hardness distribution between the zones

C. Fracture Observations

The fracture locations are shown in Figs. 11 A and B. It can clearly be seen that all of the joints were fractured outside the weld area and, except for joint “c”, on the advancing side. Defect free joints and defective joint were fractured in the HAZ. Moreover, it is clear that all weld joints show the same shear fracture mode. Both the weld joints fabricated with the threaded pin fractured and the weld joints fabricated with the pentagonal pin fractured at a 45° shear mode. SEM micrographs of the fractured surfaces of the joints and base metal are shown in Fig. 12. The base metal is covered with small dimples which are almost smooth. However, the fractured surface of the weld joints has dimples of varying size. A conclusion that can be drawn from Fig 12 is that the fractured surface of the joints fabricated with the threaded pin has larger dimples and some small voids. It is thought that these voids were formed from the breaking up of second-phase particles inside the dimple. In order to determine the second-phase particles inside the dimple and on the weld area, EDS analyses were performed. Figure 13 shows the particles. Analyzing the particles in Fig. 13A, the results show that the particles are Mg, and Si – rich precipitation. These particles can be Mg₂Si precipitates mostly existing in AA 7075 [8]. The selected particles on the nugget zone are shown in Fig. 13B. The light grey particle referred to as 1 is a Si, Fe, Zn – rich precipitation, and the Cu, Mn and Cr also exist in small amounts when compared to other alloys. However, the dark grey or black particles are composed of a mainly Si, O – rich precipitation, and a small amount of Cu and Zn is also found.

Fig. 19 Fracture location (A) and fracture type (B)

Fig. 10. SEM micrographs of fractured surface for some welding conditions and base metal

percentage of elongation showed a higher value for the second condition in each group. The *WS/TRS* ratio, together with pin geometry, has an effect on the mechanical and microstructural properties. The fracture of each joint is located outside the weld area. A brittle fracture and a 45° shear fracture occurred in all of the joints. The width of the thermo-mechanically affected zone is significantly influenced by the pin geometry and welding parameters value. The highest width was obtained in joints fabricated at a 63/630 ratio and by pentagonal pin geometry. In this condition, the maximum strength (431.38MPa) was achieved. The maximum elongation (4.62%) was achieved at the 63/630 ratio and with a threaded pin geometry. The minimum microhardness values were obtained between the heat affected and nugget zone. The general trend showed that there is not remarkable difference between hardness values.

The values used for tool rotational speed and welding speed were selected based on previous studies. However, the effect of coupled pin geometry with *WS/TRS* ratio was not known. After mechanical and microstructural observations, sound weld and good mechanical properties were achieved. Therefore, this study exhibits original results.

Abstract—Friction stir welding is a new innovative solid state joining method which is a widely used for aluminium alloys that are hard to weld by traditional welding techniques. Friction stir welding is successfully used for aeroplanes, trains, lightweight transport structures and boats. Distortion are importantly lower than in traditional fusion welding techniques in friction stir welding because of the low frictional heat energy input. Traditional joining techniques had number of problems which were all solved by the FSW. Tool geometry and welding speeds are main independent variables which affect the mechanical properties of welding, weld quality and cost. This experimental study, investigates the effect of welding speeds on the FSW joints performance. Welding speed are one of the significant parameter for deciding the performance of the friction stir welded joint. Different butt welded AA7075-T651 plates were manufactured by employing variable rotating speeds and travel speeds. Tensile tests, bending tests, microstructural analysis and macrostructural analysis were applied to specimens taken from welded plates in order to determine the effect of speeds on the mechanical properties of friction stir welded joints.

Keywords—Friction stir welding, mechanical properties, AA7075, aluminum al

I. INTRODUCTION

Friction stir welding (FSW) is a solid state welding method, invented at The Welding Institute (TWI) in 1991 and widely used in dissimilar and similar welding of aluminum alloys. FSW has some mechanical and metallurgical advantages compared to other traditional welding processes [1, 2].

Fig. 1. Schematic diagram of FSW [3,4]

The application of this method is shown schematically in Figure 1. The tool consists of two parts called shoulder and pin. The frictional heat is generated while the tool rotating. The material around the pin is softened because of the frictional heat input between shoulder and base material [2].

During welding, the tool moves along the weld joint [3]. One of the main advantages of FSW is that low distortion occur because of the low heat energy input [3]. The application of friction stir welding is shown in figure 2.

Fig. 4. FSW tool geometry

Chemical composition and mechanical properties of the alloy are given in Table 1 and 2.

Fig. 2. The application of FSW

Three main various zones such as Nugget zone (NZ), thermo-mechanically affected zone (TMAZ) and heat-affected zone (HAZ) are schematically shown in Figure 3.

Fig. 3. Schematic presentation of the joint [5]

During welding the Nugget zone is heavily deformed material that roughly corresponds to the location of the pin. The grains within the nugget zone are roughly equiaxed and often an order of magnitude smaller than the grains in the parent material [5].

II. EXPERIMENTAL WORKS

The base material used in the all experimental works were rolled, 5 mm thick sheets of EN AW- 7075 in the state T651 which means they were solution heat treated, stress-relieved by stretching and artificially aged. The aluminum plates were cut in a rectangular shape with 200mm breadth and 100mm width. Single pass friction stir butt welded plates were manufactured by milling machine. The FSW tool was put on a 1° tilt angle and 4.9mm plunge depth. A triangular tool made of DIN 1.7131 steel with 18mm diameter shoulder in this study as shown in Fig. 4. FSW joints fabricated using a tool with 18 mm shoulder diameter.

TABLE I. CHEMICAL COMPOSITION OF THE AA7075-T651

Si	Fe	Cu	Mn	Mg	Cr	Zn	Ti	Ni
0,07	0,17	1,57	0,028	2,53	0,19	5,74	0,23	0,058

TABLE II. MECHANICAL PROPERTIES OF THE AA7075-T651

R _m [MPa]	R _{p0,2} [MPa]	A50	Temper
581	512	15	T651

TABLE III. FSW PARAMETERS

Specimen No	Rotating Speed (rpm)	Welding Speed (mm/min)	Tool Direction of Rotating
7075-1	500	50	Clockwise
7075-2	630	63	Clockwise
7075-3	800	80	Clockwise
7075-4	1000	100	Clockwise

Tensile tests and bending tests were used for the mechanical testing of welded joints. The tensile tests and bend tests were carried out using servo-hydraulic controlled Shimadzu testing machine. Specimen dimensions were chosen according to the standard ASTM E8M. The tests were performed at room temperature and at a 2mm/min crosshead speed in machine. The dimension of tensile test specimen and bending test specimen are shown in Figure 5.

Fig. 5. Tensile test specimen (a), Bending test specimen (b)

Friction stir welded joints were cross-sectioned perpendicular to the welding direction for metallographic inspection. The specimens were polished by diamond suspension and then etched with 190 ml distilled water, 5ml HNO₃, 3 ml HCl, 2 ml HF at room temperature.

A Vickers micro hardness testing machine was used for determining the hardness distribution of the welded joint. The measurements were started at the centerline of the joint and continued throughout the base materials to each side with a spacing of 1mm and applied with a load of 100gr for 10 seconds.

III. RESULTS AND DISCUSSION

In this experimental works, AA 7075 – T651 sheets were successfully joined by FSW techniques. FSW joints have a good welded surface and don't need to post welding cleaning and machining. On the macroscopic scale, the friction stir welding joint revealed a good weld surface is seen Figure 6.

Fig. 6. Friction stir welded joint surface

The specimens were tensile tested and transverse tensile properties such as yield strength (R_{p0,2}), tensile strength (R_m) and percentage of elongation (A50) of the joints were evaluated. To determine the tensile strength of the FSW joints, tensile test specimens were fabricated in accordance with ASTM E8 in the transverse direction perpendicular to the welded line with wire erosion machine as shown in Figure 5.

TABLE IV. TENSILE TEST RESULTS

Specimen No	R _m [MPa]	R _{p0,2} [MPa]	A50
7075-1	328	437	3,9
7075-2	341	457	3,7
7075-3	343	445	3,8
7075-4	359	462	2,5

Bending tests were performed on the welded specimens are shown in figure 7. FSW joint presented allowing for very low bend angles and cracks were observed in the joint.

Fig. 7. Results of bending tests; 7075-1(a), 7075-2 (b), 7075-3(c), 7075-4(d)

Typical cross section of the welded joints under different parameters is shown in Figure 8. The size and shape of the

zones formed during welding varies depending on the pin geometry of the tool. Therefore, the stirrer pin profile has an important effect on mechanical properties.

Fig. 8. Macroscopic appearances of the joints; (a) 7075-1, (b) 7075-2, (c) 7075-3, (d) 7075-4

In the sample 7075-1, pinhole defect detected between NZ and TMAZ (see figure 8a and figure 9). Further increase in turbulence of the plasticized metal may be reason of pin hole defect. This specimen gives good results in the tensile test, indicating that these gaps do not form along the weld joint.

Fig. 9. Pin hole defect in 7075-1

The cross section of the weld joint analyzed using optical microscopy. Weld zone temperature and grain size are interrelated and can be related with the tool rotational speed in friction stir welding process [6]. Weld zone temperature increases with increasing tool rotational speed, if other welding parameters are constant [6].

Fig. 10. Microstructures in Nugget zone (NZ); (a) 7075-1, (b) 7075-2, (c) 7075-3, (d) 7075-4

Figure 10 shows microstructures in the nugget zone of the welded joints at different welding speeds. Nugget zone is characterized by a dynamically recrystallized, fine equiaxed grain structure and grain sizes decrease from the top surface to the bottom [7].

Fig. 11. Microstructures in Nugget zone (NZ); 7075-1(a), 7075-2 (b), 7075-3(c), 7075-4(d)

The heat affected zone (HAZ) is only affected by the welding thermal cycles and no plastic deformation occurs in this zone, therefore the HAZ displays similar grain structures to the base material. The heat affected zone (HAZ) is mechanically unaffected by the welding tool and the grain structure in that region resembles the parent material. The grains are slightly overgrown as a result of the exposure to welding heat.

Fig. 12. Microhardness profile of welded joints

Figure 12 shows the micro hardness profile subtracted from the micro hardness values measured along the transverse line of the weld zone. The maximum Vickers

hardness value shows in the base material. The minimum hardness is obtained at the boundary between the TMAZ and HAZ. The hardness value on the nugget zone (joint center) is higher than that of boundary because of the recrystallization and its fine equiaxed grain structure.

IV. CONCLUSION

In this experimental study, the microstructure, the macrostructure, mechanical properties and microhardness of friction stir welded aluminum alloy 7075-T651 were examined precisely with different welding parameters. The present experimental results are concluded below:

- Butt joint of 5mm 7075 aluminum alloy could be successfully made by the FSW process and joint efficiency as high as 79% of base metal could be achieved.
- Clean surface is obtained after FSW process. After the FSW, is not even necessary to clean up the weld zone.
- The maximum tensile strength of FSW joint was achieved with rotational speed of 1000rpm and traverse speed of 100mm/min.
- The microstructure in the nugget zone (NZ) presents the dynamically recrystallized, fine equiaxed grain structure and grain sizes decrease from the top surface to the bottom
- The tensile strength increase with increasing welding speed up.

Abstract— In this study, U-notch effect on the critical buckling loads of carbon/epoxy composite plates were investigated with experimentally and numerically. The effects of the different notch depths and fiber reinforced angle were analyzed. The notch depths were changed as 0, 2.5, 5 and 7.5 mm and the notch diameter was constant as 10 mm. The fiber reinforced angles of composite plates were used as $[0^\circ]_4$, $[0/45]_s$ and $[0/90]_s$. In the numerical study, linear buckling analysis was realized in ANSYS finite element software. Obtained experimental results were compared with numerical analysis results which were obtained in ANSYS. The experimental results consistent with numerical results showed that the increasing of the notch depth and fiber orientation angle were lead to decrease of critical buckling loads of composite plates as 11.51% and 66.48%, respectively.

Keywords—U notched, Composite plates, Buckling analysis.

VI. INTRODUCTION

Today, fiber reinforced and laminated composite materials have wide use special areas, like aerospace marine defense industry. To understand the strength and failure mechanisms in the composite materials gains importance to improve their mechanical performances. Composite plates can be subjected to various combine or single loads like bending, buckling or tension/compression. Plates are used often in aircraft and ship bodies and these components are influenced by air and wave that cause buckling on plates. So, buckling analysis is very important, especially for the structural components of aircrafts that were manufactured some pieces from fiber reinforced composites. Recently, the experimental and numerical studies concentrate on this work area with developing numerical analysis programs [1-11].

The central circular notch effect on the buckling behaviors of composite materials was investigated [1-6]. Turan [1] investigated buckling behaviors of adhesively patch repaired composite plates and central circular notched composite plates with experimental and numerical studies. The central circular notched composite plates were repaired with external patch and adhesive. The critical buckling loads of repaired plates were compared with central circular notched composite plates [1]. Solmaz et al. [2] researched the buckling behaviors of central circular notched composite plates with experimental and numerical studies. The numerical study was realized in ANSYS finite element software [2]. Kömür et al. [3] and Ghannadpour et al. [4] investigated buckling behaviors of central circular and elliptical notched composite plates with experimentally and numerically. In these studies, the fiber reinforced angle, layer arrangement, elliptical hole position and notch dimension effect on the critical buckling loads were investigated [3, 4]. Okutan [5] and Okutan et al. [6] researched buckling behaviors of central circular and semicircular edge notched composite plates with experimentally and numerically. Akbulut and Ural [7] analyzed buckling behaviors of corner circular notched composite plates. Akbulut and Sayman [8] researched buckling behaviors of central square hole notched composite plates. Yazıcı et al. [9] and Turan [10] investigated buckling behaviors of U notched composite plates with numerical studies and experimental studies.

In this study, linear buckling behaviors of fiber reinforced and laminated composite plates were analyzed experimentally and numerically. The composite plates were manufactured from unidirectional carbon fiber and epoxy resin matrix as $[0^\circ]_4$,

$[0^\circ/45^\circ]_s$ and $[0^\circ/90^\circ]_s$ lamina sequence configurations. The notch depths were taken as 0, 2.5, 5 and 7.5 mm and the notch diameter was taken as constant value 10 mm. The critical buckling loads were determined from the compression tests. The effect of variations of the notch depth and lamina stacking sequence on critical buckling loads were presented with using graphs. The ANSYS Finite Element Method (FEM) software was used in order to obtain buckling loads, numerically. Finally, compatible compared results for experimental and numerical analyzes were presented in graphs.

VII. EXPERIMENTAL STUDY

In the experimental study, the four layered unidirectional carbon/ epoxy matrix composite plates were used as materials that have $[0^\circ]_4$, $[0^\circ/15^\circ]_s$ and $[0^\circ/45^\circ]_s$ lamina stacking sequences with approximately 1.4 mm thickness. The composite plates were provided from *Izoreel Composite Production Company*. The U-notches were opened to the edge of composite plate with using milling cutter. The geometrical conditions of problem were presented in Figure 1. The width of composite plate was 30

mm and length of plate was 140 mm. Mechanical properties of $[0^\circ]$ laminae were given in Table 1.

TABLE I. THE MECHANICAL PROPERTIES OF CARBON/EPOXY LAMINATED COMPOSITE PLATES [1].

Property	Symbol	Value	Unit
Young module in fiber direction	E_{11}	172891	MPa
Young module in perpendicular to the fiber direction	E_{22}	10796.66	MPa
Poisson ration	ν_{12}	0.32	-
Shear module	G_{12}	3638	MPa

In order to determine the effect of the notch depth on critical buckling load, U-notched composites specimens which have different notch depths as $a=0, 2.5, 5$ and 7.5 mm for a constant notch diameter $d=10$ mm were prepared. Totally, fifteen specimens were used in experiments for fiber orientations $\theta=0, 45$ and 90 in $[0^\circ/\theta^\circ]_s$ lamina stacking sequences and notch dimensions as presented in Figure 1.

FIGURE 1. THE GEOMETRY OF PROBLEM.

The axial compression tests were realized in 50 kN capacity *Shimadzu* tensile testing machine with 1 mm/min compression speed in Ege University Mechanic Laboratory. The loads were applied to the samples until the buckling was observed. The load and displacement values composites, which were obtained from tensile testing machine and these values, were recorded in the computer. At the end of experiments, the plotted graphs were obtained from these records. The experimental set-up and typical load-displacement behavior of U-notched specimens were presented in Figure 2. Linear behavior zones of load-displacement graphs of U-notched composite plates were used to determine critical buckling loads. The critical buckling load of fiber reinforced and laminated composite plate is the

maximum end of the region that has a linear function as shown in Figure 2. These determine technique was applied to the all compression load-displacement graphs of specimens to obtain critical buckling load [1, 2].

The results of experiments were evaluated at two stages. First of these; the notch depth was changed as 0, 2.5, 5 and 7.5 mm for all θ values. The second of these, the fiber orientation angle was changed as $0^\circ, 45^\circ$ and 90° for symmetric stacking sequence $[0^\circ/\theta^\circ]_s$. In addition, these results were compared with numerical analysis results.

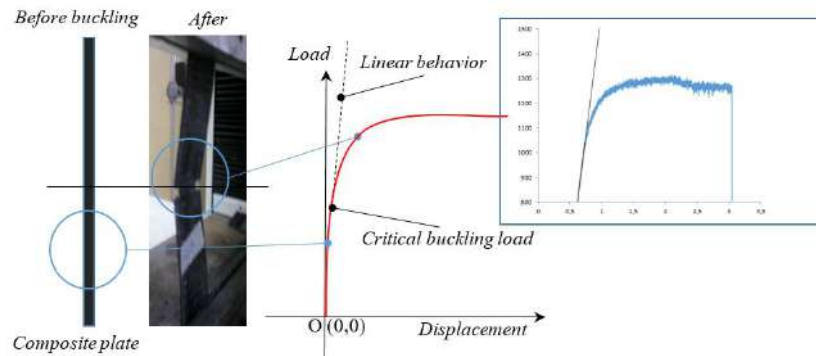

FIGURE 2. OBTAINING CRITICAL BUCKLING LOAD FROM LOAD-DISPLACEMENT GRAPH.

III. NUMERICAL ANALYSIS

In the numerical analysis, *ANSYS* finite element software used in order to obtain critical buckling loads. For all specimens, totally fifteen model was prepared and analyzed. In the modeled of problem *SOLID46* element type was used. The *SOLID46* was used layered composite materials and it had 8-node and three degrees of freedom at each node [11]. Total element and node sizes of numerical models used were linear buckling analyzes are given in Table 2. Typical mesh and boundary conditions of numerical model is present in Figure 3. Linear material properties of orthotropic composite materials in 1-2 planes given Table 1 were used as input in *ANSYS*.

TABLE II. ELEMENT AND NODE SIZES OF NUMERICAL MODELS USED IN LINEAR BUCKLING ANALYSIS.

Notch depth a (mm)	Element size	Node size
0	2000	3273
2.5	2208	3603
5	2208	3603
7.5	2464	4011

FIGURE 3. FINITE ELEMENT MODEL AND BOUNDARY CONDITION OF LAMNATED UNNOTCHED COMPOSITES (A=0).

FIGURE 4. VARIATION OF CRITICAL BUCKLING LOAD WITH NOTCH LENGTH FOR DIFFERENT STACKING SEQUENCES

With using procedure, this was explained in Section I. In the experimental study, critical buckling loads were determined, and graphs are obtained. The maximum buckling load was obtained for $[0^\circ]_4$ stacking sequence specimen when a is zero as 1650 N. The minimum critical buckling load was obtained as 250 N for $a=7.5$ mm and $[0^\circ/90^\circ]_s$ lamina sequence configurations. On the other hand, increasing of the fiber orientation angle from 0° to 90° decreased critical buckling load of U-notched carbon/epoxy plates. The buckling loads of all notched specimens and fiber reinforced specimens were compared with $a=0$ having $[0^\circ]_4$ stacking sequence specimen. The calculated decreasing rates according to the $a=0$ were presented for different notch depths in Table 3. It can be seen that the U-notch decreased the buckling loads of composite plates as seen Figure 4. The minimum and maximum percent change ratios of buckling loads for $a=2.5$, 5 and 7.5 mm were calculated as 11.51% and 66.48% rates, respectively.

2.5	11.51	36.36	39.63
5	25.45	52.48	61.57
7.7	46.96	64.46	66.48

The table 3 was showed that the effect of fiber reinforced angle on buckling load was very important parameter. Also, the critical buckling loads decreased with increasing θ . When the fiber orientation angle was increased from 0° to 45° , decreasing rate was obtained approximately in 17.7-28% interval. When the fiber orientation angle was increased from 45° to 90° , the decreasing rate was obtained approximately in 2-9% interval. It can be seen from these results that 0° fiber orientation angle whose axis is identical with compression load is the most strength against the buckling. The increasing of θ effectively is decreased buckling loads up to 45° for all notch depth. Then increasing of θ from 45° up to 90° does not decrease buckling load much as changing of θ from 0° up to 45° . This situation can be explained as compression loading on fiber orientation axis causes to be blocked by fibers. Because fibers have more strength for tensile load than matrix materials.

TABLE III. PERCENT CHANGE RATIOS OF CRITICAL BUCKLING LOADS FOR DIFFERENT NOTCH DEPTHS (%).

Notch depth a (mm)	$[0^\circ]_4$	$[0^\circ/45^\circ]_s$	$[0^\circ/90^\circ]_s$
-------------------------	---------------	------------------------	------------------------

--	--	--	--

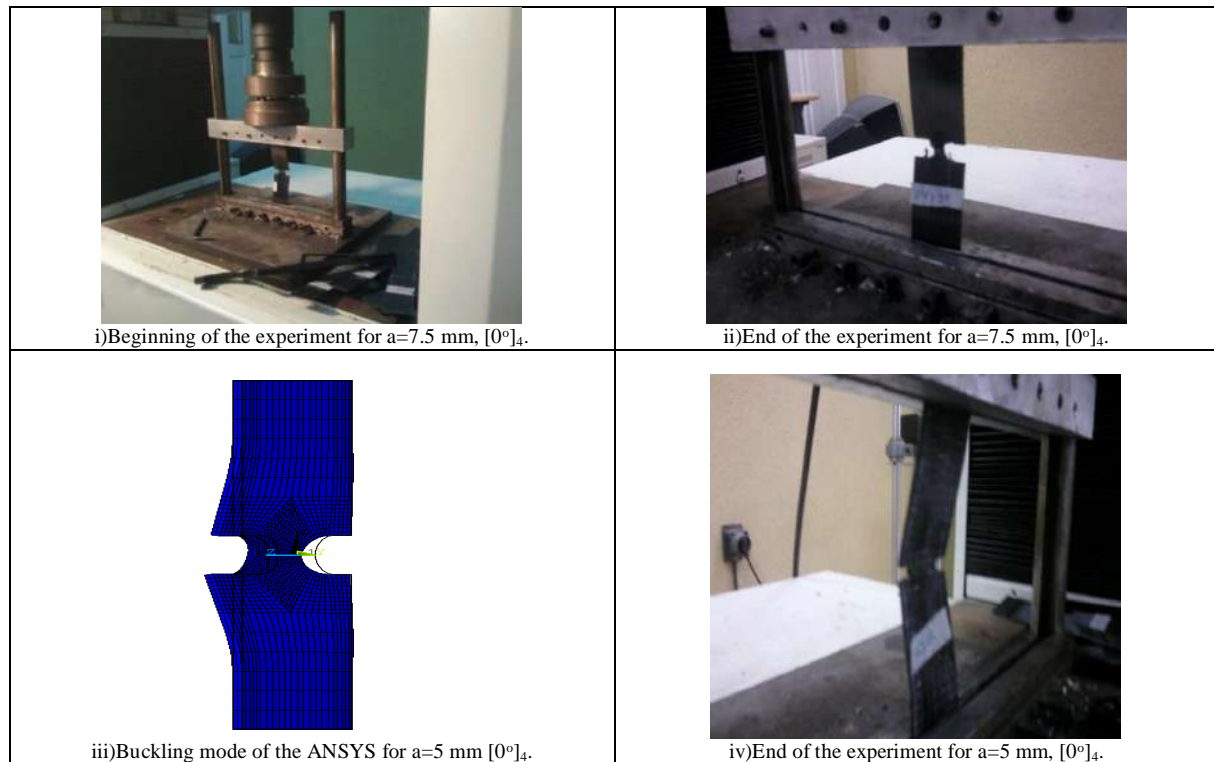

FIGURE 5. EXPERIMENTAL AND NUMERICAL BUCKLING MODES .

In the experimental study, the failure starting and propagating were observed, additionally. The failure mechanisms were showed in Figure 5. Stress concentrations at the tip of notch occur because of the notches. This situation leads to buckling starting at this location. When the ultimate failure was realized, it was expected that the composite plate can cracking and breaking occurred (Figure 5).

Comparative results of experimental and numerical analyzes are presented in Figure 6. It can be seen from these results that experimental and numerical results are very close. As in

experimental results, numerical buckling loads decreased with increasing notch depth and fiber orientation angles. Numerical results are greater than experimental results in some models. However, the opposite is true for some models. The maximum converge ratio was obtained for $[0^\circ/90^\circ]_s$ stacking sequence specimen when $a=2.5$ mm as +14.16%. The minimum converge ratio was obtained as +1.29% for $a=2.5$ mm and $[0^\circ]_4$ lamina sequence configurations.

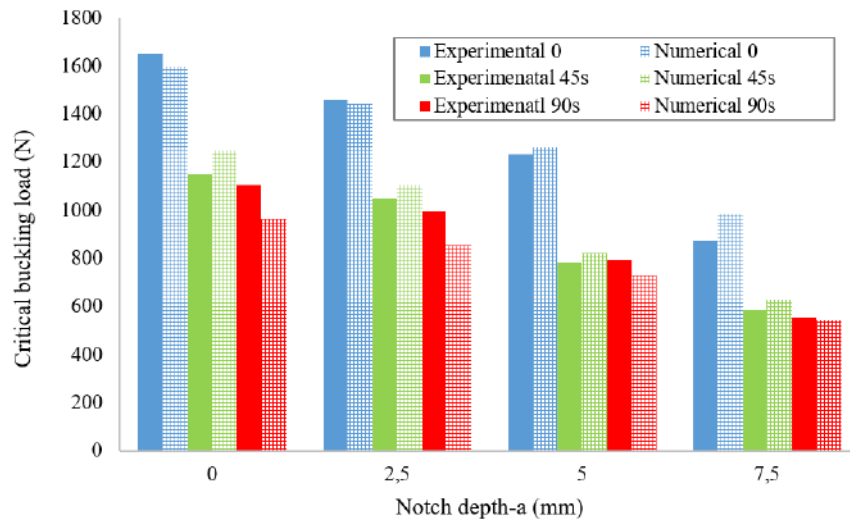

FIGURE 6. EXPERIMENTAL AND NUMERICAL TEST RESULTS FOR DIFFERENT NOTCH DEPTH OF $[0^\circ/\theta^\circ]_s$ COMPOSITES .

IV. CONCLUSIONS

In this study, linear buckling behaviors of carbon fiber reinforced/epoxy composite plates having different U-notch depths as $a=0, 2.5, 5$ and 7.5 mm for a constant notch diameter $d=10$ mm for fiber orientations $\theta = 0^\circ, 45^\circ$ and 90° in $[0^\circ/\theta^\circ]_s$ lamina stacking sequences were analyzed experimentally and numerically. The some of aspects are concluded as follows:

- The critical buckling loads were decreased with increasing notch depth as 11.51% and 66.48.2% rates according to the composite plates having semi-circular notch.
- The critical buckling loads decreased with increasing fiber orientation angle θ . When the fiber orientation angle was increased from 0° to 45° , percent decreasing rate was obtained in 17.7-28% interval. If the fiber orientation angle was increased from 45° to 90° , at this situation percent decreasing rate was obtained in 2-9% interval. In other words, 45° results are close to the 90° results.
- Effect of notch depth on failure and fracture behavior can be expected situation. However, important point of this research can be said that effects of variation of notch depth and fiber orientation angle on buckling loads are close to each other.
- Generally, obtained results shows that the fiber orientation angle effect on the critical buckling load is important parameter and 0° fiber orientation angle have more strength to the buckling. So, if designers use laminated composites having unidirectional carbon fiber applied buckling load, more 0° lamina on load

axis should be chosen in manufacturing process of laminated composite plates.

- Experimental results were obtained in accordance with numerical results in 1.29% and 14.16% interval. It can be said that the finite element method is very accurate and applicable for more complex analyzes of structural components.

Abstract— The aim of this study is to analyze the effect of pH on the stress corrosion cracking of AZ91 Mg alloys using slow strain rate test (SSRT) method in different media; acidic, basic and neutral NaCl solutions. Slow strain rate test indicated that AZ91 Mg alloys in basic environment were the least susceptible, while the most susceptible to stress corrosion cracking in acidic environment. SEM images showed that intergranular stress corrosion cracking was evident for AZ91 Mg alloys in acidic and basic solution, whereas in neutral environment, transgranular corrosion cracks were observed.

Keywords—AZ91 Mg alloy, stress corrosion cracking, SSRT

VIII. INTRODUCTION

The need of light materials particularly in sectors of automotive, aviation, microelectronics and telecommunication lead engineers to be more creative in choosing materials. Magnesium and its alloys with a quarter density of steel and with two third density of aluminum while its specific strength (strength/weight) is more than both of them, magnesium has properties very good enough to play the role as being a light material.

Magnesium and its alloys have become one of the ideal materials because of being the lightest structural material in order to decrease vehicle weight to the minimum value and in turn to decrease exhaust gas emission to minimum. Moreover magnesium and its alloys have been predicted to be used as orthopedics implants due to being light, bio-solvable and having capability of loading. Although these materials have significant mechanical properties like high specific strength, they have some disadvantages such as bad corrosive features and stress corrosion susceptible that restrict the usage in this area.

The incidence of SCC may increase because of increasingly usage of Mg parts in structural applications compared with the previous non-structural applications. Service conditions are becoming more severe, particularly in the automobile industry,

where cast Mg components are increasingly used in load-bearing applications [1].

Stress corrosion cracking of Mg alloys have been studied by many researchers in the literature. Some common alloys (such as AZ91, AZ31 and AM30) are susceptible to SCC failure even in a mild environment such as distilled water [1]. Mg-Al alloys have been reported to SCC in different media such as air, distilled water and chloride-containing solutions [2]. Miller [3] indicated that SCC occurs in distilled water for AZ91, AM60 and AS41 Mg alloy. Arnon and Aghion [4] found SCC in AZ31 in %0,9 NaCl. It has been reported that AZ91 Mg alloy has TGSCC in 0.5 M MgCl₂ [5].

Environmental effects such as hydrogen, atmosphere, solution composition, electrochemical potential, pH, temperature, coating have been studied to analyze effects of stress corrosion susceptibility of magnesium alloys [1]. There are a few reports on the influence of pH on SCC in the literature and they all agreed that SCC does not occur in chloride-chromate solutions with pH values greater than 12 [6].

This study presents stress corrosion resistance determined by the SSRT test method at different pH values of commonly used AZ91 Mg alloys.

IX. EXPERIMENTS

A. Test Materials

The material used was as-cast AZ91 Mg alloy including (wt.%) 9.231Al, 1.348Zn, 0.286Mn, 0.148Si, 0.012Fe, 0.004Cu and balance Mg. (The composition ratio is not given for the elements below 0.001%.) Untreated 16 mm diameter rod specimens were produced on CNC machines in accordance with ASTM E 8 Test Method standards (Standard Test Methods for Tension Testing of Metallic Materials). The specimen preparation steps are as follows:

1) The surfaces of all samples were polished using 1000, 2000 grit silicon carbide papers,

- 2) All samples were cleaned with distilled water and acetone,
 - 3) Dried in cool air.
- The picture of the produced samples is given in Figure 1.

Fig. 1. Used tensile samples for SSRT test (Unit:mm)

B. Slow Strain Rate Test (SSRT)

In this study, slow strain rate test (SSRT) was applied and the stress corrosion behavior of alloys was investigated. The experiments were carried out in accordance with ASTM G-129 00 standard. Slow deformation in operation was provided by Shimadzu brand universal tensile testing device. The corrosive environment is provided by acidic (pH = 2), basic (pH = 11) and %3.5 NaCl neutral environments with artificial corrosion cell mounted on the tensile testing device. The experimental setup used is shown in Figure 2.

Fig. 2. Schematic picture of SSRT experimental setup

Acidic solution was prepared by adding HCl to 3.5% NaCl solution to decrease the pH value to 2.0, and NaOH was added to 3.5% NaCl solution until pH = 11.0 to obtain a basic solution.

The stress corrosion crack index was calculated by cracking the test specimens in the abovementioned media and at a deformation rate of $6.66 \times 10^{-7} \text{ s}^{-1}$. Stress corrosion crack index can be determined in two ways. Determination of the ratio of the tensile strength value in the corrosive environment to the tensile strength in air in the first sample; And the second is to determine the crack time of the sample in the corrosive environment relative to the crack time of the air sample. Stress corrosion resistance of material with low stress index of crack cracking is low and stress corrosion resistance of material with high index is high.

X. RESULTS

Stress corrosion tests of AZ91 Mg alloy were carried out in acidic, basic and 3.5% NaCl solutions by the slow strain rate test method. Firstly the AZ91 magnesium alloys were subjected to the SSRT test in the air environment, and as a result of the test, the tensile strength was about 146 MPa and the cracking time was about 13 hours. Secondly, the specimens were subjected to the SSRT test in an acidic environment, and as a result of the test, the tensile strength was approximately 77.5 MPa and the cracking time was approximately 6.3 hours. Thirdly, the samples were subjected to the SSRT test in a basic environment and the tensile strength was approximately 106.8 MPa and the cracking time was approximately 7.5 hours. Finally, they were subjected to the SSRT test in neutral 3.5% NaCl and the tensile strength was approximately 89.4 MPa and the cracking time was approximately 6.8 hours. SSRT results are shown in Figure 3.

Fig. 3. SSRT test results of AZ91 Mg alloy in air, acidic, basic and 3.5% NaCl solution

Fig.4. I_{SCC} of AZ91 Mg Alloys

TABLE 1. STRESS CORROSION CRACK INDEXES OF AZ91 Mg ALLOY

Atmosphere	Cracking Time (Hour)	I_{SCC}
Air	13,03	-
Acidic (pH=2)	6,27	0,481
%3,5 NaCl	6,80	0,521
Basic (pH=11)	7,46	0,572

Stress corrosion crack indexes of AZ91 magnesium alloys are given in Table 1 and Figure 4. As shown in the diagram, the SSRT test of the AZ91 magnesium alloy in the 3.5% NaCl solution resulted in a stress corrosion crack index (I_{SCC}) of the lowest acidic (pH = 2) and the highest basic (pH = 11). The AZ91 magnesium alloy has been found to be susceptible to stress corrosion crack at three of the working environments (acidic, basic and neutral) and is found to be the acidic medium was the least stress corrosion resistance (or the highest tensile corrosion sensitivity). It can be said that the environment in which the stress corrosion resistance is highest (or at least the tensile corrosion sensitivity) was the basic environment.

The fracture surfaces of AZ91 Mg alloys in acidic, basic and %3,5 NaCl solutions with the slow deformation rate are given Fig. 4. The AZ91 Mg alloy showed inter granular corrosion cracks in acidic and basic media, whereas in neutral environment, trans granular corrosion cracks were observed.

Fig.5. SEM images of AZ91 Mg alloys in solution (a,b) %3,5 NaCl, (c,d) acidic, (e,f) basic

XI. DISCUSSION

In the study conducted, it was found that the stress corrosion resistance of AZ91 magnesium alloys in 3.5% NaCl solution is weak. Especially, as the pH value decreases, tensile corrosion resistance decreases significantly. Depending on the pH value of magnesium alloys, stressed corrosion behavior appears to be a similar effect to corrosion behavior.

[1] and [9] found that the amount of aluminum in the alloy affects corrosion and stress corrosion. (1998): Mg-Al alloys with 2-8% by weight of Al increase the concentration of Al and decrease the amount of corrosion. Low Al contents of about 2-4% Al are caused by α -Mg extensions surrounded by a double-phase $\alpha + \beta$ -eutectic phase at grain boundaries. On the contrary, pure beta bands tend to precipitate along the grain boundaries along the grain boundaries due to the solidification rate in high additions of 6 to 9 wt% Al. If the amount of Al is up to 10%, the Al-rich α phase will cause microsegmentation during solidification and this value will be the appropriate local concentration [9]. [10] β -phase is a very stable and effective cathode in solution. Beta phase, one barrier and the other a galvanic cathode. If the beta phase is present in small quantities in the precipitate between the particles in the alpha matrix, this

acts mainly as a galvanic cathode and accelerates the corrosion of the alpha matrix. If the amount of β phase is large, then β phase can act as an anodic barrier to prevent corrosion of the alloy. The β phase is beginning to appear when Al is more than 2% by weight. As a result, up to 10% of Al content increases corrosion and stress corrosion resistance. For this reason, the stress corrosion resistance of the commonly used AZ91 Mg alloy compared to other AZ31 and AZ61 Mg alloys is likely to be high.

XII. CONCLUSIONS

The effect of pH value on SCC behavior of AZ91 Mg alloys can be summarized as follows.

1. As the pH value decreases, the stress corrosion crack index of AZ91 Mg alloys decreases. This means that stress corrosion susceptibility increases.
2. Studies to improve the stress corrosion resistance of AZ91 magnesium alloys in industrial applications, automotive, defense industry, aerospace, and especially in implant applications in recent years are inadequate, and extensive studies are needed to be done in this regard.

Development Of an Artificial Neural Network That Can Predict Pressure Drop in Pipes With Different Roughness

Ahmet Beyzade DEMİRPOLAT, İsmail Hakkı ŞANLITÜRK, İhsan DAĞTEKİN, Haydar EREN

Mechanical Engineering Department
Firat University
Elazığ, Turkey
ihsanliturk@firat.edu.tr

Abstract—Effect of pressure loss and pressure change in the entrance and fully developed flow region of different pipes which have different roughness have been investigated. Turbulence effects have been accounted for pressure measurements. A neural network have been developed for obtaining pressure drop. Input of the network is pipe material, diameter, flow rate and time. Comparison of the experimental values with the neural network results has been shown graphically. As a result, it was seen that designed neural network predicts pressure drop values accurately.

Keywords— *friction, internal flow, surface roughness, neural networks*

I. INTRODUCTION

The fluid flow in the tubes is commonly utilized in the heating and fluid distribution networks. In such applications, the fluid is often forced to flow in a flow region by a pump. It is necessary to pay special attention to the friction which is directly related to pressure drop and load loss in the pipe flow. At this point, external factors cause the friction to come to the market. One of these external factors is pipe roughness. In this study, an artificial neural network was designed in MATLAB Neural Network program to calculate the pressure drop when the roughness, pipe diameter, pipe material and flow time is entered, using the data obtained by experiments with 5 pipes in different roughness to investigate the effect of pipe roughness on pressure loss.

Numerous studies have been carried out on in-pipe flows. One of the most important of these studies is the relation equation between pressure drop and the flow called Hagen-Poiseuille flow, which developed by G. Hagen (1797-1884) and J. Poiseuille (1799-1869) [1-2].

Cyril F. Colebrook developed the Colebrook equation by combining the available data for smooth and rough piping and for turbulent flows in 1939. Hunter Rouse in 1942 and Lewis F. Moody plotted the relationship between friction factor and Reynolds number two years later, which known as the Moody diagram. The Moody diagram and the Colebrook equation can

only be used with a deviation of fifteen percent due to the size of experimental errors [3-4].

Bhatti and Shah [5] and Kaysa and Crawford [6] have studied the hydrodynamic transit lengths. These studies for finding the pressure loss and friction factor are usually carried out on artificially roughened pipes.

II. EXPERIMENTAL STUDY

The fluid used for performing the experiments was water. Red paint was added in the water for visibility. Five pipes with different roughness were selected for experimental study as iron, PPRC, copper, aluminum and galvanized steel, respectively. The diameters of the pipes were changing from 20,5mm to 27,75mm. The range of the flow rate was changed between 0,92879257m³/s and 0,000247525m³/s. Hydrodynamics transition length and fully developed flow range were taken into account when selecting the pipe lengths. Measurement ports were placed on entering and exit of the pipes. Ports also were placed with narrow spacing for hydrodynamic transition range on those pipes, too.

The flow rate was measured with a hydraulic tank, and static pressure values were recorded by a camera for a time range of 105s. Pressure values then extracted from recorded videos by image-processing technique. The experiments were repeated for 5 different pipes. Fig 1. Show the experimental setup.

Figure 1. Experimental setup

III. NEURAL NETWORKS

A neural network is a powerful tool for problems doesn't have a mathematical model. Since there are assumptions in building a mathematical model, physics of the problem may not be fully represented. A neural network can be built to represent a problem correctly after have trained with experimental data. When building a neural network model, memorization of the problem should be avoided. In this study, a FFBP (Feed Forward Back Propagation) neural network consisted of one input, one hidden, and one output layer was used. The number of input layer cells is 4 as material, diameter, flow rate and time. The output is a single cell as pressure drop. The number of hidden layer cells was determined by inspecting regression results as given below in Table I.

The total of 1575 data points [7] was used in the design of the neural network. %70 of the data was used for training, %15 for validation, and remaining %15 for testing.

As input and output cell numbers are fixed, the neural network was trained and simulated for numerous sizes of the hidden layer. According to results that given in Table I, network size of 4x24x1 was selected and used in this study. Regression and performance results for the selected network has been shown in Fig 2 and 3, respectively.

TABLE I. FFBP NETWORK SIZE AND TRAINING RESULTS

	Network size (Input x Hidden x Output layer)					
	4x12x1	4x16x1	4x18x1	4x20x1	4x24x1	4x28x1

Figure 3. Performance results of the FFBP neural network

IV. RESULTS AND DISCUSSION

The pressure drop corresponding to the change in flow rate, time and pipe material and diameter has been obtained experimentally. The developed neural network has been predicted accurately the pressure drop corresponding to given parameters. This network can be used to determine pressure drop in other pipes.

ABSTRACT: The aim of this paper is to investigate the effects of the coiled springs wrapped around a thin rod and located in the entrance of a concentric heat exchanger on heat transfer and pressure drop. The outer surface of the inner tube was maintained at constant temperature (100 C) by continuous contact with saturated water vapor introduced and filled into the annular space between the inner and outer tubes and discharged by a channel, like a teapot. The surface temperatures of the inner pipe, inlet and outlet temperatures of the air and pressure loss through the pipe were measured. The measurements were carried out for the Reynolds number ranged from 6500 to 42000. The only design parameter were considered as the diameter of the springs ($d_1=0.25$ cm, $d_2=1.0$ cm and $d_3=1.5$ cm) which is wrapped to the thin rod. It will be showed and detailed in the following sections. Nusselt number and friction factor were found out based on the measurements. New empirical correlations were found for the results.

Keywords— *turbulator, coiled springs, concentric heat exchanger, pressure drop, heat transfer*

I. INTRODUCTION

The increase of heat transfer in exchangers means saving energy and using energy efficiently. Given the ever-increasing need for energy and the reduction in energy resources, the use of heat transfer is better understood to improve the heat transfer in heat exchangers.

In present study, a coiled spring wrapped around a thin rod inserted in a concentric tube is used to enhance heat transfer. The coiled spring inserted tubes have been used as one of the passive heat transfer enhancement techniques and are the most widely used tubes in several heat transfer applications, for example, heat recovery processes, air conditioning and refrigeration systems, chemical reactors, food and dairy processes. Before introducing the tabulated heat exchanger system in the present study a short blink to the literature will help to understand the effects of the usage of the fins on heat transfer and pressure drop.

Some experimental results for local heat transfer coefficients were presented for a converging channel with rib roughening elements with the cross-section being maintained square from inlet to exit by Abraham and Vedula [1].

Heat transfer and pressure loss in an air to water double pipe heat exchanger were experimentally investigated by Sheikholeslami et al [2].

A circular-ring and perforated circular-ring turbulators were placed in annular pipe. Results indicated that using perforated circular-ring turbulators leads to obtain lower heat transfer enhancement than the circular-ring turbulators. An experimental and numerical work were carried out to study the heat transfer enhancement in a heat exchanger square-duct fitted with oblique horseshoe baffles by Skullong et al [3].

Promvonge [4] studied the increase in heat transfer rate using conical ring with three different diameter ratios and placed with three different arrangements.

El Sayed et al. [5] investigated the effects of height, thickness, inter-fin spaces, number and tip-shroud clearance of fins on the heat transfer, fluid flow and pressure drop.

Naik et al. [6] proposed a design correlation which shows the distribution of optimal rib spacing for a wide range of rib geometries and operational conditions.

Sahin et.al [7] investigated the effects of the longitudinal and lateral separations of consecutively enlarged-contracted arranged fin pairs, widths of the fins, angle of attack, heights of fins and flow velocity on the heat and pressure drop characteristics by using the Taguchi method.

Arulprakasajothi et al [8] aimed to investigate for to circular tube with conical strip inserts as turbulators in a laminar flow condition, using staggered and non-staggered conical strips.

Cakmak and Yildiz [9] performed a study and investigated the influence of the injectors with swirling flow generating on the heat transfer in the concentric heat exchanger.

In present study, the diameter of springs wrapped around thin rod and Reynolds number have been the investigated as parametric values. Heat transfer by means of Nusselt number and pressure drop by means of friction factor are the results of the experimental study.

2. EXPERIMENTAL SETUP

The main structure of the experimental setup was already explained in a previously published paper by Eren et al [10, 11]. Schematic view of the setup is presented in Figure 1. The

air is blown by a fan and its speed is regulated by an inverter. An anemometer was used for measuring the velocity of the air. Pressure differences between the inlet and outlet of the exchanger are measured by an inclined manometer.

Figure 1 Experimental Setup [10]

Figure 1 Coil springs wrapped to the thin rod

The heat exchanger is a classical type concentric tube of which outer surface of the inner tube is heated by the condensation of a stream of flowing water vapor. The inner and outer diameters of the inner tube are respectively 65 and 66 mm and the length of the tube is 900 mm. As an outer tube, a 1 mm-thick flat plate with dimensions of 700x1200 mm is rolled to obtain a circular tube with a diameter of 210 mm [10, 11].

The outer surface of the inner tube was kept at a constant temperature (100 C) by continuous contact with saturated water vapor introduced and filled into the annular space

between the inner and outer tube and discharged by a channel. The surface temperatures were measured by T-type thermocouples located every 50 mm distance along the tube length. The mean local wall temperature was determined by means of calculations based on the readings of the thermocouples. The inner and outer temperatures of air were also measured at certain points inside the tube. The pressure loss was maintained by an inclined manometer [10, 11].

3. DATA REDUCTION

All of the experiments are performed under the steady state conditions. Each run takes approximately 30 min. Heat transfer and pressure loss data are parameterized with the Reynolds number which is varied from 6000 to 12000. Re number is found as follows:

$$Re = \frac{VD}{\mu} \quad (1)$$

where V is the velocity of the air at the inlet, μ is kinematic viscosity of the air, D is the inner diameter of inner tube.

The average Nusselt number is found by logarithmic mean temperature difference:

$$LMTD = \frac{T_1 - T_2}{\ln \frac{T_1 - T_m}{T_2 - T_m}}$$

where T_1 is the difference between mean wall temperature and inlet temperature of the air ($T_1 = T_w - T_i$), and T_2 is the difference between mean wall temperature and outlet temperature of the air ($T_2 = T_w - T_o$). The mean wall temperature T_w was determined by means of calculations based on the readings of the thermocouples [10, 11].

The net heat is obtained by subtracting the heat loss from the gained heat occurred because of the water vapor on the surface. The outer surface of the test tube was well insulated and necessary precautions were taken to prevent leakages from the system. Thus, the convection heat transfer to the surrounding is neglected. Also the conductive heat loss through the thickness of copper tube, and radiation between the air and copper surface is neglected. The mentioned neglected heat rates are less than 0.5% of the total heat obtained by heating the surface by water vapor [10, 11].

Net heat is equal to the heat transfer rate occurred by logarithmic mean temperature difference, LMTD:

$$Q = \dot{m} C_p (T_o - T_i) = h A (LMTD)$$

$$h = \frac{Q}{A (T_o - T_i)} \quad (3)$$

where the fluid properties C_p , and k are found based on bulk temperature of the air.

Then average Nusselt number can be calculated as follows:

$$Nu = \frac{h D}{k} \quad (4)$$

The measured pressure loss is used to calculate the friction factor:

$$f = \frac{\Delta P}{L} \frac{D}{\rho V^2} \quad (5)$$

In order to compare the experimental results of the turbulent tube, a smooth tube flow is also tested. In addition, the well-known empirical formula of Dittus-Boelter and Blasius are used for comparisons [12].

$$Nu = 0.023 Re^{0.8} Pr^{0.4} \quad (6)$$

$$f = \frac{0.316}{Re^{0.25}} \quad (Re > 2 \times 10^4) \quad (7)$$

where Prandtl number of the air is considered based on the average of inlet and outlet temperatures.

4. RESULTS AND DISCUSSIONS

The design parameters in this study are the coil spring diameter wrapped on the thin rod (d) and Reynolds number. The effects of mentioned parameters on heat transfer and pressure loss are presented in Figure 3, 4 respectively. For all cases Nu number increases with increasing Re number.

The friction factor decreases with increasing Re number, because friction factor inversely changes to the square of the air velocity.

Figure 3 Nu versus Re with respect to hole diameter

Figure 4 f versus Re with respect to hole diameter

5. CONCLUSIONS

In present study, coil spring turbulators cause some heat transfer enhancement. Major results of the experiments are as follows:

- ☞ Turbulators not only produce more turbulence than the smooth tube but also increase heat transfer area.
- ☞ Highest heat transfer and friction factor are observed for the smallest diameter of the holes on the plates.
- ☞ Highest heat transfer and friction factor are observed for the highest distance between two plates.

- ✓ The location of the hole seems has no great importance on either heat transfer or friction factor.
- ✓ Heat transfer increases with increasing Re , however friction factor decreases with increasing Re .
The recommendation of the authors is to make an optimization analysis for diminishing the pressure loss.

Abstract— Drying is use to describe a process involving removal of the required amount of humidity from any material. Removal of the humidity in the material is done with different shapes and methods. In the drying technique, the factors such as the nature of the product, its structure, ambient conditions, air quality and speed are effective. In this study, it is aimed to design a impinging jet drying oven due to its ability to provide high heat transfer coefficient, easy to manufacture and low cost. Here; The drying of wet fabric dyed with air jets has been taken into consideration. Thus, the usability of the jet was investigated in textile drying. For this purpose, an adiabatic oven was designed and manufactured. The hot air jet is placed at the opening of the luer with the lid opened from the top of the oven and the drying process which is caused by the hot jet being applied to the fabric placed in the oven is examined.

Keywords— impinging jet, drying, dyed fabric, heat transfer

I. INTRODUCTION

People have often benefited from solar heat in the drying of materials that will meet their needs from the earliest times. This method is often performed on its own in nature and has benefited from solar heat, for example in the drying of various cereals, legumes, fruits and also some textile products. Since the earth is dry with solar heat, it is impossible to get dry everywhere and always by this way. In addition, a variety of methods have been developed for the drying out of many products due to the increasing number of products over time and the fact that many of these products lose their properties while drying under the sun's heat.

Numerous theoretical and experimental investigations have been carried out on drying methods. During drying, the product must be supplied with heat continuously. There are convection drying, heat conduction drying and radiation drying methods according to the heat transfer method in the heat energy dryings.

In the case of convection drying, the intake of the moisture in the product to be dried is ensured by hot and at the same time dry air flow. The temperature of the dry air can be

increased depending on the type of dryer and the speed of passage through the dryer (such as 60-100 C).

In the case of drying by conduction, while the product to be dried remains stationary or moving, heat is transferred to the material from the hot surface it is in contact with during drying.

Impinging air jets (nozzles), due to the high heat and mass transfer occurring in the loading region, single and including multiple, textile, paper and wood drying, cooling of electronic components, the glass sheet tempering, heat treatment, industrial many as cooling the gas turbine blade is often used in practice [1].

In certain regions, large spaced luer arrays are used, where the step between single or luer is large in desired drying processes, while jet arrays are used in large surface drying environments (paper, textile etc. products). The evaporative drying rate axes are increased by hot air jets located in the normal direction of the moving web (paper, plastic, etc.) surface [2].

During the production and rehabilitation process of the textile products, the moisture they get to their structures is removed by drying. drying the textile product by removing moisture on the product shape; Pre-drying by mechanical methods and natural drying on the product without loss of heat, and drying by heat transfer [3].

However, drying the product with heat (main drying) can damage both its structure and its economic value. With this, drying of textile products requires essential drying, and drying steps must be carried out effectively without damaging the product [4].

Avci et al. studied theoretically the jet-drying of thin film strips coated with ink on thin film layers [5]. In another work, they have made an analogy between mass transfer and heat transfer in the drying of ink ribbon [6].

The economic analysis of industrial drying by jet blower drying was done by Etemoğlu and useful information about the applicability of the system was given [7]. Multi jet environments have been created in the practice of impinging jet drying.

II. DESIGN PARAMETERS

The design parameters to be considered in the drying systems in which the impinging air jets are used include:

- nozzle width (diameter)
- nozzle shape
- nozzle height
- air velocity
- air temperature
- distance between nozzles

A. determining the optimum nozzle width or diameter for multi nozzle systems, the designer should consider the fan power, the number of nozzles needed, as well as the effect of the nozzle width (diameter) on heat transfer. Nozzle width affects the average heat transfer coefficient. At a constant fan power, the average heat transfer coefficients increase with decreasing nozzle diameter.

B. Air Velocity (V_E) : The electrical power required by the fans should provide a pressure increase that will compensate for local and friction losses in the system and provide sufficient air velocity to be delivered over the sample to be dried. Heat transfer coefficients are proportional to air jet velocity (V_E). The increase in air velocity requires a significant increase in fan power and also causes an undesirable increase in the noise level of both fans and jets.

C. Air Temperature (T_A) : The air temperature to spray on the sample to be dried is a parameter that will directly affect the heat flow as it will change the difference between air and sample temperatures. At the same time, the energy used to transport the air to the T_A temperature will also affect the total cost [1].

D. Distance between Nozzles X_n : The distance between loops is directly related to the optimum free area (A_f). The free area (A_f) is the ratio of the exit area of the nozzle to the heat transfer surface area and is a basic parameter to be considered.

Figure 1 represents a typical jet flow. Hot air is sprayed from the nozzle to the stagnant area. As the distance from the output point increases, the momentum transfer between the jet and the environment causes the jet free boundary to expand and the constant velocity core to contract. The velocity profile is not constant throughout the jet cross section, the velocity decreases as the distance from the nozzle exit increases. Within the impact

zone, the flow slows down in the upright (Z) direction, accelerates in the cross (R or X) direction, and the zone defined as the "wall jet" occurs [1].

Fig. 1. Impinging jet flow

III. MATERIALS AND METHOD

The aim of this design is to perform temperature determinations of various points on the fabric of the jet drying apparatus, which are influenced by the heater power and the change of nozzle diameter to the drying time.

Xps plates were used as insulation material in the design.

Fig. 2. Insulation material (xps plate)

A wire cage is designed in the oven which is insulated from all the corners in order to hang the fabric to be dried to the size of the design.

Fig. 3. Wire cage used in experiment

The top of the oven is opened and a heater fan is installed to create the jet effect.

Fig. 4. Designed oven for drying

Three different nozzles were used to observe the effect of changing the diameter of the nozzle.

Fig. 5. Nozzles used in experiments

Fig. 6. Dimensions of oven

Mass change measurements during the experiment were made with Radwag PS/600/C/1 precision scale.

Fig. 7. Radwag PS/600/C/1 precision scale

- Before starting the experiments, the test setup connections are checked and then the precision scale and anemometry are checked for known values.
- The two-stage heater fan is operated at the initial air speed. Temperature measurement is performed with the aid of a thermocouple connected to the datalogger.
- Then, after the necessary time has elapsed, the fabric is measured with the precision scale. In order to ensure correctness, each experiment is repeated at least three times and the accuracy of the data is checked.

Fig. 8. Experimental setup

- After entering the first experimental data in to the computer , the parameters such as fan speed and nozzle diameter are changes according to the previously prepared workflow diagram and the experiments are completed.

•

IV. RESULTS AND CONCLUSIONS

During the experiments wet- dry mass, Reynold number , jet velocity, flow rate datas are obtained. The data are given in the following table.

TABLE XVI. DATA FOR 0.0109M³/S FLOW RATE

Flow rate=0.019 m ³ /s				
M _{wet} (gr)	M _{dry} (gr)	T _{amb}	V _{jet} (m/s)	Re
346	340	21,5	5,4	16500
380	358	21,5	10,2	22667
372	334	21,5	18,15	30250

TABLE XVII. DATA FOR 0.013M³/S FLOW RATE

Flow rate =0,013 m ³ /s				
M _{wet} (gr)	M _{dry} (gr)	T _{amb}	V _{jet} (m/s)	Re
347	342	21,5	8	24444
348	325	21,5	15,125	33611
358	320	21,5	26,88	44800

	D 5.5 cm	D 4cm	D 3cm
T ₁ (C°)	48,3	50	60
V ₁ (m/s)	5,40	10,2	18,15
T ₂ (C°)	52	60	73,6
V ₂ (m/s)	8	15,125	26,88
T _∞	21,50	21,50	21,50

Fig.9. Nu_{local} for 0.013 m³/sn

Fig.10. Nu_{local} for 0.019 m³/sn

Fig.11 Vjet -% Mass change for 0.013 m³/s

TABLE XVIII. NOZZLE OUTLINE DIAMETER TEMPERATURE DATA

Fig.12. Vjet -% Mass change for 0.019 m³/s

In this study, effects of nozzle diameter, and jet velocity changing on dyed fabric were examined. When the results were analyzed, it is seen that the increase of the jet speed positively affects the drying.

Rapidly reaching high temperatures of drying chamber negatively affected the experiment. In subsequent studies it is planned that more precise testing conditions be achieved by redesigning the heating, cycle rate and drying chamber dimensions.

Abstract— In this study, exhaust muffler system is simulated to determine the inlet temperature, velocity, pressure with assumed gas properties. Exhaust muffler system is important for engine efficiency about its temperature and back pressure. The noise is caused by gas velocity, so this parameter can be accounted in issue of noise pollution. In this study, commercial software ANSYS-CFX is used and Computational Fluid Dynamics (CFD) analysis is performed. Steady-state analysis is made to receive behavior of the system under assumed conditions.

Keywords-- Exhaust Muffler, CFD analysis, SST Model, CFX

XIII. INTRODUCTION

There are numerous studies about exhaust systems at different types of engines. Numerical studies are made by Computational Fluid Dynamics (CFD) methods by using different software.

Xu et al. is used Solidworks flow simulation to analyze theoretical design of a gasoline engine exhaust pipe. The simulation is made to obtain results that impact of designed exhaust system on engine power, emission and economy [1]. Rajadurai et al. simulate pressure drop CFD analysis for an exhaust muffler. In analysis glass wool is used as porous domain and assembled in muffler. One dimensional (1D) analysis is made via Star CCM+, the results are compared with experimental studies [2]. Mundhe and Deore use Star CCM+ software to analyze perforated muffler in automobile exhaust system. Reducing exhaust gas noise level and noise pollution are the objective of their study [3]. Tutunea et al.

perform CFD analysis on resistance exhaust muffler. Effect of internal flow field on muffler's performance at different designs and constructions is analyzed [4]. Xu and Zhou analyze flow field based on CFD for automotive exhaust system. It is researched that the influence of the distance between sub-muffler and the main muffler on flow field [5]. Tambe et al. analyze semi active exhaust muffler of an internal combustion engine. The exhaust noise generated from engine is reduced by using new construction of system [6]. Puneetha et al. use CFD analysis to study backpressure in single cylinder diesel engine's exhaust muffler. The gas velocity, airflow streamlines and pressure plots, back pressure are results of the study [7]. Tutunea et al. study on aerodynamic performance of the muffler with CFD method. This method is used to explore pressure distribution and pressure loss with modification of structure in the muffler [8]. Yao et al. conducts computational and experimental analysis of reactive muffler with structural optimization. Acoustic insertion loss and pressure loss is a result of aerodynamic CFD analysis. [9]. Pandhare et al. compare two muffler design wit simulation upon gas flow, back pressure, noise by using for ci engine. ANSYS Fluent software is used while simulating CFD analysis [10]. Mishra et al. make experimental and numerical studies on effect of exhaust muffler on back pressure, chamber velocity and temperature. Different muffler structures are analyzed with using different fuels. ANSYS Fluent software is used for numerical analysis [11]. Özkan et al. examine inner design effect on flow and acoustics properties of reactive muffler. Porosity and perforated length are assumed as various parameters to analyze their effects on acoustic properties and pressure drop. ANSYS CFX software is used for CFD analysis [12]. Om Ariara Guhan et al. use ANSYS CFX software to study on

pressure drop and uniformity index of chosen exhaust system. Based on the study, individual system contributions to the total pressure drop and flow uniformity have been analyzed and improvement areas of the existing system for better flow uniformity have been suggested [13]. Durat et al. make CFD and experimental analysis on thermal performance of exhaust system of a spark ignition engine. Three dimensional (3D) CFD analysis are made for whole exhaust pipe. The CFD results of analysis are in good agreement with experimental data [14]. The present work involves CFD study of the exhaust muffler system on gas velocity, pressure drop and temperature. Solid Works software is used for design purpose and system was computationally analyzed by using ANSYS CFX software.

XIV. MUFFLER DESIGN

When sound waves move, they have to suppress air, which creates friction. The more waves back and forth, the more energy they lose and the less noise they generate. The main purpose of the muffler is to cause the sound waves to lose energy and to reach the atmosphere with less energy, that is, less noise pollution. In general, the exhaust silencer includes the front pipe, the inner pipe, the expansion units, the resonance circuit and the tail pipe portions. Figure 1 shows a photograph of the exhaust silencer modeled in the study.

Fig. 1. Exhaust muffler photograph

The design of the exhaust muffler used in the study is drawn by SolidWorks software. Then this model is defined in the ANSYS-CFX to create a mesh structure. SolidWorks model can be seen in Fig. 2.

Fig. 2. Solid model of exhaust muffler

XV. CFD ANALYSIS

Analytical solutions to the Navier-Stokes (N-S) equations can be accepted to exist for only simple flows which are under ideal conditions. Equations are replaced by algebraic approximations to make calculations for complex flows in numerical methods. The calculation is carried out in ANSYS CFX software, which uses CFD method, the movement of the fluid is modeled by the N-S equations, the Reynolds averaged SST turbulence model. Workbench V15.0 CFD numerical codes are used for 3D analysis.

A. CFD Mesh

Mesh structure is generated by CFX tool from CAD model. In the paper; the exhaust muffler as seen in CFD analysis is divided into 1067305 tetrahedral elements and 209694 nodes for mesh generation. Average mesh skewness value is 0.2388. Mesh density in the resonance circuit is higher than in other regions.

Fig. 3. Mesh structure of geometry

B. CFD Model

N-S Equations are solved by the CFX codes which use finite volume method to discrete N-S Equations. Thermal analysis is chosen to get temperature results of flow. The analysis made is steady state, so the solver neglect the time derivative terms, so Mechanical Energy is $K = \frac{1}{2} U^2$. The

mechanical energy equation is derived by taking the dot product of U with the modified momentum equation: $\nabla(\rho U \otimes U) = -\nabla p + \nabla \cdot \tau + S_M$. Eq. (1) is the modified mechanical energy equation of CFX [15]:

$$\nabla \cdot (\rho U K) = -U \cdot \nabla p + U \cdot (\nabla \cdot \tau) + U \cdot S_M \quad (1)$$

Subtracting this equation from the modified total energy equation: $\nabla \cdot (\rho U h_{tot}) = \nabla \cdot (\lambda \nabla T) + \nabla \cdot (U \cdot \tau) + U \cdot S_M + S_E$ yields the thermal energy equation. Eq. (2) is modified equation from The Thermal Energy Equation of CFX [15]:

$$\nabla \cdot (\rho U h) = \nabla \cdot (\lambda \nabla T) + U \cdot \nabla p + \tau : \nabla U + S_E \quad (2)$$

The term $\nabla \cdot (U \cdot \tau)$ represents the work due to viscous stresses and is called the viscous work term. The term $U \cdot S_M$ represents the work due to external momentum sources and is currently neglected. With further assumptions discussed in a moment, the thermal energy equation is obtained. The term $\tau : \nabla U$ is always positive and is called the viscous dissipation. With further assumptions discussed in a moment, the thermal energy equation is obtained. Equation 3 is modified equation from the Thermal Energy Equation of CFX [15]:

$$\nabla \cdot (\rho U h) = \nabla \cdot (\lambda \nabla T) + \tau : \nabla U + S_E \quad (3)$$

Generally, Reynolds Averaged Navier-Stokes (RANS) equations are the modified average of unsteady N-S equation. Turbulence models base on the RANS equations [15]. While averaging, there is a need of additional terms like *reynolds (turbulent) stresses* in fluid. The analysis is made as steady-state condition, so modified Eq. (4) and (5) is the RANS transport equation [15]:

$$\frac{\partial}{\partial x_j} (\rho U_j) = 0 \quad (4)$$

$$\frac{\partial}{\partial x_j} (\rho U_i U_j) = -\frac{\partial p}{\partial x_i} + \frac{\partial}{\partial x_j} (\tau_{ij} - \overline{u_i u_j}) + S_M \quad (5)$$

Where τ is the molecular stress tensor. The mentioned *reynolds stress* can be expressed in Equation 6 as $\rho \overline{u_i u_j}$ [15]:

$$-\rho \overline{u_i u_j} = \mu_t \left(\frac{\partial U_i}{\partial x_j} + \frac{\partial U_j}{\partial x_i} \right) - \frac{2}{3} \delta_{ij} \left(\rho k + \mu_t \frac{\partial U_k}{\partial x_k} \right) \quad (6)$$

Shear Stress Transport (SST) turbulence model is used for simulation. Highly accurate predictions of the amount of flow and the onset separation under adverse pressure gradients are given by SST model. The transport of the turbulent shear stress is accounted by SST model [15]. The main reason is

that k- ϵ and k- ω models do not account for the transport of the turbulent shear stress. The proper transport behaviour can be obtained by a limiter to formulation of the eddy-viscosity. The relation between kinematic and dynamic viscosity is $\nu_t = \frac{\mu_t}{\rho}$. Equation 7 is the modified equation from the eddy-viscosity of CFX [15]:

$$\nu_t = \frac{\alpha_1}{\max(\alpha_1 \omega, S F_2)} \quad (7)$$

Where F_2 is blending function, ω is turbulent frequency, S is an invariant measure of the strain rate.

k is turbulent kinetic energy: $k = \frac{1}{2} \overline{u_i^2}$ Total enthalpy is given in Equation 8[15]:

$$h_{tot} = h + \frac{1}{2} U_i^2 + k \quad (8)$$

μ_t is turbulent or eddy viscosity. It is decided by The parameters of model. If time derivative is neglected RANS energy equation [15] becomes Equation 9:

$$\frac{\partial}{\partial x_j} \left(\lambda \frac{\partial T}{\partial x_j} - \rho \overline{u_j h} \right) + \frac{\partial}{\partial x_j} [U_i (\tau_{ij} - \rho \overline{u_i u_j})] + S_E \quad (9)$$

C. Boundary Conditions

There are four boundary conditions in the analysis. These are inlet, opening, adiabatic walls between expansion chambers and outside wall of muffler assumed at fixed temperature. In this study, there is no experimental work, so parameters in literature are used for boundary details. Inlet and opening boundary conditions and air flow path can be seen in Figure 4.

Fig. 4. Boundary conditions of exhaust muffler

D. Properties Of Exhaust Gas

Input conditions in the model are defined in simulations with data obtained from the study of Pandhare et al. Table I shows the inlet properties of exhaust gas [10]. The other

parameters, functions of gas temperature, are calculated from some equations given in study of Durat et al. The parameters are calculated from Equations 10-12 [14].

Table I. Inlet gas properties

Inlet gas properties	
Density	0.696 (kg/m ³)
Enthalpy	503400 (J/kg)
Temperature	500 (K)
Velocity	10.9748 (m/s)
Dynamic Viscosity	2.7e-5 (kg/m.s)

$$\rho = \frac{353}{T_g} \quad (10)$$

$$C_p = 962.097 + 0.1507 T_g \quad (11)$$

$$TC = 8.459 \times 10^{-3} + 5.7 \times 10^{-5} T_g \quad (12)$$

Where T_g is gas temperature, ρ is density, C_p is specific heat, TC is thermal conductivity. Calculated parameters can be seen in Table II.

Table II. Inlet other features

Thermal Conductivity and Specific Heat	
Thermal Conductivity	0.0369 W/mK
Specific Heat	1037.44 J/kgK

XVI.RESULT AND DISCUSSIONS

In this section the attention will be directed to the results of simulation. In Fig. 5-9 the detailed results about the velocity variation is presented. The highest velocity is observed at the inner pipe because of smallest diameter. At this maxima the velocity increases near 2 times of the inlet velocity.

The faster an exhaust pulse moves, the better it can scavenge out all of the spent gasses. So the guiding principle of exhaust pulse scavenging is that a fast moving pulse creates a low pressure area behind it. This low-pressure area acts as a vacuum and draws along the air behind it [11].

Fig. 5.Velocity contour of whole system

Fig. 6.Velocity vector

Fig. 7.Velocity streamline

In Fig. 6 and 7 the detailed velocity plots are seen respectively for entrance and exit zones. In the entry zone the velocity is higher at the corrugation way as expected. At the exit zone velocity becomes more uniform and the maxima is observed at the center.

Fig. 8.Velocity contour near to entrance

Fig. 9.Velocity contour near to exit

Fig. 11.Pressure gradient streamline

Fig. 12. Pressure gradient vector

Figs. 10-12 represent the simulated pressure values. Evaluating all figures at the same time it will be seen that, the vacuum helps better circulation of exhaust gas. The maximum pressure occurs near to the exit chamber.

Fig. 15. Temperature contour before out zone

XVII. CONCLUSIONS

CFD simulation of exhaust muffler is done via ANSYS CFX software. The CFD simulation software can be used in numerical analysis. Through aforementioned study, the results as exhaust muffler's pressure field, temperature field and gas velocity are obtained. Numerical analysis gives opportunity for engineers to have information about new designs of exhaust muffler systems before production.

As a future work, exhaust mufflers have different geometrical structures can be modeled and compared with each other. Velocity, pressure and temperature parameters can be assumed as variable for comparison of new designs. Whole exhaust system can be modeled to have information about interaction between engine efficiency and exhaust system.

Abstract— In this study, buckling analysis of isotropic steel plates was investigated in two parts, pre-buckling and post-buckling. It was used ANSYS® finite element package program for numerical solutions. Buckling analysis was performed for linear and non-linear condition of steel plates with square and circle holes in various sizes at center. The analytical solution of the plate buckling under pressure force, the results compared with the numerically found critical buckling values, are given graphically.

The values found were found to be compatible with the literature solutions. It has been observed that the maximum critical load values occur in the plates without geometry discontinuity. Parallel to the increase of the hole dimensions on the plates, critical buckling load values decreased and deformations increased.

Keywords— buckling, plates, critical buckling load ling

I. INTRODUCTION

Plates are building elements used in many sectors, especially air craft and ship industry. Buckling analysis of plates is of great importance for such work environments.

Steel was used as an isotropic material and the condition before and after buckling was analyzed for this material. The study by Timoshenko was taken as a reference for the pre-buckling condition [1]. The results of the study are verified using the ANSYS® program. For the post-buckling situation, Hu et al. has been studied [2]. The results analytically found in the study were compared to the results obtained with the ANSYS® program for the same problem. It was determined that the values found were compatible with the literature solutions.

Many researchers have investigated the buckling behavior of plates used as machinery or building elements in designs. Studies on the subject have concentrated on plaques, plates

and plates with various gap and delicate bars. Star, Y.O. And Günay, E., in case of St 37 steel rectangular plates supported by rectangular reinforcement elements, buckling analysis was studied [3]. Güngör, M., analyzed buckling of plates subjected to static loading in single and double direction [4]. The change of plate buckling loads with isotropic material and a rectangular space of different sizes in the middle by Zihni S. has been calculated for different boundary conditions [5]. Hacıoğlu, E. examined thermal spalling of plaques. Critical buckling conditions were investigated for isotropic and anisotropic plates with in-plane displacements inhibited in operation, depending on the uniform temperature change [6]. Cıvlek, Ö. Et al. Two and three-dimensional bending, buckling and free vibration analysis of homogeneous and isotropic rectangular plates by differential quadrature method [7]. Tekin, A. investigated the problem of rectangular thick plaque buckling of delaminated sandwich. The effect of plate material and geometric parameters on critical values has been investigated [8]. Özyigit, P. and Sofiyev, A. have examined the thermal buckling analysis of shallow spherical shells [9]. Bingöl et al. They experimentally and theoretically investigated the buckling behaviors of circular plates made of aluminum and composite materials [10]. Virtual et al. Critical buckling stresses of isotropic and orthotropic rectangular thin plates supported by simple support and transversely supported under shear loading were investigated [11].

Linear and nonlinear buckling analysis was performed for steel plates with dimensions of 10x10, 20x20 and 30x30 mm² and 200x200x2 mm³ dimensions with holes Ø10, Ø20 and Ø30 mm in diameter at the center of the study. Buckling analysis on isotropic steel plates; Pre-buckling and post-buckling.

II. MATERIALS AND METHODS

As a consequence, the deformation characteristics of many elements subjected to loading vary, and this is called buckling,

in which the deformation mode becomes unstable and the system results in another stable state search. The steady state of the system is explained by the predictability of the behavior of the load effect of that system and the inability of the system to predict how its behavior will be unstable.

The graph obtained from the buckling test is shown in Fig.1. Linear analysis for post-buckling behavior of the system and non-linear analysis for post-buckling behavior is also required. The small displacement theory of the plates in the linear analysis and the large deformation theory of the plates in the nonlinear analysis are used. The difference that separates these two theories is the difference of the deformation equations. In linear analysis, the plate changes in

the non-linear analysis, while the middle plane does not change shape.

A. Linear Analysis (Theory of Small Deformations)

The derivation of the plate differential equation can be started by grouping the loads carried by the thin plates.

These;

- Internal moments and shear forces
- Axial and central shear forces

Such a grouping makes it easier to see and understand the force and moment balances on the differential plate element.

Fig. 9. Buckling test graph [12].

Taking into account the balance of internal moments and shear forces and the balance of axial and central shear forces, the general plate equation (1) used in linear buckling analysis is obtained.

$$\frac{\partial^4 w}{\partial x^4} + 2 \frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = \frac{1}{D} \left(q_z + N_x \frac{\partial^2 w}{\partial x^2} + N_y \frac{\partial^2 w}{\partial y^2} + 2N_{xy} \frac{\partial^2 w}{\partial x \partial y} \right) \quad (1)$$

B. Nonlinear Analysis (Large Deformation Theory)

The Small Deformation Theory of Plates' assumes that there is no deformation in the middle plane of the plate. However, as a consequence, the plaque element bends, and as a result, an elongation occurs in the middle plane. The "Great Deformation Theory of Plates" also accounts for this prolongation of the plaque in the middle plane. This theory was developed by von Karman [14].

$$\frac{\partial^4 w}{\partial x^4} + 2 \frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = \frac{t}{D} \left[q_z + \frac{\partial^2 \phi}{\partial y^2} \frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 \phi}{\partial x^2} \frac{\partial^2 w}{\partial y^2} - 2 \frac{\partial^2 \phi}{\partial x \partial y} \frac{\partial^2 w}{\partial x \partial y} \right] \quad (2)$$

C. Plain Critical Load Account Exposed to Two Side Pressing:

As shown in Fig. (1) is applied to the critical buckling stress, if it is subjected to a uniformly distributed compressive force from two sides of a simple supported rectangular plate of length a, width b;

$$\sigma_{iakr} = \frac{D \pi^2}{t b^2} \left(\frac{mb}{a} + \frac{n^2 a}{mb} \right) \quad (3)$$

equality is found.

The analytical formulation of Timoshenko's critical stress value of a simple supported plate subjected to pressure forces at two ends is given in Equation 3. In the form;

σ_{iakr} : The analytical critical stress value (MPa) for the isotropic material, m is the number of waves along the x-axis, n is the number of waves along the y-axis, a is the plate length, b is the plate width, t plate thickness (mm), D: Bending stiffness.

$$D = \frac{E t^3}{12(1-\nu^2)}$$

Fig. 10. Plate exposed to pressure force at bothends.

In this study, in order to prove the correctness of the applications made, the solutions of the eigen problem and the nonlinear problem were solved and compared with the studies in the literature. Then, in the plate of dimensions 200x200x2 mm³, circular holes with dimensions of 10x10, 20x20 and 30x30 mm² and Ø10, Ø20 and Ø30 mm were drilled in the middle, and linear and nonlinear buckling analysis was performed for isotropic steel plate.

D. Solving the Eigenvalue Problem for Isotropic Materials

If the desired mode of buckling is specified, the appropriate buckling stress is obtained by writing the appropriate values of m and n, that is, a plurality of critical buckling values can be calculated by changing the buckling characteristics.

The steel plate was selected in dimensions of 200x200x2 mm³. Steel Elasticity Module $E = 210,000$ MPa, Poisson's Ratio $\nu = 0,3$.

In the ANSYS® program, E and ν values for a x b x t dimensions are entered and a simple support boundary condition of four edges is applied as shown in Fig.3. The end element model Shell 181 type contains 400 elements and 441 nodes.

A total of 8 buckling modes were investigated for different values of m and n. The deformations occurring in each plane versus the eight mode values on the plate as a result of buckling are shown in Table 1. The analytically found critical stress results and the results found with the ANSYS® program are given in Table 1 as a comparative example.

Fig. 11. Finite element model for applied boundary conditions and force.

TABLE XIX. % ERROR RATE BETWEEN σ_{iakr} AND σ_{ANSYS}

$m \times n$	σ_{ANSYS} (N/mm ²)	σ_{iakr} (N/mm ²)	% Relatif hata oranı
1x1	76.225	75.920	0.40
2x1	119.92	118.625	1.08
3x1	217.05	210.889	2.84
2x2	308.585	303.680	1.59
4x1	362.525	342.826	5.43
3x2	364.84	356.402	2.31
1x2	485.685	474.500	2.30
4x2	496.035	474.500	4.34

E. Nonlinear Problem Solution for Isotropic Materials

After the solution of the true problem, the nonlinear problem was solved. The work that Hu et al. [2] conducted analytically for nonlinear problem solving is discussed [2]. The results analytically found in this study were compared with the results obtained with the ANSYS® program for the same problem.

Hu et al. Obtained the results shown in the following graph of a nonlinear analysis of square plates subjected to compressive forces in two directions under simple support boundary conditions.

Fig. 12. Change of the ratio $\sigma_{ort} / \sigma_{cr}$ on the isotropic plate with respect to the ratio of δ/t [2].

Fig. 13. Change of the ratio $\sigma_{ort} / \sigma_{cr}$ on the isotropic plate with respect to the ratio of $\varepsilon / \varepsilon_{cr}$ [2].

In this study, the analytical results of the nonlinear analysis for square plate with dimensions of 200x200x2 mm³ are compared with the numerical results obtained with the help of the finite element method and Figures 4 and 5 are given.

F. Effect of the hole in the plate center to buckling

The presence of holes in the platens is a notch effect. Linear and nonlinear buckling analyzes on steel plates with square and square holes have examined the effect of hole size and geometry on critical buckling load. Based on the solution for the plate which does not contain discontinuity in the previous section, holes were opened on the plate geometry and re-networked.

Fig. 14. Finite element model and boundary conditions for square hole plate.

Fig. 15. Finite element model and boundary conditions for circular perforated plate.

The variation of the critical buckling load for the linear analysis with the hole sizes is shown in Fig.8.

Fig. 16. Change in critical buckling load for circular and square hole plates with hole dimensions.

Fig. 17. Load-strain diagram of nonlinear buckling analysis for square hole plate.

In the nonlinear analysis of the same models, the model was subjected to a load at twice the critical buckling load obtained from the linear analysis and the displacement results in the z direction were obtained. The results of the nonlinear buckling analysis obtained for the steel plate are shown in Figure 9 and Figure 10.

Fig. 18. Dairesel delikli plak için non-lineer burkulma analizi

RESULTS

- Figure 8 shows that the highest critical load value occurs in the plate without holes. Figure 9 and Figure 10 show that as the hole measurements increase, the critical load decreases as the cross-sectional area of the plate decreases and the amount of deformation increases.

- Critical buckling loads for plates with Ø11 mm circular and 11 × 11 mm² square holes were found to be approximately the same values. However, it was seen that the hole geometry in the smaller scale had no effect on the critical buckling load.

- As the hole measurements grew, the critical load decreased as the cross-sectional area of the plate decreased. The buckling critical load values are found to be larger in the

circular hole models than the square hole models, but all of these values are lower than the critical load values obtained for the non-hole geometry.

Abstract— In the present paper, thermal and mechanical behavior of a welded joint is analyzed by using ANSYS commercial software, which works base on finite element method. The transient temperature distribution on the welded plate and the displacement and von Misses stress are the extracted results from the analysis. As the plate material two different steel alloy are used; DP600 and DP1000. The welding material is the St37. The initial temperature is assumed to be 300 K, whilst the temperature of welded zone is 1773 K.

Keywords—thermo-mechanical analysis, couple field analysis

III. INTRODUCTION

As is known a welding joint is a point or edge where two or more pieces of metal or plastic are joined together. Butt, corner, edge, lap and the tee are the five types of welding joints. The welding is not only a mechanical application but also an important thermal problem, since the temperature differences affects the mechanical behavior of the material. In literature there have been many papers including thermo-mechanical analysis. Some of them can be summarized as follow.

Teng et al. [1] performed a numerical analysis to describe the thermomechanical characteristics of the T-joints in fillet welds. The effects of flange thickness, welding penetration depth and restraint condition of welding on the residual stresses and distortions were discussed. Teng et al. [2] also analyzed the thermos-mechanical characteristics of welding sequence in single-pass, multi-pass butt-welded plates and circular patch welds. This was achieved by performing thermal elastoplastic analysis by using commercial software ANSYS. Barsoum and

Lundback [3] modeled 3D welding material and performed some tests. The residual stress predictions showed good agreement with the experimental measurements.

Lindgren [4] used finite element simulation in order to predict temperature fields, residual stresses and deformation due to welding in 2D and 3D geometries. Kong et al. [5] predicted the temperature field and thermally induced residual stress in the hybrid laser–gas metal arc welding process. Zain-ul-abdein et al. [6] investigated the effect of metallurgical phase transformations upon the residual stresses and distortions induced by laser beam welding in a T-joint configuration using the finite element method. Long et al. [7] investigated distortions and residual stresses induced in butt joint of thin plates using metal inert gas welding.

In this study, a butt welded plate is analyzed numerically. The temperature, displacement and stresses after because of the welding joint are obtained. The problem is transient and the total solution time is 2 hours. The initial temperatures are 1773 K and 300 K respectively for welded plate and normal plate. The stress and displacement analyzes are performed base on the elastic material behavior using ANSYS-Structural.

II. PROBLEM DEFINITION

It is considered that an electric arc welding has been applied to the DP plates (DP600 and DP1000) in a single pass. The butt welded joint is simulated two dimensional (Fig. 1).

The thermal and mechanical properties of the welding material depending on the temperature variation is presented in Table 1. Similarly, the thermo-mechanical properties of the base materials DP600 and DP1000 are listed respectively in Table 2 and 3. Finally the chemical composition of the two base materials are exhibited in Table 4.

III. NUMERICAL ANALYSIS

The ANSYS commercial software has a large class of coupled field analysis problems in the multi solver mode. In the presented couple field analysis there are two physics; thermal and structural, and each physics is created as a field with an independent solid model and mesh. Transient heat conduction problem is solved to obtain the temperature variation 2 hours after the welding. As told before, the initial temperature of base material and welding material is respectively 300 K and 1773 K. It is assumed that there is natural convection on the top side of the material having heat transfer coefficient as $13 \text{ Wm}^{-2} \text{ K}$ and bulk temperature as 300 K.

In the thermal model the element type for the 2D simulation is *Quad 4 node 55*, namely *PLANE55*. A mesh accuracy is obtained as the preparation of the simulation, and 0.5% accuracy is obtained at about 19706 elements and 20038 nodes.

In the present analysis, the structural element type is *PLANE182*. The bottom line is assumed to be a fixed support as shown in Fig. 2. Temperature distribution at certain time steps, obtained from the thermal analysis is saved and then used as boundary conditions in the structural analysis. Finally, the mechanical behavior of the welding material is assumed to be elastic.

Fig. 2. Boundary conditions for the structural analysis [8]

V. RESULTS AND DISCUSSIONS

The transient temperature distribution on the whole plate, in case of base material is DP600, is given in Fig 3. By checking the temperature contour plots, it can be seen that, the temperature has the minimum value 400 K on the edge sides of the base material at the last set, and 405 K at the welding point, which means the plate is still warmer than the ambient air. Fig 4 presents the temperature contour in the case of using base material DP1000. If the attention is paid to the last time step, it will be seen that the lowest temperature is 402 K at the edges of the base material, 405 K at the welding point. Comparing two base materials it is clear that in the case of using DP1000 the edge of the base material is quite warmer than the case of using DP600. This result can also be seen in the temperature versus time graph in Fig. 5.

Fig. 3. Temperature distributions on the DP600 plate (K)

Fig 4. Temperature distributions on the DP1000 plate (K)

Fig. 5. Temperature versus time variation on a point on the welding joint

Now it is the time to present some structural analysis results and discuss about them. First result is the deformed and un-deformed shape of the plate because of the welding. In Fig 6a and 6b the deformed and un-deformed shapes of the plates respectively for DP600 and DP1000 are presented. Although both figures look like same, the displacement is quite higher for DP600 than that of DP1000.

Fig. 6. Deformed and un-deformed cases of the plates

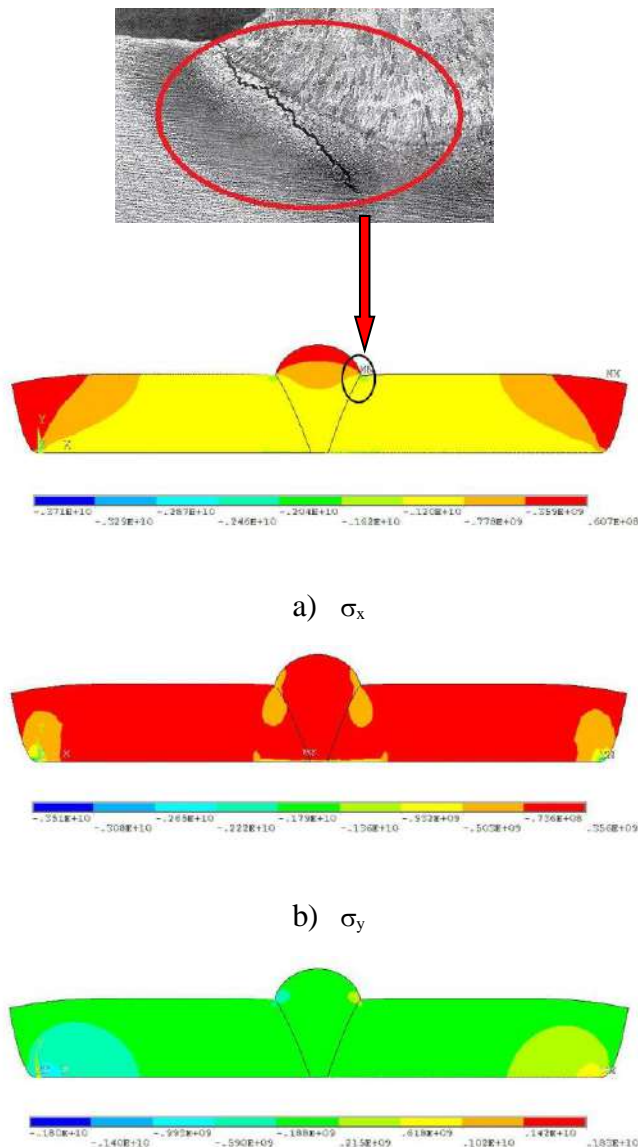

In Fig 7(a-c) and 8(a-c) the stress analysis of the plate is presented. In Fig 7a, the stress along the x-direction, σ_x is shown. It is seen that the maximum stress is observed at the top and edge sides, but seems to be uniform at the rest of area. The σ_x is nearly symmetric at the plate. Absolute maximum values are lower than the absolute minimum values. The interface between the base and welding material

are the points under the risk of fracture because of the high σ_x values seen there.

The stress on especially the welding joint is the probability of the fracture on that point. It is well described with the photo on Fig 7a.

In Fig 7b, the stress along the y-direction is shown. The values for the stress look like same with the σ_y values. But it should be noted that, the min and max values are not same.

If we quickly blink at the Fig 7c, it will be seen that the σ_{xy} namely the shear stress is as important as the σ_x and σ_y because of the values.

c) σ_{xy}

Fig. 7. Structural analysis for DP600

In Fig 8(a-c) the contour plots of the σ_x , σ_y , σ_{xy} are presented. General trend is nearly same to the Fig 7(a-c), that's to say, to the DP600 base material, except for the values. All of the stress values regardless of the type are lower in the case of DP1000 than that of DP600.

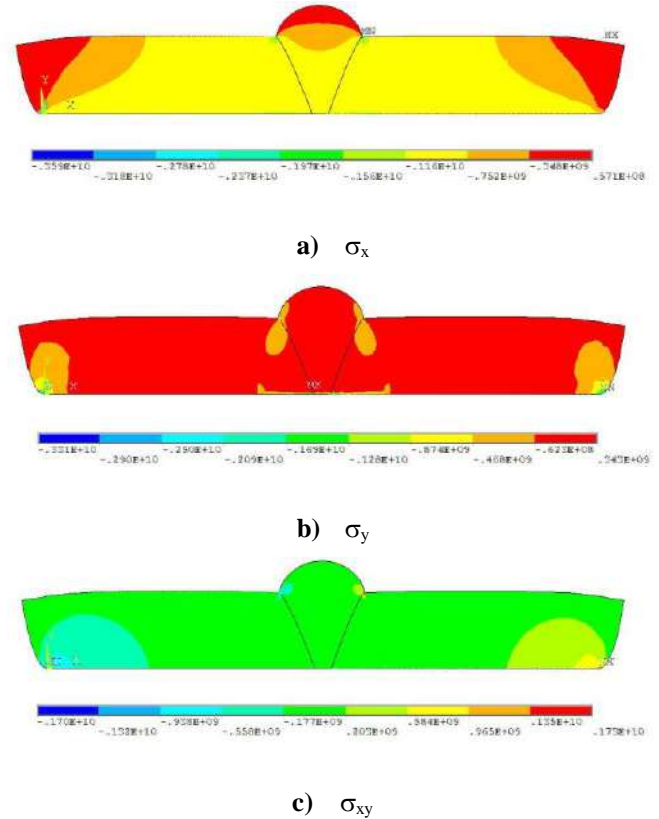

Fig. 8. Structural analysis for DP1000

The three stresses; σ_x , σ_y and σ_{xy} at a selected node on the DP600 and DP1000 base materials are exhibited respectively Fig 9a and Fig 9b. The values of three stresses show that shear stress has nearly the maximum values of all. It can be said that σ_{xy} cannot be neglected anymore.

Final plot (Fig 10) is another comparison of the base materials. It shows the σ_{xx} for two base material. DP1000 seems to have higher values than DP600 does.

a) DP600

b) DP1000

Fig. 9 Comparisons of the stresses

Fig. 10. σ_{xx} for DP1000 and DP600.

VI. CONCLUSIONS

In this study, a two-dimensional couple field analysis of an electric arc welding application including thermal and structural effects is analyzed by using commercial software ANSYS. Transient thermal distribution on ST-37 plate is obtained for all time intervals until it reaches 7200 s. In accordance to this the temperature distribution, deformation and the stresses σ_x , σ_y and σ_{xy} are found. The major conclusions can be listed as follows:

- ✓ The minimum temperature on the plate at the last time step is lower for DP600 than that of DP1000.
- ✓ The three stresses σ_x , σ_y and σ_{xy} are all lower for the case of DP1000, which can be concluded that DP1000 has less probability of fracture than DP600.
- ✓ The displacement is also lower for the base material DP1000.

Abstract—In manufacturing industry, particularly which involve free form surfaces, formation of burr on the exit surface is a cost effective problem, and hence its minimization is an important goal in drilling process. The relationship between drilling parameters and burr formation has been investigated in variety of perspectives. It has been mentioned that vibration has a relation to the rate of burr formation. In this study the relation of machine vibration to the burr's height was investigated. Drilling experiments were conducted on a piecework with a free form surface where the drill exit surface was at 15°, 30° and 45° tangential angles. It was observed that average power of longitudinal or thrust vibration signal had an inverse relation to the measured burr's heights, while feed rate had a positive relation when spindle run at 2800 rpm.

Keywords: free form surfaces, vibration, burr formation, drilling

I. INTRODUCTION

In modern manufacturing industry such as medical, aerospace and automotive variety of structures with free form surfaces are widely used. Drilling processes made on such free form surfaces results with some burrs on the exit surface of material. Removal of burr formation in drilling process of free surface materials causes additional operations and costs. Therefore, reduction or totally abolition of burr has become an important objective in drilling process. In order to achieve this, it is necessary to investigate the effects drilling parameters on the formation of burrs and estimate the relationship going between them. It is considered that vibration turned up during drilling also has a relation to the formation of burr. There are some studies in the literature that investigate the relationship of vibration to other drilling parameters and burr formation. Among these studies some examples are:

Roukema and Altintas [1] proposed a 3D dynamic model for drilling contained rigid body motion, torsional-axial and lateral vibrations. Their model allowed virtual testing of various drilling scenarios in time domain and it ensured to predict the hole oversize because of grinding errors on the tool.

Sevim and Genc [2] analyzed the vibration occurred due to cutting forces in drilling with CNC milling machine. They used Al 7075 work piece for their study. They offered low feed rate and high spindle speed to reduce the vibration in drilling Al 7075.

Chang and Bone [3] developed a model to predict exit surface burr height which occurred in vibration assisted drilling (VAD) and conventional drilling of Al 6061-T6 materials. Their model included a hypothesis expressing that only the positive part of the thrust force is responsible for the formation of burrs. They found the suitable vibration frequency for drilling by their approach.

Okamura et al. [4] searched for an interaction between vibration conditions and chip formation, burr formation and drilling temperature on drilled Titanium alloy specimen. They found that in low-frequency vibration, the drilling temperature decreased and exit burr height and burr width reduced.

Adachi et al. [5] by using vibratory drill compared the cutting characteristics of vibratory drilling and conventional drilling. They asserted that the burr size in low frequency vibratory drilling was smaller than burr size occurred in conventional drilling.

Azarhoushang and Akbari [6] studied on ultrasonic assisted drilling and compared it with conventional drilling in terms of cylindricity, circularity, surface roughness and hole

oversize. According to their idea, because of ultrasonic impact action, thrust force reduces and thus plastic deformation decreases, and so smaller chips and burrs occur.

Li et al. [7] studied on vibration drilling of laminated composite materials. They developed a step multi-element varying-parameter vibration drilling model and thus they lowered the exit burr height to 41.55% using this model.

Chang and Bone [8] carried out an experimental study for lowering the size of burr in drilling. They designed a work piece holder which vibrated at ultrasonic levels to set an ultrasonic assisted drilling system. The results obtained with the use of this system revealed that as the vibration frequency became higher than a certain limit, the burr size became small. This technique was said to be more effective than conventional drilling.

Heisel et al. [9] used an ultrasonic assistance in drilling of short holes. They measured the vibration amplitude with and without load by using the change of stimulation power. They reached minimum burr size in case of there was no stimulation but when the power started raise the burr size tended to decrease.

Kadivar et al. [10] drilled Al/SiCp metal matrix composites with ultrasonic assisted drill. In this study, a comparison was made between workpiece vibration system and tool vibration system from burr height, drilling force sand surface roughness of views. When vibration was applied to workpieces, higher thrust force, smaller burrs and smaller surface roughness were achieved compared to conventional drilling.

From the information given above it is understood that there is a relation between vibration and burr formation in drilling process. The purpose of this study is to demonstrate the relationship between vibration and exit burr height at the drilling of free-form surfaces where the drilling forces are much more complex.

II. MATERIAL AND METHOD

For drilling experiments, Al 7075 material, which is also widely used in studies in the literature, was selected. The chemical composition and mechanical and physical properties of Al-7075 alloy are tabulated in Tables 1 and 2[11].

CHEMICAL COMPOSITION OF Al -7075		PHYSICAL AND MECHANICAL PROPERTIES OF Al -7075	
Element	Chemical Composition (wt.%)	Parameters	Values
Al	Balance	Density (g/cm ³)	2.81
Zn	5.1-6.1	Hardness (HB)	60
Mg	2.1-2.9	Ultimate tensile	228

Cu	1.2-2.0	strength (MPa)	
Fe	0.5	Elongation at break (%)	16
Si	0.4	Tensile yield strength (MPa)	103
Mn	0.3		
Ti	0.2		
Cr	0.18-0.28		
Others	0.15		

A curve which contain 15°, 30° and 45° tangential angles, was created using the B-spline theory [12]. A free form surface was designed by means of Solid Works software from the prepared curve. An Al 7075 plate was milled with CNC to obtain a workpiece with a free-form surface.

Since the workpiece has a free-form surface, its thickness varies along curvature of surface. Thus, the channels were opened on the flat surface of the workpiece to provide uniformity between tool feed distances. The channels and holes are shown in fig. 1.

Fig. 1. The workpieces solid model with channels and holes.

The drilling experiments were conducted by HSS drilling tools which have 118° point angle and 7,5 mm diameter. Each tool was used in only one drilling operation. Drilling operations were performed in dry conditions.

Vibration and acoustic emissions were measured by Vibra ZEB VM-7D+ vibration meter during the tests. The vibration sensors built within this device recorded vibrations come up on longitude, transverse, vertical axes. The experimental set up with vibration meter is shown in Fig.2. The signals were recorded at 2048 (sps) sampling frequency.

Fig. 2. The experimental setup.

The images of workpiece were captured by scanning with David s3-3 3D scanning device. Using these 3D data with GOM Inspect software. Burr heights were measured by the method widely used in the literature [13-15]. For each hole, the arithmetic average of the burr height values measured from four points as shown in Fig.3.

Fig. 3. Shows how burr height was measured.

In order to detect a clear correlation between vibration signal and burr heights the vibration signals filtered by a second order band-pass Butterworth filter with $f_L=40$ and $f_H=53$ Hz. cutoff frequencies. The central frequency of filter was set in such a way that to match with the spindle speed $(2800 \text{ (rpm)}/60 \text{ (sec)}) = 46.6 \text{ Hz}$. In this way the other remaining minor spectral components caused by tangential frictions were excluded. Also the spectra of vibration signals were achieved by using Fourier transform given by

$$S(f) = \int s(t) \exp(-j2\pi ft) dt \quad (1)$$

to analyze the signals in terms of their spectral contents. The obtained filtered vibration signals and signals spectrums are shown in Fig. 4 (a, b and c) for each particular feed rate and tangential angle of exit surface mentioned above. Each panel of the Figure contains longitudinal, transverse and vertical vibration signals which are labeled on the Figure. As can be seen from the Figure for all types of vibration the peaks of signals tend to increase with the increase of feed rate, however it was noticed that the best parameter which could be derived for correlation was the power of longitudinal vibratory signal given by

$$P = \frac{1}{N} \int_1^N \widehat{s(t)}^2 dt \quad (2)$$

where, $\widehat{s(t)}$ is the filtered version of $s(t)$ and N is the number of data points averaged. This correlation may not be a perfectly linear, but seems to be a reasonable one to be used in controlling the drilling system to reduce the burrs' rates.

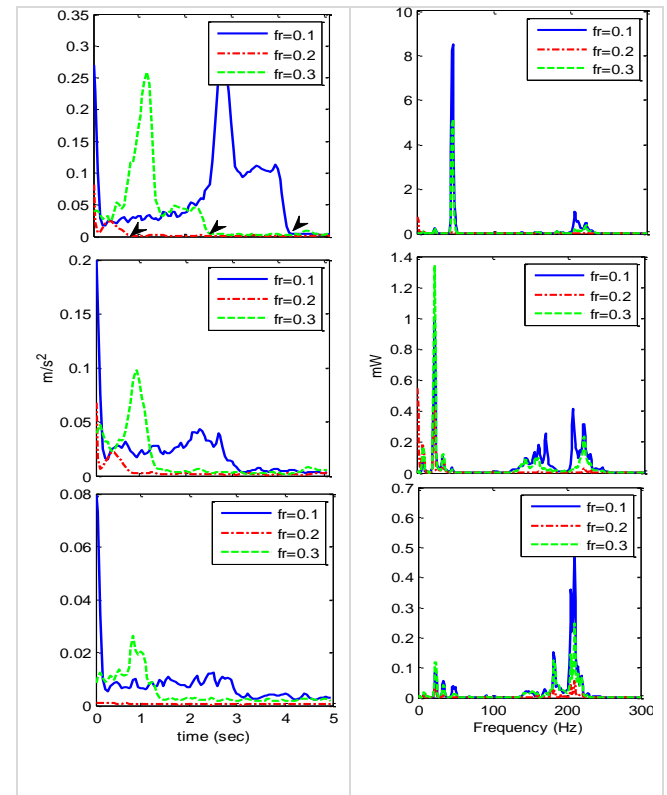

Figure 4. The vibration temporal and spectral signals for 15° exit surface, Longitudinal (upper panel); Transverse (middle panel); vertical (lower panel); Arrows show the exit time of drill from surface.

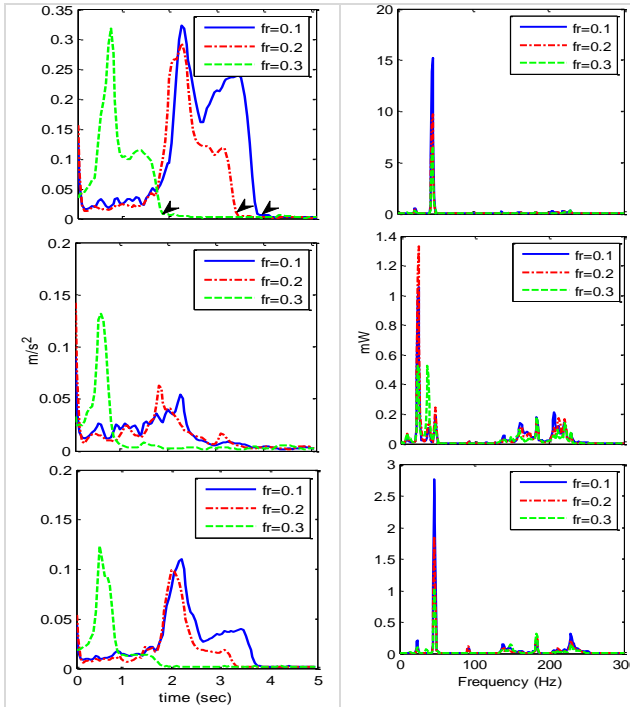

Figure 5. The vibration temporal and spectral signals for 30° exit surface, Longitudinal (upper panel); Transverse (middle panel); vertical (lower panel); Arrows show the exit time of drill from surface.

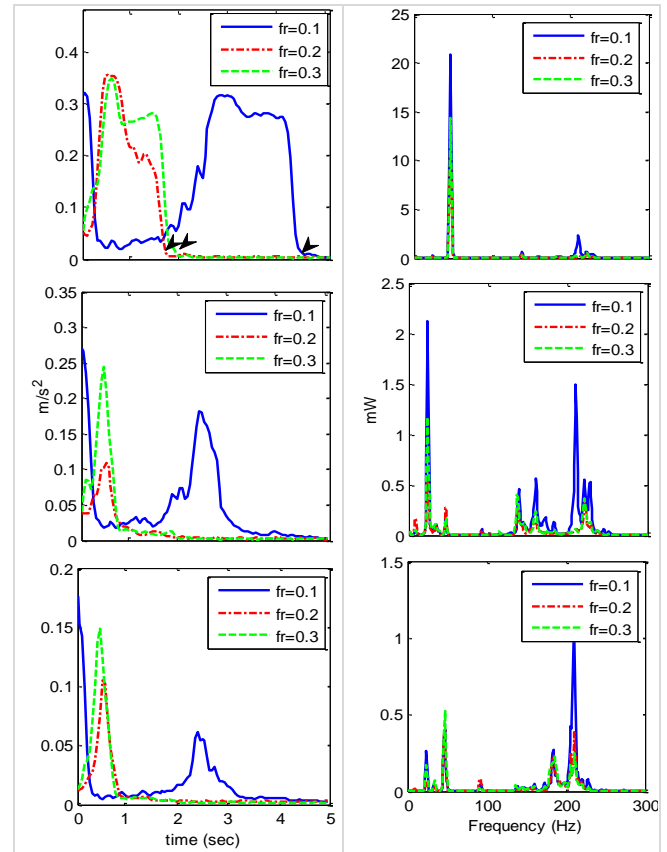

Figure 6. The vibration temporal and spectral signals for 45° exit surface, Longitudinal (upper panel); Transverse (middle panel); vertical (lower panel); Arrows show the exit time of drill from surface.

III. RESULT AND DISCUSSION

A solid model having free form surface shown in Fig 1. was drilled with a tool having 2800 (rpm) spindle speed in such a manner that the exit surfaces were with 15°, 30° and 45° tangential angles. The obtained vibration signals are processed as mentioned in previous section and displayed in Figure 4 (a, b and c). The obtained results in this particular study are tabulated in TABLE III. It is found that the burr heights increase with the increase of feed rate while the longitudinal vibration signal's average power decreases. That is, the signal's power had an inverse relation to the measured burr's heights.

In order to arrive at a significant conclusion in relation to the impact of vibration on the burr's characteristics on uniform exit surfaces a few studies published in literature was analyzed in this perspective. Chang and Bone [3] investigated the impact of vibration on drilling process, and demonstrated that longitudinal vibration assisted drilling performs minimum burr rate compared conventional methods. They have found that burr height reduced to approximately 0.085 microns at 8 KHz thrust vibration. It had also been demonstrated that thrust force considerably reduces with

vibratory drilling [5] and remains almost the same or very slightly reduced levels with the increase of elongation.

In another explanatory study it had been mentioned that ultrasonic vibration in feed direction at 21 KHz could improve the hole quality (10 microns peak) considerably [6]. In that study a quality improvement up to 60% had been achieved. It had been shown that average burr height reduces to 0.4 mm at 20 kHz and 4 microns (pk-pk) vibration amplitude under (3.18mm diameter drill, 4000RPM, 1.90 mm/s feed rate) conditions [8].

Kadivar et al. [10] analyzed the influence of ultrasonic assisted system on finished surface quality in terms of burrs' height values. They had demonstrated the system for tool vibration and workpiece vibration and compared the obtained results. They revealed that workpiece vibration was better, particularly when vibration was applied to workpiece higher thrust force and smaller burr rates were found.

From the above analytical information it can be considered that a vibration (in thrust direction) assisted drilling process resembles to a percussion drill applied on rough surface. Therefore the increase of quality of finished exit surface with VAD system should be quite natural as compared to conventional drilling process.

The proportionality of burr's height to feed rate acquired in this study is in line with the results found in the literature [16,17]. The decrease of burr height with the increase of average power of longitudinal vibration signal can be considered as a good association. This inverse correlation established between average power of longitudinal vibration signal and burr's height can also be linked to the information found in the literature. Here, the power of longitudinal vibration was considered rather than transverse or vertical signals' powers, because of that CAD systems had been developed based on the vibration imposed in thrust direction. With the application of this systems, as discussed above, the drilled exit surface roughness increased with the increase of vibration amplitude up to a certain limit. Our finding is along the lines of this information. The relation of vibration of drilling machine to feed rate for uniform surfaces has somewhat been demonstrated in [2] and the displayed results are similar to ones found in this study. The proportionality of average signal power mentioned here, has not been sufficiently discussed in the literature. Therefore it needs to be considered by other studies which to be conducted in the future.

TABLE III. EXPERIMENTAL PARAMETERS

Hole Number	Exit Surface Angle(°)	Feed Rate (mm/rev)	Average Burr Height (mm)	Mean Power of vibration signal(mW)
1	15	0.1	0.0847	1.20
2	15	0.2	0.2012	0.0044
3	15	0.3	1.3168	1.28
4	30	0.1	0.2943	1.99
5	30	0.2	0.4172	1.55
6	30	0.3	1.4269	1.75

7	45	0.1	0.5115	2.48
8	45	0.2	0.6427	2.27
9	45	0.3	1.5624	3.81

IV. CONCLUSIONS

In this study the relation of machine vibration to the burr's height was experimentally investigated. From the experiments conducted on a free form piecework (at 15°, 30° and 45° tangential angles) an inverse correlation between mean power of longitudinal vibration signal burr's heights as well as a positive relation with feed rate were found out, when spindle speed was 2800 rpm. These findings can be confidently associated to the information found in the literature [6, 8,10]. However the proportionality mentioned here has not been sufficiently discussed in the literature, and therefore remains to be further investigated.

Abstract—In this study the mechanic properties and behaviours of the most commonly used in industry and works under various environmental influences hollow circular composite shafts were examined experimentally and numerically. In addition for circular hollow composite shafts glass is used as a fiber material and epoxy resin is preferred as a matrix material. The composite shafts that are in different lengths such as 80mm, 200mm, 250mm and one inner (Dinner=12mm) and outer (Douter=17mm) diameters are used for three point bending test. The composite shafts were manufactured in different orientation angles ($\theta=45^\circ, 60^\circ, 75^\circ, 80^\circ, 88^\circ$) by using filament winding method. The bending behaviour of manufactured circular hollow shafts were tested and repeated for each specimen. As a result of numerical and experimental analyses, it was observed that the bending and torsion behaviours of hollow circular composite shafts vary depending on the orientation angles. Additionally, FEA (finite element analysis) model of the hollow circular glass/epoxy shafts was created and analyzed by using ANSYS workbench. Results of the finite element analysis are compared with values of the bending stress and the modulus rupture in torsion (RT) obtain by experimental tests. The experimental and numerical analysis results were found to be close to each other.

Keywords—Composite shafts, Filament winding, Orientation angle, Three-point bending test, Torsional test

I. INTRODUCTION

In this study, glass/epoxy composite material were used in the three point bending and torsional test. Amounts of bending stress and the modulus rupture in torsion (R_T) of the composite material were examined experimentally and numerically. Moreover, the effects of orientation angle was studied on the bending stress and the modulus rupture in torsion (R_T). And also the novelty of the paper is the first time in that dimensions and load materials are used.

Apart from the fact that shafts, which are used in every field of technology, are among the most important power transfer elements. They are exposed to tensile, compression, bending and torsional stresses due to their operational characteristics. Since shafts transmit power from one machine element to the other, they can be exposed to torsional stress,

which is the most hazardous one of all. Since shafts are exposed to bending due to the elements found on the top of them as well as being exposed to torsion due to rotating, their constructions, designs and calculations are generally made according to combined stresses. However, hollow shafts are usually preferred in the cases in which lightness is required. For this reason, hollow shafts are used in automotive industry and space industries. The following studies were found when a topic-related literature review was made. The variation of the foam solidification rate is another strategy for controlling the micro-and macro-structure. For example, a high cooling rate could decrease the micro-pores and grain sizes in the cell walls that have negative effects because they promote stress concentration and thereby crack initiation. Recently, the potential use of integral-skin foams as stiffening elements inserted in thin-walled tubes (called ex situ FFTs) was evaluated [1]. The deformation mode of ex situ FFTs is a combination between individual components, characterised by failure due to propagation of a main crack visible on the outer surface of the tube, a behaviour that is typical for the individual integral-skin foams. This is a well-known behaviour due to constrained deformation of the foam that does not allow to form a plastic hinge. Therefore, in case of materials with low ductility the failure of the tube is easily reached [2]. Yu et al. Studied the impact behaviour and failure mechanism of sandwich beams and optimized the Gibson model was proposed. Quasi-static three-point bending tests at different temperatures were carried out for sandwich beams with aluminium face sheets and closed-cell aluminium foam core in previous study of ours [3-9]. Qin and Wang derived a new yield condition including the effect of the core strength and studied the finite deflection response of a slender sandwich beam with axial restraints or fully clamped transversely loaded by a flat punch. The effects of the elastic properties of the face sheets and aluminium foam cores on the failure modes are not taken into consideration [10]. As pointed out by Steeves and Fleck, this approach is pertinent to the case of sandwich beams with weak face sheets, and it is inappropriate for the case of strong faces [11]. Mujika et al. for determining in-plane shear properties of unidirectional composite materials, consider a three-point bending test stating that normal and shear stresses change from point to point in the specimen, depending on fibre orientation angle and specimen geometry [12]. El-Hassal and Khashaba studied the fatigue behaviour of unidirectional glass fibre reinforced polyester (GFRP) composites under in-phase

combined torsion/bending loading concluding that torsional fatigue strength was significantly lower than pure bending strength and that the endurance limit of combined torsion/bending fatigue strength was approximately half the fatigue limit of pure bending fatigue strength [13]. Meijer et al. investigate the optimum wind angle, lay-up (stacking sequence), diameter, thickness and other variables for the specific loading conditions in order to obtain the best configuration [14]. Fawaz and Ellyin proposed a multi-axial model for life prediction, based on the modification of a reference fatigue curve to account for the actual load ratio and multi-axial loading condition [15, 16]. Quaresimin et al. reanalysed some of the multi-axial fatigue data available in the literature to verify the accuracy of life prediction by Fawaz and Ellyin method and by a polynomial function criterion [17]. Quaresimin and Carraro studied the biaxial fatigue behaviour of unidirectional composites using tubes made of glass/epoxy plies, with the fibres oriented at 90° with respect to the tube's axis and tested under combined tension-torsion loading [18]. The same authors report an extended study using tubular specimens with three different lay-up ([90n], [0f/90u,3] and [0f/90u,3/0f]) tested under combined tension-torsion loadings showing that the presence of shear stress significantly reduces the life spent for initiation of the transverse crack, for a given value of the transverse stress and the crack nucleation resistance of the [0f/90u,3/0f] tubes is slightly higher than that of the [90u,4] ones [19]. Quaresimin et al. compare the evolution of fatigue damage in laminates with measuring on tubes tested under tension-torsion loading conditions. Using a designed lay-up of the laminates able to introduce a local multi-axial stress state comparable to that present in the tubes subjected to external multi-axial loading these authors showed that the evolution of fatigue damage in multidirectional laminates tested under uniaxial cyclic loading and tubes tested under external multi-axial (tension-torsion) loading was basically the same [20]. Schmidt et al. analysed the damage development in glass fibre winding specimens during biaxial fatigue loading using non-destructive testing methods which reveals that initiation of final failure in the specimens is caused by local fibre waviness [21]. El-Kadi and Ellyin observed that for a given maximum stress in tension-tension loading the fatigue life increases with the increasing of stress ratio [22]. El-Assal and Khashaba studied the fatigue behaviour of unidirectional glass fibre reinforced polyester (GFRP) composites under in-phase combined torsion/bending loading concluding that torsional fatigue strength was significantly lower than pure bending fatigue strength and that the endurance limit of combined torsion/bending fatigue strength was approximately half the fatigue limit of pure bending fatigue strength [23].

II. MATERIALS

In this study, glass ($600 \text{ gr} \times \text{m}^{-2}$) fibers were used as fiber material for hollow circular composite shafts; and epoxy resin was preferred as the matrix material. The fiber volume ratio (V_f) of the glass composite material was determined as 45%. The hollow circular composite shafts manufactured from 80mm, 200mm and 250mm-long glass/epoxy material with inner ($D_{\text{inner}}=12\text{mm}$) and outer ($D_{\text{outer}}=17\text{mm}$) diameter, which consisted of three layers, were subjected to three point bending and torsional tests separately. Composite shaft to have

geometrically different lengths (80mm, 200mm and 250mm in length) were utilized (Fig. 1).

Fig. 1. A test specimens of glass/epoxy

III. MANUFACTURED METHOD

As the manufacturing method in this study was used the most commonly used method in the literature called wet filament winding method (Filament winding machine) (Figure 2). The glass fibers were wound over the rollers in the form of three layers at the orientation angles, $\theta=45^\circ$, 60° , 75° , 80° , and 88° . The manufactured circular hollow composite shafts were designed in given lengths according to ASTM standards and were made available for three point bending and torsional tests in accordance with ASTM standards.

Fig. 2. Filament winding machine

IV. EXPERIMENTAL STUDIES

A. Experiment of three point bending

Glass/epoxy hollow circular composite shafts consisting of 3 layers having different lengths (80mm, 200mm and 250mm) and one inner diameter ($D_i=12\text{mm}$) were subjected to three-point bending test (Fig. 3). Three-point bending tests were carried out at room temperature and a test speed of 1 mm x

min-1. According to the ASTM 790-00 standards, maximum tilt values were obtained by applying bending forces to the every center of the shafts for all samples placed between two supports (Fig. 4).

B. Experiment of torsion

The torsion tests were performed at room temperature through the location-type Shimadzu AG-X universal device with 250 kN load cell. The torsion test device operates at the range of 1° - 360° degree/minute (Fig. 7). In this study, the torsion tests were performed at the speed of 20° degree/minute for each sample. In accordance with ASTM standards, all the samples were placed between two jaws in the way that they would be in perpendicular position (Fig. 8). As the result of the fact that the upper jaw remained fixed and the lower jaw turned, a torsion torque was applied on the samples, and then the maximum modulus of rupture in torsion (R_t) was obtained (Fig. 11).

RESULT AND DISCUSSION

[11] Effect of orientation angle on bending stress

a

b

Fig. 11. Bending stress- orientation angle and length curve of glass/epoxy for three-point bending stress: a) Experimental, b) Ansys

The values of bending stress of glass/epoxy hollow circular composite shafts were analyzed for both experimental and ansys according to the orientation angle,

As displayed in the graphics, it was observed from the both experimental and ansys that the values of bending stresses decrease as the fiber orientation angle is increased (Fig. 11),

The highest bending stress of three separate hollow circular composite shafts was found to reach a maximum value in both experimental and ansys when the orientation angle is at 45° (Fig. 11),

As will be seen in the graphics; the experimental and numerical analysis results were found to be close to each other (Fig. 11).

□ Effect of orientation angle on modulus of rupture on torsion (R_T)

a

b

Fig. 12. R_T -Orientation Angle and length curve of glass/epoxy for torsion stress; a) Experimental b) Ansys

The values of modulus of rupture in torsion (R_T) of hollow circular glass/epoxy composite shafts were analyzed both experimental and ansys according to the orientation angle. Accordingly;

As will be seen in the graphics; it was observed from both experimental and ansys that as the orientation angle of the fiber increased, the values of the modulus of rupture in torsion of glass/epoxy shafts decreased (Fig. 12).

It was seen that the modulus of rupture in torsion had reached the maximum value in both experimental and ansys when it was at 45° orientation angle (Fig. 12). Separately, since the number of translocations among the fibers will increase once the orientation angle is extended, the values of modulus of rupture in torsion diminishes, as well.

As will be seen in the graphics; the experimental and numerical analysis results were found to be close to each other (Fig. 12)

VI. CONCLUSIONS

In this study, the bending stresses and the modulus rupture in torsion (R_T) of circular hollow shafts manufactured from glass/epoxy composite materials were examined experimentally and numerically at different orientation angles. The circular hollow composite shafts were manufactured by being wound on the rollers at $\theta=45^\circ, 60^\circ, 75^\circ, 80^\circ, 88^\circ$ orientation angles through the use of the filament winding method. Each circular hollow composite shaft that was manufactured was subjected to three point bending and torsion tests. The significant results obtained from the three point bending and torsion tests were mentioned below,

The highest bending stress of hollow circular glass/epoxy composite shafts was found to reach a maximum value in both experimental and ansys when the orientation angle is at 45°,

it was observed that the values of bending stresses in both experimental and ansys decrease as the fiber orientation angle is increased,

It was found that in both experimental and ansys the values of bending of hollow circular composite shafts increase as their wall-thickness increase. This is due to the reduction of the ratio between the inner diameter and the outer diameter. In other words, when the wall-thickness is decreased, it is obvious that the strength will also decrease,

The displacement ratio in the material will also increase as the length of the material increases. Owing to the fact that the deflection is increased as a result of an extension in length, stress ratio will also fall under the same force.

As will be seen in the graphics; it was observed from both experimental and ansys that as the orientation angle of the fiber increased, the values of the modulus of rupture in torsion of glass/epoxy shafts decreased.

It was seen that the modulus of rupture in torsion had[3] reached the maximum value in both experimental and ansys[4] when it was at 45° orientation angle. Separately, since the[5] number of translocations among the fibers will increase once[6] the orientation angle is extended, the values of modulus of[7] rupture in torsion diminishes, as well.

As seen in graphics in both experimental, ansys, three point bending and torsion tests the optimal winding angle was found to be between 45° and 60°,

As will be seen in the graphics in both three point bending and torsion tests; the experimental and numerical analysis results were found to be close to each other.

Abstract—In this study, elasto-plastic stress distribution was analyzed V-notched 5754 Aluminum plates by using finite element method, numerically. An experimental study was conducted in order to validate numerical results. Fundamental parameters for notched plates are the notch length and the notch width. With using these parameters, five different notch geometries were prepared. The un-notched and notched specimens were tested under uniform tensile load. Force and displacement graphs of Aluminum plates were obtained at the end of the experiments. Material properties was defined with using un-notched plate test results for input data of the finite element analysis program ANSYS. Firstly, compatible experimental and numerical reaction force-displacement graphs were given then the effect of notch dimensions on the plastic stress distribution was presented with contour graphs.

Keywords—5754 Aluminium; V-notched; elasto-plastic; finite element analysis; stress analysis

I. INTRODUCTION

The materials are damaged in various ways. Much of the damage is caused by structural deformations called fractures. The purpose of the studies related to fracture is to be able to increase the structural strengths of the materials with higher values. Numerical modeling is widely used to investigate the mechanical properties and failure of materials such as isotropic and composites. In order to obtain real stress distribution on structural components in numerical results, it is very important accurately to define behavior material as input data for numerical programs like ANSYS, ABAQUS. Generally, isotropic materials like Steel, Aluminum etc. show elasto-plastic stress-strain behavior under effect of one dimensional stress situation. So, yield stress and non-linear stress-strain behaviors of these type materials must be known. Today, numerical studies concentrate to this research area of elasto-plastic materials with using finite element method.

An experimental and numerical study was conducted to measure the distribution of stresses occurring on the bolt passage region of the bolt-on joints using hybrid composites. According to the analysis of two models developed according to finite element models, hybrid composites have shown that they increase mechanical strength in bolted joints [1]. Models were developed by measuring the responses of braided composites

during elasto-plastic analysis of the matrix during biaxial loading [2]. In order to investigate the mechanical behaviors of the assembled structures in composite layers, numerical models were created and elasto-plastic analyzes were made to produce solutions [3-4]. It was developed numerical models with elasto-plastic analyzes in the detection of damage progression in different axial loading states of reinforced composite [5-6]. Damage determinations were made by performing elasto-plastic analysis of the composite plates prepared with different notched and perforated fiber cores [7]. A new orthotropic elasto-plastic constitutive model has been developed to predict the inelastic response of composite materials under high velocity impact conditions [8]. Nonlinear material response of a sandwich beam with bilinear elasto-plastic constitutive relations for the transverse normal and shear stresses of the core based on the proposed high order sandwich panel theory was improved [9]. A ductile fracture model developed for V-notched structural steels under three-axis tensile loading was developed and analyzed [10]. For elasto-plastic materials, the effect of the material length and crack length on the Q-stress value near the crack tip was investigated under tension [11]. The elasto-plastic damage model was applied to analyze the finite elements of structural joints and the feasibility of the connections in the developed model was verified [12]. Evaluation of notch effects in low cycle fatigue problems generally requires strain calculations. The numerical model was prepared in V-notched form, and the effects of elasto-plastic normal stresses were investigated in predicting the notch behavior during stress. [13]. The fracture behavior under torsion of v-notched round bars made of gray cast iron was investigated. The results showed that Mod III can help evaluate the numerical and theoretical models for fracture of notches in load [14]. Stress-strain comparisons were made during the loading of V-notched Aluminum plates depending on the notch size change. Elasto-plastic analyzes were carried out for tensile behavior in the cracked region in notched plates to develop different numerical models [15-16].

In this study, elasto-plastic stress behavior of V-notched 5754 Aluminum plates is investigated with numerical analysis. Firstly, load-displacement graphs of un-notched Aluminum plates were obtained at the end of tensile tests. Material model of 5754 Aluminum was defined in finite element package program with using stress-strain graph of un-notched plates.

Numerical analyzes were achieved for different notch lengths and depths. Obtained reaction force-displacement results of numerical study were compare with experimental test results. Plastic stress distributions on plate for different V-notch geometries were given with using contour plots.

EXPERIMENTAL STUDY

[12] Preparing V-Notched Specimens

V-notched 5754 Al plates were prepared for the experimental tests with the dimensions of $H=200\text{ mm}$ in length and $W=40\text{ mm}$ in width from the $t=1.94\text{ mm}$ thick as shown in Fig. 1. In Fig. 2, Aluminum plates which have totally five different notch types are shown. Three specimens were prepared from each test. The dimensions of the Aluminum plates used in this study are shown in Table 1.

FIGURE. 1. DIMENSIONS OF V-NOTCHED ALUMINUM PLATE.

FIGURE. 2. SPECIMEN TYPES PREPARED FOR THE EXPERIMENTS.

TABLE 1. DIMENSIONS OF THE V-NOTCHED SPECIMENS PREPARED FOR EXPERIMENTS.

Specimen Type	$a\text{ (mm)}$	$b\text{ (mm)}$
A Specimen	30	20
B Specimen	20	30
C Specimen	20	20
D Specimen	20	10
E Specimen	10	20

B. Tensile Testing

Three Aluminum specimens of each type notch were prepared. Tensile test was applied to all the specimens. Tensile tests were performed at the speed of 1 mm/min on an Instron 8801 tensile test machine. Tensile tests of Aluminum plates

varying according to notch width and length have been made and finally, the load-displacement values of the plates were recorded and graphics were obtained. To determine the mechanical properties yield stress, Young module etc. of the 5754-Aluminum plate, the un-notched specimens were tested.

C. Experimental observations and results

Graphs were drawn by taking the test results of all Aluminum plate types subjected to tensile test. The stress-strain diagram of the 5754 Aluminum plate without the notch is as shown in Fig. 3. As a result of the tests, the mechanical properties of the 5754-Al plate were determined and are shown in Table 2. The load-displacement graph of un-notched Aluminum plates and notched plates is as shown in Fig. 6. Maximum load values of notched Aluminum plates in Fig. 4, the maximum elastic load values of the plates are shown in Fig. 5, so the effect of the notch size variation is compared.

modeling was done in ANSYS. A finite element model was created for the V-notched plate.

III. FINITE ELEMENT ANALYSIS

A. Modeling of V-notched plate

Data obtained from experimental tests were used for elasto-plastic stress analysis of numerical models. In order to analyze the stresses on the plates used in the study, V-notched plate

The mechanical properties of the Aluminum plate shown in Table 2; Young module (E): 69000 MPa, Poisson's ratio (ν): 0.33 and *SOLID186* element type were entered in ANSYS program.

Approximately, 4300 elements and 25000 nodes used in mesh. Solution analyzes were performed in the range of $\Delta L = 1.5 \text{ mm}$ elongation values in horizontal direction ($-x$ axis) and reaction force values of plate were calculated and graphs were prepared.

Elasto-plastic stress analysis was performed for the solution of the prepared model. The finite element mesh model prepared for V-notched plates is shown in Fig 7.

Shear module (G)	25940 MPa
Tensile strength (X_T)	246.72 MPa
Elongation at fracture (ϵ_K)	0.126
Young module (E)	69000 MPa
Poison's ratio (ν)	0.33
Yield stress (σ_Y)	132 MPa

FIGURE 7. MESH MODEL OF V-NOTCHED SPECIMEN FOR C SPECIMEN.

B. Stress Analysis Results

Reaction forces and stress distributions were obtained according to the type of each sample that was created by the model. For example; in the graph shown in Fig. 8, the experimental results of the E specimens and the load-displacement values of the numerical results are compared. It can be seen that results of experiments and numerical analysis are compatible in Fig. 8.

For V-notched Aluminum plate types, stress analysis was performed by choosing constant elongation value ($\Delta L = 0.05 \text{ mm}$). The σ normal stress distributions, on the notch regions of Aluminum sheets are shown in Fig. 9. The stress distribution of all samples is plotted at the same maximum and minimum stress range. It can be said that normal stress increases with increasing notch depth. On the other hand, notch width is a not effective parameter as notch depth on stress distribution.

FIGURE 8. COMPARISON OF EXPERIMENTAL AND NUMERICAL RESULTS OF A = 10 MM, B = 20 MM V-NOTCHED SPECIMEN.

Fig. 10 shows variation of plastic stress distribution in loading axis with different elongation values for C specimen ($a = b = 20 \text{ mm}$). Normal stresses increase with increasing elongation values. Maximum stress values are obtained at notch tip. On the other hand, stress concentrations are seen near the notch tip zone. Plate start to the bending situation for a large values of elongation. So, negative stress values are read opposite of notch tip on free plates edges.

FIGURE 9. STRESS DISTRIBUTION OF V-NOTCHED ALUMINUM PLATES FOR $\Delta L = 0.05$ MM.

FIGURE 10. VARIATION OF PLASTIC STRESS DISTRIBUTION IN LOADING AXIS WITH DIFFERENT ELONGATION VALUES FOR C SPECIMEN.

IV . CONCLUSIONS

In this study, non-linear stress analysis was performed of Defects like notch and crack etc. on plates are very dangerous for strength. This situation is approved with experiments method and stress analyzes obtained from ANSYS package showed that elongation of un-notched plates is so much bigger than notched plates. The results of the study can be summarized as follows:

- When the behavior of the Aluminum plates under the tensile load is evaluated, the notch width is constant; It has been observed that as the notch length of the plate decreases, the values of maximum load, maximum elastic load and elongation amounts increase very clearly.

- When the behavior of the Aluminum plates under the tensile load is evaluated, the notch length is fixed; It has been observed that as the notch width of the plate decreases, the values of maximum load, maximum elastic load and elongation amounts increase at the small ratios.
- It has been observed that the load values change more significantly in the evaluations made due to the reduction of the notch depth, opposite to the notch width. So, it can be said that V-notch depth is more important parameter than V-notch width for tensile loading in plates.
- In order to obtain numerical results of sample types; yield values were obtained from the stress-strain diagram of the Aluminum material obtained from the experimental results for un-notched plate. This data was analyzed by elasto-plastic stress analysis in ANSYS.
- V-notched Aluminum plate models were calculated by performing elasto-plastic analysis for the reaction forces versus the determined elongation amount of ΔL . As shown in Figures, experimental and numerical results are found to be very close to each other in all plate models.
- When the stress analysis of V-notched Aluminum plates is examined; It is seen that the greatest stresses on the plate concentrate on the tip of the notch.
- Plate models in which the same notch width is constant and the notch neck variation is numerically solved. It has been observed that the C sample ($a = 20 \text{ mm}$ $b = 20 \text{ mm}$) has the greatest σ_x normal stress value.
- Designers of structural components should decide and define their design considering notch depth and effect of non-linear stress behavior should be investigated for ductile materials analysis due to compatible experimental and numerical results.

ACKNOWLEDGMENT

The authors would like to thanks to the Department of Mechanical Engineering, Faculty of Engineering, Dicle University for assistance in performing tensile tests of Aluminum plates used in the works.

Abstract— In this study, laminar flow and heat transfer in a duct mounted rectangular blocks (electronic components) to the duct upper surface and sinusoidal undulating bottom wall are numerically investigated. Two simulated electronic components are subjected to a uniform heat flux of 250 W/m². The lower and upper surface of the duct is insulated. As the working fluid Air is used (Pr = 0.71). Computations are conducted for different Reynolds numbers (Re = 500, 1000, 1500, 2000, 2500). The steady state, incompressible, two-dimensional and laminar flow were considered cases. The wavelengths and wave amplitude of sinusoidal surface of the duct are varied from 0.02 to 0.08 during the analysis. Obtained results have been presented as local Nusselt numbers and shear stress.

Keywords— Laminar flow, Sinusoidal Surface, Friction factor, Electronic Components (Blocks)

• INTRODUCTION

System temperature is crucial for efficient and safe operation of the systems. The heat generated for system security must be removed from the system. At present, many researchers are working on the development of more efficient cooling system not to exceed a certain value of temperature of electronic components [1]. Because of inadequacy of forced and natural convection mechanisms for heat transfer to outside (operating temperature must be below 70°C), usage of microchannel cooling system which has high ratio of heat transfer area to volume has gained high importance. These systems include many microchannel in different geometry of the structure. For an optimum design, the flow and heat

transfer characteristics of the channel (heat transfer coefficient, friction factor, hydraulic diameter, number of channels, etc.) need to be known.

Nomenclature

μ	: Dynamic viscosity (Pa.s)
a	: Amplitude (m)
h	: Heat transfer coefficient (W/m ² K)
h	: Block height (m)
H	: Channel height (m)
k	: Thermal conductivity (W/m.K)
L	: Channel length (m)
Nu_{mean}	: Mean Nusselt number
Nu_x	: Local Nusselt number
p	: Wavelength (m)
ϕ	: Viscose loss function
T_o	: Flow inlet temperature (K)
U_o	: Inlet velocity (m/s)
u, v, y	: Velocity components in x, y and z directions respectively (m/s)
w	: Block width (m)
x, y, z	: Dimensionless Cartesian coordinates
ν	: Kinematic viscosity (m ² /s)
ρ	: Fluid density (kg/m ³)
τ	: Surface shear stress $\tau = \mu \frac{du}{dy}$ (N/m ²)

In this study, the effect of sinusoidal surface on the cooling of electronic components in a rectangular channel has been investigated. Firstly, the effect of the fluid surfaces at different Reynolds numbers of components in a rectangular channel has been examined. The local and mean Nusselt numbers have been obtained. Secondly, components bottom surface have been changed as sinusoidal surface and analysed with different amplitude and Nusselt number value on the components surface for the period. The ratio between these two results (Numean-u/Numean-s) is calculated. In addition to this, surface shear stress on the block surface over undulated surface have been presented.

[13] LITERATURE

In today, many electrical and electronical items that contain electronic circuit structure have been widely used in the global world. When electronic circuits expose to electrical current,

Electrical current on electronic circuits causes heat rising and power loss of the system ($P = I^2R$). The amount of power loss must be same with the amount of power that was previously specified in catalogues. Once the system exceeds the specified amount, they can not work safely and efficiently. In the electronic circuits temperature rise is uncontrollable so, cooling method for such systems is emerged. There are lots of previous studies about cooling of the system in the literature. Furthermore, new researches on cooling for the electrical circuit continue to increase day by day.

Mohammed et al. [2] numerically studied of the effect of using nanofluids on heat transfer and fluid flow characteristics in rectangular shaped microchannel heat sink (MCHS) for wave amplitude range of $125 \mu\text{m}$ - $500 \mu\text{m}$. In microchannel heat sink (MCHS), water flow and heat transfer have been simulated and the results compared with straight microchannel. As a result of simulation, the performance of MCHS has been recorded better than straight microchannel in the same section. Furthermore, increasing the amplitude of the microchannel led to increase both friction factor and shear stress.

Wang and Chen [3] researched the rates of heat transfer for Newtonian fluid (laminar, incompressible, steady and 2D) through symmetrical undulating wall using a simple coordinate transformation method. The impacts of the wavy geometry, Prandtl number and Reynolds number on the skin-friction and Nusselt number have been analysed in detail. The results present that increasing Reynold number and the amplitude-wavelength ratio caused to increase the amplitudes of the Nusselt number and the skin-friction coefficient.

Guzmán et al. [4] examined the enhancement characteristics of heat transfer in asymmetric wavy wall channels using the spectral element method on simulations of the mass, momentum and energy equations. The heat transfer characteristics, transition scenarios and flow bifurcation were determined by increasing the Reynolds numbers for three geometrical structures. With this study, notable heat transfer enhancements were captured during the appropriate

transitional Reynolds number range for asymmetric wavy channel.

Sui et al.[5] studied laminar liquid-water flow and heat transfer using numerical simulation for three-dimensional wavy microchannels with rectangular cross section. The simulation results figure out that when liquid coolant flows through the wavy microchannels, secondary flow (Dean Vortices) may be generated during the liquid coolant flowing through the wavy microchannels. Furthermore, quantity and the vortices location can change on the flow direction, leading to chaotic advection, which may greatly effect and increase the convective fluid mixing. Therefore, the wavy microchannel shows much better heat transfer performance that of straight microchannel at the same cross section. It was observed that the pressure drop of the present wavy microchannels may be much smaller than the heat transfer enhancement. Moreover, the relative wavy amplitude of the microchannels on the flow direction can be changed for different useful aims.

Szumbariski et al. [6] theoretically and numerically analysed the issue of mixing enhancement a viscous incompressible flow in a channel with wavy walls. The obtained results were compared and the first experimental results were verified with the same rectangular cross-section flow channel.

□ PHYSICAL GEOMETRY AND SOLUTION METHOD

A. Physical Properties and Geometry

This study has been conducted with ANSYS software. The differential equation problems have been solved by algebraic equations. Then, velocity and temperature distribution have been determined in the solution area. The geometry of the problem was displayed in the subsequent Figure 1. Upper and bottom surfaces of the channels were insulated. In order to obtain flow and heat transfer characteristics of the problem, continuity, momentum and energy equations have been utilized with the boundary conditions. In the research, air and its thermal properties at temperature of 25°C were used as the fluid. The vertical component of the fluid velocity has been assumed to be zero.

Fig. 1. Physical geometry and parameters

Some parameters used in the model geometry are given below.

$$\begin{aligned} Y &= a \sin(\pi x/p) & w &= 2/3H & H &= 0.06 \text{ m} \\ L_2 &= 0.20 \text{ m} & L_3 &= 0.18 \text{ m} & L &= 0.64 \text{ m} \\ h &= 1/3H & L_1 &= 0.18 \text{ m} \end{aligned}$$

The continuity, momentum and energy equations and boundary conditions for the problem can be written as:

Continuity equation:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \quad (1)$$

X-Momentum equation:

$$\rho \left(\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} \right) = -\frac{\partial P'}{\partial x} + \mu \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} \right) \quad [10]$$

Y-Momentum equation:

$$\rho \left(\frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} \right) = -\frac{\partial P'}{\partial y} + \mu \left(\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial z^2} \right)$$

Energy equation:

$$\rho c_p \left(u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} + w \frac{\partial T}{\partial z} \right) = k \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} \right)$$

Boundary conditions:

Channel inlet: $u = U_0$, $v = 0$ and $T = T_0$

Channel upper and bottom surfaces: $u = v = 0$

Heat flux on the block surfaces: $q = 250 \text{ W/m}^2$

Nondimensional numbers: $Nu_x = h_x/k$, $Re = U_0 H/\nu$

B. Benchmark for Validation

Mabarki et al. [14] numerically analysed the laminar flow and heat transfer regimes using forced convection in a rectangular horizontal channel. In order to simulate electronic components three blocks have been mounted to the bottom wall of the channel. Each block is 0.25 cm height (h), 2 cm width (w). The 2-D horizontal plane channel is 1 cm height (H) and 20 cm length (L). The fluid temperature and heat flux generated by each block have been taken 20°C and 1000 W/m², respectively. The upper and bottom walls have been assumed as adiabatic. The working fluid has entered to the channel with uniform velocity and temperature. A rectangular cross section bar has been mounted to the upper wall to increase heat transfer rate and control the fluid flow.

As a result of the research, the best enhancement of heat transfer was observed by a rectangular control element attached to the upper wall of the channel. The study proves that the control element significantly effects to increase heat dissipation and causes to reduce the temperature of the blocks simulated the electronic components. For Reynolds number of 547, maximum local Nusselt numbers have been obtained on 1st block upper left corner and 2nd block top corner, $Nu_x = 23$ and $Nu_x = 16$, respectively.

In order to verify this research, same conditions, materials and parameters, which were used in Mabarki's study [14], have been selected and solved for the defined problem. At the end of the calculation, simulation results proved that outputs were nearly same when compare Mabarki's research [14]. For instance, in this study, maximum local Nusselt numbers of 1st and 2nd blocks have been recorded as $Nu_x = 24$ and $Nu_x =$

10.5, respectively. Figure 3.2 presented the some results of current study and Mabarki's study for validation.

Fig. 2. Comparison of Nu_x values for both blocks ($Re = 547$)

IV. RESULTS AND DISCUSSION

A. Analysis of Local Nusselt Numbers on Undulated Channel

In the following figures, variation of Nu_x numbers have been defined at a channel with undulated surface and heated blocks surfaces. These expressions, characterized heat transfer from blocks to fluid, have been obtained temperature distribution results in solution of Navier-Stokes and energy equations. According to the results, the maximum local Nu_x number has been observed at the left bottom corner of the 1st block. The Nu number values have decreased through flow direction of the bottom surface and continued to reduce at the right surface of the block. Furthermore, the effect of Nu numbers on the bottom surfaces of the blocks are higher than that of the side surfaces of the blocks. This is because enhancement of the heat transfers from block surface to fluid results from deterioration and rupture of the boundary layer [1]. The same fluctuations are observed on the 2nd block as well.

Fig. 1. shows heat transfer variations in the channel with referencing amplitude and wavelength of undulated surface, the maximum local Nusselt number (Nu_x) for Reynolds of 2500 has been observed at 1. Block of undulating channel

during the values of $a = 0.02$ (m) and $p = 0.08$. At the rates of $a = 0.005$ and $p = 0.02, 0.04$ and 0.08 , decrease of local Nusselt number (N_{ux}) has been obtained during constant amplitude and high wavelength for all Reynolds number values ($Re = 500, 1000, 1500, 2000, 2500$) used in the analysis. The Reynolds number rates increases, also increasing the N_{ux} numbers. Namely, heat transfer enhances.

Moreover, in Fig. 2. the maximum N_{ux} number has been observed at the conditions as $a = 0.01$ and $p = 0.02, 0.04$ and 0.08 for Reynolds of 2500 and $p = 0.04$ values. Like the previous case, as the Reynolds number increases the N_{ux} numbers are also increasing.

As a result of the evaluations, enhancement of Nusselt numbers has been determined for the constant wavelength and high amplitude. On the other hand, the decreasing of mean Nusselt numbers has been recorded for constant amplitude and double the wavelength.

Fig. 3. Change of N_{ux} number with respect to Re number on the 2. Block ($a = 0.005, p = 0.08$)

Fig. 4. Change of N_{ux} number with respect to different Re numbers on the 1. Block ($a = 0.02, p = 0.02$)

B. The Ratio of mean Nusselt Numbers on the Undulated Channel to Straight Channel (Nu_{mean-u}/Nu_{mean-s})

Fig. 5 shows the ratio of mean Nusselt numbers on the sinusoidal undulating channel to straight channel (Nu_{mean-u}/Nu_{mean-s}) for various Reynolds numbers. The maximum value in these rates has been noted on second block left surface with Reynolds of 500. Furthermore, the maximum recorded mean Nusselt number can be listed as second block right surface, first block right surface, second block bottom surface, first block left surface and first block bottom surfaces, respectively. Graphic changes indicate the same results that prove such ratio decreases with the increasing of Reynolds number.

In comparison the previous amplitude and wavelength values, different structure occurred as expected with amplitude of $a = 0.02$ and wavelength of $p = 0.04$. At the first block right surface, a parabolic graph change has been observed with the $Re = 500, 1000$ and 1500 . The maximum value takes place with the Reynolds of 1000.

Fig. 5. The ratio of mean Nu numbers on the undulated channel to straight channel (Nu_{mean-u}/Nu_{mean-s}) for different Re numbers ($a = 0.005, p = 0.02$)

Fig. 6 indicates the change of surface shear stress along the block mounted upper wall surface. As it seen as Re number increases surface shear stress is increasing especially on top surface of the blocks.

Fig. 6. Changes of surface shear stress values on block surfaces for different Re numbers ($a = 0.02, p = 0.02$)

RESULTS AND DISCUSSION

In this study, laminar flow and heat transfer in a duct mounted two blocks (as electronic components) to the duct upper surface and sinusoidal undulating bottom channel have been analysed numerically. With this study, some obtained important results are summarized as follows:

The maximum Nu number values have been occurred on undulated channel with amplitude of $a = 0.002$, wavelength of $p = 0.008$ and Reynolds of 2500.

Obtained results prove that the as Reynolds number increases local Nux and mean Numean numbers are increasing. That means that the heat removing from electronic components are enhanced.

Another investigation has been performed on Nusselt numbers with different undulated surface periods and amplitude values. As amplitude is fixed with increasing of wavelength local Nusselt numbers, Nux, are decreasing. That is, the heat transfer are decreasing.

Furthermore, as wavelength is fixed with increasing of amplitude local Nusselt numbers, Nux, are increasing. That is, the heat transfer enhances.

Abstract— For this study, woven glass and carbon fibres reinforced composite materials have been produced with eight laminates. For experimental study, specimens with 10 mm internal hole were prepared. Then, these specimens have been repaired by using adhesive and composite patches. For repair of the damaged specimens different patch parameters were used. Necessary curing temperature and pressure were applied to the specimens in laboratory conditions. By performing the unidirectional tensile test, the ultimate failure loads of these repaired specimens were indicated. By comparing these ultimate failure loads of repaired specimens, the effects of patch parameters on the ultimate failure strength are investigated. These repair parameters are patch thickness, patch bonding length and patch geometry.

Keywords— Laminate Composite Materials, bonded repair, patch, adhesive, failure strength

I. INTRODUCTION

By performing technological improvements, applications of composite materials have been increased both commercial and military aircraft structures applications in recent years. Because, these type materials have excellent properties. Due to high cost of these materials, maintenance of them, have been important. In industry, for composite materials, repair of spare parts have been preferred than replacement of spare parts. Sometimes, replacements of the damaged spare parts are costly and unnecessary. More structures with defects or local damages can be repaired successfully with composite patch bonding by using adhesive.

In industry, various repair techniques have been successfully applied. Among them, adhesively bonded structural repair has gained more favour than mechanically fastened structural repair for the reason that fiber reinforced composites are essentially bonded in nature. Therefore, in recent years, considerable experimental and numerical studies have been conducted to investigate the influence of different repair parameters on the stress distributions, ultimate strength and stress intensity factor of the bonded repaired structures [1].
